Abstract Large data sets covering large areas and time spans, and composed from many different independent sources, raise the question of the obtained degree of harmonization. The present study is an analysis of the harmonization with respect to the moment magnitude M_w within the earthquake catalogue for central, northern and northwestern Europe (CENEC). The CENEC earthquake catalogue (Grünthal et al., J Seismol, 2009) contains parameters for over 8,000 events in the time period 1000–2004 with magnitude $M_w \geq 3.5$. Only about 2% of the data used for CENEC has original M_w magnitudes derived directly from digital data. Some of the local catalogues and data files providing data give M_w , but calculated by the respective agency from other magnitude measures or intensity. About 60% of the local data give strength measures other than M_w and these have to be transformed by us using available formulae or new regressions based on original M_w data. Although all events are thus unified to M_w

magnitude, inhomogeneity in the M_w obtained from over 40 local catalogues and data files and 50 special studies is inevitable. Two different approaches have been followed to investigate the compatibility of the different M_w sets throughout CENEC. The first harmonization check is performed using M_w from moment tensor solutions from SMTS and Pondrelli et al. (2002, 2007). The method to derive the SMTS is described, e.g., by Braunmiller et al. (2002) and Bernardi et al. (2004) and the data are available in greater extent since 1997. One check is made against the M_w given in national catalogues and another against the M_w derived by applying different empirical relations developed for CENEC. The second harmonization check concerns the vast majority of data in CENEC related to earthquakes prior to 1997 or where no moment tensor based M_w exists. In the case, an empirical relation for the M_w dependence on epicentral intensity (I_0) and focal depth (h) was derived for 41 master events, i.e., earthquakes, located all over central Europe, with high-quality data. To include also the data lacking h , the corresponding depth independent relation for these 41 events was also derived. These equations are compared with the different sets of data from which CENEC has been com-

posed and the goodness of fit is demonstrated for each set. The vast majority of the events are very well or reasonably consistent with the respective relation, so that the data can be said to be harmonized with respect to M_w , but there are exceptions, which are discussed in detail.

Keywords Earthquake catalogue · Europe · Moment magnitude M_w · Harmonization check

1. Introduction

Earthquake catalogues covering different national catalogues meet the challenge how a harmonization of the strength measure could be achieved. It is a well known fact that magnitudes can differ substantially between national seismological agencies. Not least is this the case with local M_L and duration based (M_d) scales.

Although a general problem in regional earthquake cataloguing, previous studies attempting to quantify the harmonization are not known to the authors. The particular task of this study is to analyse the compatibility and reached harmonization of the M_w values given in different local catalogues contributing to a regional data base or derived from other strength parameters in these. The regional seismicity data file which is the subject of this analysis is the catalogue of earthquakes in central, northern and northwestern Europe (CENEC) by Grünthal et al. (2009). CENEC contains about 8,000 earthquakes with $M_w \geq 3.50$ and covers Europe north of the Mediterranean region (N of 44°N; Fig. 1). The objective of the new catalogue is to provide a harmonized strength measure in terms of M_w , a goal one can approach but hardly fully realize since it is based on many sub-regional, national and local earthquake catalogues or data files,

Fig. 1 Epicentre map according to the CENEC catalogue, which encompasses the study area of this paper

and also numerous special studies on certain events or sets of events.

This study aims at quantifying the compatibility of the sets of M_w values in CENEC, based on the different earthquake catalogues, which have been calculated from different other magnitude types or intensity. About 60% of the CENEC M_w entries have been calculated using regressions or existing local transformation formulae derived or selected by Grünthal et al. (2009). For most of the remaining events, “original” M_w given in the national catalogues, such as the Italian, Romanian, or Swiss, have also been calculated from other magnitude concepts or intensity. Thus, only about 2% of the CENEC entries have truly original M_w determined directly from digital records or are subject of special studies with M_w derived, e.g., from intensity data points. Such data, i.e., the M_w after Pondrelli et al. (2002, 2007) available since 1997 and the Swiss moment tensor solutions (SMTS) available since 1999, together with the M_w from special studies, have the highest rank in the priority scheme of CENEC.

For the data to be of value in various seismological studies, notably seismic hazard, it is important not only that the catalogue contains the same type of magnitude, in our case M_w , but that this is harmonized. Of special concern is the long term behaviour of the pre-instrumental parts of the catalogues. Firstly, we compare M_w values from truly original, i.e., moment tensor based, data sources with (1) M_w given by the local catalogues and datafiles, (2) M_w calculated from other strength measures in the local catalogues and datafiles according to a hierarchy of empirical relations. Secondly, a relation of M_w vs. intensity and focal depth is established based on original, high-quality parameter data, the so-called master events (Section 3). This relation, based on 41 events, is then compared with the individual M_w data in or derived from the different national catalogues to evaluate and quantify the degree of harmonization. A depth-independent equation is also derived based on the same 41 events and compared with the individual data.

Fig. 2 a M_w from moment tensor solutions (SMTS and Pondrelli et al. 2002) vs. M_w given by local catalogues and data files used in CENEC. The M_w values of SMTS and Pondrelli et al. (2002) are given in CENEC, having higher hierarchy rank than the ones in the local catalogues. **b** M_w from moment tensor solutions (SMTS and Pondrelli et al. 2002, 2007) vs. M_w calculated from other strength measures according to the algorithms for the local catalogues in CENEC established by Grünthal et al. (2009)

2. Comparison of original and calculated M_w values

The first type of harmonization check treats original M_w , i.e., based on moment tensor solutions by Pondrelli et al. (2002, 2007) and the Swiss moment tensor solutions, available since

1997 and 1999, respectively.

We first compare these high-quality M_w values with the M_w provided by several national catalogues, i.e., CPTI Working Group (2004), Oncescu et al. (1999), INFP (2007), ISC, Fäh et al. (2003) and ECOS (2006) (Fig. 2a). Altogether, there are 37 data pairs in CENEC. 76%

References for events with $M_w \geq 3.5$ before 2005 are given in the Grünthal et al. (2009) catalogue. For the other events, the references are: 1983-09-11 Langer (1986), 2000-01-20 Hinzen (2003), 2004-06-21 ECOS06 (see Grünthal et al., 2009, Annex 1), 2005-01-14, two events, GRF (ibid.), 2005-09-06 ZAMG07 (ibid.), 2008-05-07 R. Musson, pers. communication

of the data pairs are within the ± 0.2 and 91% within the ± 0.5 M_w unit bounds. This shows that the sets with original M_w are largely compatible with M_w in the catalogues mentioned. The M_w according to SMTS and ECOS, and Pondrelli et al. (2002, 2007) and CPTI Working Group (2004), respectively, are not identical although provided by the same respective agency.

In a second comparison, the original SMTS and Pondrelli et al. (2002, 2007) M_w values are checked against M_w values of the local catalogues calculated from other strength measures according to dependent algorithms established by Grünthal et al. (2009) (Fig. 2b). There are 100 data pairs, with 94 original M_w entries from SMTS, five from Pondrelli et al. (2002) and one from Pondrelli et al. (2007). 14 events with calculated $M_w < 3.5$ are not included in this data set, although they occur in CENEC, since SMTS or Pondrelli et al. (2002, 2007) have $M_w \geq 3.5$. On the mean the calculated M_w are 0.08 units lower than the original. 38 of the 100 data pairs are within the ± 0.2 and 88 within the ± 0.5

M_w unit bounds. Twelve of the data pairs are thus outliers with the calculated M_w more than 0.5 units different from the original. Five of the outliers are from IMO07, three from LDG, two from ISC, and one each from IMO and INGV (cf. Table 2 with respect of the used notation of national catalogues).

3. Master event relation

Any harmonization study requires a data set with which the investigated data can be compared. The relative test criterion is in our case a set of 41 earthquakes with carefully determined parameters, i.e., the seismic moment or moment magnitude, M_w , the maximum or epicentral intensity, $I_{\max}$ or I_0 , and the hypocentral depth h (Table 1).

Since the target area of this study is the same as for CENEC, we select the master events from the region which is central to this catalogue and has a sufficient level of seismic activity. Thus, the master events are from Austria, Belgium, France, Germany, Hungary, Italy, Netherlands, Slovenia, Switzerland and United Kingdom.

The lower magnitude threshold for the master events is $M_w = 3$. The largest earthquake in the area, where the master events have been taken, is the Friuli earthquake of May 6, 1976 with an original $M_w = 6.4$.

The intensities of the master events since 1992 have been carefully determined using the European Macroseismic Scale, EMS-98 (Grün-

Fig. 3 Master event regressions and used data points. **a** Depth dependent relation, Eq. 1; **b** depth-independent relation, Eq. 2. *Dashed lines* show the 68% confidence bounds of the latter relation, whereas the confidence bounds for the depth dependent relation cannot be visualized in a simple manner.

Fig. 4 Comparison of $M_w(\text{SMTS})-I_0$ data points of CENEC with the depth dependent master event relation

thal, 1998) or its test version, the EMS-92 (Grünthal, 1993). What concerns the general compatibility of good quality assignments of intensities according to different twelve-degree scales, we refer to Musson et al. (2009). In our study, only earthquakes with an intensity of I_0 or $I_{\max} \geq V$ were considered. Intensity V coincides roughly with the chosen magnitude threshold of $M_w = 3$. Further criteria to select master events related to high quality intensities are either the availability of macroseismic maps with intensity data points, which allows to con-

firm the reliability of the I_0 ($I_{\max}$) value, or that the macroseismic data evaluation was made by a scientist, assuring a good quality I_0 ($I_{\max}$) assignment. The epicentre or meizoseismal area must not be offshore. A minimum focal depth of 5 km was chosen to avoid a bias in the $I_{\max}$ reading due to the areal density of localities in the considered parts of Europe.

A chi-square regression of M_w on I_0 and h was performed for the 41 selected events. This provides a general possibility to introduce individual errors for the used data. Since the errors are not precisely known for the individual data points, however, we set a general error in intensity of 0.25, and in M_w of 0.15 for events from 2000 onward and 0.30 for events before 2000. The 0.15 value was obtained by Braunmiller et al. (2005) for Swiss earthquakes, but it is valid for all Swiss moment tensor solutions SMTS for M_w (J. Braunmiller, pers. communication). The

Fig. 5 Comparison of the local catalogue for Austria to the master event relations: Eq. 1 data with depth (*top*) and Eq. 2 data without depth (*center*). The share of events within the 95% confidence limits is given in each of the plots (here 100% in both cases). The depth-independent plot additionally shows the 95% confidence limits. The bottom figure shows the histogram of ΔM_w . This description and the legends of the plots are valid also for Figs. 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, and 20, although in a few cases, there are data only for one of the M_w - I_0 plots

Fig. 6 Belgium, Luxemburg (see caption to Fig. 5)

influence of the error in source depth is negligible if $\sigma(h) < h$ (Stromeyer et al., 2004). This is a further reason to consider depths of 5 km and larger only.

The chi-square regression of M_w on I_0 and h with respect to the master events yields

$$M_w = 0.667 I_0 + 0.30 \log(h) - 0.10,$$

$$\sigma = 0.31 \dots 0.37 \quad (1)$$

The obtained relation is valid in the applied ranges of I_0 and h (see Table 1). In Figure 3a, the relation is plotted together with the input data. The error σ (the 68% confidence interval) of M_w predicted by equation (1) depends on the regression error and the uncertainties of the three estimated regression parameters. Its variation with I_0 and h is small compared with the accuracy of the used magnitude data.

For many data sets to be tested, only a few or no h values exist. To be able to check also the data without depth assignment, a regression for the 41 master events omitting h yield

$$M_w = 0.682 I_0 + 0.16 \quad \sigma = 0.32 \dots 0.36 \quad (2)$$

Figure 3b shows this relation and its 68% confidence bounds for a new predicted magnitude. The similarity of the prediction errors σ of the equations (1) and (2) demonstrate the weak depth dependence of the data.

4. Statistical test criterion for comparing data sets with the master event relation

The statistical test for our harmonization check is a comparison between appropriate data sets in CENEC with the master event relations. We do not argue that the two empirical relations between the parameters of the master events are valid for the whole area of CENEC, rather we perform a relative test of how the relation of the

Fig 7 a Bosnia-Herzegovina, Croatia, Serbia-Montenegro, and Slovenia (see caption to Fig. 5). **b** Slovenia – ZivS catalogue (see caption to Fig. 5)

earthquake parameters M_w , I_0 and in one case h for each local catalogue in CENEC agrees with the master event relations.

To quantify the performance we choose the 95% confidence interval of the equations (1) and (2) as reference and count the number of catalogue entries in these regions. This is done separately for the data points with and without an assigned depth h . Additionally, the mean and the standard deviation of the differences ΔM_w between the local catalogue entries and the master event relations are calculated.

Before the results for the different national data sets are discussed, we check how the truly original M_w entries in CENEC (which have the highest priority) behave with respect to the master event relations. There are 19 entries with such high-quality M_w , all from SMTS, which have an I_0 of V or larger and a focal depth between 5 and 25 km according to the national

data. Depicted against the range of the master event relation in Fig. 4, the test of the goodness of fit reveals that 95% of the data are within the 95% confidence limit.

5. Comparison of the master event relation with local catalogue data

Different national parts of the CENEC database (Table 2) are tested against the derived master event relations, equations (1) and (2), for the degree of harmonization. Data after 2004, the final year of CENEC, have been added where available. It is checked to what extent the M_w from each of the national parts of the CENEC catalogue are in agreement with the M_w according to the master event fit as a function of I_0 and h , equation (1), and only I_0 , equation (2), respectively. This is of special concern, since the

Fig. 8 Czech Republic (see caption to Fig. 5)

Fig. 9 Fennoscandia (see caption to Fig. 5)

majority of the significant earthquakes in the different parts of the CENEC study area has intensity as the only strength parameter. Solely events with epicentre onshore and an original I_0 entry in the respective national catalogue are used. The data are restricted to $M_w \geq 3.5$, $I_0 \geq 5$ and $5 \leq h \leq 25$ km, as for the master events. The comparisons, both with and without considering the focal depth, are described below. Consequently, data whose M_w originate in a special study or in any of the SMTS or Pondrelli et al. (2002, 2007) data bases are not part of the test.

The local NE European catalogues by Boborikin et al. (1993), Nikonov (1992), Pagaczewski (1972) and Wahlström & Grünthal (1994) in the Grünthal et al. (2009) catalogue have too few data to be tested. The IMO (2007a,b) (Iceland) and INGV (2007) (Italy)

catalogues give no intensities. Contributions from ISC and NEIC bulletins are lacking intensities in our area of application, the Atlantic Ocean. The test results for all other catalogues used by Grünthal et al. (2009) are described below and shown in the Figures 5-20. In these descriptions, we make use of the acronyms of the catalogues (see Table 2).

Austria

The Austrian earthquake data files ZAMG and ZAMG07 provide M_L , I_0 and h . For the reference of these and other abbreviated local catalogue notations, see Table 2. Only two events are lacking a h value. The comparison of the data with the two versions of the master event relation is shown in Fig. 5. The upper part contains the 165 data with h , which have a 100%

Fig. 10 a France – SisFrance catalogue (see caption to Fig. 5). b France – LDG catalogue (see caption to Fig. 5)

coincidence with the master event relation within the 95%-confidence limits. The ascent in the data is almost the same as for the master events. In the intensity range up to $I_0 = 6$, M_w seems to be slightly underestimated with respect to the master events. The two data points lacking a h value are in good agreement with the reference relation. This is illustrated in the lower part of Fig. 5.

Belgium, Luxembourg

The scarce data above the set parameter thresholds from the data files for Belgium and Luxembourg ORB and ORB07 show a quite good coincidence with the master events (Fig. 6). 83% of the data with h and 90% without h are within the 95%-confidence bounds. The mean values of the differences ΔM_w of the M_w values of the local data from the master event relations are negligible (Table 2) but the standard devia-

tions of ΔM_w are somewhat greater than the prediction errors σ of eq. (1) and eq. (2), respectively.

Bosnia-Herzegovina, Croatia, Serbia-Montenegro and Slovenia (lat. $\geq 44^\circ\text{N}$)

The HHM catalogue is the major data source for Bosnia-Herzegovina, Croatia and Serbia-Montenegro and is also used for some events in Slovenia (Fig. 7a). 123 data points from this source provide focal depth and intensity values. 90% of these data are within the 95%-confidence bounds of the master event relation. The ascent of the data is almost the same as those for the master events. For the 137 events without h , 97% of the data are within the 95% master event confidence limits.

For Slovenia, ZivS is the main data source. The 190 data points from this catalogue exhibit an excellent coincidence with the master events (Fig.

Fig. 11 Germany (see caption to Fig. 5)

Fig. 12 Hungary (see caption to Fig. 5)

Fig. 13 Italy (see caption to Fig. 5)

7b) in that all data with and without h , respectively, are within the 95%-confidence bounds.

Czech Republic

We have only seven data points above the given parameter thresholds. Therefore, the data from the two catalogues for the Czech Republic CAS and GFU are treated together. All data with and without h , respectively, fall within the 95%-confidence limits (Fig. 8).

Fennoscandia sensu lato (Denmark, Finland, Norway, Sweden, the Baltic republics and adjacent areas)

Although the onshore data for Fennoscandia from the data sets FEN and FEN07 show a distinct scatter, 98% of them with h and 71% without h are within the 95%-confidence bounds. The ascent of the M_w - I_0 behaviour is slightly steeper than that of the master event relations (Fig. 9). There is a tendency of either underestimated intensities or overestimated M_w for the data without h . A closer look shows that the two $I_0 = \text{VII}$ events, in 1819 and 1904, as well as four of the five most “anomalous” events with $I_0 = \text{V}$ and V-VI, are located in coastal regions of Norway, with possibly in-

Fig. 14 Netherlands (see caption to Fig. 5)

complete intensity data. This may explain the relatively low intensities with respect to the master event relation. The more modern data which contain h show better agreement with the master event relations.

France (lat. $\geq 44^\circ\text{N}$)

The French data consist of two quite different data types, the SisFrance data (Fig. 10a), represented in terms of I_0 only, and LDG data (Fig. 10b) starting in 1962, giving only M_L . The corresponding M_w have been calculated with the procedures described in Grünthal et al. (2009). The SisFrance data, where h is lacking throughout, are within the 95%-confidence bounds of the corresponding master event relation, but show a distinctly different ascent, which originates in the used relation between M_L , I_0 and h

Fig. 15 Poland (see caption to Fig. 5)

Fig. 16 Romania (see caption to Fig. 5)

by Levret et al. (1994). For LDG, intensities from SisFrance have been used. The LDG data with depth assignments show a scatter around the master event curve, with 81% of the data being within the 95%-confidence bounds, resulting in a slight underestimation of M_w especially at larger magnitudes. The data without depth values behave as the SisFrance entries.

Germany

The different data sets for Germany (Table 2) behave similarly and have been processed jointly. The 182 data points with h are all within the 95%-confidence bounds of the master events (Fig. 11). A similar behaviour is shown by the 90 data points without h , 99% of which are within the 95%-confidence limits.

Hungary

The main Hungarian data sources (Table 2) also

show a similar M_w - I_0 - h behaviour. 94% of the 36 data points with h and 99% of the 135 without h are within the 95%-confidence limits. The generated M_w are mostly underestimated by about 0.1 magnitude units (Fig. 12).

Italy (lat. $\geq 44^\circ\text{N}$)

The Italian data in CENEC have two sources. The M_w -based CPTI04 is used up to July 2001 and have no h values. The M_L - and M_d -based INGV (2007) data used from August 2001 on provide h values but no intensities, and therefore, as stated above, this catalogue is not part of this study.

The CPTI04 data agree well with the master event relation for intensities $I_0 \geq 7$ (Fig. 13). For $I_0 < 7$, the corresponding M_w values are distinctly higher. The lower ascent in the M_w - I_0 relation for the CPTI04 data is obvious. 66% of the data are within the 95%-confidence bounds.

Fig. 17 Slovakia (see caption to Fig. 5)

The mean of ΔM_w is 0.54. The part of Fig. 2 applying to CPTI04 data is in good agreement with the M_w values from SMTS and Pondrelli et al. (2002).

Netherlands

The scarce data in CENEC for the seismically not very active Netherlands are shown in Fig. 14. They are from the Hou catalogue and its successor file KNMI. There are only five data points with a h value which fulfil the parameter criteria. All of them are in the 95%-confidence limits. 92% of the twelve data points which are lacking a h value are in the 95% confidence limits. The mean values of ΔM_w are not greater than 0.1.

Poland

Also in Poland the seismic activity due to natural tectonic events is very minor. There are only

two data points in GLM with h . They coincide very well with the master event curve. 23 data points exist without h . Also they agree very well with the corresponding master event relation (Fig. 15).

Romania

From the Romanian data in CENEC, the Onc catalogue and its continuation INFP, there are 111 data points with a h value in the selected range (Fig. 16). 77% are within the 95% confidence limits. The mean of ΔM_w is 0.25 indicating higher values of the data with respect to the master events. The ascent in the Romanian M_w - I_0 -data is fully compatible with the master event relation. Only two data points are lacking h . They both fall within the 95%-confidence bounds.

Slovakia

From the Lab data file for Slovakia, 27 data points with h and 88 data points without h fulfil the parameter criteria (Fig. 17). The scatter in the data is very low and all data in both sets are within the 95%-confidence bounds. The mean values of ΔM_w are nearly zero.

Switzerland

The ECOS catalogue for Switzerland and its continued data file ECOS06 (from 2001 onward) are calibrated for M_w and therefore used without modification in CENEC. A characteristic increase of completeness and reliability of the ECOS data approximately since 1975 could be achieved, connected to the high-sensitive telemetry seismic array. According to the descriptions of the ECOS-catalogue by Fäh et al. (2003), it is motivated to differentiate between the time period before 1975 (Fig. 18a) and that from 1975 onward (Fig. 18b). The part of Fig. 2 applying to Switzerland shows that the M_w values from SMTS are not identical with those from Fäh et al. (2003) and its continuation ECOS06 in each case, although they all originate from the same agency (ETH Zurich). However, the overall agreement is good.

Fig. 18 **a** Switzerland before 1975 (see caption to Fig. 5). **b** Switzerland since 1975 (see caption to Fig. 5)

In the period before 1975, there are 82 data points with h and 348 data points without h in the considered parameter range. Only 43% of the data with h are within the 95%-confidence limits, but 95% of those without h .

In the data set with h there is a clear overestimation of M_w with respect to the master events, with a mean deviation of 0.83. There are, e.g., seven events of $M_w \geq 5.0$ in the upper part of Fig. 18a with an I_0 of 5, and also seven events of $M_w \geq 5.5$ with an I_0 of 6. In the data set without h there is a large peak of almost 300 events with $\Delta M_w = 0.3$, which is not distinguishable in the centre plot of Fig. 18a due to overlapping data points.

The period since 1975 shows a better coincidence with the master events. All data with h are within the 95%-confidence limits and the

mean shift is reduced to 0.35. There is only one data point lacking h in this set, and this falls outside the 95%-limit.

Since the data sets from the two periods behave quite differently, conclusions based only on one part, e.g., in seismic hazard assessment, may be biased.

Ukraine

The entries for the Ukraine encompass mainly two data sources, KU and KSh. The KU catalogue has the highest priority, it is calibrated in M_w and has a lower threshold of $M_w = 5.1$. The KSh catalogue, which requires a conversion to M_w , is used in CENEC for smaller events. The entries of both catalogues have h values. The KU data show a clear overestimation of M_w with respect to the master events. Only 19% of

Fig. 19 a Ukraine – KU catalogue (see caption to Fig. 5). b Ukraine – KSh catalogue (see caption to Fig. 5)

the data are within the 95%-confidence bounds (Fig. 19a). On the contrary, the fit between the converted KSh data with the master event relation is excellent (Fig. 19b), with all data within the 95%-confidence range with a slight underestimation of M_w by 0.10 magnitude units.

The different behaviour of M_w in the two data files requires attention in using them jointly in different studies. A further calibration of KU is recommended.

United Kingdom

The data for the United Kingdom Mus and Mus06 show a fairly large scatter around the master event relations. Of the 59 data points providing h values, 88% are within the 95%-confidence limits (Fig. 20). The mean of ΔM_w is 0.18. 88% of the 17 data points without h values are within the 95%-confidence bounds. The mean of ΔM_w is here 0.02. The ascent in the M_w - I_0 plot of the data coincides very well with that of the master events.

Table 2 summarizes the comparison of the data from the national catalogues to the two master event relations. It shows the number of

events in each national file, the respective percentage of data within the 95%-confidence range, and the mean and the standard deviation of ΔM_w . For the data with h , 15 national catalogues out of 18, and for the data without h , 15 catalogues out of 17, have more than 80% of the data points within the 95% confidence range. We judge this as a good overall degree of a harmonization of CENEC. However, some of the national catalogues with original M_w have parts which do not behave as the selected master events. These are the CPTI04 data up to July 2001, the Onc/INFP data with h , the ECOS data with h before 1975 and the KU data above $M_w = 5.1$. Of the catalogues with calculated M_w , only the FEN/FEN07 data without h fall below the 80% limit.

6. Discussion and conclusions

Based on the results presented in this study, harmonization tests of seismicity data bases composed of different independent data sets should inevitably be introduced. Moreover,

Fig. 20 United Kingdom (see caption to Fig. 5)

such tests should be quantitative. We propose and apply here two different tests to check the degree of harmonization in the earthquake catalogue for Europe north of 44°N (CENEC), focussing on M_w values.

Harmonization tests could quantify the reliability of other parameters than M_w or target the degree of identification of, e.g., fake quakes in regional long term seismicity data files, to give just a few examples of multifarious harmonization tests.

We have performed two test types with respect to M_w in the CENEC data set: Firstly, the comparison of M_w values from truly original, i.e., moment tensor based, data sources with (1) M_w given by the local catalogues and datafiles, and (2) M_w calculated from other strength measures in the local catalogues and datafiles. Secondly, based on 41 earthquakes in different

parts of central Europe, all with high-quality data - the master events - the relations $M_w = 0.667 I_0 + 0.30 \log(h) - 0.10$ (1) and $M_w = 0.682 I_0 + 0.16$ (2) were derived. Comparing the different data sets contributing to CENEC with these relations, using the percentage of data falling within a 95% confidence range as the measure, eleven sets out of 18 have a very good to excellent fit ($> 90\%$ of the data) to eq. (1) and 14 sets out of 18 to eq. (2). A perfect fit according to this measure (99-100% agreement) is obtained for nine and eleven of these sets, respectively, and a fair to good fit (70% - 90% agreement) for three sets relative to eq. (1) and one set to eq. (2). There is a poor fit ($< 70\%$) only for two sets compared to eq. (1) - ECOS/ECOS06 (Switzerland before 1975) and KU (Ukraine) - and one set compared to eq. (2) - CPTI04 (Italy). The users of the data files with poor fit should be aware that the M_w values show a different behaviour than those from the data which are more compatible to the master events. Either the master event relation is not applicable in the “anomalous” cases or the values should be calibrated to conform with the others. It is beyond the scope of this study to elaborate this in more detail and to apply any adjustments. For the vast majority of the data sets and events, the tests show a harmonized catalogue over large areas and time spans, suitable to use, e.g., in large-scale seismic hazard studies.
