### Abstract

At geothermal plants, process failures often occur due to corrosion and scaling processes. Especially after heat extraction, sulfate reducing bacteria contribute to corrosion processes by producing reduced sulfur compounds. In biofilms containing scales such as iron sulfides, corrosion processes are enhanced. In a mobile bypass system located at the geothermal plant in Neubrandenburg (North German Basin), the influence of biofilm formation on corrosion and scaling was investigated. Short-term heat shocks were successfully tested in the bypass system in order to reduce biofilm formation and thus to diminish corrosion and scaling processes.

## 1. Introduction

In geothermal fluids after heat extraction, frequently sulfate reducing bacteria (SRB) are found [1]. SRB contribute to the corrosion process indirectly by the formation of reduced sulfides and/or directly by the uptake of electrons from the metal to the microbial cell [2,3]. SRB form biofilms on the metal surface. The dissolved iron ions precipitate with the sulfides. Thus, SRB do not only contribute to the corrosion process, but also deliver the reactant for the scaling process [4]. Lerm et al. [5] showed a high abundance of SRB at the cold side of a geothermal heat store in Neubrandenburg (North German Basin). There, the submersible pump was strongly affected by pitting corrosion. Lerm et al. [5] concluded that the formation of biofilms on the pump containing corrosion relevant SRB was the main reason for the damages. Würdemann et al. [1] observed a strong reduction in the injectivity and thus, a clogging of the near well area due to scaling products and biofilm formation in the cold store at the Berliner Reichstag. In the joint project “BioKS”, measures to diminish biofilm formation are investigated in order to reduce corrosion and scaling processes in geothermal plants. However, the inhibition of microorganisms with biocides is difficult in terms of environmental concerns and local regulations. In addition, high fluid flow rates require high amounts of biocides resulting in high costs. Thus, other measures need to be developed. In this paper, first results of the influence of heat shocks – short-term non-heat-extracting periods – on the biofilm formation in a bypass system are presented.

## 2. Material and Methods

### 2.1. Experimental setup

The bypass system was located in Neubrandenburg at a geothermal heat store. The heat store consists of two sides, a “warm” side with a temperature of approximately 80 °C and a cold side with a temperature of around 47 °C. The salinity is 130 g L<sup>-1</sup>, the sulfate concentration varies between 900 mg L<sup>-1</sup> at the cold side and 1100 mg L<sup>-1</sup> at the warm side. More information about the site is given at Kabus and Wolfgramm [7], Obst and Wolfgramm [8] as well as Lerm et al. [5]. The bypass system was installed at the top facility at the warm side. The hot geothermal fluid from the warm side was cooled down with a heat exchanger in the bypass system to 40 °C and flowed through two parallel pipes. In these pipes, unground and ground (120 grit) corrosion coupons were installed. More information regarding the bypass system is provided in Würdemann et al. [6].

The experiment lasted 59 days. Every two weeks, the heat exchanger was switched off for 6 h, while one pipe was closed and one pipe remained open. Thus, in the closed pipe the temperature remained at ~ 40 °C and in the open pipe, the temperature increased to 78 °C due to the hot geothermal fluid. At the end of the experiment, the pipes were removed from the bypass system, transported to the laboratory and the coupons were withdrawn under an anaerobic mobile glovebox to avoid any exposure to oxygen.

### 2.2. Chemical and molecular biological analyses

In order to determine the corrosion rates, the clean coupons were weighted before and right after the exposure to the fluid. After the fluid exposure, the surface of the coupons was cleaned with 3 M HCl. The material of the coupons was mild steel (1.0038) with a density ( $\rho_C$ ) of 7.856 g/cm<sup>3</sup> and the dimensions of 3 mm x 25 mm x 100 mm. Thus, subtracting the holes in the coupons for its fixation in the bypass tube, the surface area of the coupons ( $A_C$ ) was 5683 mm<sup>2</sup>. The corrosion rate (CR) was calculated according to Eq. (1).

$$CR = \Delta m / (\rho_C * A_C * t) \quad [\text{mm/a}] \quad (1)$$

The biofilm layer and scales on the coupons were analyzed using a Scanning Electron Microscope (SEM) from Hitachi S-4700 with a Noran Nordlys II Energy Dispersive Spectrometer (EDS). Bacteria and SRB on the coupons were quantified by quantitative PCR (qPCR). Analyses of bacterial 16S rRNA [9] and *dsrA* genes for SRB [10,11]

were conducted with the StepOnePlus™ real-time PCR System (Applied Biosystems, Carlsbad, CA, USA) using Power SYBR® Green PCR Master Mix (Life Technologies, Carlsbad, CA, USA).

### 3. Results and Discussion

In the geothermal plant in Neubrandenburg, damages on the submersible pump due to microbial influenced corrosion were observed. In order to develop measures against corrosion damages, the influence of short-term heat shocks on the biofilm formation was investigated. After the fluid exposure at a constant temperature in pipe 1 and with heat shocks in pipe 2, the biofilm layers differed strongly in their thickness. On the coupon exposed to heat shocks the biofilm layer was much thinner than the layer on the coupon with constant temperature (Fig. 1).

Fig. 1. The biofilm layer on the coupon treated with heat shocks (pipe 2) is much thinner than on the coupon with constant 40 °C (pipe 1).

Corresponding to the lower thickness of the biofilm layer after heat shocks, the abundance of Bacteria as well as the abundance of the SRB were about 1000-fold lower and thus, strongly reduced (Fig. 2a). Correspondingly, the corrosion rates were fivefold lower (Fig. 2b). Furthermore, the corrosion rates also differed depending on the treatment of the coupon surface. The ground coupons were less influenced by corrosion than the unground coupons.

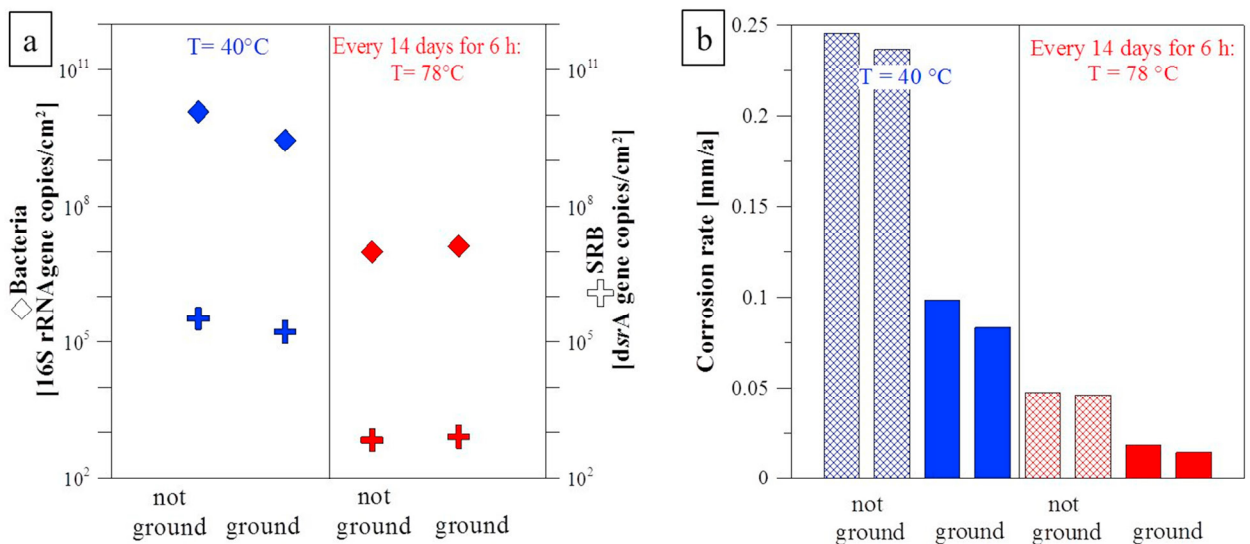

Fig. 2. (a) Lower abundance of Bacteria and SRB on the coupons with heat shocks, (b) lower corrosion rates of the coupons with heat shocks.

SEM images combined with EDS analyses showed that the solid material phases on the coupon were dominated by iron sulfides and calcium carbonates (Fig. 3 a-d). Microorganisms in the form of elongated rods were frequently found in close relation to iron sulfides as shown in Fig. 3d. This suggests that those microorganisms might be SRB. According to Lerm et al. [5] and Westphal et al [12], SRB affiliated to *Desulfotomaculum*, *Desulfobalobium* and

Candidatus *Desulforudis audaxviator* dominated in the geothermal fluid in Neubrandenburg. According to Kuever and Rainey [13], Ollivier et al. [14] and Jungbluth et al. [15], those organisms have an elongated morphology. Also, SRB were detected by qPCR on the coupons. In the near future, the microorganisms on the coupons will be characterized in detail and more temperature regimes will be tested in the bypass system.

Fig. 3. (a-d) SEM pictures and EDS results of the biofilm with microorganisms (MO) covered with minerals on the coupons without heat shocks after the exposure to the fluid in the bypass system located at the geothermal store in Neubrandenburg.

#### 4. Conclusions

Short-term heat shocks are a simple, inexpensive and environmentally friendly procedure to reduce corrosion and scaling processes triggered by SRB. Hereby, the heat exchanger extracts less heat than usually from the produced hot geothermal fluid. Thus, the fluid flows temporarily with a higher temperature through the plant into the injection well in order to expose the attached biofilms on the technical components of the geothermal plant to a heat shock.

#### Acknowledgements

We thank the public utilities of the city Neubrandenburg for providing access to the topside facility of the geothermal heat store and to allow for the installation of the bypass system and the conduction of experiments. The Federal Ministry for Economic Affairs and Energy (Bundesministerium für Wirtschaft und Energie) is thanked for the funding of the project BioKS (0324029A).
