Vjacheslav SPICHAK (Geophysical Research Centre, Moscow, Russia, e-mail: spichak@dol.ru) Michel Menviel (University Paris Sud, Orsay Cedex, France, e-mail: menviel@geol-u.psud.fr)

A Bayesian approach is used for inversion of MT-data in three-dimensional media. Complex three-dimensional structure is considered as composed from elementary homogeneous domains. The information available is determined in terms of the a'priori probability law of the conductivity distribution.
The parameters to be found are the a'posteriori conductivity values in the region of search. Thus, the solution of the inverse problem is reduced to the search for the a'posteriory conductivity distribution by means of successive solution of the forward problem for the a'priori values of the conductivities preset in the homogeneous domains. The solution of the forward problem is fulfilled using the program FDM3D. Iterative solution of the system of linear equations saves the time of calculations due to use of the previous results as good starting points for the next ones. The iteration process converges to the correct solution in the most cases in 15-20 iterations, which enables to solve the inverse problem in a reasonable time. Numerical experiments made using synthetic MT data indicate that the results of inversion are rather stable with respect to the a'prori range of the conductivity palette in each domain of the region of search and to the a'prori probability density function, however, they are very sensitive to increasing / decreasing of it's dimensions in comparison with those of the real target. An example of the ecological problem solution (detection of seawater invasion into a shallow coastal fresh water aquifer and mapping the boundaries of the salty water) by means of Bayesian inversion of synthetic AMT data is considered.

ERROR ANALYSIS OF THE SEVEN ROTATIONAL INVARIANTS OF THE MAGNETOTELLURIC IMPEDANCE TENSOR

A. K. AGARWAL and J. T. Weaver (both at the School of Earth & Ocean Sciences, University of Victoria, Victoria, B.C., Canada, V8W 3P6, emails: numod@uvvm.uvic.ca and weaver@phys.uvic.ca)

In a previous presentation, the magnetotelluric tensor was characterized by seven independent rotational invariants each with its own physical interpretation associated with its numerical value becoming vanishingly small. In practice, the invariants will never vanish precisely because of noise in the measured data and because the idealized conditions under which the vanishing of the different invariants occur (such as two- dimensionality of the regional structure or real distortion of the complex tensor elements by a small-scale, near-surface, three-dimensional anomaly) are never more than approximately realized in nature. In this paper the analysis is taken a stage further by investigating the propagation of errors in the various invariants when Gaussian noise is added to synthetic data generated by a numerical model comprising a small conductive cube embedded in the surface of a layered earth and near a two-dimensional regional fault line. The effect of the noise on the seven invariants and their resulting stability is discussed, and conclusions are drawn about the general usefulness of the invariants in determining the regional direction of strike and in decomposing the tensor into its two-dimensional regional form.

PERCOLATION THEORY WITH EMBEDDED NETWORKS – A MODEL FOR THE CONDUCTION MECHANISM IN THE MIDDLE CRUST.

LABENDZ, Daniel

Electromagnetic deep sounding measurements often indicate a high conductive layer (HCL) in the middle crust (15-20 km) which very often exhibits an electrical anisotropy with respect to the two horizontal directions. A cause of the high conductivities has not been identified inambigiously but graphite or saline fluids are the major players. With the aid of mixing laws, percolation theory and an embedded 2D/3D network approach we model the heterogeneous rock matrix in order to determine the "electrical connectivity" of the highly conductive phase. An essential result is the electrical anisotropy, which indicates a deviation from the perfectly interconnected case.
We will present results of the dependence between connectivity and percolation probability as well as the embedding factor. It is not necessary to impose a fractal geometry on the model by incoporating embedded networks. However, in percolation experiments with large networks the resulting cluster at the percolation threshold has fractal geometry. Using magnetotelluric data containing anisotropy it becomes possible to calculate an indicator which can help to determine the cause of the high conductive layers. With the help of 3D networks the importance of vertical connectivity (conductivity) can be discussed.

3D SOURCE EFFECTS ON MT AND GDS DATA

PATRICIA MARTINELLI and Ana Osella Ciudad Universitaria - Pab. I - Departamento de Fisica - 1428 - Buenos Aires - Argentina

Usually, MT and GDS data are interpreted assuming a spatially uniform external magnetic field. This assumption has proved to work well in many cases, and its validity implies that the impedance tensor Z, and the tipper T, are independent of the unknown inductive field. Nevertheless, in some occasions, as for example in studies at high or low latitudes, this hypothesis fails, especially for hourly periods.
In previous works we proposed a 2D MT modelling method based on the application of Rayleigh scattering theory; later, the possibility of a 2D external field was introduced in the formulation. Here, we present the solution for general 3D inductive fields, and we give examples of the kind of distortions that such fields can produce on Z and T, and how these distortions can modify the final models obtained. In the last term, we propose a procedure to overcome the problem, using instead of Z and T other quantities that do not depend on the external field

A NEW METHOD OF GEOELECTRICAL PROSPECTING BY VERTICAL ELECTRIC CURRENT SOUNDINGS

V. MOGILATOV, Institute of Geophysics SB of RAS, Universitetsky Pr., 3, Novosibirsk, 630090, Russia, fax: 7-383-2333432, e-mail: VMogilat@uiggm.nsc.ru

Some advantages and problems of a new geoelectrical prospecting method, vertical electric current soundings (VECS) are discussed. This method is based on using a new source, circular electric dipole (CED). It is unique source for the electrical prospecting, which excite only TM (transverse magnetic) field. The source is installed in the following way. One of the transmitter poles is grounded in the central point. The other pole is uniformly grounded around with a radius determined by the depth of investigation desired. It can be defined as a noninductive source. The most interesting CED properties in the low frequency regime are as follows. CED has no magnetic field of its own. It is a pure TM exciter, which differs from a loop (only TE excitation) and from a line, which is both TE and TM exciter (a"line" here means a cable or insulated wire grounded at its end points). The normal magnetic field on the earth's surface (and above it) of a layered medium is absent (within the quasi-static approximation), and only a radial electric component exists. A CED field is at right angles to the loop field and has azimuthal symmetry. The CED field is always governed by a vertical medium structure (at the latter transient stage as well) rather than by the total longitudinal conductivity. An interesting result was obtained: in marine electrical prospecting a sea water layer will not play such a crucial role when a CED is used as in applying a loop or a line. In a medium with non-conducting basement the decay of the CED field is exponential. The transient process is more fast than in the case of a loop or a line. The CED can be also considered as a ground analogue of another known source, a vertical electric line. Besides, the CED a pure galvanic source that does not excite a long-term transient field. Thus it seems to be a new useful means to study IP processes. The author consider results of the initial field tests in the Ukraine (ore body) and in the Tartar republic (oil target).

DIGITAL THREE-COMPONENT FLUX-GATE MAGNETOMETER FOR STUDIOS AND MEASUREMENTS OF ELECTROMAGNETIC INDUCTION (EMI) VARIATIONS

An. P. NAUMOV (D.I. Mendeleyev Institute for Metrology / VNIIM, St Petersburg, 198005, Russia, email: slovo@mail.line.ru) V.A.Prishepo and V.I.Sheremet (both at VNIIM, St Petersburg, 198005, Russia, email: hal@onti.vniim.spb.su)

This device, the digital three-component flux-gate magnetometer, was developed at Institute of Metrology for decision of problem of the coordinate determination of natural sources. This is source of EMI geovariations and sources of tectonic ULF magnetic impulses. The vector probe of magnetic field is a base of flux-gate magnetometer. Direct and inverse transducer form part of the probe described. As a direct transducer a new three-component flux-gate probe is used. As a inverse transducer there is used a system of three-component coil windings of which are placed on a cubic of ceramic. The inverse transducer cube is mechanically linked to a rectangular quartz prism normal to faces of which form a base coordinate system. Referencing the axes of the vector transducer for magnetic induction to the axes of the base coordinate system is effected using reference magnetic and optic measuring devices. The accuracy of flux-gate magnetometer - 5,0 nT, measurement range +/- 65.280 nT, a minor quantum 0,1 nT and range of frequency from 0 to 6 Hz.

DYNAMIC ELECTROMAGNETIC DIAGNOSING OF ECOLOGICALLY DANGEROUS OBJECTS

OLEG SAPUZHAK, Yaroslav Sapuzhak, Olena Neganova, Oleg Romanjuk (Carpathian Branch of Subbotin Institute of Geophysics NASU, 3b, Naukova str, 290601, Lviv, Ukraine, tel./fax +380 322 648563, email: olgs@carp.lviv.ua)

Methodology is developed for quick diagnosing of ecologically dangerous objects and for determining unstable energy active parts inside them. It is based on analysis of diurnal variations of electromagnetic parameters and includes the following stages: - analysis of existing geological and geophysical data on the object under investigation and static geoelectric modelling of its cut; - application of mathematical and physical modelling to study the geoelectric cut and determining the optimal schemes and parameters of field observations technique; - recording and analysis of diurnal variations parameters obtained by the methods of natural and artificial electromagnetic field; - processing and analysis of field observations data, designing the temporal and profile (or planar) characteristics of studied parameters; - complex interpretation of obtained data including determining the potentially dangerous energy active parts and their dynamic modelling, conclusions and recommendations.
Active parts revealed may become the subject of more detailed and lasting planar and continuous observations. In its most part the methodology is based on methodological approaches, mathematical modelling software, equipment for physical modelling and high accuracy electromagnetic measurements originally developed in CBSIG NASU.

PROPERTIES OF ROTATION INVARIANT MAGNETOTELLURIC IMPEDENCE TENSOR: A CASE STUDY FROM THE ARCHAEN PROTEROZOIC CONTACT OF THE SINGHBHUM CRATON AND THE ADJOINING MOBILE BELTS

K.K. ROY and S. Srivastava (both at Department of Geology and Geophysics, Indian Institute of Technology, Kharagpur - 721 302, India, Email: kkroy@gg.iitkgp.ernet.in) A.K. Singh (Department of Applied Earth Sciences, Delft University of Technology, Delft, The Netherlands)

Properties of the Magentotelluric rotation invariant tensors (RITs) are studies on the field data collected from the Singhbhum craton and the adjoining Protozoic mobile belts. It is observed that the RIT apparent resistivies and phases viz., determinant, central and average can be used for 2D/3D modelling and plotting of pseudosections and surface plots. Two eigen values of the impedence tensor Z generate apparent resistivities computed from the two eigen values is equal to the determinant apparent resistivies. The arithmetic mean of the two phases obtained from two eigen values gives the determinant phase. Central apparent resistivity is equal to the average apparent resistivity plus the apparent resistivity obtained from the diagonal elements of the impedence tensor. Rotation invariant property exists in presence of noises in the MT field data. Rotation invariant plots show more consistent data with less error bar and statistical fluctuations. Models with RITS show more consistent results.

IS THE MAGNETOTELLURIC IMPEDANCE TENSOR OR THE INDUCTION MATRIX A NORMAL PHYSICAL VALUE?

VLADIMIR SHUMAN (Institute of Geophysics of the Ukrainian National Academy of Science, 252680, Palladina str. 32, Kiev, Ukraine, Email: earth@igph.kiev.ua).

The concept of the tensor surface impedance and induction matrix in the theory of geoelectromagnetic methods is considered. It is a well-known fact that a wealth of experience in practical determinations of the impedance matrix or the induction matrix elements has shown the accuracy attained is much below the accuracy in measuring field variations and not always suit the geophysicists requirements. When identifying induction matrices, the scatter of values usually increases in comparison with impedance identifications. The correct formulation of the problem of MT-date processing and inversion is in these approximated model evidently difficult. Using the known results of Aboul-Atta and Boerner (1975), we have obtained accuracy local boundary conditions associating the normal and tangential components of electromagnetic field on closed discontinuity of media whose particular case are the approximated of Rytov-Leontovich. The horizontal gradient and geomagnetic depth sounding methods are special cases of the theory developed. The concept of the density of electromagnetic field helicity and its reflection in the structure of Maxwell's equations in an isotropic medium is analysed. This approach seems very likely to by more universal and better conforms with the logic of the date processing of MT-experiment and the problems of the monitoring of the dynamically process in comparison with the conventional conception of the tensor impedance or the induction matrix.

MAGNETIC AND ELECROMAGNETIC INDUCTION EFFECTS IN THE ANNUAL MEANS OF GEOMAGNETIC ELEMENTS

Crisan DEMETRESCU, Venera Dobrica, Nadejda Ciocoiu (all at Institute of Geodynamics, 19-21 J.L.Calderon Str., R-70201, Bucharest, Romania, email: crisan@geodin.ro)

The solar-cycle-related (SC) variation in the annual means of the horizontal and vertical components of the geomagnetic field at European observatories, for sets of data between 1950-1995, is used to infer information on the magnetic and electric properties of the interior, characteristic to the observatory location, by identifying and analysing the magnetic induction component and respectively the electromagnetic induction component of the SC variation. The latter is further analysed in terms of response functions Q (internal/external) and W (vertical/horizontal) and mantle resistivity.

INSTRUMENTATION FOR RECORDING AND ANALYSIS OF LOW LATITUDE PC3 GEOMAGNETIC PULSATIONS IN SOUTH-EAST AUSTRALIA EMPLOYING INDUCTION COIL MAGNETOMETER TECHNIQUE

I. A. ANSARI (Department of Physics, Aligarh Muslim University, Aligarh (U.P.), Pin Code: 202 002, India)

Geomagnetic pulsations of Pc3 type are quasi-sinusoidal variations in the earth's magnetic field with a period range of 10-45 sec. The spatial and temporal variations in Pc3 wave polarisation and signal phase are vitally important since they provide evidence which can be directly related to wave generation mechanisms both inside and external to the magnetosphere and propagation modes inside the magnetosphere. An array of four low latitude induction coil magnetometer stations was established in south-east Australia to study the characteristics of low latitude Pc3 geomagnetic pulsation over a longitudinal range of 17 at L = 1.8 and a latitudinal range of IO° over L=1.8 to 2.7. The geomagnetic north-south (X) and east-west (Y) components of variations in the 5-100 MHz band were recorded on slow speed frequency modulated analogue magnetic tape along with a 5 sec. time channel. Chronometers with an accuracy of 10 msec. per day were employed. Data were later digitised in the laboratory with a 5 sec. sample rate using the time channel pulses. The resulting X(t) and Y(t) time series were used to study dynamic spectra, polarisation ellipticity, major axis azimuth directions and the percentage of polarised wave power from the coherency matrix method. Interstation cross-spectral parameters were also studied. The recording and analysis instrumentation has been described.

ELECTROMAGNETIC INDUCTION IN THIN SHEETS BELONGING TO DIFFERENT SYSTEMS OF COORDINATES

Attia A. ASHOUR (Math. Dept., Faculty of Science, Cairo University, Giza, Egypt, email: ashour@frcu.eun.eg) Moustafa S. Abou-Dina (Math. Dept., Faculty of Science, Cairo University, Giza, Egypt, email: msaboudina@frcu.eun.eg)

In electromagnetic induction problems in thin sheets if the boundaries involve natural surfaces in different coordinate systems, it will not be possible to use functions or harmonics belonging only to one system of coordinates. However, such problems involving mixed spherical, spheroidal and cylindrical boundaries can be treated using the relations between the different harmonics belonging to those systems which are found in the old literature (e.g. Copson (1936), Hobson (1955)....) and which have been collected by Smythe (1968). To illustrate this method, we solve the model problems of electromagnetic induction by a time varying magnetic field in: (1) A uniformly conducting spherical shell enclosed in a co-axial uniformly conducting infinite cylindrical shell. (2) A uniformly conducting spherical shell enclosing a perfectly conducting concentric oblate speroidal shell.

MODELLING THE INDUCTION LOG RESPONSES IN A 3D FORMATION WITH TILTED BOREHOLE AND INVADED BEDS USING THE INTEGRAL EQUATION APPROACH

Dmitry AVDEEV, Alexei Kuvshinov, Oleg Pankratov (all at Institute of Geoelectromagnetic Research, Russian Academy of Sciences, 142092 Troitsk, Moscow region, Russia, email: avdeev@gemri.msk.ru), and Gregory Newman (Sandia National Laboratories, Org. 6116, P.O. Box 5800, Albuquerque, NM 87185-0750, USA, email: ganewma@sandia.gov)

Three-dimensional (3D) frequency-domain solver, previously built for the magnetotelluric, controlled-source and airborne applications (Avdeev et al., 1996; 1997; 1998), is now developed for the induction logging problem. The solver calculates the responses in 3D models including a steeply, up to 90 degrees, tilted borehole and invaded beds, and accounts for displacement currents, induction polarization effects, anisotropy of the beds resistivities and cylindrical geometry of the borehole. The solver exploits the volume integral equation (IE) approach which has been originally presented in (Singer, 1995) as modified iterative dissipative method, and later generalized in (Pankratov et al. 1995, 1997). The IE approach is based on a Neumann (Born) series expansion, which is always convergent, even for extreme resistivity contrast.
For tilted boreholes in layered formations, there are no known analytical solutions. Therefore, our solution was first checked against the mode matching solutions (Chew et al., 1984; Liu, 1993) for vertical borehole models. Excellent agreements were obtained. Comparisons with staggered grid finite difference solution (Newman and Alumbaugh, 1995) were then conducted for a vertical and 45 degree tilted boreholes intersecting a horizontal bed boundary. These comparisons were again excellent, and demonstrate for the first time, verifiable induction log responses in the presence of tilted boreholes.

GA1.02/E/28-A1 1605-03

EFFECTIVE INVERSION OF MT DATA OF THE TIEN SHAN TYPE

Mark BERDICHEVSKY, Nina Golubtsova (both at Geological Department of Moscow State University, Moscow 119899, Russia, email: berd@geo.geol.msu.su) Leonid Vanyan (Shirshov Institute of Oceanology, Moscow 117218, Russia, email: vanyan@geo.sio.rssi.ru)

MT-soundings carried out in the mountains of Kirghyz Tien Shan (Trapeznikov et al,1997) show that the crust of this region consists of four major elements:1.heterogeneous sedimentary cover, 2.resistive upper crust, 3.heterogeneous conductive layer in the middle and lower crust, 4.subvertical conductive zones (faults) crossing the upper crust. This geoelectrical structure is referred to as the structure of the Tien Shan type. Interpretation of MT-data of the Tien Shan type needs special approaches. So, we constructed a schematic 2D model of the Tien Shan type and tested different approaches to inversion of MT-data. On this basis an effective bimodal algorithm has been elaborated, being slightly affected by sub-surface inhomogeneities. It consists of three levels: 1)inversion of induction arrows, 2) inversion of TE phase curves, 3) inversion of TM apparent resistivity curves. The first level gives basic information on deep layers (particularly, on conductive layer in the middle and lower crust) and subvertical zones. The second and the third levels help to gain details of structures and evaluate the upper crust resistance. This algorithm opens the way to effective interpretation of MT-data in the joint Russian-Chinese project involved into the study of the Nothern Tien Shan.

GA1.02/W/27-A1 Poster 1605-04

SCALE MODELLING OF THE FREQUENCY SEA-FLOOR CSEM SOUNDING IN PRESENCE OF 3D INHOMOGENITY

Zalina Djatieva and Leonid Vanyan (both at Shirshov Institute of Oceanology, 36 Nakhimov Ave., 117851 Moscow RUSSIA, e-mail: djatieva@geo.sio.rssi.ru) Alexey Kuznetsov and Yury Popov (both at VNII Geophysics, 5 Kievskoe shosse, 143300 Naro-Fominsk RUSSIA)

One of the proper ways to solve the problem of analyzing a 3D inhomogenity influence is to use a scale modelling. A scale modelling of the sea-floor frequency sounding was carried out in an electrolytic tank. The model consisted of three layers and included an underwater graben. Transmitter and receiver were placed parallel to each other. The dipole - dipole system was moved near the bottom across the graben. Electric field was measured at frequency band 0.63…8.0 MHz. According to the EM scaling these frequencies correspond to low frequencies used in practice.
An electric field magnitude strongly decreased when the dipole-dipole system was crossing a graben border. Unexpectedly attenuation curves inside 3D graben look like respective 1D curves. Probably this feature is due to the horizontal skin-effect attributed to the sea-floor frequency sounding. The presence of the graben results in a valuable shift of the apparent resistivity curve in comparison with the model without inhomogenity (graben).

GA1.02/L/04-A1 Poster 1605-05

MODELLING THE ELECTROMAGNETIC FIELDS IN A THREE-DIMENSIONAL SPHERICAL EARTH USING INTEGRAL EQUATION APPROACH

Alexei KUVSHINOV, Dmitry Avdeev, Oleg Pankratov (all at Institute of Geoelectromagnetic Research, Russian Academy of Sciences, 142092 Troitsk, Moscow region, Russia,
email: akuvsh@igemiras.msk.ru), and Sergei Golyshev (Institute of Terrestrial Magnetizm, Ionosphere and Radiowave Propagation, Russian Academy of Sciences, 142092 Troitsk, Moscow region, Russia, email: s.golyshev@mtu-net.ru)

We present numerical solution of Maxwell's equations in a spherical, full three-dimensional (3D) Earth's model allowing for an anisotropy of electrical conductivity. The solution exploits the volume integral equation (IE) approach which has been originally presented in (Singer, 1995) as modified iterative dissipative method, and later generalized in (Pankratov et al. 1995, 1997). The IE approach is based on a Neumann (Born) series expansion, which is always convergent, even for large conductivity contrast.
Our solution was first checked against the 3D Cartesian solution (Avdeev et al., 1997) for the models with an isotropic, and anisotropic, upper mantle local conductor that is embedded in radially symmetric section. The models are excited by Dst source. Very good agreements were obtained. Comparison with staggered grid finite difference solution (Uyeshima and Schultz, 1998) was then conducted for a model including surface and upper mantle conducting layers. The layers have hemispherical, longitude dependent, distributions of conductivity. This comparison was again very good.

GA1.02/P/02-A1 Poster 1605-06

FINITE ELEMENT MODELLING OF MAGNETOTELLURIC FIELDS IN 2-D STRUCTURES WITH ARBITRARY ANISOTROPY

YUGUO LI and Ulrich Schmucker (both at Institute of Geophysics, University of Göttingen, Herzberger Landstraße 180, 37075 Göttingen, Germany, email: yli@willi.uni -geophys.gwdg.de Josef Pek (Geophysical Institute, Academy of Sciences of the Czech Republic, Bocní II/1401, 14131 Prague 4-Sporilov, Czech Republic, email: jpk@ig.cas.cz)

An algorithm for the numerical modelling of magnetotelluric fields in 2-D structures with arbitrary anisotropy is presented. Each anisotropic block is assigned a symmetric 3 x 3 conductivity tensor. The problem leads to a coupled system of partial differential equations for the strike-parallel field components Ex and Hx , to be solved with the finite element (FE) method. The system of linear FE equations for the primary field components is solved by the preconditioned conjugate gradient method. For the iterative solution, only the non-zero elements on and below the diagonal of the sparse coefficient matrix, arranged into a one dimensional array, are stored, which largely reduces the memory requirements of the solution. Subsequently, strike-perpendicular field components Ey and By , are evaluated numerically by the spline interpolation.
Our FE program has been tested by comparison with results from other methods, yielding satisfactory agreement. Three model types of anisotropy will be used to demonstrate their effect upon MT responses: horizontal, vertical and dipping anisotropy. They simulate the splitting of ra-curves and tensor impedances with significant diagonal elements, as observed at many places.

GA1.02/W/07-A1 Poster 1605-07

INVERSION OF CSEM DATA FROM FINITE-LENGTH LINE SOURCE EXCITING A 2D EARTH

Xinyou Lu, Martyn Unsworth and John Booker, Geophysics Program, Box 351650, University of Washington, Seattle, WA 98195, USA, Email: xinyou@geophys.washington.edu

In practice, a real CSEM electrical source is composed of a length of grounded straight wire. Often, to improve signal-to-noise ratio, either a long grounded wire is used or receivers are close to the source for strong signals. The approximation of the infinitesimal dipole may not always valid. Therefore, the length of a long grounded wire source has to be considered. We have extended our CSAMT-RRI inversion algorithm (Lu, et al., 1998) for data from electrical dipole to accommodate data from a finite-length line source. CSAMT-RRI combines 2.5D EM finite-element forward modelling method developed by Unsworth et al. (1993) and the rapid relaxation inversion (RRI) of Smith and Booker (1991).
In order to invert data from a finite-length line source, we extend the 2.5D EM finite-element method for line source. The 2.5D EM finite-element method is flexible for various sources. The nature of the source is introduced by the primary field, which is defined as EM fields in wavenumber domain (kx, y, z) for a simple conductivity structure, where x is defined as the strike direction.
The EM fields in domain (kx, ky, z) can be derived in closed form for 1D layered earth, then the required primary field can be computed readily. Once the primary field is given, the method can cope with any 2D model. We have investigated the effect on the EM fields, apparent resistivities and phases from the length of line source. The algorithm is tested on field data as well as theoretical models.

BOUNDARY ELEMENT METHOD(BEM) AND 2D OR 3D GEOELECTRICAL STRUCTRURE ANALYSIS

Jiadong QIAN (Center for Analysis and Prediction, China Seismological Bureau, P. O. Box 166, 63 Fuxing Ave. Beijing ,100036 , China , email: jdqian@sdb.cdsi.ac.cn) Qingzhong Ma (Department of Geology and geography, Lanzhou University , Lanzhou , 730000 , China) and Xianjin Mao (Seismological Bureau of Yunnan Province, Kunming, Yunnan Province, China)

Recent studies show that the effect of heterogeneous structure on the survey in geophysics , e.g. geoelectrical prospecting , should be taken into account more sufficiently . The previous methods with analytic solutions , however ,could only be suitable for a few typically simplified patterns and numerical methods , such as Finite Element Method(FEM), Finite Difference Method(FDM) etc., usually demand huge amount calculations with inconveniences. This paper deals with the applications of Boundary Element Method(BEM) in the survey of apparent resistivity on the site with the 2D or 3D geoelectrical structure with better accuracy, more convenience and less computations than the previous ones. Furthermore, much more complicated cases in horizontally layered models with 2D or 3D heterogeneous bodies contained inside some of layers have been also dealt with in the paper with the treatment of the infinitely extended interfaces between adjacent layers . The special basic solutions in BEM have been taken to let the infinitely extended interfaces "disappeared", so that the integral equations only contain the term of integral along the boundaries of heterogeneous bodies without the demands for taking the integral along the infinitely extended interfaces into account. The method (BEM) and the approaches shown in this paper, have provided good tools for solving the problems in geoelectrical prospecting in which the effects of heterogeneous structures should be taken into account , and could give a good base either for forward problems or inverse ones in the same conditions. Some examples of the research on these aspects have been shown in this paper.

MONTE-CARLO METHOD IMPLEMENTATION FOR DIRECT PROBLEMS OF INHOMOGENEOUS CONDUCTIVE MEDIUM ELECTROMAGNETIC SOUNDING

Vladimir L. Saveliev, OLEG L. KROTOFF, Institute of Ionosphere, Almaty, Kazakstan

Using the transformation of Maxwell equations to integral form, the electromagnetic field disturbances was represented as the interference of virtual photons, scattered on the conductivity inhomogeneties. The FORTRAN code with flexible configuration options for simulation of virtual photons scattering have been created. The scheme with possibility to take into account the symmetry of the sources was considered. The results of calculations for simple models was compared with analytical solutions. The number of calculations was carried out for the various configurations of scattering objects. Also the efficient calculation algorithm for the mediums with piecewise-constant conductivity was created and implemented as FORTRAN code.

NEURAL NETWORK BASED RECONSTRUCTION OF THE PARAMETERS OF 3D GEOELECTRIC STRUCTURES

Vjacheslav SPICHAK (Geophysical Research Centre, Moscow, Russia, e-mail: spichak@dol.ru) Kouichiro Fukuoka (OYO Co., Urawa, Japan, e-mail: fukuoka-kouichi@oyonet.oyo.co.jp) Toru Mogi (Kyushu University, Fukuoka, Japan, e-mail: tmogi@mine.kyushu-u.ac.jp) Irina Popova (Geoelectromagnetic Research Institute, Troitsk, Russia, e-mail: mpopov@isan.troitsk.ru)

Three-dimensional (3D) inverse problem of geoelectrics is solved by means of the Artificial Neural Network (ANN) approach. The properties of the supervised ANN are studied using the synthetic MT data base created for 3D conductivity model of the typical fault zone. Different groups of MT field components and their transfomations as well as data compression ways are studied in order to find those which provide the best recognition abilities. The influence of the volume and structure of the training data pool (including the "gaps" and "no target" effects) on the recognition properties is estimated. Results of numerous ANN testings demonstrate that it possesses good interpolation and extrapolation abilities. The effect of noise is studied by means of mixing the synthetic MT data with 30%, 50% and 100% Gaussian noise. A special

noise treatment technique based on testing as well as teaching data pre-processing is suggested. A case history is considered. CSAMT data measured in the MINOU fault area (Kyushu Island, Japan) are interpreted by means of trained ANN in terms of 3D conductivity structure. The results of interpretation match the apriori geological information and the inversion of other geophysical data.

PHYSICAL MODELLING NATURE ELECTROMAGNETIC FIELDS: MODERN STATE AND POSSIBILITY

Kobzova Valentina, Ladanivsky Boris and Moroz Ivan (all at Karpathian Branch of Subbotin Institute of Geophysics NASU, 3-b Naukova str., 290601 Lviv Ukraine, email: va@carp.lviv.ua)

Present report aims acquaiting oneself with the state of modern physical modelling of electromagnetic fields in inhomogeneous media which are characteristic of real geoelecteic situations. Physical modelling method may be used when immadiate observation, theoretical compulation or mathematical modelling is impossible or very expensive. To realize this method the specific laboratory installations is necessary. They must answer complicated technical requirements due to which these installations are considered by restricted usage. The laboratory installation "Model" worked out in Ukraine contains electrolytic tank 5.0 x 5.0 x 0.7 m where one creates multi-layer inhomogeneous geoelectric section scale models. Variations both of natural electromagnetic field or man-made sources are simulated by harmonic plane-homogeneous or dipole field. Automatic measuring and recording of electromagnetic field provides interpreting programmes. Opportunities for this nontraditional method may be shown by obtained results. We have modelled electromagneyic fields anomalies generated by interfaces of continental and oceanic crust in subduction zones,deep electric signals arising before earthquakes in seismoactive zones, nonstationary heat fields, some 3D inhomogeneity and anisotropic media, some type of ionospheric sources, daily and bottom surface relief.

QUASI-ANALYTICAL APPROXIMATIONS IN 3-D EM MODELLING

Michael ZHDANOV and Gabor Hursan (both at the University of Utah, Department of Geology and Geophysics, Salt Lake City, UT 84112, USA, email: mzhdanov@mines.utah.edu) Vladimir Dmitriev (Moscow State University, Moscow, 119899, Russia.

Quasi-linear (QL) approximation introduced by Zhdanov and Fang (1996) has been proved to be a powerful tool in 3-D EM forward modelling solution. It is based on an assumption that the anomalous electrical field within an inhomogeneous domain is linearly proportional to the normal field with some tensor coefficient called electrical reflectivity tensor. In this paper we introduce a new way to compute the QL approximation. It is based on a simple analytical formula for electrical reflectivity tensor calculation. This approach leads to construction of the quasi-analytical expressions for anomalous electromagnetic field for 3-D models. These solutions accelerate dramatically the forward EM modelling and make it practical an inversion over complicated 3-D inhomogeneous geoelectrical structures.

THEORETICAL STATEMENT OF SEISMOELECTRICAL PROBLEM IN POROUS WATER-SATURATED MEDIA

Boris S. SVETOV (Geoelectromagn. Res.Inst. RAS , Troitsk , Moscow reg., Russia, e-mail: svetov@geo.igemi.troitsk.ru), Valeriy P. Gubatenko (State Techn. Univ., Saratov , Russia).

Rocks are porous water saturated media.As a result of electrolyte ions absorption double electric layers are appeared on the boundaries of solid and fluid phases.Under an influence of pressure gradient the fluid flow and electric current are occured (an inverse electroosmosis).The current generates electric and magnetic fields.If a rock is in an alternating elastic field then such mechanism cases electromagnetic field generation. The interaction of elastic and electromagnetic fields in porous water-saturated medium may be described by complex selfconsistent system of partial differential equations. The solution of the system is extremly severe.An approximate solution of the problem may be found by sequential solving of 4 subproblems : 1) Lame equation for elastic field in the medium with effective parameters of Gassman.The result of the subproblem is a solid phase displacement Us. 2)Averaged equations of fluidodynamics in porous fluidosaturated medium. Under known Us a displacement of fluid phase Uf and pressure gradient grad P are found.3)Averaged equations of electrokinetics. Convection electric current Jex and electrokinetic coefficient Q ,which connects the current with pressure gradient , are found.4)Electrodynamic equations, in wich the obtained convection current plays role of extrinsic current.The sources of this current and electric field are occured in the areas where pressure gradients and petrophysical properties of medium (specific surface of porous space and permeability) are varied.

ELECTROMAGNETIC SOUNDINGS IN POLARIZABLE MEDIA (RESULTS OF MODELLING)

Vladimir V.Ageev and Boris S.SVETOV (both at Geoelectromagnetic Research Institute RAS, Troitsk, Moscow region, Russia , e-mail: svetov@geo.igemi.troitsk.ru).

It is well known, that induced polarization (low frequency dispertion - LFD) of rocks influences on electromagnetic (EM) soundings results. Usually LFD is approximated by Cole-Cole formula with exponent C 1. The more C the faster IP process decays. Apparently the value of C is connected with the physico-chemical nature of IP process. It may be shown, that at some restrictions on polarizability C may be 1£C£2 . At these values IP decay becomes oscillating. Such processes may be observed in so named bianisotropic medium. The mathematical modelling of EM fields of electric and magnetic dipoles above conductive and polarizable sections was performed. It was established: 1) At transient soundings the greatest influence is observed in the late stage, 2) The IP influence on EM soundings depend on the type of source and receiver of the field. At galvanic exitation and reception of the field the IP influence is much more than at inductive ones. In the case and in the late stage IP process predominates at C£3/2. Practically, in the case EM soundings are IP ones. 3)At inductive source electrodynamic process predominates at C≥1/2. In the case LFD of conductivity may lead to the increase of the depth of studies and of the resolution of the EM sounding. It corresponds to some degree to the experience of "high - resolution" electroprospecting. But in some cases IP distortions of EM sounding curves makes them non-interpretable by standart present-day methods. In the form the problem of interpretation becomes nonunique. To make it unique it is necessary to perform and to interpret jointly different types of soundings.

ON THE WAY OF TO THE EFFECTIVE SOLUTION OF TRANSIENT 3D MODELLING PROBLEM AND ITS APPLICATION TO GEOTHERMAL EXPOLORATION

Elena Fomenko (Geoelectromagnetic Research Institute RAS, Troitsk, BOX 30, Troitsk 142092, Moscow region, Russia, Email: igemi@pop.transit.ru) Toru MOGI (Department of Earth Resources Enginering, Department of Earth Resources Engineering, Graduate School of Engineering, Kyushu University 6-10-1 Hakozaki, Higashi-ku, Fukuoka, 812-8581, Japan Email: tmogi@mine.kyushu-u.ac.jp) Tatsuya Kajiwara (JMC Geothermal Endinering Co. Ltd, Takizawa, Iwate, 020-01, Japan)

We have developed a new 3D modelling scheme of TEM data. The scheme based on the staggered grid finite difference formulation for electrical field (Newmann,1995; Fomenko, 1998) with 'natural choice' continuous components of tangential electric field at the center of the edges and normal components of magnetic field at the center of each cell, opposite to well-known programs with discontinuous E-field at the face of the cells (Mackie and Madden, 1994; Smith, 1996; Weidelt,1995).
At first primary electrical field, excited by the electrical dipole source on the layered earth, is calculated. We introduced new kernels and extracted singularity analytically for halfspace kernel at all 3D grid in order to greatly accelerate the convergence of Fourier-Bessel integrals. Then seconary field, induced by the electrical charge accumulated at three-dimensional anomalous structures, is calculated in the frequeincy domain using BCGS-group methods. Due to 'natural choice' of components, all components of magnetic field are stably derived from derivatives of electrical field. At last transient vertical magnetic field is obtained from the Fourier transformation of the wide frequiency range data.

GA1.02/E/03-A1 Poster **1605-16**

CONSERVATIVE MODELLING OF 3D ELECTROMAGNETIC FIELDS WITH NATURAL CHOICE CONTINIOUS COMPONENTS OF THE FIELDS FOR PERSONAL COMPUTERS

Elena FOMENKO (Geoelectromagnetic Research Institute RAS, Troitsk, BOX 30, Troitsk 142092, Moscow region, Russia, Email: igemi@pop.transit.ru)

A new high effective 3D modelling scheme of MT data with conservation of electic current and magnetic flux is developed for personal computers. The scheme based on the staggered rectangular nonuniform grid finite difference (FD) formulation for the secondary electrical field with 'natural choice' continuous components of tangential electric field at the center of the edges and normal components of magnetic field at the center of face of each cell, opposite to well-known programs with discontinuous E-field at the face of the cells (Mackie and Madden, 1994; Smith, 1996; Weidelt, 1995). Due to 'natural choice' of E-field, all components of H-field are stably derived from curl E operation.
The speed of convergence of 13 band complex symmetrical system of linear equiations was investigated for modern powerfull BiCG methods. It is shown that good preconditioning of the matrix allows to decrease computation time in 10-20 times, especially for the low frequiencies and high resistivity contrast, and greatly increase the accuracy of solution. The results are pesented for Jacobi, SSOR and ILU preconditioners. During iterative process due to computer round-off errors Bi-CG vectors slightly lose orthogonality, it leads to appearence 'fictive currents' and greatly influences at the speed of convergency. The special module of correction of div-free current J was made similar to Smith's [1996] one, which allows greatly improve the speed of convergency and accuracy.
Due to effective combination good choice staggered grid, simple but effective precondutioner, support of div-free current J and powerfull solvers program requires extremely small size of memory - 850 Kb/ 1000 nodes of the grid and allows obtain high accuracy for relative residual ||b-AX||/||b|| < 1.E-10 withind one-two hundreds iterations on the grids of medium dimensions - 30000 nodes. The obtained FD solution has the same accuracy as other FD and IE programs (Mackie, Wanameker, Weidelt et all) on the models of COMMEMI project and more fast speed of convergency then latter ones.

MCMC INVERSION OF MT DATA IN 1-D SITUATIONS WITH PIECEWISE SMOOTH MODELS

M. MENVIELLE (CETP, 4 Avenue de Neptune, F-94100 SAINT MAUR, FRANCE and Universite Paris Sud, FRANCE), D. Marques, M. Roussignol (Universite de Marne la Vallee, FRANCE) and M. Lavielle (Universite Paris V, FRANCE)

In the Bayesian approach, the inverse problem solution can be obtained from a posteriori probability density function of the model parameters given the data and the a priori information. Stochastic algorithms based upon MCMC (Monte carlo Markov Chain) methods have already been developed to solve the Bayesian inverse problems in MT 1-D situations with an a priori probability density function which favour smooth models. The domain under study is divided into a large number of thin horizontal homogeneous layers whose thickness is fixed, and the model parameters are the conductivity of each layer. For each layer, the a priori and a posteriori laws are digitised over a limited set of conductivity values.
We use the same approach with a modified a priori probability density function which favour piecewise smooth models. We present an application of this MCMC algorithm to the inversion of both synthetic and field magnetotelluric data.

PRELIMINARY RESULTS FROM AN MT-SURVEY AROUND IOANNINA AREA, NW GREECE

G. BALASIS, N. Bogris, A. Abdulla and K. Eftaxias Solid Earth Physics Institute Panepistimiopolis, Zografos, Athens 15784, Greece

The magnetotelluric (MT) method is used towards the understanding of an eventual correlation, between the geoelectrical structure and the sensitivity of a region in recording Seismic Electric Signals. During the last years, MT measurements (frequency range 0.001-100 Hz) were made along a number of profiles, each one running approximately 20-30 km, that cross the Ioannina area in northwestern Greece. Mohr Circle Analysis as well as Groom-Bailey decomposition were applied to the full dataset defining dimensionality and strike. Preliminary results of modelling of the Ioannina electromagnetic response data using two-dimensional (2-D) inversion algorithms were also obtained.

MAGNETOTELLURIC STUDIES OF THE KYRGYZ TIEN SHAN

Vlad Batalev and Anatoly RYBIN (both at Scientific Station of the Institute for HighTemperatures - Association, Russian Academy of Sciences, 720049, Bishkek, Kyrgyz Republic, E-mail: rybin@laurel.gdirc.ru)

Over a period of 15 years, magnetotelluric and magnetovariation measurements (more than 300 soundings of period range 0.1-1800 s and 10 long period sites) were collected along a series of long and short submeridional profiles across the Tien Shan interplate orogen in Kyrgyzstan.
Frequency analysis of the inhomogeneity and asymmetry MT parameters distribution and examination of Hilbert transform relationship had allowed to suggest a superposition of the regional 2D and local 3D electrical structures. After distortion impedance analysis and correction (static shift removing and Groom-Bailey decomposition) a 2D inversion was performed and revealed a highly conductive widespread zone at mid-low crustal depths (20-50 km) and narrow upper crustal conductor located near the regional fault systems.
One more interesting result was obtained at the Fergana range area. Extensive 2D modelling revealed a high resistivity (50000 Oh.m and more) structure along the Talas-Fergana deep fault. Estimated thickness is about 10 km, the length more than 150 km and the depth from 6-8 km to 40-50 km. Enigma consists of the object resistivity is essentially higher than is attributed to anyone of the high resistivity blocks for obtained geoelectrical model beneath the Kyrgyz Tien Shan.
Comparative analysis of electromagnetic images of mid and deep crust with velocity profiles from seismic tomography data had demonstrated a stable correlation of low resistivity with low velocity of seismic waves.
The fluid conception of the crustal electrical conductivity was suggested.

INVERSION OF THE WEST CARPATHIANS GDS DATA FOR A THIN SHEET CONDUCTANCE

V. Cerv(1), M. Menvielle(2,3), J. Pek(1), O. Praus(1) (1) Geophysical Institute, Acad.Sci. Czech Rep. Bocni II/1401, CZ-14131 Prague 4, CZECH REPUBLIC (2) Centre d'Etudes des Environnements Terrestres et Planetaires, CNRS/UVSQ, 4, Avenue de Neptune, F-94107 SAINT MAUR DES FOSSES CEDEX, FRANCE (3) Universite Paris Sud, F-91405 ORSAY CEDEX, FRANCE

Previous electromagnetic investigations carried out in the area of West Carpathians and the surrounding units, based on the distribution of the induction vectors and on available magnetotelluric data, evidence significant contrasts of the electrical conductivity in the middle and lower crust. The electromagnetic effects of the conductive asthenosphere at various depths on surface induction data is evaluated on the basis of the 3-D forward modelling and thin sheet approximation. For the modelling of the superficial layer an electromagnetic imaging program is used based on the thin sheet approximation. The sheet is digitised in homogeneous square cells, and a Markov chain is used to determine the a posteriori law of the conductance in each cell given the data and an a priori knowledge on the conductance. The obtained map of conductivity is presented and discussed in the tectonic framework of the region.

A MAGNETOTELLURIC STUDY OF THE SEISMIC-ACTIVE REGION OF NORTHERN BOHEMIA

Cerv V. , Pek J. (both at Geophysical Institute AS, 141 31 Praha 4, Czech Republic, email: vcv@ig.cas.cz), De Santis A. , Di Mauro D. (both at Istituto Nazionale di Geofisica, Rome, Italy, email: desantisag@ing750.ingrm.it), Manzella A., Volpi G.(both at C.N.R., International Institute for Geothermal Research, Pisa, Italy, email: adele_m@iirg.pi.cnr.it),Zaja A., Praticelli N. (both at Dip. Geologia, Paleontologia e Geofisica,Padua University, Padua, Italy, email: zaja@epidote.dmp.unipd.it)

A three-year Italian funded project allowed a cooperation between some Italian Institutions and the Geophysical Czech Institute with the objective of studying, from the electromagnetic point of view, the Northwest Bohemia (Czech Republic), a region interested by a peculiar seismicity characterised by micro-earthquake swarms occurring during apparently quiescent intervals between large macro-seismic swarms. During 1997, fifteen high-frequency magnetotelluric (MT) stations were installed in an area where 80% of the seismicity of the entire region has been recorded since 1986. This area showed a high electromagnetic noise, probably connected with the nearby industrial zone of Sokolov. 2D and 3D techniques were used to study and then model the MT characteristics. The results show a conductive structure in the depth range of 0.5 to 3 km that could be connected with the presence of the locally buried granitic massif. Models considering this shallow structure can explain most of the features found in the experimental data. The possibilities of detecting some conductive bodies connected to fracturation, thermometamorphism or paleofluids at the focal depth have been tested.

ELECTROMAGNETIC STUDY OF CENTRAL ITALY

De Santis A., Di Mauro D., (both at Istituto Nazionale di Geofisica, via di Vigna Murata, 605 00143 Rome, Italy; fax: +39065041181; email: desantisag@ing750.ingrm.it) Cerv V., Pek J. (both at Geophysical Institute AS, 141 31 Praha 4, Czech Republic; email: cv@ig.cas.cz)

During recent years Central Italy have been studied by means of a Magnetovariational technique. This research made it possible to propose 2-D models along several profiles of this area. In order to evaluate the effects of both the near surface sediments and the sea on our induction data, a novel conductance map of the investigated region is here presented and the contribution of the superficial layers is evaluated. Then a 3-D model is designed, whose the most evident feature is a deep conductive structure beneath the Apennines.

SOME EXPERIMENTAL RESULTS OF "KOLA PROBE" PROJECT

Fainberg, Ed., ABRAMOVA, L., Barsukov P., Vasilieva T., Kuksa Yu. Geoelectromagnetic Researches Inst. RAS. 142092 Troitsk, Moscow reg., box 30, Russia E-mail: abramova@geo.igemi.troitsk.ru

The experimental measurements were carried out at Kola Peninsula. The TEM-FAST system in one-loop configuration has been used in this experiment. The objective of the project was investigation of the induced polarization (IP) effect, estimation and monitoring of IP's parameters. Analysis of the field data allowed defining conclusions: Phase of the registered processes is opposite to a phase of inducing currents in the whole time-domain range; the amplitudes of the measured processes are proportional to cube of a loop size, while for induction processes in near zone it should be proportional to a fourth degree of a loop size; magnetic susceptibility effects were not detected. Field data have been interpreted within the class of Cole-Cole models. Determined parameters of the models were used to construct synthetic sounding curves for the system with transmitter loop 4km* 4 km and various configurations of receiving loops. Analysis of synthetic curves has shown that induced polarization processes can produce powerful negative signal in whole time-domain range. This work is supported by the Russian Foundation of Basic Researches, grant 97-05-64585.

GA1.02/E/35-A2 Poster **0930-07**

ANISOTROPY AND TERRAIN EFFECT ON MT DATA FROM TAURIDE TECTONIC BELT (SWTURKEY)

Aysan GÜRER and O.Metin Ilkisik (both at University of Istanbul, Faculty of Engineering, Dept. of Geophysical Engineering, Avcilar Campus, Avcilar, 34850, Istanbul, Turkey,
email: agurer@istanbul.edu.tr)

The Tauride belt has the most complicated geology among the six main tectonic belts of Anatolia. The collision tectonics between the African and Eurasian plates in Lower Miocene in the south lead to thickening in the crust and uplifting of the region. This resulted in development of Tauride mountain chain. The Hellenic subduction arc is one of the prominent tectonic events in the south of the region. The closure of Neo-Thethys Ocean in Late Cretaceous caused emplacement of the alloctonous units and formation thrust zones in western Taurides. These discontinuties are formed by late Miocene-Pliocene and Late Quaternary compression and Pliocene and Quaternary graben forming extension phases. The magnetotelluric (MT) studies were carried out in the western Tauride region in 1986, 1987 and 1997-1998 summers. A considerable anisotropy is observed in MT data from some certain sites that are located near to the strong terrain discontinuties. In some regions it is suspected that both of the topographic and tectonic discontinuties may contribute to the observed anisotropy together. It is important to separate the effects of the topography and subsurface tectonic structures on the MT responses especially in the regions where the geology is very complex. There are such MT sites on the 160 km long Elmali profile in western Taurides. The terrain effect on the data from some selected sites along this profile will be removed by the distortion stripping off technique. As the result faults and 2D geological structures will appear more clearly on the MT sections by the separation of terrain and tectonic effects and deep relations of the fault and trust zones in the western Tauride belt that is situated in northern edge of Hellenic subduction zone will be explained more precisely.

ANALYSIS OF DISTORTED GDS TRANSFERFUNCTIONS FROM THE PENNINIC ALPS OF EASTERN SWITZERLAND

Marcus GURK (Groupe de Géomagnétisme, Institut de Géologie, Université de Neuchâtel, Rue Emile-Argand 11, CH 2007 Neuchâtel, email: marcus.gurk@geol.unine.ch

We have carried out at least 64 MT and GDS soundings in the Alps of eastern Switzerland to get first information about the electrical conductivity distribution of this region. One of the main findings was an anomalous directional behaviour of the real indcution arrows in the period range of T= 1-300 s on the mesozoic sediments (Bündnerschiefer). These sediments are situated between the Aar and Gotthard massifs to the North and the crystalline penninic nappes (Adula, Tambo and Suretta) to the South. Deep geoelectrical surveys in the Southern Alps revealed the existence of a substratum with high resistivity values (15 000 - 40 000 ohmm). These values strongly suggest the existence of lateral conductivity contrasts of 1 to 10 000 and deep penetration depths of the electromagnetic field in the host medium from the mesozoic sediments. A particular geometry of the tectonic units in the investigation area leads to the assumption that telluric currents induced in remote areas and finally channelled in surface boundaries of the sediments are responsible for the anomalous directional behaviour of the induction arrows.
The analysis of the GDS transfer functions yields following conclusions: 1) a spatial decoupling of induction processes. 2) the mesozoic sediments in the investigation area are local condcutive inhomogeneities. 3) a remote L shaped crustal conductive structure of regional extension with an azimuth of 45°N can cause the observed magnetic distortion of the GDS data

CONDUCTIVITY OF EARTH CRUST AND UPPER MANTLE OF UKRAINE

SERGEY KULIK, Tatjana Burakhovich (Institute of Geophysics of National Academy Science of the Ukrainian, Palladina str. 32, Kiev,252680, Ukraine, 252 Email: kulik@sabbo.net)

After a long time of studies by methods of magnetotelluric sounding and magnetovariation profiling a great amount of experimental material has been accumulated for construction a map of electro-conductivity of Earth crust and upper mantle using a technique of 2D and 3D modelling of magnetotelluric field. As a result, we received new data on electro-conductivity in different geological areas from procembrian crystalline Ukrainian Shield to alpine Ukrainian Carpathian Mountains. It's shown that contact between old East - European and more young West-European platforms is characterized by a series of high conductivity anomalies on depths of 20-30 km and width of anomalous areas of 50-60 km. In some cases, conductivity anomalies lie in the Earth Mantle on depths from 50 to 120 km with the resistance - 20 Ohm. A 600 km long anomaly is found on the Ukrainian Shield. In hercinian areas of Dnipro- Donec fault and Donbass electro-conductivity anomalies lie on depths from 10 to 20 km with the total longitudinal conductivity up to 10000 S. In Crimia's cimerids a conductor lies at the depth of 110 km and in the western Crimia an area of conductivity was discovered in the crust and upper mantle. Alpine Carpathian Mountains are characterized by the Carpathian conductivity anomaly at the depth of 12 km. It is possible to separate the nature of anomalous areas into two basic types. The first type consists of anomalous objects where increased conductivity is defined by the specific composition of rocks in the Earth crust, like a possible presence of grafitisides or accumulation of ore elements. The second type consists of objects with increased conductivity and also anomalously high values of heat flow. A presence of highly mineralized fluids and anomalously high temperatures at big depths and consequently, partly melted rocks, caused by tectonical activization is probable there. In number of places horizontal size of areas of increased electro-conductivity is significantly bigger than size of heat flow anomalies . In other places spatial position of geo-electrical and heat flow anomalies coincides.

CHARACTERIZATION OF THE TRANSITION ZONE BETWEEN SOUTH PORTUGUESE AND OSSA MORENA ZONES FROM MT DATA AND RHEOLOGICAL PROFILES

Eugenio ALMEIDA, Fernando Santos, L. A. Mendes-Victor (Centro de Geofísica da Universidade de Lisboa, R. Escola Politécnica, 58, 1250 Lisboa, Portugal, email: dfams@fc.ul.pt) Jaume Pous, Alex Marcuello, Pilar Queralt (Departament de Geodinamica i Geofísica, Universitat de Barcelona, Martis Franques s/n. Barcelona, Spain, email: jaume@natura.geo.ub.es)

The transition between the South Portuguese Zone (SPZ) and the Ossa Morena Zone (OMZ) is made up of a major geosuture, which is indicated by the Beja-Acebuches ophiolite. Several geological data suggest that this suture is a result of an oblique collision, with a northward propagation, between SPZ and OMZ.
With the aim to characterize this transition zone Universities of Lisbon and Barcelona carried out a magnetotelluric survey. The 2D inversion model obtained, from 20 MT sites, revealed a large conductivity body (<10 Ohm m) with depth and thickness increasing from south to north. Considering heat flow values and seismic models, average rheological profiles were calculated for OMZ and SPZ. Average values of thickness and total strength of the lithosphere were estimated from those profiles. The observed distribution of seismic focal depths, in those zones, correlates well with depths suggested by the rheological profiles. A good correlation between soft layers and low electrical resistivity layers is also observed.

GA1.02/W/15-A2 Poster **0930-11**

A THREE-DIMENSIONAL MAGNETOTELLURIC INVESTIGATION OF THE VILARIÇA DEPRESSION (NE PORTUGAL)

Fernando SANTOS, Liliana Matos, Luís Mendes- Victor (Centro de Geofisica da Universidade de Lisboa, R. Escola Politecnica, 58, 1250 Lisboa, Portugal, email: dfams@fc.ul.pt) António Mateus (Departamento de Geologia da Universidade de Lisboa) and Eugénio Almeida (Instituto Politecnico Tomar)

Magnetotelluric observations were carried out at 30 locations on the main tectonic depression associated with the Manteigas-Vilariça-Bragança fault, in northeast Portugal. The Vilariça Fault Zone (VFZ) is one of the major elements of the late Hercynian strike-slip network in the NW Iberia and the Vilariça depression (20 km long and 2-3 km wide). It is an example of intraplate neotectonic activity, since it is a pull-apart basin resulting from left-lateral strike-slip displacement of the VFZ during Quaternary times.
A three-dimensional magnetotelluric model of the studied zone was constructed based on the preliminary two-dimensional interpretation of three magnetotelluric profiles across the depression. The main tectonic structure represented by the segment of the Vilariça fault, oriented NNE-SSW, is well displayed in the model. The Quaternary sedimentary fill of the depression is expressed by low resistive bodies, surrounded by more resistive bodies, which are associated with metasedimentary formations which are overlying a high resistive gneissic basement.

FIRST ELECTRIC FIELD OBSERVATIONS IN THE CAM-1 CABLE BETWEEN MADEIRA AND LISBON

Fernando SANTOS, António Soares, Jorge Miranda, Luís Mendes-Victor (Centro de Geofisica da Universidade de Lisboa, R. Escola Politecnica, 58, 1250 Lisboa, email: dfams@fc.ul.pt) and the ISO-3D Group.

The voltage difference between the ends of the CAM-1 cable, a retired telephone cable between Madeira Island and Lisbon, has been monitored since November 1998. The cable is 1,100 km long and its end, near Lisbon (Portugal), is grounded to the ocean bottom. A previous analysis of the cable, carried out before the installation of the instrumentation, showed that the cable conditions have not significantly changed during the last year. Monitoring of the cable is being done at a sampling rate of 1 s but only the average values, taken over 30 s, are recorded. We present the first months data series, a preliminary analysis of the results and we discuss the possibilities open with the availability of this cable to regional scale studies. A new MT station in Porto Santo (Madeira) is foreseen to allow ocean transport and Earth electrical structure modelling.

GA1.02/W/14-A2 Poster **0930-13**

THE COMBINATION OF LARGE SCALE DC AND MAGNETOTELLURICS

E. SCHNEIDER, J.B. STOLL (both: Institute of Geophysics, University of Goettingen, Herzberger Landstr. 180, 37075 Goettigen, Germany, email: edgar@geo.physik.uni-goettingen.de)

Layers of a high electrical conductivity are often found in the middle crust of central europe. The MT-method is sensitive to high conductivities, so the top of such a layer can be resolved quite well whereas the buttom is hard to detect. In contrast, DC-sounding is sensitive to high resistivities. The combination of both methods can increase the resolution of the electrical parameters of the earth. Theoretical work about this combination was already done in the past, but field data is very rare. With a new generator/transmitter system the university of Goettingen can achieve a long scale field setup with transmitter-receiver distances of more than 50km. The poster presents measurements made in the Muenchberg gneisse massif, a crystalline nappe in the variscian part of southern Germany. The MT data reveals apparent resistivities lower than 1 Ohm*m. Aim of the combined analysis is the resolution of a shallow layer of high conductivity.

GA1.02/W/04-A2 Poster **0930-14**

JOINT INTERPRETATION OF FOUR GEOPHYSICAL METHODS FOR THE DETERMINATION OF THE ELECTRIC RESISTIVITY IN THE UPPER CRUST

Klaus Spitzer, Bernhard Fluche (Joint Geoscientific Research Institute, Stilleweg 2, D-30655 Hannover, Germany. Email: klaus.spitzer@gga-hannover.de, bfluche@gga-hannover.de) Wolfgang Storz (Hydrogeologie GmbH, P.O. Box 1330, D-04855 Torgau, Germany, Email: HGNTorgau@aol.com)

Within the framework of a research programme, field measurements with four different geophysical methods (well logging, DC geoelectric soundings, magnetotellurics (MT) and vertical gradient method) were carried out in the central part of Germany. The objective of this research program was to combine different geophysical methods for an integrated interpretation of the subsurface structures and to better understand the physics of the involved current systems.
On seven sites - five of them lay on a profile with a length of 50 km - magnetotelluric measurements have been carried out and were accompanied by DC soundings. At almost each site measurements with different electrode configurations have been performed. Additionally, at the central site also bore hole and vertical gradient measurements were conducted. One result of this project was to show the correlation between the DC sensitivities and the static shift in the MT measurements, another one to give an interpretation of the MT data with a reasonable resistivity model and the correction of the shifted MT data.
The distribution of the electric resistivity is investigated with electric and electromagnetic methods covering scale lengths varying over orders of magnitude. Borehole measurements yield information on the resistivity in close vicinity of the hole (metre range) whereas DC soundings penetrate into a depth of some hundred metres and MT measurements up to 100 km. In order to eliminate the static shift from the MT data the vertical gradient method was also applied. This method is similar to MT but the horizontal electric field components are replaced by the vertical gradient of both horizontal magnetic field components obtained by measurements on the surface and in a bore hole. Since the conductance at this location is known then distorted MT data can be corrected.

RESULTS OF MAGNETOTELLURIC MEASUREMENTS IN CENTRAL GERMANY AS A PART OF A JOINT INTERPRETATION

Bernhard FLUCHE, Klaus Spitzer (Joint Geoscientific Research Institute, Stilleweg 2, D-30655 Hannover, Germany. Email: bfluche@gga-hannover.de, klaus.spitzer@gga-hannover.de Wolfgang Storz (Hydrogeologie GmbH, P.O. Box 1330, D-04853 Torgau, Germany,
Email: HGNTorgau@aol.com)

In 1996, magnetotelluric (MT) measurements were carried out in a region in the central part of Germany. These measurements were part of a campaign where different geophysical methods - borehole measurements, DC soundings and the vertical gradient method - were conducted besides MT. The area was located at the northern edge of the Central German Cristalline Zone. The geology of this region can be described by almost horizontally layered tertiary sediments with a slight dip from NW to SE. Underneath, these layers are followed by the zechstein base in approximately one km depth. In the northwestern part the measuring area is confined by the Rhoen mountains.
The MT measurements and DC soundings were carried out at five sites along a profile of 50 km length. The raw MT data seem to be rather uniform at all sites. After determining a nearly frequency-independent Swift angle of approximately 40 degrees a remarkable splitting of the apparent resistivity curves for both polarization modes is achieved. The direction of the Swift angle corresponds to the main geological strike. The splitting can either be explained by an anisotropic crust or by a rather simple 2D-resistivity model which matches most of the observed data in a wide period range. We prefer the latter explanation because of the geological situation of this region. While the phases could be explained well, discrepancies occurred in the fit of the resistivity curves. As a reason for this misfit we assume a static shift effect at least at one site. It is planned to find a procedure to eliminate this effect by using the results of the vertical gradient method and the DC sensitivities.

MAGNETOTELLURIC STUDY OF THE TETHYAN SUTURE ZONE, ROMANIA

Dumitru STANICA (Geological Institute of Romania, 78344 Caransebes Str.,1, Bucharest 32, Romania, Email: stanica@ns.igr.ro)

Magnetotelluric measurements have been carried out at 28 locations along a 320km west-east profile, crossing the Tethyan Suture Zone, which represents a complex tectonic unit constituted of ophiolitic and sedimentary formations, belonging to the Tethyan ocenic crust. The impedance tensor decomposition technique has been used to derive regional 2D resistivity and phase responses corresponding to the electromagnetic induction in orientation parallel and perpendicular to both the Tethyan suture and the major structural units. The model obtained by using 2D forward modelling (finite element method) reveals a large conductive zone (about 20km wide) to be associated with the Tethyan suture, placed between two blocks of continental crust: Inner Dacides (having a thickness of 22 - 25km), towards west, and Median Dacides (with a thickness of 28 - 30km), towards east.

A DENSE MT PROFILE ACROSS THE IAPETUS SUTURE ZONE IN S.W. SCOTLAND

S.TAUBER (1), O.Ritter (2), G.Dawes (1) and R.J.Banks (1), (1) Dept. of Geology and Geophysics, The Univ. of Edinburgh, UK, (2) GeoForschungsZentrum Potsdam, Germany

The resolution of MT is inherently limited by the attenuation of the electromagnetic fields. Nonetheless relatively thin vertical conductors associated with fault and shear zones have been detected in recent MT studies indicating the ability of the MT method to map zones of past or present zones of weakness in the earth crust. Previous MT profiles across the Iapetus Suture in southern Scotland and central Ireland have detected a highly conductive middle crust. The observations, limited in spatial density and frequency range, and of mixed quality, have been interpreted as indicating a quasi-continuous horizontal conductor at depths of 8-12 km, rising to less than 5 km at the inferred location of major faults and shear zones. A new MT profile with increased site density and frequency range crosses the suture zone in S.W. Scotland. The profile crosses a major fault, a ductile shear zone, and a number of outcrops of black shales which mark the base of thrust wedges, all created during the Caledonian orogeny and closure of the Iapetus ocean. In addition, the area is cut by later faults which have caused differential uplift of the Caledonian rocks along strike, affording "windows" to different structural levels. The principal cross-strike profile is supplemented by measurements on shorter parallel profiles and observations along the strike. 2-D inversion modelling suggests that high conductivity occurs in a number of thin vertical blocks (rather than a continuous layer) that correlate with the black shale outcrops.

LONG OFFSET TENSOR APPARENT RESISTIVITY STUDIES OF THE TAUPO VOLCANIC ZONE, NEW ZEALAND

H.M. BIBBY, T.G. Caldwell and G.F. Risk (Institute of Geological and Nuclear Sciences, PO Box 30-368, Lower Hutt, New Zealand. Email: h.bibby@gns.cri.nz)

The Taupo Volcanic Zone (TVZ) is the centre of rhyolite volcanism in New Zealand and is characterised by large-scale ignimbrite eruptions, numerous caldera centres and more than 20 active geothermal systems. Three long-offset multiple-source (tensor) bipole-dipole surveys, which together span the width of the TVZ, have been used to determine the resistivity structure down to depths of 5-8 km. These data have been interpreted using the constraints provided by extensive shallow (< 1 km) resistivity mapping made with the Schlumberger array.
The deep resistivity structure defines three distinct regions within the TVZ, with boundaries approximately parallel to the eastern margin. These zones appear to reflect the tectonic and hydrothermal processes that are occurring within the TVZ. The eastern zone of the TVZ is about 15 km wide and is characterised by highly conductive rocks (< 10 m) that extend that extend from about 2 km to at least 3.5 km depth. The conductive nature of these rocks is believed to reflect clay minerals within volcanoclastics which have infilled a series of overlapping and coalescing calderas. About 70% of the geothermal discharge of the TVZ (4200 MW) occurs through this region. To the west of this zone lies the Taupo Fault Belt, beneath which resistivities are an order of magnitude higher (>300 m) to depths of at least 7 km. In contrast to the eastern zone, the Taupo Fault Belt has low heat flux, high seismicity and is undergoing rapid tectonic extension. The third zone occurs at the west of the TVZ is conductive at depths below 500m, reflecting thick ignimbrite sheets whose low resistivity is believed to be caused by clay minerals produced by diagenetic alteration.

The resistivity observations support a model of convective heat transport in the TVZ. The thickness of high resistivity in the Taupo Fault Belt constrain the depth of the base of the convective zone that in turn represents the transition from brittle to ductile behaviour in the TVZ.

A MAGNETOTELLURIC STUDY OF THE CENTRAL VOLCANIC REGION, NEW ZEALAND

Malcolm INGHAM (Institute of Geophysics, Victoria University of Wellington, PO Box 600, Wellington, New Zealand, email: Malcolm.Ingham@vuw.ac.nz)

The Central Volcanic Region (CVR) of is a wedge-shaped area in the central North Island within which lie nearly all of New Zealand's active volcanoes and geothermal fields. Previous geophysical studies indicate that the CVR has a thin crust overlying a highly anomalous mantle. Earlier magnetotelluric soundings and bipole-dipole resistivity data have shown that within the eastern part of the CVR low resistivity exists at depths beneath about 1-2km. Little is known, however, of the deep resistivity structure of the region and how this relates to the extensive volcanic and geothermal features.
New broadband magnetotelluric soundings have been made on a transect of the CVR in the vicinity of Rotorua where the CVR has a width of about 75km. Initial indications are that the results confirm a sharp decrease in resistivity across the eastern boundary of the CVR but present a much more complex structural picture in the western part of the region.

ELECTRICAL STRUCTURE OF THE HIKURANGI MARGIN, NEW ZEALAND

Malcolm INGHAM (Institute of Geophysics, Victoria University of Wellington, PO Box 600, Wellington, New Zealand, email: Malcolm.Ingham@vuw.ac.nz) Kathy Whaler (Department of Geology & Geophysics, University of Edinburgh, Kings Buildings, West Mains Road, Edinburgh EH9 3JW, UK, email: kathy.whaler@ed.ac.uk) Don McKnight (Institute of Geological & Nuclear Sciences, PO Box 30368, Lower Hutt, New Zealand, email: d.mcknight@gns.cri.nz)

Broadband magnetotelluric soundings have been made at over 40 locations along and across the Hikurangi Margin on the east coast of the North Island of New Zealand. A 2D inversion of data from 19 sites along a 130km transect crossing the central southern part of the Margin shows a considerable variation in electrical resistivity structure. The onshore part of the Hikurangi forearc, comprising Cretaceous to Pliocene sediments is marked by a resistivity of less than 10 ohm-m down to a depth of about 5km. Further west exposed Mesozoic greywacke basement has a much higher resistivity. At the north-west end of the transect low resistivity to several kilometres depth corresponds to the Tertiary sediments of the Wanganui Basin. Beneath the eastern part of the transect there is no clear indication of a low resistivity zone associated with the top of the subducted plate at around 10-15km depth. Seismic refraction data from this part of the Margin similarly does not require a low velocity zone at the plate interface although amplitude modelling of seismic data from 100km further to the south-west does suggest the existence of such a feature. Data and results from both this transect and a second transect further to the south will be presented.

THE COAST EFFECT IN GEOMAGNETIC PULSATIONS AT ANTARCTIC OBSERVATORY DUMONT D`URVILLE KLEIMENOVA N.G., KOZYREVA O.V., BITTERLY J., SCHOTT J.-J.

The many years geomagnetic pulsations observations at Dumont d`Urville observatory show an unusual large enhancement of the vertical Z-component relating to the horizontal ones. This effect could be caused by induction ocean electric currents along coast line where this station is located. The frequency distribution of the geomagnetic transfer function for the daytime cusp pulsations has been analyzed. It was found that the value of this function is strongly and nonlinear depended on the pulsation frequency. The preliminary result showed some almost constant frequency maxima at about 2.0-2.5 mHz, 11-13 mHz, 20-25 mHz, 30-32 mHz, 38-42 mHz. The spectral distribution in frequency range 2-10 mHz may change from one event to another. The transfer function dependence on the geomagnetic activity, local time and season has been studied.

A GEOMAGNETIC INDUCTION STUDY ACROSS THE EAST COAST OF AUSTRALIA, AND ITS RELEVANCE TO HIGH-RESOLUTION AEROMAGNETIC SURVEYS

Peter R. MILLIGAN (Australian Geological Survey Organisation, GPO Box 378, Canberra, ACT 2601 Australia, email: Peter.Milligan@agso.gov.au) Adrian Hitchman (Research School of Earth Sciences, Australian National University, Canberra, ACT 0200 Australia, email Adrian@rses.anu.edu.au) F.E.M. (Ted) Lilley (Research School of Earth Sciences, Australian National University, Canberra, ACT 0200 Australia, email: Ted.Lilley@anu.edu.au)

Geomagnetic variations measured close to a coastline usually show an enhanced vertical (Z) component. This is known as the "coast effect" (CE), and has been well documented by many studies at various continental margins for longer period variations (several minutes to many hours). The effect at micropulsation periods (a few seconds to several minutes) is relatively unknown.
At mid-latitudes, total field (F) variations, as measured by airborne surveys, also include influences from the CE, as Z variations provide a significant input to F. Most CE studies have not included information on F, which is important for accurate reduction of airborne magnetic survey data.
Time variations in three components of the geomagnetic field were recorded along a profile across the east coast of Australia, from the deep ocean to well inland. The instruments all used high-resolution ring-core fluxgate sensors, and sampled at 10 s or better. Z variations at long periods show the classical CE, although at short periods induction vectors at the coast point south, parallel to the coast. Close to the coast, induction at short periods may be complicated locally by a river and its estuary. F variations are more complex than Z, particularly at short periods - at the coastline, they are reduced in amplitude, but display a phase reversal and amplitude enhancement offshore.

IMPLICATIONS OF DEEP RESISTIVITY STRUCTURE OF THE TAUPO VOLCANIC ZONE, NEW ZEALAND

Y. Ogawa, S. Takakura, T. Uchida, N. Matsushima, T. Tosha, Y. Nishi(Geological Survey of Japan, Tsukuba, 305-8567, Japan, email:oga@gsj.go.jp) T.G. Caldwell, H. M. Bibby, S. L. Bennie (Institute of Geological and Nuclear Sciences, Lower Hutt, P.O. Box 30368, New Zealand)

We investigated the resistivity structure of the crust and upper mantle across the Taupo Volcanic Zone (TVZ) of North Island, New Zealand, which is a region of back-arc extension. We had 16 wide-band (0.01-1800s) sites and 8 long period (20s -13,000s) sites along a 150km profile. Induction arrows and impedance decompositions support a regional strike of N45deg E. A deep resistivity model obtained after 2D inversions showed the followings. (1) The surface conductors down to 5km depth correspond to known caldera structure and active geothermal fields. (2) A deeper conductor (at 15km) was found beneath the Taupo Fault Belt (TFB), consistent with the seismic Moho depth and the seismic reflective layer offshore. This location also coincides with the area of concentrated extension inferred from recent GPS data. These suggest that the conductor is a magmatic melt. (3) Upper mantle beneath TVZ below 20km depth is relatively conductive. Consistency with a region of high seismic attenuation suggests a partial melting zone.

SWELL: MAGNETOTELLURIC INVESTIGATION OF THE HAWAII HOT-SPOT

ANTONY WHITE and Graham Heinson (School of Earth Sciences, Flinders University, GPO Box 2100, Adelaide 5001, Australia, email: antony.white@flinders.edu.au, graham.heinson@flinders.edu.au) Steven Constable (Scripps Institution of Oceanography, La Jolla, CA 92093-0225, USA, email: sconstable@ucsd.edu)

From April to December 1997, 8 ocean floor magnetotelluric sites and 8 hydrophone sites were occupied in a joint MT/seismic study of the Hawaii Swell. The MT objective of the experiment was to image melt accumulation beneath the 1000 km wide, 1 km high area of the swell. MT and geomagnetic depth sounding estimates over periods of 600-100,000 seconds were obtained.
The ocean floor electric field was remarkably uniform across all sites; this is a common feature seen in ocean floor MT experiments. In conjunction with land magnetic field variations measured on Hawaii this produces a 1-D inversion showing uniform conductivity of 10 ohm-m to great depth beneath Hawaii itself. In general, the MT data range from >100 ohm-m at short periods to 10 ohm-m at long periods and show effects due to the Hawaiian Islands and their associated bathymetry. A 2-D inversion which includes bathymetry suggests that a molten layer (< 20 ohm-m) rises beneath the island chain by about 50 km vertically and over a lateral scale of 400 km.

SWAGGIE: SOUTHERN WATERS OF AUSTRALIA GEOELECTRIC AND GEOMAGNETIC INDUCTION EXPERIMENT

ANTONY WHITE and Graham Heinson (School of Earth Sciences, Flinders University, GPO Box 2100, Adelaide 5001, Australia, email: antony.white@flinders.edu.au, graham.heinson@flinders.edu.au) Steven Constable (Scripps Institution of Oceanography, La Jolla, CA 92093-0225, USA, email: sconstable@ucsd.edu) Peter Milligan (Australian Geological Survey Organisation, GPO Box 378, Canberra, ACT 2601, Australia, email: pmilliga@agso.gov.au) Ted Lilley (Research School of Earth Sciences, Australian National University, Canberra, ACT 0200, Australia, email: Ted.Lilley@anu.edu.au)

In April-May 1998, 53 magnetotelluric (MT) and magnetometer sites were occupied to study the crustal structure of the southern margin of Australia. Of these, 23 were land sites on Eyre Peninsula, South Australia, 18 were long period (40-100,000 seconds) marine MT sites and 12 were short period (0.1-1000 seconds) shallow marine MT sites. The marine instrument array stretched from the coastline, across the continental shelf, and into the deep ocean. It thus extended the investigation of the Eyre Peninsula Anomaly (EPA), a major linear electrical conductivity structure, of 3,000-10,000 Siemens total conductance, which has previously been mapped from the coastline to about 500 km inland. The marine data show that the EPA can be traced to the edge of the continental shelf, confirming it as a continuous crustal feature associated with major regional tectonic faulting.
High frequency MT results were dominated by the oceanic swell whose EM signal was several orders of magnitude larger than that induced by ionospheric activity. This signal was also evident in towed magnetometer and self potential (SP) data. 500 km of this latter data revealed a strong marine SP anomaly of up to 200 mV. There is little correlation of the SP and magnetic data, suggesting a non-ferrous source. It is possible that the SP signal is associated with graphite mineralisation within a mylonite zone evident in southern Eyre Peninsula, but not directly coincident with the conductivity anomaly.

GEOELECTROMAGNETIC INVESTIGATION AT SEYMOUR ISLAND, ANTARCTICA

M. Mamaní (1), D.Trad (2), B.Castiglione (3) (1)Univ. Nac. de La Rioja; CONICET, Ortiz de Ocampo 1700. La Rioja. (2)CONICET, Mendoza, Argentina (3)Univ. Nac. de La Rioja y Univ. Nac.de Cuyo, Argentina.

In order to investigate the near surface conductive layers at Seymour island, next to Antartic peninsula, four magnetotelluric soundings were carried out (Mara 1,2,3 y 4) in 1996. Three soundings were performed on the central plateau and the fourth next to the coast. Electromagnetic recordings in the range of periods from 0.0025 s to 250 s were obtained in each locatiion, aparted 1400 m each other. Recorded data in one place (Mara3) were found to be noise contaminated, due to the proximity of Base. A robust program was used for processing and the three soundings on the plateau were principally used for the interpretation. All sites show a similar results: on the plateau 1D modellings give an estimation for the depth of permafrost's bottom of 170 m with 53 – 98 ohmm. Toward the coast the permafrost becomes thinner and more conductive. The sub permafrost has a thickness of 300 m with a resistivity less of 3 ohmm. An average thickness of 5 km for the sedimentary cover was estimated at the plateau with a resitivity less of 10 ohmm and constituted by Terciary and upper Cretacic formations in agreement with previous MT soundings (Fournier et al 1980).

GEO-ELECTRICAL STRUCTURE UP TO LOWER MANTLE DEPTHS BENEATH INDIAN REGION DERIVED FROM 27-DAY VARIATION AND ITS HARMONICS

E. CHANDRASEKHAR (Indian Institute of Geomagnetism, Dr. Nanabhoy Moos Road, Colaba, Mumbai - 400 005, India, e-mail: esekhar@iig.iigm.res.in)

C-response function estimates have been determined by Z:H method, utilizing two years of continuous records of geomagnetic data, recorded during 1975-77, at a chain of 13 stations, encompassing Himalayan collision boundary, confined to 75 E longitude band, extending from equatorial to polar regions. This unique latitudinal distribution of stations has facilitated to test statistically, the validity of P_1^0 assumption of the inducing field. With the combined analysis of Sq and 27-day variation and its harmonics, an integrated conductivity-depth profile is obtained, involving all stations. The derived conductivity profile has shown that the internal structure of the Earth beneath the Indian region could be viewed as a stack of inhomogeneous layers from surface up to a depth of 1200 km. In the depth range of about 850 km, the

presence of "mid-mantle conductor" is observed, compatible with the other regional and global models. The tectonic interpretation of the derived conductivity-depth profile and its correlation with seismic wave velocity profile is discussed. Statistically reliable C-response estimates at individual sites are obtained only for 6 stations,situated in mid-latitude region. Single site response estimates have revealed that at stations north of Himalayan boundary, the obtained depth estimates are rather low, compared with those, obtained at stations situated south of Himalayan boundary. It is still not clear, whether Himalayan collision boundary can be treated as a major discontinuous boundary, even at lower mantle depths. The average depth of perfect substitute conductor in Indian region, at stations free from lateral heterogeneities is found to be 1200 (+/-200)km with an average conductivity of 0.7 (+/-0.3)S/m.

ELECTRICAL CONDUCTIVITY STRUCTURE BENEATH THE BAY OF BENGAL

E. JOHN JOSEPH (Geological Survey of Japan, 1-1-3, Higashi, Tsukuba-shi, 305-8567 Japan, email: john@gsj.go.jp) H. Toh (Ocean Research Institute, University of Tokyo, Tokyo, 164 Japan) H. Utada (Earthquake Research Institute, University of Tokyo, Tokyo, Japan) R.V. Iyengar (Indian Institute of Geomagnetism, Colaba, Mumbai, India) J. Segawa (School of Marine Science and Technology, Tokai University, Japan)

Seafloor magnetometer array experiments were conducted in the Bay of Bengal to delineate the subsurface conductivity structure in the close vicinity of the 85 degree East Ridge and Ninety East Ridge (NER), and also to study the upper mantle conductivity structure of the Bay of Bengal. The experiments were conducted in three phases. Array 1991 consisted of five seafloor stations across the 85 degree East Ridge along 14 degree North latitude with a land reference station at Selam (SLM). Array 1992 also consisted of five seafloor stations across the 85 degree East Ridge along 12 degree North latitude. Here we used the data from Annamalainagar Magnetic Obervatory (ANN) as land reference data. Array 1995 consisted of four seafloor stations across the NER along 9 degree North latitude with land reference station at Tirunelveli (TIR). OBM-S4 magnetometers were used for seafloor measurements. Geomagnetic Depth Sounding (GDS) method was used to investigate the subsurface lateral conductivity contrasts. Vertical gradient sounding (VGS) and horizontal spatial gradient (HSG) methods were used to deliniate the depth-resistivity structure of the oceanic crust and upper mantle of the Bay of Bengal. The observed seafloor 3-component magnetic field variations show that the Electromagnetic induction process in the Bay of Bengal may be 3-dimensional. We made an attempt to solve this 3-D problem numerically and followed two approaches, namely (1)thin-sheet modelling and (2) 3-D forward modelling. Thin-sheet and 3-D forward model calculations jointly show that the observed induction arrows could be explained in terms of near surface features such as deep-sea fans of the Bay of Bengal, the 85 degree East Ridge and the sea water column above the seafloor stations. VGS and HSG responses provided depth-resistivity profile as a resistive oceanic crust and upper mantle followed by a very low resistive zone at a depth of 250-450 km. This depth-range fairly agrees with the seismic low velocity zone of the northeastern Indian Ocean, derived from seismic tomography. Thus we propose an electrical conductivity structure for oceanic crust and upper mantle of the Bay of Bengal.

CRUSTAL STRUCTURE IN THE KOYANA REGION OF WESTERN MAHARASTRA, INDIA, USING MAGNETOTELLURIC STUDIES

C.K. RAO, S.G. Gokarn (Indian Institute of Geomagnetism, Colaba, Mumbai, email: kamesh@iig.iigm.res.in); Yasuo Ogawa (Geological Survey of Japan, Tsukuba, Japan, email: oga@gsj.go.jp)

Magnetotelluric studies were conducted along East-West profile in seismically active Koyana region of western Maharastra passing through Guhaghar-Karad-Vite. The survey region is covered by Deccan flood basalts. The impedances were decomposed and the strike angle estimated to be North three degrees East, which coincides with the strike direction of Western ghats in the survey region. The interpretation of the data shows the thickness of the Deccan flood basalts varies considerably along the profile. The thickness varies from 900 m at the western end of the profile to 200 m at the centre of the profile (edge of Western ghats). Towards eastern side the thickness varies from 2000 m to 600 m. The basement shows step like feature on entire profile. A conductive body of 20 ohm-m observed at the station 10 to a depth of about 3 km, beyond which sensitivity analysis failed to show the depth extent. This conductive body is understood to be a fault present in the region. Mid-crustal conductor is not seen in this region due to noise in the period range 1-10 sec. Lithosphere-asthenosphere boundary is observed at some of the stations at a depth of 100 km.

MAGNETOTELLURIC TRAVERSE ACROSS THE ARCHAEAN PROTEROZOIC CONTACT IN SUKINDA COLLISON ZONE, EASTERN INDIA

K.K. ROY and S. Srivastava (both at Department of Geology and Geophysics, Indian Institute of Technology, Kharagpur - 721 302, India, Email: kkroy@gg.iitkgp.ernet.in) A.K. Singh (Department of Applied Earth Sciences, Delft University of Technology, Delft, The Netherlands)

Magnetotelluric survey was conducted across the low grade granite green stone belt of Archaean Singhbhum craton and Proterozoic high grade granulite terrain of Eastern ghats. 2-D RRI algorithm was used for interpretation of MT data. Use of rotation invariant parameters viz., determinant, central and average viz., apparent, resistivities and phases. The detailed study shows the faults located just north of the Sukinda collision zone could be detected and mapped by the parameters with minimum static shift effect viz., all the phases, the parameters generated out of magnetic transfer functions, magnetic components, twist and shear etc. RRI model gives 130km as the depth of the electrical lithosphere - asthenosphere boundary. The signatures for the vertical faults extended upto 12 to 15kms from the surface. Pseudo - 3D surface plots of apparent resistivities and phases show the signature of the Archaean - Proterozoic contact. Qualitative interpretation has a big role to play in Magnetotellurics. Most of the MT parameters totaling 30 have some role to play in MT data interpretation. They are non trivial. Since, rotation invariant parameters should be used for modelling and interpretation.

ELECTRICAL CONDUCTANCE MAP OF INDIA

T. HARINARAYANA and K. Naganjaneyulu (National Geophysical Research Institute, Hyderabad - 500 007, India, tel +91-40-7170141, fax +91-40-7171564, email: postmast@csngri.ren.nic.in

Electrical conductance is one of the important parameters in the interpretation of electrical and electromagnetic data. Study of the distribution of conductance parameter in a region helps to understand the subsurface geoelectrical structure. Based on the results obtained from about 500 shallow electrical resistivity soundings, 200 deep resistivity and magnetotelluric soundings and also the geological sections derived from a few deep seismic soundings and deep boreholes, an attempt has been made here for the first time to construct the regional electrical conductance map of India. Since the data is widely distributed more emphasis is given on the data from sedimentary basins, conducting regions such as rift zones, Alluvium covered areas etc. and the present study is limited to upper crustal depths. The map thus prepared shows a good correlation with major geological features. The regions in Arunachal Pradesh, Assam and Cambay region in western part show comparatively high conductance values of the order of 2000-4000 Siemens. The results of these studies are compared with other regional maps of India and discussed.

MAGNETOTELLURIC SURVEY OF TAIWAN

Chow-Son Chen (Institute of Geophysics, National Central University, Taiwan.
Email: chusen@sal.gep.ncu.edu.tw)

The Island of Taiwan is located in the active boundary between the Philippine Sea plate and the Eurasian plate. The relative plate velocity between the Philippine Sea plate and Eurasian plate is at about 7.1 cm per year in the direction of about N50˚W. While the Philippine Sea plate is subducting northwestward from the Ryukyu Trench in the northeast of Taiwan, the Eurasian plate is subducting beneath the Philippine Sea plate along Manila Trench in the south of Taiwan. Although this overall plate configuration in the vicinity of Taiwan has been well defined by seismicity, the composition and nature of the crust, which are closely correlated to the electrical structures, are basically unknown. The magnetotelluric investigation (MT) was undertaken during the recent three years with more than 50 soundings uniformly covering the Island of Taiwan. The Occamị_s inversion, which produces a model that is maximally smooth in resistivity structure, was used to produce a 1D model for each sounding data. The organized 3D plot indicates that the resistivities variations observed to be closely correlated to the change of the surface geology of Taiwan down, at best, to a shallow depth of the upper 20 km. Beneath this depth, there exists a regional zone of sharply-decreasing electrical resistivity. The appearance of the low resistivity zone at depth about 20 km underneath Taiwan is both very interesting and significant. Based on the temperature estimates and some drill holes, it is probably caused by a structural zone with densely interconnected fluid phase. One possibility for the origin of such fluids is through dehydration of the crust, which has previously been invoked as an explanation for the common occurrence of low resistivities in the continental crust. In other wards, the recent Taiwan Orogeny has formed an evident decollement structure in which the upper zone above the depth of 20 km exhibits entirely independent structural style from the lower one. MT observations seem to support the model of thin-skinned Taiwan orogeny.

UNDERSTANDING OF SEISMOTECTONICS THROUGH A WINDOW OF CRUSTAL CONDUCTIVITY

Y Fujinawa 1, N Kawakami2, J Inoue 2, Y Honkura3 1: Nat. Res. Inst. Earth Science and Disaster Prevention 2: Geothermal Energy Research and Development Co., Ltd. 3: Tokyo Institute of Technology

Wideband (0.002~20,000Hz) magnetotelluric measurements (MT) observations have been conducted along three traverses in the central Tohoku district of the northeastern Japan arc at 78 observation sites in order to image the conductivity profile. The experiment is expected to provide an example of more reasonable interpretation of seismo-tectonics in the crust based on results of conductivity measurement. Analysis is performed to obtain reasonable 2-D models using the MT impedance tensor corrected for the effects of the subsurface 3D condutivity heterogeneity. Smooth two-dimensional georesistivity models were obtained by applying the Generalized Rapid Relaxation Inversion (GRRI) algorithm to the corrected impedance tensors assuming NS direction as the regional 2D structural strike, which is inferred from the tensor decomposition procedure, and is in general agreement with the strike of geological units. The whole crust is seen to be homogeneous in conductivity without enhanced conductivity in the lower crust where the resistivity is relatively high in agreement with results in the northern part of the Tohoku district, but in contrary to the stable continental crust. The northernmost cross section is more complex possibly because of the presence of Quaternary volcanoes and an active geothermal source area in the vicinity. The resistivity profiles delineate clearly two clear near surface conductive anomalies in the fracture zone between the Dewa Hill and Central Basin Range and in the Kitakami, Abukuma river regions of Quaternary or Tertiary sediment as well as several smaller resistivity anomalies. Conductors or their boundaries in the crust in the west of the Sekiryo Mountain Range generally correlate well with mapped faults or pre-Tertiary tectonic lines and sisimicity. And several buried fault are suggested from the earthquake hypocenter and conductivity distribution. The conductivity distributions,seismic velocity and active fault are combined to interpret the seismo-tectonics and geologic regime associated with the subduction processes.

CONSTRAINTS ON THE ELECTRICAL CONDUCTIVITY BENEATH THE JAPAN SEA BY MT RESPONSE OF THE JAPAN SEA CABLE (JASC)

Tadanori GOTO (Aichi University of Education, Kariya, Japan), Hisayoshi Shimizu, Hisashi Utada (University of Tokyo, Tokyo, Japan), Yoshikazu Tanaka (Kyoto University, Kumamoto, Japan), Kiyofumi Yumoto (Kyushu University, Fukuoka, Japan), Valerian Nikiforov (Pacific Oceanographic Institute, Vladivistok, Russia), Nick Palshin, Renat Renat Medzhitov, and Leonid Vanyan (Shirshov Institute of Oceanology, Moscow, Russia)

Electrical potential difference between Nakhodka (Russia) and Naoetsu (Japan) has been observed by using the Japan Sea Cable (JASC) since 1996. Our aim in this study is to estimate MT response by using the JASC potential data, and to constrain the conductivity structures

beneath the Japan sea and the West Pacific region. MT response was obtained from the observed JASC voltage for the frequency range from 300 to 30,000 seconds.
Magnetic data from several observatories were used for testing the inhomogeneity of the source field. Three-dimensional forward modelling, using a code by Mackie et al. (1993), was carried out to examine how each structure is constrained by the observed JASC MT response. Obtained implications are follows: The high conductance of the upper mantle (the depth range of 100 - 400km) beneath the Japan sea is well constrained by the JASC MT response. the JASC MT response is also sensitive to the conductivity of the crust. The crustal effect is recognized such as 'static shift'. The conductivity of the lithosphere beneath the Japan sea affects the JASC MT response, although it is smaller than the effects of the upper mantle and the crust.

PRELIMINARY RESULTS FROM AN EM INDUCTION STUDY IN THE PACIFIC USING SUBMARINE CABLE ELECTRIC FIELD DATA

Takao KOYAMA, Hisayoshi Shimizu, Hisashi Utada(Earthquake Research Institute, University of Tokyo, Yayoi 1-1-1, Bunkyo-ku, 113-0032, Japan, Email: tkoyama@eri.u-tokyo.ac.jp , shimizu@enkumi.eri.u-tokyo.ac.jp , utada@utada-sun.eri.u-tokyo.ac.jp)and Alan D. Chave (Woods Hole Oceanographic Institution, Woods Hole, MA 02543, USA, Email: alan@whoi.edu)

This paper reports first results of an EM induction study over the entire North Pacific region to elucidate the electrical conductivity structure in the deep mantle. Geoelectric field data measured by using submarine cables in the region that have been retired from telecommunications service are analyzed for this purpose. Geomagnetic data are obtained from standard observatory sources for Honolulu, Guam, Kakioka and so on. The electric potential measurements in the Pacific were initiated over the past decade by the independent efforts of US and Japanese research groups, and the data have now been merged to make a comprehensive dataset. The network of submarine cables consists of HAW-1, HAW-2, and HAW-3 (extending from California to Hawaii), TPC-1 (connecting Hawaii to Midway, Midway to Guam, Guam to Philippines, and Guam to Ninomiya, Japan), TPC-2 (connecting Hawaii to Guam and Guam to Okinawa), COMPAC (connecting Hawaii to Fiji), OKINAWA (connecting Okinawa and Ninomiya). By using these datasets, we can estimate MT responses and try to obtain a model of semi-global conductivity structure beneath the Pacific. A "semi-global model" means that we may have to take sphericity of the earth and the source field configuration into consideration because of the size of area of interest This talk will present preliminary results toward this goal.

MAGNETOTELLURIC MEASUREMENTS ACROSS THE BACKBONE RANGES OF NORTHEAST JAPAN ARC

Y. Ogawa (Geological Survey of Japan, Tsukuba, 305-8567, Japan, email:oga@gsj.go.jp)T. Goto (Aichi Univ. Educ., Kariya, Japan) M. Mishina (Tohoku U., Sendai, Japan) M. Uyeshima (ERI, Univ. Tokyo, Tokyo, Japan)T. Kasaya, M. Ichiki, N. Oshiman (DPRI, Kyoto Univ., Uji, Japan)S. Sakanaka (AVL, Kyoto Univ., Kumamoto, Japan)Y. Takahashi, T. Nishitani (Akita Univ., Akita, Japan)Y. Takahashi, Y. Honkura (Tokyo Institute of Technology, Tokyo, Japan) H. Satoh(Hokkaido Univ., Sapporo, Japan)H. Murakami(Kochi Univ., Kochi, Japan)

Wideband magnetotelluric(MT) measurements were conducted across the backbone range of Northeast Japan, which is a typical subduction system. The objective of the study is to reveal the deep structure of the active faults which run on both side of the mountain ranges. We had 15 MT sites along a 45km profile which goes across the mountain ranges. We used simultaneously 5 sets of 5 component MT systems and 5 sets of telluric-only systems. Preliminary two-dimensional inversion results using TM mode revealed the deep sub-vertical conductors corresponding to the active faults, which were recently imaged by the reflection seismic data on the same profile. These conductors imply fractured zones of the active faults. The whole profile is also underlain by lower crustal conductor at around 20km depth. The sub-vertical conductors may be linked to the deep conductor.

THIN-SHEET MODELLING OF THE MAGNETOTELLURIC FIELD IN THE TIEN SHAN AREA

Leonid VANYAN (Shirshov Institute of Oceanology, Moscow117218, Russia
email: vanyan@geo.sio.rssi.ru), Xiangru Kong (Institute of Geophysics, CAS,100101 Beijing, China, email: xrkong@mail.c-geos.ac.cn), Mark Berdichevsky and Anastasia Kazurova (both at Geological Department of Moscow State University, Moscow 119899, Russia, email: berd@geo.geol.msu.su)

Eastern Tien Shan mountains belong to China while the Western Tien Shan occupies Kirgyzstan territory. Geophysicists of the Institute of Geophysics (Beijing), Shirshov Institute of Oceanology (Moscow) and Moscow State University started a joint Project for uniting the magnetotelluric data obtained in Russia and China and further developing the deep conductivity model of the Tien Shan area. Interest in this region is due to four circumstances: 1. High heat flow values, 2. Very thick crust (up to 60km), 3. Cenosoic activation (25-30 millions of years ago), 4. Existence of a conductive layer in the deep crust which is supposed to be caused by fluids released at the dehydration process initiated by temperature increase.Interpretation of united MT-data demands separation of deep and surficial effects. To this end, authors compiled a map of sedimentary basin conductance and constructed a model with the inhomogeneous thin sheet (sediments) underlied by a deep layered structure (the Earth's crust and upper mantle). The thin-sheet technique of quasy-3D modelling shows that the Chu, Tarim and Jungar basins surrounding Tien Shan mountains cause strong electromagnetic anomalies, which distort MT-curves and induction arrows. The results of the modelling serve as a basis for correcting magnetotelluric and magnetovariation data. This work was partly supported by the Russian Basic Research Foundation (Projects 96-05-10037 and 99-05-64187).

MT MEASUREMENTS IN THE NORTHERN TIANSHAN MOUNTAINS AND JUNGGAR BASIN, WESTERN XINJIANG AUTONOMOUS REGION

Guoze ZHAO, Yan Zhan, Ji Tang, Junmeng Zhao and Guangwen Jin Institute of Geology, Seismological of China, Beijing 100029, China, email: zhaogz@public.bta.net.cn

MT data have recently been obtained at 61 sites along a profile about 700km long and oriented approximately N-S in the western Xinjiang autonomous region. The profile stretches from the middle of the Tianshan mountains in the south, through the Junggar basin, ending in the Artai Mountains at the north end. Impedance tensor ecomposition and RRI 2-D inversion are used for data interpretation. The electrical structure of the crust and lithosphere beneath the profile can be divided into three units, from south to north: (1) the Tianshan fold system; (2)the Northern Tianshan-Junggar fold system and (3)the Artai fold system. The Bolokenu-Arqikekuduke fault, Erqisi fault belt and Darbute fault are found to be lithospheric faults.
A contour plot of the conductive layer near the surface can be compared with sediments that have the greatest thickness of about 10km, in the southern part of the Junggar basin. There are some low resistivity blocks in the crust of the northern part of the Junggar basin at a depth of about 15-20km with about 20 km thickness. No conductive layer in the crust was found in the Tianshan mountains and Artai mountains. The thickness of the lithosphere for the three units is about 160km, 120km and 160-180km, respectively. The above results are supported by seismic data observed along same profile.

TECTONIC SETTING AND CRUSTAL RESISTIVITY STRUCTURE IN THE INDONESIA ISLAND ARC

Toru MOGI (Department of Earth Resources Eng., Kyushu University, Fukuoka 812-8581, Japan, email: tmogi@mine.kyushu-u.ac.jp) Djedi S. Widarto and Edy M. Arsadi (both at RD Ctr for Geotechnology-LIPI, Jalan Sangkuriang, Bandung 40135, Indonesia,
email: widarto@bdg.centrin.net.id) Yoshikazu Tanaka (Aso Volcanological Laboratory, Kyoto University, Choyo-son, Aso-gun, Kumamoto Pref., 869-1400, Japan,
email: tanaka@aso.vgs.Kyoto-u.ac.jp) Susumu Nishimura (Kyoto Institute of Natural History, Yoshida-Kawaramachi, Sakyoo-ku, Kyoto 606-8305, Japan, email: S_nishimura@pop07.odn.ne.jp)

A magnetotelluric survey has been made at three areas, where the plate is subducting in different style, such as normal subduction, oblique subduction and collision, in the Indonesia island arc. Style of volcanic and geothermal activities are reflected by these tectonic setting.
In a normal subduction area, central Java, high resistivity zone which refered to old marine sediment was seen in fore arc side and low resistivity zone reflected high temperature lower crust was appeared in back arc side. As for oblique subduction area, southern Sumatra island, remarkable low resitivity zone reaching to the deeper depth was found along the transcurrent fault zone (Great Sumatra Fault) which is moving by dragging of the oblique subduction, and where some pull-a-part basins were formed. The Australian continent plate is colliding at the eastern Sunda arc of Flores area. The upper crust of the Flores area is relatively high in resistivity beneath the recent volcanic front. From these result, we have characterized crustal structure based on the resistivity structure.

ANOMALOUS DIRECTIONAL BEHAVIOUR OF INDUCTION ARROWS ABOVE THE FAULTS OF RED RIVER IN VIETNAM.

TRUONG QUANG HAO. Institute of Geophysics Hanoi, Box 411, Buudien, Boho Hanoi Vietnam, email: tqhao@igp.ncst.ac.vn).

The analysis of transient geomagnetic variation events recorded by a simultaneously operated chains of magnetometers across the Red river from SAPA,XUANGIAO to PHORANG, YENBAI, PHUTHUY and from HOABINH to HUATRAM,PHUTHUY and BACGIANG indicated an interesting feature:A reversal sign of the vertical field fluctuations is located at the faults of Red River. The induction vectors for short period events of geomagnetic variations at two sides of the faults show an anti paralleled direction. This fact points the existence of high electrical conductivity in the faults with high seismicity zone. The estimation of geoelectrical parameters as longitudinal conductivity and the depth of location of this high conductivity were made(G=1/1000.000.000 S.m , h= 20 Km). A subsequent magnetometer array is suggested in order to study the region of high conductivity in detail for mapping of subsurface structures for regional tectonic studies.

AN INTERPRETATION OF MT DATA OVER THE BENUE TROUGH, NIGERIA

E.A.ARIYIBI, :Department of Physics,Obafemi Awolowo University, Ile-Ife ,Nigeria.

Magnetotelluric(MT) measurements were performed simultaneously at three sites spaced at about 100km from each other in the Middle Benue trough.The three sites are: Lafia(8.50 N,8.50 E) ,Makurdi (7.75N,8.50E) and Oturkpo(7.25N,8.25S). Night and day events were selected from the data and processed before analysis.Induction vectors and rho*vs Z* curves were obtained and used to model and understand the subsurface structure at the middle of Trough. The induction vectors at Lafia(LAF) point to the Chain lineament and at akurdi(MAR) to the Charcot lineament ,which according to aeromagnetic result trend in NE-SW direction.These lineaments mark the strutural boundary of the trough.The induction vectors at Oturkpo (OTU) point to a narrow fault zone within the trough. The rho* vs Z* curve suggest the presence of a crustal conductor at the middle of the trough. An earth model is derived from results of several 2D models which compared favourably with observed field data.

MAGNETOTELLURIC STUDIES OF THE CALDAS NOVAS GEOTHERMAL AREA, BRAZIL

PATRICIA P. DE LUGAO, Geosignal/Baker Hughes, USA, email: lugao@geosignal.com; Sergio L. Fontes, Observatorio Nacional/CNPq, Brazil, email: sergio@on.br; Emanuele F. Laterra, Observatorio Nacional/CNPq, Brazil, email: laterra@on.br

A magnetotelluric (MT) survey was conducted in the Caldas Novas geothermal area located in the state of Goi\'as, central part of Brazil. The region of Caldas Novas is a popular tourist spot due to its hot water springs. The purpose of this MT survey was to provide more information on the geoelectrical structure of this important geothermal reservoir. The area of the Serra de Caldas is located on the NE border of the Paran\'a Basin, over the Canastra Arch in the SE portion of the state of Goi\'as. It is constituted by an anticline that is supported by quartzites that resisted erosion and that belong to a sequence of upper Precambrian metasediments. The lithology does not follow stratigraphic layering, but superposition imposed by the tectonic movement (Ribeiro et al., 1994). From a tectonic point of view, the Serra de Caldas has an elliptical shape with 15 and 9 kilometers in diameter, with the major axis coinciding with the N10W direction (Campos et al., 1980) bounded by fracture zones with trend NW-SE. Most geothermal waters occur within this region (Anjos et al., 1994). Data were acquired along two profiles crossing the Serra de Caldas with a total of 25 MT stations. Frequencies of acquisition were in the range from 0.008 to 176 Hz. Spacing between stations were usually around 5 km. Apparent resistivity and phase data from the transverse electric (TE) and transverse magnetic (TM) modes are consistent for both profiles. Very high (100,000's ohm-m) apparent resistivity values in the TM mode indicate either distortion caused by 3-D resistive structures or by topography of the mountains. Two-dimensional (2-D) inversion and three-dimensional (3-D) modelling suggests a basin-like model with very high resistivity block structures associated with concentric faulting below the Serra de Caldas and extending to depths of approximately 20 km. This model is in good agreement with gravity data and the available geological information in that area. The high resistivity associated to the depression in the MT model can be interpreted as caused by the low permeability quartzites which form the Serra de Caldas.

IMAGING THE ONSET OF ANDEAN DEFORMATION IN THE NORTHERN SIERRAS PAMPEANAS ARGENTINA

M. CRISTINA POMPOSIELLO (CIRGEO, Ramirez de Velasco 847,1414 Buenos Aires, Argentina, email: cpomposi@mail.retina.ar) John Booker and Shenghui Li (both at Geophysics Program, University of Washington, Seattle WA 98195 USA, email: booker@geophys.washington.edu and shenghui@geophys.washington.edu) Alicia Favetto and Ana Osella (both at Dpto. de Fisica, Univ. Buenos Aires, Ciudad Universitaria, Pabellon I, 1428 Buenos Aires, Argentina, e-mail: favetto@df.uba.ar and osella@df.uba.ar) Claudia Sainato (Catedra de Fisica, Fac.Agronomia, Univ. Buenos Aires, Av. San Martin 4453, 1417 Buenos Aires, Argentina, email: csainato@ciudad.com.ar)

The Sierras Pampeanas (SP) of Argentina are a region of active thick-skinned deformation between stable cratonic South America and the Andes. The Tucuman Plain (TP) lies just east of the most easterly active faults (which dip west). In October 1998, we collected 18 wideband magnetotelluric sites along two east-west transects of the TP. The nothern transect coincides with industry seismic reflection data reprocessed to image structure to almost 40 km. The southern transect crosses an large, low temperature geothermal reservoir. For the northern line, we conclude: (1) There is essentially no distortion of deep electrical structure information by the highly uniform near-surface. (2) Beginning at 10 km and perhaps extending to the Moho, the lower crust beneath the TP has very low resistivity (below 1 Ohm-m). (3) To the east, the top of the low resitivity dips steeply eastward to the Moho and continues in weaker form horizontally under the resistive cratonic crust. This dip is essentially orthogonal to the dominant dip of seismically imaged active faults at the same location. The southern line is more difficult to interpret with very conductive shallow structure probably associated with geothermal alteration that strongly distorts the electromagnetic fields.

MAGNETOTELLURIC INVESTIGATION OF THE DAMARA BELT IN NAMIBIA

O. Ritter, P. Ritter, V. Haak (GeoForschungsZentrum Potsdam, Telegrafenberg, D-14473 Potsdam, Germany, email: oritter@gfz-potsdam.de)

Within the framework of an integrated geophysical and geological project we recorded broadband magnetotelluric and GDS data along a 33-site profile in NW Namibia. Preliminary interpretation of the impedances and induction arrows indicates three conductive features associated with different period ranges: (1) numerous small scale structures in a generally resistive upper crust which is typical for the granites and metasediments of the Damara belt, (2) two interconnected subvertical conductors in the middle crust and (3) the influence of the South Atlantic in a distance of approximately 150 km. To examine this complex conductivity structure we compare electric and magnetic decomposition methods and discuss modelling results. The geometry of two near-vertical conductivity anomalies connected by a subhorizontal conductor in the mid crust is consistent with the distribution of shearzones produced by ramp tectonics during the late stages of the Panafrican Damara orogeny. The high conductivity is likely due to graphite in shearzones, as suggested by the discovery of graphite-rich myolitic marbles along the SW extension of the Waterberg Fault, which correlates with the southern conductivity anomaly.
Results from the crystalline of Sweden are compared with coincident VES measurements over a narrow 200 meter wide valley near Stockholm. Both methods define the resistive boundaries of the valley and a small, shallow resistive block in the middle of the valley. Results from a waste dump site in the Netherlands, where a number of geophysical techniques have been applied to trace the leakage of conducting fluids in the form of plumes, show good agreement with standard VES and TEM measurements. 2-D inverse models give a very clear indication of the lateral extension of the plume.

PALAEOGEOGRAPHY AND GEODYNAMIC EVOLUTION OF PALAEOZOIC TERRANES IN THE CALEDONIAN-APPALACHIAN OROGEN

Conall MAC NIOCAILL (Dept. of Earth Sciences, University of Oxford, Parks Road, OX1 3PR, UK, email: conallm@earth.ox.ac.uk); Ben van der Pluijm and Rob Van der Voo (Dept. of Geological Sciences, The University of Michigan, Ann Arbor, MI 48109-1063, USA, email: vdpluijm@umich.edu; voo@umich.edu)

Since J. Tuzo Wilson's, now classic, demonstration of a proto-Atlantic (or Iapetus) ocean the Caledonian-Appalachian orogen has been a key area in the construction of Palaeozoic palaeogeographic models. The latitudinal positions of the main palaeocontinents involved in the orogeny (Laurentia, Baltica, Avalonia and, later, Gondwana) are now relatively well established, with the northward convergence of Baltica and Avalonia, with respect to an equatorial Laurentia, during the Ordovician leading to a final closure of the Iapetus ocean in the Silurian. In recent years, however, there has been considerable debate as to the relative longitudinal positions of these palaeocontinents, with some workers advocating a shared Middle-Ordovician tectonic history between Laurentia and the South America margin of Gondwana. Similarly, the palaeogeography and origin of several of the accreted terranes that are now found along the orogen has been the subject of much discussion. Recent work, which combines palaeomagnetic, faunal and geochronologic data, has produced an internally consistent history of terrane migration and accretion in the Northern Appalachians, involving the presence of arcs along the Laurentian and Avalonian margins, and possible intra-oceanic arcs or seamount complexes within the Iapetus Ocean in the Ordovician. However, the picture is less clear when it comes to the origin and accretion of other Ordovician terranes, such as the Precordilleran Terrane of South America. Recent palaeomagnetic data have confirmed a Laurentian origin for the Precordilleran Terrane in the Early Cambrian but the precise mechanism of its Middle Ordovician transfer to the South American margin of Gondwana remains in dispute.

GA1.04/W/06-A4 **0930**

A NEW INITIATIVE FOR PALAEOMAGNETIC WORK IN THE TASMAN FOLD BELT

Mark A. LACKIE (Department of Earth and Planetary Sciences, Macquarie University NSW, Australia 2109, email: mlackie@laurel.ocs.mq.edu.au); Phillip W. SCHMIDT (CSIRO Exploration and Mining, North Ryde NSW, Australia 1670, email: p.schmidt@syd.dem.csiro.au); David A. Clark (CSIRO Exploration and Mining, North Ryde NSW, Australia 1670, email: d.clark@syd.dem.csiro.au)

Despite much effort Gondwana's early Palaeozoic apparent polar wander path remains ill-defined particularly for the Siluro-Ordovician segment. Rocks of this age in the Tasman Fold Belt cover a wide range of lithologies but most do not appear to contain grains of optimum stability to allow the pole path to be unambiguously defined. In our continuing effort to address this problem we have begun a study of volcanics and mineralisation/alteration systems in central-western NSW and northern Queensland. Normally it might be expected that the problems with structure and age control of mineralised/altered rocks are insurmountable, however, the systems we have targetted are well dated, they cover a broad geographical area and the structures of the parent rocks are well known. Given the magnitude of the problem we feel this approach is justified. Often haematite accompanies the alteration and it is the palaeomagnetic signature of this mineral that we particularly seek. So far sampling has been undertaken at deposits in western and central-western NSW. Pilot samples were collected from fresh and altered rocks of the Late Silurian Wondalga Granodiorite, the Late Ordovician Gidginbung Volcanics at Temora and gabbroic diorites and monzodiorites of the Early Silurian Wallundry Suite. As well, samples were collected from the Late Ordovician Tettenhall Monzodiorite and Tallwood Monzonite and their associated hornfels, usually within the Forest Reefs Volcanics. In areas of no outcrop samples were taken from oriented drill core. The results obtained from preliminary measurements taken on the above samples will be discussed.

GA1.04/W/01-A4 **0950**

TECTONIC ROTATIONS IN THE CALEDONIAN-APPALACHIAN OROGEN DEDUCED FROM PALAEOMAGNETIC REMANENCE

Mark SMETHURST and Trond Torsvik (Geological Survey of Norway, Leiv Eirikssons vei 39, N-7040 Trondheim, Norway, email: mark.smethurst@ngu.no)

Palaeomagnetic remanence has been used extensively in orogenic belts to determine the former latitudinal positions of terranes and to construct detailed palaeogeographies of former oceanic tracts. Less attention has been paid to the information offered by palaeomagnetic remanence on the paleo-orientation of terranes. Rotation of terranes was an important part of the late stage tectonic development of the Caledonian-Appalachian orogen; rotated terranes have been recognised at intervals along the full length of the orogen. We assembled palaeomagnetic data from Britain and Ireland (Caledonides) and Newfoundland (NE Appalachians) to map the extent and timing of tectonic rotations associated with the final closure of Iapetus. Special attention was paid to links between the complex pattern of Silurian rotations recognised in the Irish Caledonides and the equally complex pattern of rotations recognised in Silurian rocks of the Appalachians in Newfoundland.
The palaeomagnetic record carried by Silurian volcanics and sediments in Newfoundland is complicated by magnetic anisotropy. A study of the anisotropy in the two rock types will accompany the history of tectonic rotations.

GA1.04/W/40-A4 **1010**

REMAGNETIZATION AND OROGENIC FLUIDS: TESTING THE HYPOTHESIS IN THE CENTRAL APPALACHIANS

R. Douglas ELMORE (University of Oklahoma, USA)

The migration of orogenic fluids is a popular, although largely untested hypothesis invoked to explain widespread chemical remagnetization in sedimentary rocks. Preliminary paleomagnetic and geochemical studies in the central Appalachians indicate that a relationship between orogenic fluids and remagnetization is not straightforward. For this study, samples were collected for fold tests from Paleozoic units in the Valley and Ridge province in West Virginia. Samples from the Devonian Helderberg Fm. contain a synfolding late Paleozoic magnetization with the best grouping at ~60% unfolding (D = 155/ I = -4). Rock magnetic studies indicate that the magnetization, interpreted to be a CRM based on high unblocking temperatures and moderate burial depths, resides in magnetite. Samples from the overlying Oriskany sandstone on the same fold contain a similar synfolding magnetization (~55% unfolding; D = 171/I = 5) in magnetite, although it is weaker and the decay not as linear. Fold tests on these units from a second fold produced similar results. Similarly, a fold in the Ordovician Trenton Fm. also contains a synfolding magnetization with best grouping at 25% unfolding (D = 163/I = 5). However, the fluid histories of the Oriskany and the two limestone units differ significantly. Stable isotope and fluid inclusion data from veins indicate that low salinity (7 to 15 wt.% NaCl equiv.), high temperature (155 to 225oC minimum) fluids migrated through the Oriskany. In contrast to the results from the Oriskany, fluids in the Helderberg and the Trenton were restricted to 'in-situ' high-salinity, low temperature brines. This is consistent with previous diagenetic studies which indicate that most of the Helderberg in West Virginia was only subjected to burial diagenetic processes with only localized alteration by warm exotic fluids. Although the results from the Oriskany are consistent with remagnetization by orogenic fluids, the connection is more difficult to make in the Helderberg and Trenton which do not contain evidence for such fluids.

PALAEOGEOGRAPHY AND GEODYNAMIC EVOLUTION OF PALAEOZOIC TERRANES IN THE VARISCAN AND ALPINE FOLDBELTS

TAIT J, Schätz, M., Zwing, A., and Bachtadse, (V. Inst. f. Allg. Angew. Geophysik, Ludwig-Maximilians-Universität München, Theresienstr. 41, 80333 München)

Early and pre-Variscan terranes in Europe, particularly in southern realms, have undergone multiple deformational phases making determination of the pre-collisional plate configuration difficult. Nevertheless, recent geological, palaeogeographical and palaeomagnetic findings have lead to significant improvements in our understanding of the Palaeozoic orogenic events. Palaeomagnetic studies of several different Palaeozoic sequences in central and southern Europe demonstrate that the so-called "Armorican Microplate" was in fact an assemblage of (semi)autonomous terranes or microblocks, which are now separated by major tectonic discontinuities. The term 'Armorican Terrane Assemblage' (ATA) is now used to refer to these Palaeozoic elements. They had similar drift histories during the Palaeozoic, and the Rheic Ocean separating Avalonia from the ATA closed in Late Silurian/Early Devonian times. The situation for the southern margin of the ATA, especially sections which are belong to the Alpine realm, is complex and the palaeogeography of the various terranes remains unclear due to the strong Alpine overprint and deformation. Recent palaeomagnetic data from the eastern and southern Alps point to a more independent history of these units, which is in accordance with their general faunal and lithofacial records. These Alpine terranes rifted from the northern margin of Gondwana in Ordovician times, and drifted northwards

PALEOMAGNETIC AND ROCK MAGNETIC RESULTS FROM A LATE DEVONIAN INTRUSIVE COMPLEX (FRANKENSTEIN GABBRO, ODENWALD, GERMANY)

A. ZWING, V. Bachtadse, H. Soffel (Institut für Geophysik, Ludwig-Maximilians-Universität München, Theresienstr. 41, 80333 München, Germany.
email: azwing@magbakt.geophysik.uni-muenchen.de)

Paleomagnetic results from late Devonian and Carboniferous rocks in the internal part of the European Variscides (Massif Central, Vosges, Black Forest, Odenwald and Spessart) indicate large scale rotations and disagree with the systematic deviation of paleodeclinations as a function of the overall structural trend, which has been observed in the Iberian, Armorican and Bohemian Massifs. In this context the paleomagnetic and rock magnetic properties of the Frankenstein Gabbro (Odenwald, Germany) were studied in detail. The Frankenstein intrusive complex was subjected to rapid cooling in late Devonian times (363 ± 7 Ma) and not reheated above 200°C (Kirsch, 1988) since then. A magmatic layering, indicating the orientation of the paleohorizontal was observed in the field and in the orientation of the AMS-ellipsoids. During stepwise thermal and alternating field (AF) experiments three components (A,B,C) of magnetisation could be identified. Component A is parallel to the present day geomagnetic field in the study area and the result of a recent VRM. Component B reflects presumably a magnetic overprint of Permo-Carboniferous age. Component C has been identified in 124 samples from 22 sites. The resulting overall site mean based on stable endpoints and remagnetisation circle intersections (Dec=198°/Inc=40°; VGP: 15°S/9°W) is interpreted to be of primary origin. This is supported by a positive baked contact test and a positive reversal test. Component C is predominatly characterised by unblocking temperatures of 580°C and in few samples over 600°C, indicating magnetite and hematite as the carriers of the characteristic remanent magnetisation. The study of polished sections revealed two types of hematite and suggest primary hematite lamellae in ilmenite and secondary hematite overgrowth as carriers of Component C and Component B, respectively. Comparing the resulting palaeopole position to the reference Apparent Polar Wander Path for stable Europe indicates 20° anticlockwise rotations of the region studied. This is significantly less then published by Edel (1991) based on palaeomagnetic data for the Odenwald, Spessart, Black Forest and the Vosges.

GA1.04/W/16-A4 1140

THE ROTATIONS OF THE VARISCAN BELT DURING THE CARBONIFEROUS COLLISION

Jean-Bernard Edel (EOST-Institut de Physique du Globe, 5 rue Descartes, 67084 Strasbourg Cedex, France, email: Jean-Bernard.Edel@eost.u-strasbg.fr)

Paleomagnetic investigations carried out on the Paleozoic outcrops of the European Variscides, demonstrate that at least 90% of the Visean volcanites and plutonites have undergone magnetic overprinting during Carboniferous to Jurassic times. In general, sediments contain only young overprints. Thanks to the overprinting phenomenon, a nearly continuous paleomagnetic record, interpretable in terms of geotectonic evolution, was obtained for each massif. After 340 Ma, which is the age of most of the investigated units, the geotectonic evolutions of the Armorican Massif, Central Massif, Vosges, Black Forest, Odenwald, Spessart, Bohemian Massif and Sudetes were nearly the same:- From 340 Ma up to 330-328 Ma, the presently striking SW-NE Variscides were oriented SE-NW (Cn-Cp magnetic components; mean VGPs: 16°S/46°E to 31°S/50°E) and likely underwent a N-S drift along the margin of Baltica.; - A prominent compression phase (the Sudetic phase), probably resulting from blocking of the eastern Variscides against the south-western margin of Baltica, marked the end of the drift and led to uplift, folding, wrenching and magnetic overprinting (Cp overprints). Primary Cp components were recorded in syn-tectonic dykes dated around 330 Ma.; - The compression became strong enough to give rise to a 70-80° clockwise rotation (Cp-B) that closed the Lizard-Giessen oceanic basin; - After the closure, the convergence continued and high pressure metamorphism was recorded along the Saxothuringian - Rhenohercynian boundary. During the relaxation that followed the rotation, large-scale post-tectonic overprinting (B directions, mean VGP: 10°N/124°E) in relation with low-grade metamorphism affected all outcrops of the internal Variscides.- In the time range 320-303 Ma, still under pushing of Gondwana, the whole Variscides east of the Iberian-Armorican arc, rotated clockwise by 40-50° (B-A1). The Rhenohercynian zone was thrusted over the Caledonian Brabant block. After acquisition of the primary and secondary A1 magnetizations (mean VGP: 32°N/153°E), the clockwise rotations continued, up to the end of the Alleghanian convergence in the Middle Permian (270 Ma);- In the Latest Carboniferous- Early Permian (300-270 Ma)…,

GA1.04/L/07-A4 1200

PALAEOMAGNETISM AND PALAEOGEOGRAPHY OF THE BARRANDIAN TERRANE IN THE BOHEMIAN MASSIF: ASPECTS OF INTERPRETATION

MIROSLAV KRS,Otaker Man and Petr Pruner (Institute of Geology, Academy of Sciences, Rozvojov´ 135, 165 02 Prague 6 - Lysolaje, Czech Republic. email: inst@gli.cas.cz

Palaeomagnetic data inferred for the Variscan and pre-Variscan formations of the Bohemian Massif (BM) were interpreted in terms of tectonics and palaeogeography. The evaluation of the data from the BM was preceeded by the study of the effect of the Trans-European Suture Zone (TESZ) on the dispersion of the European palaeomagnetic pole positions during the Variscan episode. Horizontal palaeotectonic rotations are well documented for Variscan and pre-Variscan rock complexes in the so far studied Barrandian and Moravian Zone terranes within the BM. Magnitudes of horizontal palaeotectonic rotations in the BM affected by the Variscan tectonism are notably similar to those in the Western Carpathians affected by Alpine tectonism. Senses of the rotations are, however, different with clockwise rotations prevailing in the BM and counterclockwise rotations prevailing in the Western Carpathians. To guarantee a critical evaluation, the BM data were recalculated into the form of palaeolatitudes and palaeomagnetic declinations for a single reference point in the Barrandian area and interpreted in the context of all-European data recalculated for the same reference point. The study of tectonics and palaeography of Canbrian to Devonian rock formations in the Barrandian area, which is considered as a peri-Gondwanide terrane with affinities to Armorica, may serve as a case history of study of a terrane incorporated into a stable lithospheeric plate, with some new aspects of interpretation of the palaeotectonic rotations. Here, the Barrandian terrane became a part of the European Plate as a component of emerging Pangea supercontinent in the final phase of the Variscan orogeny.

MOSCOVIAN PALEOMAGNETIC POLE FROM THE EDJELEH FOLD (SAHARAN CRATON, ALGERIA)

Mohamed. El-Messaoud. DERDER, Boualem Bayou, Hamou Djellit and Mohamed Amenna (CRAAG, BP 63, 16340 Bouzareah, Algiers, Algeria, email: mderder@hotmail.com); Bernard Henry (Géomagnétisme et Paléomagnétisme, IPGP and CNRS, 4 avenue de Neptune, 94107 Saint-Maur cedex, France, email: henry@ipgp.jussieu.fr)

Numerous paleomagnetic studies of Paleozoic formations have been conducted in the Illizi basin. Although these studies have led to the determination of new African Upper Paleozoic paleomagnetic poles, no paleomagnetic tests can be performed. Therefore a new study was carried out in a Moscovian (310 Ma) formation located in the Edjeleh anticline, the only area where important dips can be observed in the Upper Paleozoic series of the Illizi basin. The paleomagnetic results are similar to previous ones performed in neighboring areas, and show the existence of three magnetization components. The first one is better grouped in geographic coordinates and its corresponding paleomagnetic pole is close to Tertiary to Quaternary African poles. This component is then a Cenozoic remagnetization. The second one is slightly better grouped in geographic coordinates, but the fold test is inconclusive because all specimens are from the same limb of the fold. The paleomagnetic pole in stratigraphic coordinates is close to the previous African Permian remagnetization poles. The third component, determined by both remagnetization circles analysis and well defined ChRMs is defined by D=134.8°, I=34.2°, k=96, a95=6.9° and D=133.7°, I=32.7°, k=254, a95=4.2°, respectively before and after dip correction. The optimal value during a progressive unfolding is obtained for an approximately total unfolding, and the fold test is positive and significant. The corresponding paleomagnetic pole is 25.6°S, 59.5°E, K= 381, A95= 2.9°. Our positive fold test "validates" thus the previous Upper Paleozoic poles from the Saharan platform.

GA1.04/W/21-A4 1400

AUTUNIAN PALEOMAGNETIC POLE FROM THE MEZARIF BASIN (ALGERIA)

N. MERABET, A. Kherroubi and S. Maouche (CRAAG, BP 63, 16340 Bouzaréah, Algiers, Algeria,email: merabetn@hotmail.com); B. Henry (Paléomagnétisme et Géomagnétisme, CNRS and IPGP, 4 av. Neptune, 94107, Saint-Maur cedex, France, email: henry@ipgp.jussieu.fr)

During the last decade, a substantial number of Permo-Carboniferous poles had been determined in the Algerian Saharan basins. These poles improved the definition of the Permo-Carboniferous segment of the African Apparent Polar Wander Path. However, the knowledge of more precise kinematics evolution of this continent, which will clarify the Pangea configuration during late Paleozoic times, requires more investigations. For this purpose, a paleomagnetic study had been carried out in the Autunian series of Nekheila (Mezarif basin, Algeria), which is situated in the northern part of the stable West-African craton. A total of 122 specimens containing hematite and collected at seven (07) sites had been subjected to successive thermal cleaning steps. Visualization of orthogonal diagrams showed, after the destruction of a weak viscous component at low temperature, the existence of a dominant ChRM. The ChRM mean direction obtained, after dip correction, is defined by D=131.5°, I=18.4°, k=56, a95=7.1°. The associated paleomagnetic pole is situated at 28.0°S and 55.3° E. and is very close to that (29.1° S and 57.8° E) of the Autunian lower unit of the neighboring Abadla formation. It is also close to the Stephano-Autunian one (33.8° S and 61.4° E) of the lower Tiguentourine formations belonging to the stable Eastern Saharan craton. Thus our new datum confirms the reliability of Paleozoic paleomagnetic data obtained these last years in the Algerian Saharan craton. It improves also the precision of the mean African Autunian paleomagnetic pole and represents thus a new contribution for a better comprehension of the geodynamic evolution during the Paleozoic times.

GA1.04/W/22-A4 1420

NEW PALEOMAGNETIC CONSTRAINTS ON THE DATATION OF THE ABADLA REDBEDS (ALGERIA)

H. BOUABDALLAH, N. Merabet, and S. Maouche (CRAAG, BP 63, 16340 Bouzaréah, Algiers, Algeria, email: h.bouabdallah@lancaster.ac.uk). B. Henry (Paléomagnétisme et Géomagnétisme, CNRS and IPGP, 4 avenue de Neptune, 94107 Saint-Maur cedex, France, email: henry@ipgp.jussieu.fr).

The 2000 m thick Abadla redbeds formation (31.2°N, 2.7°W) consists of two units; a lower unit whose Autunian age is well established by the presence of characteristic microflora fossils, and an azoic and undated upper unit whose age could be either Permian or Triassic (Doubinger et Fabre, 1981, Pollen et Spores 25, 91-116). This last undated unit yields a paleomagnetic pole (Morel et al., 1981, Earth Planet. Sci. Lett. 55, 65-74) considered as a reference for the African Apparent Polar Wander Path (APWP).
Our new paleomagnetic data (magnetic direction: N = 11, D = 130.1°, I = 13.0°, k = 138, a95 = 3.6° and pole: 29.1°S, 57.8°E, A95 = 2.0°) were obtained from the better dated Autunian levels of the lower unit, and its primary origin is indicated by the stratigraphical variation of the magnetic direction. This new pole should thus take the place of the previous one in the definition of the Autunian part of the African APWP and help, along with other data from the Saharan Craton, to tightly constrain the Middle Carboniferous – Autunian segment of this APWP.
This new pole is very close to Morel et al.'s, determined from the unfossiliferous upper unit of the Abadla formation, therfore giving an Autunian age for this upper unit. Consequently, the subsidence of the Abadla basin and the deposition of the whole succession occurred during a period of less than 20-25 Myr. The accumulation rate of the sediments in the Abadla basin (100 m/Myr) is much higher than those of the other parts of the Sahara (e.g. Illizi basin, 10 m/Myr).

GA1.04/W/32-A4 1440

NEW PRELIMINARY PALEOMAGNETIC DATA FROM LATEST PROTEROZOIC - EARLY PALEOZOIC ROCKS FROM THE RIO DE LA PLATA CRATON

Augusto E. RAPALINI (Lab. Paleomagnetismo D.A. Valencio, Depto. Cs. Geológicas, Univ. Buenos

Aires, Pab. 2, C. Universitaria, 1428, Buenos Aires, Argentina, email: rapalini@gl.fcen.uba.ar); Carlos W. RAPELA (Centro de Investigaciones Geológicas, Univ. Nacional de La Plata, Calle 1 N°644, 1900, La Plata, Argentina, email: crapela@cig.museo.unlp.edu.ar)

The global paleogeographic evolution in the Late Proterozoic has apparently been governed by the breaking up of Rodinia and the later assembly of Gondwana, H. although details of this evolution are not well known. In particular, Western Gondwana was apparently formed by the coalescence of several independent cratons by the end of the Proterozoic. One of these is The Rio de La Plata craton (RP) in southeast South America. In order to better determine its paleogeographic evolution and the kinematics of Gondwana assembly, a new preliminary paleomagnetic study was carried out on Late Proterozoic - Early Paleozoic rocks exposed at Sierra de Los Barrientos (province of Buenos Aires, Argentina). Cores were drilled from: 1) subhorizontal purple claystones correlative to the Las Aguilas Fm or Balcarce Fm (Vendian - Cambrian?, 5 sites, 36 samples) and 2) basaltic to gabbric sills (K/Ar 498-450 Ma, 3 sites, 26 samples). Preliminary results after both AF and thermal demagnetization indicate high remanence stability in the samples from both units. A preliminary paleomagnetic pole obtained from the mean characteristic remanence carried by hematite in the claystones is consistent with a recently obtained pole for the RP from magmatic rocks of 550-565 Ma in Uruguay, suggesting a similar age for the claystones. These poles fall near the beginning of the APWP for the already assembled Gondwana, confirming that RP was already part of Gondwana at those times. The mean geomagnetic pole from the sills, although probably not averaging PSV, suggests high paleolatitudes. This can be interpreted easier assuming a Late Ordovician age, although other alternatives are explored.

GA1.04/L/07-A4 1500

SOME PALEOMAGNETIC CONSTRAINTS ON THE ANDEAN UPLIFT OF THE EASTERN PRECORDILLERA OF ARGENTINA

AUGUSTO E. RAPALINI (Laboratorio de Paleomagnetismo Daniel Valencio, Depto. Cs. Geológicas, FCEyN, Universidad de Buenos Aires, Pabellón 2, Ciudad Universitaria, 1428, Buenos Aires, Argentina, email: rapalini@gl.fcen.uba.ar) Osvaldo Bordonaro (CRICYT, CC 131, 5500, Mendoza, Argentina)

Paleomagnetic sampling was done on several carbonatic units (limestones to dolomites) of Middle Cambrian to Arenig age at 23 sites (140 samples) from 5 localities in the Eastern Precordillera (EP) of San Juan province (Argentina). Standard AF and thermal demagnetization indicated two different magnetic behaviours. Samples from 2 localities showed a single, postectonic component attributed to Recent viscous or chemical remagnetization. Samples from the remaining localities showed two components: a low unblocking temperature (350°C) magnetization coincident with that found at the previous localities and a high temperature one (up to 550°C). The latter was also found to be post-folding (post-Devonian, in situ mean direction: Dec: 272.6°, Inc: 68.9°, A95: 8.9°, N=11). This is not consistent with any expected direction for the study area since the Carboniferous. It is inferred that these rocks underwent substantial tectonic displacement since this magnetization was recorded. Comparison of their magnetic characterisitics with those of similar Early Ordovician limestones in the Central Precordillera and the San Rafael Block, that were remagnetized in the Permian, suggests that the same process affected the carbonatic rocks in the EP and, therefore, the age of the component is likely to be Permian. Restoration of the in situ mean direction to the expected one for a Permian remagnetization can be obtained by a 40° ccw rotation around an inclined axis of 30° Az and plunging 30° to the NE. This supports a model suggesting that the EP behaved as a series of rigid blocks during the Andean orogeny and was mainly uplifted by displacement along a major East dipping N to NE backthrust that marks its western boundary.

GA1.04/W/26-A4 1520

PALEOMAGNETIC CONSTRAINTS ON AGE OF DEFORMATION OF THE "SAMFRAU" BELT, SOUTHWEST GONDWANA BOUNDARY, ARGENTINA, DURING THE LATE PALEOZOIC

Renata N. TOMEZZOLI (CONICET-Universidad de Buenos Aires, now at S.U.N.Y. Binghamton, Department of Geological Sciences. Binghamton, NY 13902-6000; email: rtomezz@binghamton.edu), William MacDonald (S.U.N.Y. at Binghamton, Department of Geological Sciences. Binghamton, NY 13902-6000; email: wdmacdon@binghamton.edu)

Following the paleomagnetic study of the Sierras Australes thrust and fold belt (Tomezzoli 1997), we have extended our studies westward, in rocks of similar late Paleozoic ages. This zone constitutes the "Sam Frau geosincline" of Du Toit (1927). The current studies involve rocks from Mendoza and La Pampa Province. The previous paleomagnetic study in Sierra de la Ventana yielded two paleomagnetic poles, one syntectonic in the Lower Permian and one pretectonic in the Lower Upper Permian. The objectives of the current work are: regional comparisons; improving the APWP of the late Paleozoic - early Mesozoic of South America; location of the top of the Kiaman; determination of the Permian - Triassic boundary; establishing the age of the deformation by region to evaluate time - transgressive migration; exploration of AMS signatures to evaluate regional deformation; and a better understanding of the assembly, deformation, and fragmentation of Gondwana / Pangea. ReferencesDu Toit, A., 1927. A geological comparison of South America with South Africa, Carnegie Intitute of Washington Publications. 381, 1-157. Washington.Tomezzoli, R.N., 1997. Geología y Paleomagnetismo en el ámbito de las Sierras Australes de la provincia de Buenos Aires. Tesis doctoral, Universidad de Buenos Aires, inédita, 306 p.

GA1.04/E/11-A4 1610

PALEOMAGNETIC RESULTS FROM THE MID-PROTEROZOIC RICHTERSFLYA SUPERGROUP OF QUEEN MAUD LAND, ANTARCTICA - THE KALAHARI CRATON-GRUNEHOGNA PROVINCE CONNECTION

D.L. JONES & M.P. Bates (both at University of Zimbabwe, Harare, Zimbabwe) G.Hodgkinson & B.Corner (both at University of the Witwatersrand, Johannesburg, S. Africa) & C.McA.Powell (University of Western Australia, Perth, Australia)

The Umkondo Group of Zimbabwe (UGZ) includes dolerites, part of the Umkondo Igneous Event (UIE), widespread throughout southern Africa. The dolerites are reliably dated at 1100 Ma with a well established paleomagnetic (UIE) pole at 65 N and 36 E (alpha-95 = 6 deg). Paleomagnetic results are reported from 54 sites in the Richtersflya Supergroup (RSG) of Queen Maud Land (QML). Sites are mostly in igneous rocks intruded into unconsolidated RSG sediments but include 4 sites in sediments & one in lavas. Published results for the RSG suggest an age also close to 1100 Ma. Extensive af & thermal demagnetization of samples reveals a mean remanence direction of D = 234, I = -4 with k = 25 & alpha-95 = 4 deg giving a pole at 232 E, 8 S. Paleomagnetic & rock magnetic results suggest this remanence is held in single domain grains of magnetite and hematite (sediments only) and, notwithstanding a regional low-grade metamorphism, that it is primary. Rotation of QML into its familiar Gondwana position results in a difference of only 6 deg between the mean poles for the UIE & RSG providing strong support for the view that the UGZ & the RSG are contemporaneous & that the Kalahari craton & Grunehogna Province of QML were in close proximity 1100 Ma ago.

GA1.04/E/15-A4 1630

PALEOMAGNETISM OF THE 1.73 GA URUGUAYAN DIKE SWARM, RIO DE LA PLATA CRATON: IMPLICATIONS FOR A MESOPROTEROZOIC SUPERCONTINENT

Manoel S. D'AGRELLA-FILHO and Igor I. Gil Pacca (Instituto Astronômico e Geofísico, Universidade de São Paulo, São Paulo, SP, 3386, 01060-970, Brazil, email: dagrella@iag.usp.br)

The Uruguayan dike swarm intrudes country rocks of the Rio de La Plata Craton that were deformed and metamorphosed to high grade during the 2200-1900 Ma Transamazonian orogeny. 40Ar/39Ar plateau ages for igneous hornblende (1727±10 Ma) and biotite (1725±10 Ma) are taken as the best estimate for the emplacement of the Uruguayan swarm.
AF and thermal demagnetization on 78 samples collected from 19 mafic dykes revealed a multicomponent behavior. The most representative component (Dm=9.5°; Im=-34.9°; K=16.6; a95=9.0°; N=17) includes both polarities, and is displayed by the majority of the dykes. Rock-magnetic experiments suggest that this component is carried by Ti-poor titanomagnetites, most of them in single domain/pseudo single domain structures.
The corresponding Uruguayan dikes (UD) pole (337.0°E; 74.4°N) does not agree with a pole of similar age from the Richtersveld Subprovince nor with poles from the Kaapvaal Craton, in a pre-Atlantic configuration of South America and Africa. However, if the Rio de La Plata Craton is rotated 109° counterclockwise around an Euler pole at 250.5°E; 23.1°S, the UD pole falls on the 1750-1700 Ma time interval of the Laurentia apparent polar Wander path. In this reconstruction, the eastern border of the Rio de La Plata Craton fits to the southwestern border of Laurentia (North America in its present position). The northern border of the Rio de La Plata Craton, in a proposed supercontinent reconstruction, fits to East-Antarctica.

GA1.04/E/16-A4 1650

PRELIMINARY PALEOMAGNETIC RESULTS OF A SEDIMENTARY SEQUENCE FROM THE MESOPROTEROZOIC AGUAPEÍ GROUP, AMAZONIA CRATON

Manoel S. D'Agrella-Filho and Igor I. Gil PACCA (Instituto Astronômico e Geofísico, Universidade de São Paulo, São Paulo, SP, 3386, 01060-970, Brazil, email: dagrella@iag.usp.br)

The Aguapeí basin from Central-Western Brazil (Amazonia Craton) has been interpreted as a NNW/SSE aulacogen associated with the development of the marginal WNW-trending Sunsas Belt. They are geographically separated by the Paragua Block. Recent Proterozoic reconstructions of supercontinents have considered the Sunsas belt as an exposition of the Grenville belt produced during the Laurentia-Amazonia collision at the end of the Mesoproterozoic (1300-950 Ma).
Paleomagnetic results of sedimentary samples collected from 10 nearly horizontal stratigraphic levels from the Aguapei Group and of samples from a basic dike cutting these sediments are presented. Alternating field and thermal demagnetizations of these rocks yielded a northern (southern) direction with moderate to steep negative (positive) inclination. Magnetization is carried by magnetite in the dike samples and by hematite in the sediments. No radiometric dating is yet available to constrain the age of this direction. Although not far from the present geomagnetic field, its corresponding pole is compared with other Grenvillian poles in the configurations proposed for the Mesoproterozoic Rodinia supercontinent.

GA1.04/P/02-A4 1710

PALAEOMAGNETIC AND ROCK MAGNETIC STUDY OF A DEEPLY EXPOSED PRECAMBRIAN METAMORPHIC TERRANE: THE CHARNOCKITE BELT OF SOUTH INDIA

S. BASU MALLIK, G Bandyopadhyay and A.K. Das (Department of Geological Sciences, Jadavpur University, Calcutta -700 032, India) J.D.A Piper (Geomagnetism Laboratory, Department of Earth Sciences, University of Liverpool, Liverpool L69 7ZE, U.K.)

The Archaean-Early Proterozoic craton of South India is bounded by a broad E-W zone from Mangalore in the West to Madras in the east dominated by granulites and charnockites uplifted from depths of 25-35km and cooled at ~2600Ma. To the north Precambrian terranes are dominated by Archaean supracrustal belts in gneissic granitoids and granite. The boundary zone grades from granulite to upper greenschist facies. We have sampled the central and eastern sectors of this transitional belt. Intensities and susceptibilities of magnetisation are strong in the granulite and charnockite facies and comparable to younger basaltic rocks. They therefore provide a strong contributing source to deep crustal magnetic anomalies. Thermomagnetic determinations and thermal demagnetisation show remanence carried mostly by low-Ti magnetite. Titaniferous hematite occurs rarely in the granulite facies and pyrrhotite is present in the lower grade terranes. Hysteresis, KLT and KHT studies show dominantly multidomain magnetite although most samples have stable remanence probably because domains are pinned by shape effects. Anisotropy of susceptibility is low in comparison with many metamorphic rocks with little preferential fabric. This accords with the dominantly-static metamorphism producing charnockite facies. In the centre of the belt a NNW-SSE shallow axis is defined by the uplift magnetisations. With other early Proterozoic palaeomagnetic results from the Indian Shield data show that it occupied a low latitude location probably rotating anticlockwise at ~2600Ma and moving into high latitudes before moving back to low latitudes by ~2400Ma.

GA1.04/P/03-A4 1730

PALEOMAGNETIC INVESTIGATION OF THE CAMEROON VOLCANIC LINE

R-U. Llbangoh and I. G. PACCA (Unit for Geophysical and Volcanological Research, B.P. 370 Buea, Cameroon)

Paleomagnetic investigation of samples collected from the Cameroon Volcanic Line has presented six new paleomagnetic poles for the African continent at 243.6° E, 84.6°N, a95 =6.8°; 224.3° E, 81.2° N, a95 = 8.4°; 176. 1° E, 82.0°N, a95 = 8.5°; 164.3° E, 86.4° N, a95 = 3.4°; 169,4° E, 82.6° N, a95 = 4.6° and 174.7° E, 72.8° N, a95 = 9.5° belonging to rocks which have been dated by the K-Ar method at 0.4 - 0.9 Ma, 2.6 Ma, 6.5 -11 Ma, 12 -17 Ma, 20 -24 Ma and 28 -31 Ma respectively. The results are in general agreement with other palaeomagnetic poles from Oligocene to Recent formations in Africa.
The first three poles for rocks formed between 0.4 and 11 Ma are not significantly different from the present geographic pole. Together with other African poles for the same period suggesting very little movement of the African continent relative to the pole since 11 Ma. The other three poles for rocks dated between 12 and 31 Ma are significantly different from the present geographic pole showing a 5° polar deviation from the present pole in the Miocene and 13° in the Middle Oligocene.
An apparent polar wander path constructed using a compilation of paleomagnetic results from Africa including the newly determined poles shows that the African continent on the average, has been drifting approximately northwards. Using this idea and the available

geochronological data for the oldest rocks in the volcanic centres along the line a NE-SW migration of its volcanism has been proposed.

GA1.04/E/12-A5 0900

PALEOMAGNETISM AND MAGNETIC TEXTURE OF OPHIOLITE FROM THE POLAR URALS

Natalia LUBNINA (Department of Dynamic Geology, Geological Faculty, Moscow State University, Vorobjevy Gory, Moscow, Russia, email: lub@dynamo.geol.msu.ru); Alexey Didenko (Institute Physics of the Earth RAS, Moscow, Russia)

The Urals is a Hercynian nappe-fold structure, which resulted from the collision between the East-European and Kazakhstan-Siberian continents. We have chosen the Polar segment of the Urals (Voikar-Synya ophiolite massif) as the main object to study the history of its development. Petromagnetic stude of gabbro and diabase from that ophiolite massif has allowed to type of the magnetic texture and orientation of major axes of magnetic susceptibility ellipsoid. Anisotropy of magnetic susceptibility of the main part of cumulative gabbros and gabbro-norites samples does not exceed 1-2%. No reference direction of main axes of ellipsoids of magnetic susceptibility is observed. Magnetic texture of these rocks was formed under hydrostatic compression, that is indicative of primary cumulative nature of the observed layering. Oblate fabric of the most part of dyke swarm reflects a magma flow during intruding. Big and average axes of ellipsoids of magnetic susceptibility lie in planes of the dykes stretch and have Fisher's distribution on the sphere. Average direction of big axes reflects a directions of basalt magmas intruding. According to paleomagnetic data from ophiolites of the Polar Urals, paleooceanic basin was located at 8-14?N in the interval 420-490 Ma, the spreading zone striked in the NNW direction. The present Northern margin of the Siberia borded the paleoocean from the East. Paleomagnetic data from the sequences of continental slope and rise (the Lemva zone) suggest its position near the East-European Continent at 4??3.9?N in Upper Cambrian-Early Ordovician. During Ordovician the Lemva zone suffered clockwise rotation for about 50? relatively East-European Continent.

WHERE WAS TUVA TERRAIN IN ORDOVICIAN?

KAZANSKY A.Yu. (Institute of Geology UIGGM SB RAS, Academic Kopt'ug ave. 3, Novosibirsk, 630090, Russia, Email: kaz@uiggm.nsc.ru); Sennikov N.V. (Institute of Petroleum Geology, Academic Kopt'ug ave. 3, Novosibirsk, 630090, Russia, Email: sennikov@uiggm.nsc.ru); Mikhaltsov N.E., Kungurtsev L.V. (Institute of Geology UIGGM SB RAS, Academic Kopt'ug ave. 3, Novosibirsk, 630090, Russia, Email: kaz@uiggm.nsc.ru)

Tuva terrain the modern part of the southern margin of Siberian Craton is the object of unclear tectonic history. Some different scenarios are proposed to explain the uncertainties of geological history of this region (Sengor et al, 1993, Mossakovsky et al, 1993, Berzin, Dobretsov, 1993, and many others). This work was performed to clarify the relative position of Tuva on the base of paleomagnetic and biostraticrahpical data.
Paleomagnetic data were obtained from two locations in Ordovician sedimentary sequence in Uyk depression of Tuva trough (52N, 93E) which is well dated by different groups of fauna (Vladimirskaya, 1960). Sampling was performed so that the main fauna horizons fall stratigraphicaly just between the strata which was sampled peleomagnetically. Thermal demagnetization resulted in following ChRM directions: D=42, I= -8, a95=12 (location 1) and D=40, I=-19, a95=9 (location 2), which show both polarities successfully pass fold test and is quite close to pervious data (Pavlov et al., 1997). The ChRM directions obtained show sufficient differences with reference directions from Siberian APWP (Smethurst et al, 1998).
On the base on sedimentological and paleontological data (trilobites, brahiopods, conodonts, etc.) it is appeared that Tuva fauna association was developed in an individual basin, different from Altai-Salair shelf basins surrounding Siberian continent during Ordovician time. So one of the possible continents where Tuva sedimentary basin with inherent fauna association can be developed is Gondwanaland. If we accept the southern position of Tuva terrain in Ordovician, paleomagnetic data appears to be in a good agreement with paleontological and geological data. Moreover the connection between Tuva and Gondvanaland faunas still remains [Yolkin et all., 1996] in Silurian-Early Devonian and available paleomagnetic data [Pavlov et al, 1997] reinterpreted with southern position of Tuva is in a good agreement with the tectonic history of Gondvanaland during Silurian (Zhao, 1996). However, we realize that the final decision about the position of Tuva terrain is still ambiguous without additional data on palaeomagnetism, tectonics and paleobiogeography.

GA1.04/E/03-A5 0940

THE LATE VARISCAN HORIZONTAL DEFORMATIONS OF FERGANA SECTOR OF TIEN SHAN BY PALEOMAGNETIC DATA

Yu. S. RZHEVSKY (St.Petersburg State University, 14th Line 29, V.O.,199178, St.Petersburg, Russia, email: yurkov@icape.nw.ru)

The natural remanenc magnetisation of the Middle and Late Carboniferous formations has been investigated. With enployment diagrams of Zijderveld results of thermal demagnetising a samples of rocks (15-20 from the each point of selection) has revealed two NRM-components (prefolding and postfolding). Incline average of prefolding component display a Functional dependence from strike of rocks. Variations in trend of prefolding remanenc magnetisation vectors are co-ordinated with geological data on postfolding rotation of structures in Fergana sector on South Tien Shan on angles from 30 to 90 degrees against of movement hand. Late Variscan horizontal deformations are associated with the formation of horizontal flecsure-Fergana sigmoid and its further complication at the expense of movements along the Talas-Fergana Fault and the adjacent fractures.

GA1.04/E/07-A5 1000

THE MIDDLE CARBONIFEROUS PALEOMAGNETISM OF HISSAR RIDGE AND IT'S SOUTH WESTERN BRANCHES (SOUTH TIEN SHAN), AND IT EMPLOYEMENT FOR INVESTIGATE THEPROCESSES OF FOLDING

Yu. S. RZHEVSKY (St.Petersburg State University, 14th Line 29, V.O.,199178, St.Petersburg, Russia, email: yurkov@icape.nw.ru)

Around 300 oriented samples of sandstones and siltstones (Middle Carboniferous) selected from different region s of Hissar ridge and it's South - Western branches has been investigated by paleomagnetic methods. The methods of investigate are simple: thermal cleaning and revealing the NRM-components with help of the Zijderveld's diagrams. Thus, NRM of investigated rocks contains, generally, he Early Permain postfolding component , which selected with small errors A95 <= 10 degrees). Prefolding component have little size and doesn't selected. Results of this investigate has been used for Alpine folding processes. The are group Alpine large anticlines at the South-Western branches of Hissar ridge. The Middle Carboniferous rock forming the coras of structures indicated upper. The Mesozoic and Cenozoic rocks contains limbs of this folds and lies on Paleozoic rocks by steep angles (80-90 degrees).The Paleozoic rocks outeroped at coras of anticlines had been subjected only vertical movements by paleomagnetic data, and it's incline near contact with Mesosoic rocks (has step incline) doesn't exceed 10-15 degrees. Thus, investigate structures are typical stamp folds.

GA1.04/W/24-A5 1100

PALEOMAGNETISM OF DEVONIAN SEQUENCES IN VIETNAM

N T K THOA, L T P Lan and V H Nam (Institute of Geophysics, Box 411 Buudien Boho Hanoi, Vietnam, email: thoa@igp.ncst.ac.vn)

Devonian sequences exposed widely in Northern and Central parts of Vietnam. 198 oriented samples were taken from 27 sites on limestones and basalts. Paleomagnetic treatments were carried out at the Institut für Angemeine und Allgewandt Geophysik in Munich, Germany. During detailed stepwise thermal and alternating field demagnetisation experiments two components of magnetisation (A and B) to be indentified in basalts: components A is characterised by unblocking temperatures up to 300˚C and shows direction which is not significantly different to the direction of the local present day geomagnetic field. The component B characterised by maximum unblocking temperature of 580˚C, indicating magnetite as the carrier of characteristic remanent magnetisation. In limestones samples : A component is similar with viscous component and removed at 150˚C, B component characterised by unblocking temperatures of 580˚C. The resulting overal site mean direction, based on stable enpoints, (D= 16602, I=-3208, a95= 6.4, k= 29.3, N=24 sites), is interpreted to be of primary origin. This is supported by presence of normal and reserved direction of magnetisation in two kind of rocks. The second group of site of limestones yield B component with unblocking temperature at 650˚C and high saturation field with direction (D=29007, I=6507, a95=10.4, k=45.6, N=3). Comparison of magnetic hysteresic parameters of both groups shows value of Mrs/Ms and Hcr/Hc generally lie in the pseudo-single domain. At the same time for second group with the presence of hematite, wide range of Hcr/Hc and "wasp-waisted" hysteresic loop were observed. Devonian paleomagnetic data together with Canbrian and Ordovician data from region appear to support the former southern paleolatitudes of the terraine, based on paleontological, stratigraphic and structural relationships.

GA1.04/W/12-A5 1120

NEW EARLY PALEOZOIC PALEOMAGNETIC RESULTS FROM THE NORTH CHINA BLOCK AND IMPLICATIONS FOR GONDWANA

Zhenyu YANG (Institute of Geomechanics, CAGS, Beijing, China; Kobe University, Japan. Email: zyyang@kobe-u.ac.jp); Baochun Huang (Institute of Geophysics, CAS, Beijing, China); Yo-ichiro Otofuji (Department of Earth Sciences, Kobe University, Japan); Zhiming Sun and Xinghua Ma (Institute of Geomechanics, CAGS, Beijing, China)

In the last five years, we have sampled the Cambrian-Ordovician in 14 sections (28 oriented block and 1900 oriented core samples covered over 222 sites) from Henan, Shanxi, Shaanxi, Hebei and Ningxia provinces of the North China Block (NCB). The samples were measured using the CTF, 2G magnetometers at the paleomagnetic laboratories in China, France and Japan. All samples were demagnetized stepwise using thermal, AF or a composite of thermal and AF methods. Multiphase and heavy secondary remagnetization have been revealed. The characteristic remanent magnetization (ChRM) for six periods between Cambrian and Ordovician is isolated only from 400 samples. They are directed to the NW (up) and SE (down) and form two antipodal clusters after tilt correction, which differs from those of the Permian and Mesozoic. Reliability of these ChRM directions is ascertained through positive fold and reversal tests, and also a good correlation of magnetic polarity pattern in the Cambrian/Ordovician boundary and lowest Ordovician across over different continents. The latter constrains the definition of early Paleozoic polarity for the NCB.
New APWP between the Cambrian and Ordovician indicates that the NCB was located in the Southern Hemisphere around 15° in latitude during Cambrian-Ordovician time. Large motion of the NCB occurred at a period between the Early and Middle Cambrian: CCW rotation of 22.3°7.0° and northward motion of 7.2° 6.8°. Comparing Cambrian-Ordovician APW paths between North China and Gondwana, we suggest that the NCB was part of Gondwana during the Cambrian and lowest Ordovician, and started BREAKING away from Gondwana in the lower Ordovician.

GA1.04/W/28-A5 1140

NEW PALEOZOIC PALEOMAGNETIC RESULTS FROM THE ALASHAN/HEXI CORRIDOR TERRANE AND THEIR TECTONIC IMPLICATIONS

Baochun Huang (Institute of Geophysics, CAS, Beijing, China, email: bchuang@mail.c-geos.ac.cn); Yo-ichiro Otofuji and Zhenyu Yang (Department of Earth Sciences, Kobe University, Japan)

The relationship between the Alashan/Hexi Corridor (AHC) terrane and the stable North China Block (NCB), which is defined as the eastern part of the NCB beyond the Helanshan fold belt, is an unresolved problem for geologists and paleomagnetists who are interested in the Paleozoic paleogeography of the NCB. In the past three years, we sampled 566 oriented core samples over 69 sites from the eastern part of the AHC, northwest China. The sampled rocks are spanning from the Middle Cambrian to Carboniferous, and are largely composed of limestone, oolitic limestone, redbed, and quartz-sandstone. All the samples were progressively demagnetized using thermal, alternating filed (AF) or a hybrid thermal and AF methods. Through the detailed magnetic component and rock magnetic analysis, characteristic directions and secondary remagnetizations were separated. The primary origin of the characteristic directions is ascertained by positive fold and reversal tests. The Silurian and Devonian results from three sampling sections show good consistency, indicating that our results may exclude the local rotation and represent for autochthonous terrane. Comparing our results with those from the stable NCB, the AHC terrane would has been the western extension of the NCB since the Ordovician. Silurian, Devonian, and Carboniferous results from the AHC terrane may therefore be used to supply the paleomagnetic database of the NCB. Our new Carboniferous poles are distinct with the coeval ones for Inner Mongolia, Outer Mongolia, South China, Tarim and Eurasia at 95% confidence level, suggesting that these blocks were separated in Carboniferous time.

GA1.04/E/14-A5 1400

MAGNETIC FABRIC IN RELATION TO THRUST SHEET STRUCTURE OF THE EASTERNMOST RHENOHERCYNIAN

Frantisek HROUDA (AGICO Inc., CZ-621 00 Brno, Czech Republic, Email: agico@agico.cz); Jiri OTAVA (Czech Geological Survey, CZ-602 00 Brno, Czech Republic, Email: otava@cgu.cz)

The easternmost Rhenohercynian is mostly represented by flysch-like Lower Carboniferous sedimentary rocks characterized by weak anchimetamorphism to weak epimetamorphism and structures ranging from sedimentary structures, through fracture and slaty cleavage, to metamorphic schistosity. The AMS is characterized by low degree of AMS, oblate magnetic fabric, and magnetic foliation parallel to the bedding in the formations with conspicuous sedimentary structures. In formations with spaced cleavage, the degree of AMS is higher, the magnetic fabric is on transition between linear and planar, the magnetic fabric is parallel to bedding, but the magnetic lineation is parallel to the bedding/cleavage intersection line. In the formations with slaty cleavage, the degree of AMS is high, the magnetic fabric is clearly oblate, the magnetic foliation is parallel to the cleavage and the magnetic lineation is parallel to the bedding/cleavage intersection lines. In Silesian metamorphic rocks, occurring to the west, the magnetic fabric shows very similar orientation to that of the Rhenohercynian, thus indicating incorporation of these crystalline complexes into the Rhenohercynian thrust sheet structure.

GA1.04/W/36-A5 1430

MAGNETIC ANISOTROPY AND PALAEOMAGNETISM OF PLIO-PLEISTOCENE SEDIMENTS FROM THE ADRIATIC MARGIN OF THE NORTHERN APENNINES (ITALY)

Leonardo SAGNOTTI and Aldo WINKLER (Istituto Nazionale di Geofisica, Via di Vigna Murata 605, 00143 Roma, Italy, email: sagnotti@marte.ingrm.it)

The study of the magnetic anisotropy and palaeomagnetism of the Plio-Pleistocene sediments that crop out along the Adriatic margin of the central-northern Apennines (Italy) provides an opportunity to extend to the external front of the belt the analyses that were previously conducted in the central and northern Apennines and to push the geodynamic reconstruction for the region to the last few million years. Standard palaeomagnetic cores were drilled in 27 sites, distributed in the region between the towns of Ancona and Pescara, in marine fine-grained sediments of early Pliocene to early Pleistocene age.The anisotropy of magnetic susceptibility (AMS) of the studied sediments indicates a prevalent sedimentary-compactional magnetic fabric with variable overprint of the tectonic strain. The integration of the AMS data with the results from previous studies on the present-day stress field and the AMS of older sediments in the Apenninic belt allows the evaluation of the spatial-temporal evolution of the strain pattern in the area since the early Pliocene. The new palaeomagnetic data, on the other hand, provide constraints on the dynamic and the timing of the oroclinal processes that were previously recognized for the northern Apennines.

GA1.04/L/01-A5 1450

MAGNETIC FABRICS OF ORDOVICIAN AND SILURIAN GREYWACKES FROM NW ENGLAND AND SW SCOTLAND

W.H. OWENS (School of Earth Sciences, University of Birmingham, Edgbaston, Birmingham B15 2TT, UK, email: w.h.owens@bham.ac.uk)

The challenge, always, for magnetic fabric analysis is to provide reliable information that is not easily obtainable by other methods of geological enquiry. A critical review is attempted here of progress in attaining this goal, in the context of work on greywackes from the Lake District and the Southern Uplands.
These rocks lie within the Caledonian fold-belt and their magnetic fabrics, in many cases, clearly reflect that tectonic framework. The magnetic fabric we now see, however, results from a superposition of the effects of many processes, sedimentary, pre-lithification and diagenetic, as well as tectonic. As a sensitive grain fabric technique, magnetic methods might be expected to provide information on, say, current flow direction in sedimentary deposition, quantitative measures of deformation through grain reorientation, or more general, subtle indicators of processes acting. The key to such application, however, is the identification of cause and effect, the confident attribution of a fabric to a process. In complex situations, as here, a first step is to identify end-member cases, where one process either acts alone or dominates all others. Criteria can then be established to characterise the style of magnetic fabrics associated with that regime. Only when a causal link is certain can quantitative interpretation, based on empirical correlation or, ideally, an understanding of how a fabric has developed, be applied. In other cases, where multiple causes are suspected, caution is necessary.

GA1.04/W/32-A5 1510

MAGNETIC FABRIC AND FLOW DIRECTIONS IN SURGES AND ASSOCIATED PIROCLASTIC LOW DEPOSITS FROM THE NORTHERN PUNA (22.5° S-66.6° W), ARGENTINA

Silvia Singer, Juan F. VILAS and Rubén Somoza (Laboratorio de Paleomagnetismo Daniel Valencio, Departamento de Ciencias Geológicas, Universidad de Buenos Aires, Argentina,
email: singer@gl.fcen.uba.ar) Beatriz Coira (Instituto de Geología y Minería, Universidad Nacional de Jujuy, Argentina)

A study of magnetic fabric, supported by field evidences, microscopic observations and paleomagnetic data was carried out on Upper Miocene piroclastic deposits from the Northern Puna (Central Andes of Argentina) in order to determine their flow directions. These deposits are formed by subhorizontal ignimbritic sequences associated at their bases with friable surges.These contain similar phenocryst assemblages with biotite as the main paramagnetic mineral and titanomagnetite as the predominant ferromagnetic mineral.
Both the surges and ignimbrite deposits show bulk susceptibilities that vary between 100 and 200 mSI although the ignimbrites have larger values due to these are richer in titanomagnetite, as shown by polished thin sections, NRM and satured remanent magnetisation data.
Both kinds of deposit show low to moderate degrees of anisotropy, oblate magnetic fabrics with subhorizontal foliation planes. In spite of these similitudes different magnetic fabrics are found between the ignimbrites and their associated surges. These results will be discussed.

GA1.04/L/02-A5 1600

ALPINE TECTONIC OVERPRINT OF THE MAGNETIC FABRIC IN THE VARISCAN GRANITES OF THE WEST CARPATHIANS

Frantisek HROUDA (AGICO Inc., CZ-621 00 Brno, Czech Republic, Email: agico@agico.cz); Marian Putis (Petrology Dept., Komensky University, SK-862 00 Bratislava, Slovakia,
Email: putis@fns.uniba.sk); Dagmar Gregorova (Geophysical Institute, Slovak Acad. Sci., SK-800 00 Bratislava, Slovakia, Email: geofdage@savba.sk)

The Central West Carpathians of Slovakia, unlike the Alps and other mountain chains, do not create a continuous mountain range, but crop out as the so-called Core Mountains within the mostly unfolded Intracarpathian Palaeogene and Neogene. The graniticrocks, which are Late Palaeozoic (mostly Carboniferous) in age, occur in the central areas of the Core Mountains, being associated with Early Palaeozoic metamorphic rocks and covered by Permo-Triassic to Middle Cretaceous sedimentary rocks. The granites are mostly weakly magnetic and correspond to the S type granites. The magnetic fabric in the sedimentary rocks covering the granites can be classified as partially up to entirely deformational in origin. The magnetic fabric patterns in the granites are very similar to those in sedimentary rocks in the region of the Veporic unit because of their common ductile deformation. Consequently, the magnetic fabric in granites does not represent the intrusive magmatic fabric associated with the granite emplacement, but the deformational fabric associated with early-Cretaceous motion of the nappes and mid-Cretaceous strike-slip tectonics of the Central West Carpathians. In the Tatric Core Mountains where mid- to late-Cretaceous/early-Tertiary deformation occurred in unmetamorphic to anchimetamorphic environment the granitic bodies suffered cataclasis and together with metamorphic mantle sometimes preserve pre-Alpine mesoscopic and magnetic fabrics, which differ between the Core Mountains.

GA1.04/W/39-A5 1620

MAGNETIC FABRICS OF SOFT-SEDIMENT FOLDED STRATA WITHIN A NEOGENE ACCRETIONARY COMPLEX, MIURA GROUP, CENTRAL JAPAN

EMILIO HERRERO-BERVERA (SOEST-HIGP 2525 Correa Rd., Honolulu, HI, USA, email: herrero@soest.hawaii.edu) Toshiya Kanamatsu (JAMSTEC, 2-15 Natsushima-Cho, Yokosuka 237, JAPAN, email: toshiyak@jamstec.go.jp) Asahiko Taira (ORI, University of Tokyo, 1-15-1 Minami-dai Nakano-ku, Tokyo 164, JAPAN, email: ataira@ori.u-tokyo.ac.jp)

The anisotropy of magnetic susceptibility (AMS) has been utilized for distinguishing various processes in deformation of sediments in which visible grain-scale deformation can scarcely be recognized. We have applied the AMS method on the middle Miocene-Pleistocene sedimentary sequence in the Boso and Miura Peninsulas, central Japan, which is associated with abundant synsedimentary deformation structures of folding and faulting generated in accretionary tectonics. The patterns of variation in AMS were compared to the stage of the deformation in order to understand the evolution of magnetic fabric from undeformed to deformed forms. The lineation growth and anisotropy decrease in magnetic fabrics are recognized with progress of deformation. The direction of lineation (alignment of the maximum susceptibility (Kmax) direction) develops perpendicularly to the compressive stress. The develpoment of such features is clearly recognized within the hinge zone of a ductile soft-sediment fold structure. The pattern of the shape parameters and susceptibility axes indicates that the growth of lineation occurs prior to the formation of a great circle distribution of the minimum susceptibility (Kmin) direction. This suggest that the early fabric development in sediment under a highly compressive stress regime is dominated by the grain rotation.

GA1.04/W/02-A5 1640

PALAEOMAGNETIC ROTATIONS OBSERVED ON EARLY MIOCENE DYKES FROM THE INTERNAL ZONE OF THE BETIC CORDILLERAS (SOUTHERN SPAIN)

Manuel CALVO (Dep. Física, E.P.S., Universidad de Burgos, 09006 Burgos, Spain. Email: mcalvo@ubu.es); José María Tubía and Julia Cuevas (Dep. de Geodinámica, Fac. de Ciencias, Universidad del País Vasco, Bilbao, Spain. Email: gppcuurj@lg.ehu.es)

Palaeomagnetic data from the Internal Zones of the Betic Cordilleras are relatively scarce. In this study we present preliminary palaeomagnetic results obtained on rocks belonging to an Early Miocene (22-23 Ma) dyke swarm which intrudes Maláguide and Alpujárride units in the central and western parts of the Internal Zone of the Betic Cordilleras. The aims of this study were to ascertain if relative perpendicular orientations(N-S and E-W) shown by different dyke families are of primary or secondary origin and to find out if palaeomagnetic rotations can be detected in this area.
Palaeomagnetic studies were carried out on rocks belonging to seven different sites. In addition, susceptibility-versus-temperature curves and AMS were determined. Intensities of magnetisation were found to be low, remanence being carried by pyrrothite and magnetite. Six out of seven sites offer reliable results, though dispersion is in some cases relatively high. Mean palaeomagnetic directions show both normal and reversed polarities, and strongly clockwise rotated palaeodeclinations (approx. 90-140º) are observed in all cases. As both dyke families show similar rotations, independently of their original direction, their relative perpendicular orientation seems to be of primary, intrusive origin. These rotations are in accordance with other block rotations observed in the Internal and External Betics, although their magnitudes are much stronger.

GA1.04/L/04-A6 0900

PALEOMAGNETISM OF CARBONATES AND PB/ZN MINERALIZATION IN SOUTHERN FRANCE

M.T. LEWCHUK, H. Rouvier, B. Henry and M. Le Goff (IPGP, Lab. de Géomagnetisme et Paléomagnetisme, 4 ave. du Neptune, 94107 St. Maur Cedex, France, email: mlewchuk@aol.com); D. Leach, USGS Mineral Resource Program, US Geological Survey, Mail Stop 973, Box 25046 Denver Federal Center, Denver, CO 80225

A temporal relationship between orogenesis, large scale crustal fluid migration, dolomitization, hydrocarbon localization and MVT mineralization has been inferred from geochemistry, paleomagnetism and isotopic dating in several orogenic belts and adjacent basins throughout the world. We are examining the applicability of this model for MVT mineralized carbonates from several locations in the structurally complex Cévennes region of southern France. Clay alteration dates have been used to infer an Early Jurassic age for this mineralization, although there may be conflicting geological evidence.
We isolated a single polarity, northerly, steep downward remanent magnetization during demagnetization at all locations. After partial untilting, the direction is close to the Eocene reference pole for the European Apparent Polar Wander Path. There is geological, geochemical and paleomagnetic evidence to suggest that this is the age of the magnetization. Since this magnetization is much younger than either the clay ages or maximum burial for the area the magnetization must therefore be related to fluid movement. This paleomagnetic evidence for Eocene fluid flow argues that the Cévennes district conforms to the orogenically-driven fluid-flow model for other MVT districts. The MVT mineralization is probably the product of crustal fluid migration during Pyrennean orogenesis, a process similar to virtually all other MVT deposits worldwide.

GA1.04/E/02-A6 0920

TERTIARY ANTICLOCKWISE ROTATIONS IN THE SW ALPINE REALM

Pierre ROCHETTE Frédéric Kechra, Didier Vandamme, and Frédéric Ollagney (CEREGE, BP80 13545 Aix en Provence Cdx 4, France; email: rochette@cerege.fr)

Liassic to Cretaceous marls and limestones of the European margin in SE France show a widespread remagnetization with normal polarity, carried by magnetite. This remagnetization is usually pre-folding and have a Tertiary inclination. A study of 12 sites in the Cevennes region, folded during the Pyrenean phase around 40 Ma shows no rotation with respect to Tertiary stable Europe and may point to a syntectonic remagnetization, linked to Pyrenean orogenic fluids, during the 5 Ma period of largely dominant normal polarity spanning Chrons 16-18N. In the Provencal area perfectly similar paleomagnetic behavior is observed but mean declination points toward a 15±10 degree anticlockwise rotation during Tertiary. Alternatively no rotation is implied if remagnetization occurred during Cretaceous long normal but inclination does not match. However, primary magnetizations in Paleogene sediments as well as in the 30 Ma Esterel intrusion confirms the anticlockwise rotation.
The Provencal area is surrounded to the N and W by areas showing no rotation in similar remagnetized sediments, to the S and E by the Corsica-Sardinia block and the internal alpine zones, all showing large (>30) anticlockwise rotations since 30 Ma. Therefore the Provencal area may have been partially dragged during the possibly synchronous rotation of the Apulian-Corsican-Sardinian "block", limited by dextral strike slip movement on the Penninic front and rifting in the Provencal basin. Alternatively the different rotations observed are independent and the Provencal rotation corresponds to a lateral escape during the indentation of the Apulian block into the European plate. New data from Corsica helping to understand its suturing to Apulia will be presented.

GA1.04/W/10-A6 0940

STRUCTURAL RECONSTRUCTION AT AN INTERMEDIATE STAGE OF FOLDING USING REMAGNETIZATION DIRECTION

B. HENRY and M. Le Goff (Paléomagnétisme et Géomagnétisme, CNRS and IPGP, 4 avenue de Neptune, 94107 Saint-Maur cedex, France, email: henry@ipgp.jussieu.fr);H. Rouvier (Laboratoire de Géologie Appliquée, Univ. P. et M. Curie, 4 place Jussieu, 75252 Paris cedex 05, France)

In the Cévennes area (Southwestern border of the French Massif Central), a widespread remagnetization, related to fluid migration during Eo-Oligocene times, has been pointed out (Rouvier et al., 1995). This magnetic overprint has been acquired between two phases of deformation. In two areas, several neighboring sites has been studied.
In the Durfort - Grande Vernissière area, the overprint orientation reveals that a large block underwent an important clockwise rotation since the remagnetization. The low temperature component, likely carried by goethite, shows for some of the sites also a clockwise rotation, but of smaller amplitude.
The Montagne de La Fage is presently the southern limb of an anticline, with increasing dip towards the South. According to the levels, the remagnetization shows different orientation, mainly around a vertical plane perpendicular to the main fold axis. Assuming rotation around an horizontal axis, the geometry of the main structure has been reconstructed for the time of the magnetic overprint acquisition, replacing the obtained paleomagnetic directions in coincidence with the mean orientation of the remagnetization.
H. ROUVIER, B. HENRY et M. LE GOFF, 1995. Regional remagnetization and Mesozoic levels containing "Mississippi Valley Type" deposits: the southern border of the French Massif Central. XXI UGGI Gener. Assemb., Boulder, Colorado.

GA1.04/W/20-A6 1000

PALEOLATITUDES FOR IBERIA FROM THE MIDDLE TO THE LATE JURASSIC

Maria Luisa OSETE and Cristina Osete (Dep Geofisica, Facultad Ciencias Fisicas, Complutense University, Madrid 28040, Spain, email: mlosete@eucmax.sim.ucm.es); Juan José Villalaín (Escuela Universitaria Politecnica. Burgos University. Spain);Paola Romana Gialanella (Dept. of Earth Science, Univ of Naples "FedericoII". Italy); Friedrich Heller (Institut fur Geophysik, ETH, Zurich. Switzerland)

New palaeomagnetic data are reported from 11 well dated sedimentary sections from the Betic Cordillera (southern Spain) and the Iberian Range (Central Spain) that allow to calculate the palaeolatitude of the Iberian Plate from the lower Toarcian to the Tithonian. In the investigated rocks (marly and red nodular limestones) at least two magnetic components were observed. A low-temperature component of normal polarity and maximum unblocking temperature of about 400-450˚C which has been interpreted as a secondary Cretaceous or Tertiary remagnetization. And a higher-temperature component (the ChRM) that was isolated from 450 up to 550-575˚C. The ChRM, considered as the original jurassic magnetization, exhibited both normal and reversed polarities. Directions pass the fold test and the reversal test. High palaeolatitudes (close to the present palaeolatitude of Iberia) were observed from the lower toarcian sites and lower palaeolatitudes have been obtained from upper Jurassic sites. Results have been transferred and compared with the two proposed APW paths for the North-American plate.

GA1.04/W/13-A6 1100

PALEOMAGNETISM IN NORTH-WESTERN BULGARIA : WIDESPREAD REMAGNETIZATION AND TECTONICS

B. HENRY (Paléomagnétisme et Géomagnétisme, UMR 7577 CNRS and IPGP, 4 avenue de Neptune, 94107 Saint-Maur cedex, France, email: henry@ipgp.jussieu.fr); N. Jordanova and D. Jordanova (Geophysical Institute, Bulgarian Academy of Sciences, Acad. G. Bonchev Str., block 3, 1113 Sofia, Bulgaria, email: vanedi@geophys.bas.bg);. D. Dimov (Sofia University "St Kliment Ohridski", 15 Tzar Osvoboditel Blv., 1000 Sofia, Bulgaria, email: dimo@gea.uni-sofia.bg); F. Bergerat (Département de Géotectonique, ESA 7072 CNRS, B 129, Univ. P. et M. Curie, 4 place Jussieu, 75252 Paris cedex 05, France, email: bergerat@lgs.jussieu.fr)

Paleomagnetism of Mesozoic formations, mainly Lower Triassical red sandstones and Middle-Upper Triassical carbonates, have been studied in the Moesian platform, the Stara Planina and the Prebalkan. Directions of the primary magnetization, mostly obtained in the red sandstones, are in good agreement with the Triassical data from stable Europe. There is therefore no important local rotations in these sites. In the carbonated rocks, the ChRM is of normal polarity. Positive fold test has been obtained in two sites, but progressive unfolding using all the sites points out a synfolding magnetization. Conglomerate test shows that these rocks are remagnetized. The application of the method of Surmont et al. (1990) and Shipunov (1997) using small circles intersection shows that, according to the sites, this remagnetization is prefolding or synfolding. The paleomagnetic pole of this magnetic overprint corresponds to about a Lower to Middle Eocene age, and the beginning of the main folding is at the end of the Middle Eocene. This implies that this area was locally affected by moderate folding before the main deformation. This remagnetization could be related to fluid migration during the preliminary stages of the main orogeny.

GA1.04/W/27-A6 1140

PALEOMAGNETIC EVIDENCE FOR OPENING OF THE GULF OF EDREMIT, NW TURKEY

N.ORBAY (1), M.Sanver (2), Y.Yilmaz (3), T.Isseven (2), F.Özçep (1), C.Tapirdamaz (2), M..Hisarli (1) (1- University of Istanbul, Faculty of Engineering, Department of Geophysics, 34850, Istanbul TURKEY, 2- ITU, Faculty of Mines, Department of Geophysics, Istanbul Technical University Faculty of Mines, Department of Geology, email: norbay@istanbul.edu.tr , Istanbul TURKEY)

The aim of this paleomagnetic study is to clear out the controversy, which has been created due to the different tectonic interepretations proposed on the Gulf of Edremit. For this purpose, he paleomagnetic techniques were applied to 479 samples. They are collected from 52 Neogene volcanic rocks obtained from the northern part of the Gulf of Edremit (Biga Peninsula) and around of the towns of Ayvalik, Dikili and Bergama. The remanent magnetization directions, obtained from the Lower-Middle Miocene and the Upper Miocene rock samples display, 200 clockwise and 250 counter-clockwise rotations, respectively. The remanent magnetization directions of the Lower-Middle Miocene samples, collected from the southern part of the Gulf of Edremit and the Foça area also show 190 and 300 clockwise rotations. The coeval rocks from the Bergama area, on the other hand, display 30o counter-clockwise rotation. The difference in sense of rotations from different locations of the Northwestern Anatolia may be interpreted as a result of the opening of the Gulf of Edremit during the N-S extensional regime. The different inclination angles, measured from the rocks of the western part of the studied area essentially reflect the inclined block movements, which are created by the listric normal faults duruing the development of the present E-W garben systems.

GA1.04/P/01-A6 1200

PALEOMAGNETIC RESULTS ON THE MAIN VOLCANIC OCCURRENCES FROM BAHARIYA OASES, WESTERN DESERT, EGYPT

SALAH A. MOUSA (Geophysics Dept., Fac. Of Sci., Ain Shams Univ., Cairo, Egypt.) Mohamed H. Abdel Razek (Egyptian Geological Survey, Cairo, Egypt) Karam S. Farag (Geophysics Dept., Fac. Of Sci., Ain Shams Univ., Cairo,Egypt.)

A paleomagnetic investigation has been carried out for 44 independently oriented hand blocks (comprising 336 specimens) collected from seven reasonably spaced basaltic volcanic exposures, distributed within and outer Bahariya depression. After AF and /or Thermal demagnetisations, all specimens reveal stable components of magnetisations probably of TRM origin residing mainly in magnetite and ilimenite grains. A tentative correlation of these lava extrusions, on the basis of polarity of magnetisation, has been suggested. Two distinct populations of paleomagnetic pole positions of the encountered occurrences are computed from their stable remanence orientations. Basalt Hill and El-Bahr basaltic exposures represent the first group of paleopoles which are 78.25° S/34.3° E and 78.90° S/21.7° E respectively, while the basaltic exposures of El-Hefhuf, Mandisha/El-Aguz and Maesera represent the second group of paleopoles which are 56.2° S /10.8° E , 58.9° S/19.4° E and 50.6° S/14.8° E respectively. On the other hand, west El-Tebniya basaltic exposure shows a paleopole, 36.7° S/349.5°E, intermediate between the two groups. This may indicates that the Bahariya Oases were subjected to two main alternative epsoids of volcanicity, This activity is considered to be intimately related with the late Tertiary (pre-Miocene to lower Miocene) epirogenic movements in Egypt. The present reliable Tertiary results represent a good contribution to the Egyptian paleomagnetic database.

PALEOMAGNETISM OF SE ASIA: CONTRIBUTIONS TO CENOZOIC TECTONICS

Mike FULLER and Gina Frost (HIGP-SOEST, University of Hawaii, Honolulu, Hawaii, 96822, USA, email: mfuller@soest.hawaii.edu)

SE Asia lies at the intersection of the Euroasian, Indian-Australian andPhilippine Sea Plates and as such is an area of active tectonics. Thepaleomagnetism of the region remains incompletely established, but majorpatterns are emerging. A region in the north including Myanmar andThailand exhibits a history of Cenozoic clockwise (CW) rotation andsoutherly motion. To the south in Peninsular Malaysia, Borneo, Celebes Sea and much of the Philippines counterclockwise (CCW) rotations predominate with little change in latitude. The Mesozoic basement of Palawan, which lies to the northeast of Borneo between the South China and Sulu Seas, is an exception having moved southward. Ophiolites obducted on to this basement appear to have moved northward and rotated counterclockwise. The timing and magnitudes of these rotations have not yet been satisfactorily established, but constraints on some are evident. For example, the CCW rotation of Borneo can be demonstrated to have consisted of some 40 to 50° between approximately 25 and 10 Ma and an additional similar amount between 25 and 80 Ma. The CCW rotation of Peninsular Malaysia is some 40°, but the absence of a Tertiary section on the peninsula leaves the timing of the rotation poorly constrained as post-60 Ma. The CW rotation in Myanmar and Thailand is interpreted as a response to the Indian-Eurasian collision. The southward motion of Palawan is readily interpreted as a consequence of South China Sea spreading. The rotation of Borneo follows from the convergence between the Indian-Australian plate and Eurasia which has given rise to the accretionary wedge of northwest Borneo. The timing of the rotation of Peninsular Malaysia and its tectonic explanation remain unclear, but will likely be resolved by results from Sumatra. In this area of complicated Cenozoic tectonics paleomagnetism is helping to establish tectonic history, but many of the results remain controversial.

GA1.04/W/17-A6 1420

EARLY TRIASSIC PALEOMAGNETIC POLE FROM THE KOREAN PENINSULA

Koji UNO (Division of Environmental Science, Graduate School of Science and Technology, Kobe University, Kobe 657-8501, Japan, Email: unokoji@kobe-u.ac.jp)

Greenish sandstones in the Early Triassic Nogam Formation were collected for paleomagnetic study at 23 sites in the Ryeongnam Block, Korean Peninsula. A remanent magnetization component with low unblocking temperatures by 650C is obtained from 15 sites, while reliable remanent magnetization component with high unblocking temperatures of 670-690C is isolated from 7 sites. Paleomagnetic directions of the low temperature component before tilt correction are close to that of the present Earth's geomagnetic field. The directions yield a negative fold test at the 95% confidence level, indicating a recent remagnetization. Paleomagnetic directions of the high temperature component from 7 sites significantly cluster after tilt correction (from k=36.1 to k=120.8). The fold test is positive at the 95% confidence level.
The tilt-corrected mean direction of the Nogam Formation (D=347.1, I=23.8 with a95=5.5) is regarded as a characteristic direction of the Ryeongnam Block in the Early Triassic time. The mean direction is of primary origin because of the folding age of Middle Triassic. Paleomagnetic pole calculated from primary directions of the Nogam Formation (62.5N, 336.8E with A95=4.7) shows good agreement with the coeval pole for the North China Block. The paleomagnetic evidence suggests that the Ryeongnam Block has been a part of the North China Block at least since the Early Triassic time.

GA1.04/W/11-A6 1440

SOUTHWARD DISPLACEMENT AND DIFFERENTIAL CLOCKWISE ROTATION OF INDOCHINA: PALEOMAGNETIC EVIDENCE FROM MIDDLE CRETACEOUS RED SANDSTONES IN NORTHWESTERN YUNNAN, CHINA

Ken SATO, Yuyan Liu, Zhicheng Zhu,Zhenyu Yang and Yo-ichiro Otofuji, (Department of Earth and Planetary Sciences, Faculty of Science, KobeUniversity, Kobe 657-8501, Japan
email: ken@shidahara1.planet.kobe-u.ac.jp)

Paleomagnetic samples from middle Cretaceous redbeds were collected at 20 sties around Yunlong (25.8 N, 99.4 E), northwestern part of Yunnan province, in the northern part of the Indochina block. After stepwise thermal demagnetization, high temperature component magnetization with unblocking temperature of about 675 C is isolated. Positive fold test at the 99% confidence limit shows that the high temperature component magnetization is primary for the middle Cretaceous Nanxin Formation. A tilt-corrected formation mean direction is D = 40.2, I = 49.9 with a95 = 3.9 , corresponding to a paleopole at 54.6 N, 171.8 E with A95 = 4.4. Comparison with previously reported Cretaceous paleomagnetic directions indicates that the Yunlong area has been subjected to southward displacement by 11.9, 7.5 (corresponding to 1300, 800km) with respect to the stable Yangtze craton since Cretaceous time as well as clockwise rotation through 36.3, 13.6. The amount of latitudinal displacement observed in this study is compatible with the previously observed southward displacement of the Indochina block, whereas variable amount of clockwise rotation is observed throughout the Indochina block. This study elucidates that the Yunlong area in the Simao Terrane is a northernmost part of the southward translating Indochina block. We conclude that Indochina was squeezed out from Asian continent due to collision of India accompanied with internal differential clockwise rotation.

GA1.04/L/05-A6 1500

PALEOMAGNETIC DATA OF UPPER JURASSIC-LOWER CRETACEOUS ROCKS IN CENTRAL PATAGONIA: EVIDENCE FOR TECTONIC ROTATIONS

Silvana Geuna, Ruben Somoza and Haroldo VIZAN (Departamento de Ciencias Geológicas, FCEyN, Universidad de Buenos Aires, email: sgeuna@gl.fcen.uba.ar); Eduardo Figari (YPF S.A.); Carlos Rinaldi (Instituto Antártico Argentino)

We report preliminary paleomagnetic data from a widespread distribution of sites of Upper Jurassic to lowermost Cretaceous volcanic and sedimentary rocks in the Cañadón Asfalto basin, central Patagonia. Monocomponent and multicomponent magnetizations were observed during both thermal and AF demagnetization procedures. Some sites show the presence of both normal and reverse polarities, while only one polarity is observed in others. The resulting time-averaged paleomagnetic vector of each site was compared with the expected Late Jurassic-Early Cretaceous paleofield for South America. Despite problems with the accurate definition of the APWP of this continent, the paleodeclinations of the studied rocks suggest the widespread occurrence of vertical axis rotations. In contrast, the unconformable overlying Cretaceous rocks in the region do not show paleomagnetic evidence of vertical axis rotations. This indicates that most tectonic rotations detected in rocks of the Cañadón Asfalto basin are coeval with, and perhaps closely related to the opening of the South Atlantic Ocean.

GA1.04/W/15-A6 1520

PALEOMAGNETISM ON MESOZOIC SEDIMENTS FROM SOUTHERN SIERRA MADRE ORIENTAL. EVIDENCE FOR POST CRETACEOUS DIFFERENTIAL TECTONIC BLOCK ROTATIONS.

Juan José VILLALAÍN (Dpto. de Física, E. Politécnica Superior, Universidad de Burgos, 09006-Burgos, Spain, email: villa@ubu.es); Daniel Rey (Dpto. de Geociencias Marinas, Universidad de Vigo, 36200-Vigo, Spain); V. Carlos Ruiz & M. Luisa Osete (Dpto. Geofísica, Univ. Complutense, 28040-Madrid, Spain); Cecilia Caballero (Instituto de Geofísica, UNAM, 04510, México DF, México)

This paper reports on Upper Triassic to Upper Cretaceous rocks from the southern Sierra Madre Oriental. This chain has traditionally been interpreted as a Laramide fold belt, related to an upper Cretaceous-lower Tertiary orogenic event. The 22 sites investigated are representative of the variety of lithologies and ages that crop out in the Guayacocotla antiform. The structure of the NRM shows several common features in despite of their geographical distance, age disparity and lithological variety of the sampling sites. Their main palaeomagnetic characteristic is the presence of a stable reversed polarity component that generally unblocks between 450 and 500°C. The majority of the fold test results indicate that this component is a post-folding overprint, although there are a few cases indicating the contrary. Consequently we have concluded that the NRM of the investigated samples is dominated by a pervasive overprint that has affected rocks of different age and lithology distributed over a large area of the southern section of the western Sierra Madre in Mexico. This remagnetisation event was first suggested by Böhnel et al. (1990). Comparison of the overprint directions with the lower Tertiary North American expected direction indicates two important features: 1) The inclination of the overprint is consistent with the expected lower Tertiary directions for North America. 2) The palaeodeclination values indicate the existence of differential anticlockwise palaeomagnetic rotations in a very consistent distribution.

GA1.04/W/33-A6 1540

TECTONIC CENOZOIC EVOLUTION OF THE CENTRAL ANDES (28˚-40˚ LAT. S) ON BASIS OF PALEOMAGNETIC AND GEOCHEMICAL DATES

GUILLERMO H. Ré (Lab. D. Valencio - UBA - Cdad. Universitaria, P.2, 1428 Bs.As., Argentina; email: indio@gl.fcen.uba.ar); Juan F. Vilas (CONICET - Lab. D. Valencio - UBA - Cdad. Universitaria, P.2, 1428 Bs.As., Argentina; email: vilas@gl.fcen.uba.ar)

The region understood between the 28° and the 40° S is characterized to present two clearly different subduction stiles. Flat-slap subduction occurs among 28° and 33° S and normal subduction to the south of the 34°. In the north sector, it was carried out magnetostratigraphic studies in six localities. Additionally, paleomagnetic information corresponding to other eight localities was compiled. In the south sector it was carried out paleomagnetic and geochemical studies in fourteen localities, and the available geochronological information was compiled for the same ones. As a consequence of the obtained results it arises that the north sector presents a highly compressive tectonic, for events of different duration, at least from the 18 Ma.
On the other hand, in the south sector it was determined the existence of a group of distensives events and compressive that affected the district from the 20 Ma. These results might indicate that as a consequence of the reduction in the Nazca plate subduction angle (effective from the 10 Ma.) distensives events in the south sector that could be related with the compressive events that occurred in the north with equivalent time. This relationship may indicate the existence of a tensional field that would act as element of compensation of the cortical stress induced by the different subduction's regimens.

GA1.04/E/17-A4 Poster 0930-01

MAGNETIC SUSCEPTIBILITY AND PARTIAL ANHYSTERETIC REMANENCE ANISOTROPIES IN THE MAGNETITE-BEARING GRANITE PLUTON OF TOURAO, NE BRAZIL

Ricardo TRINDADE (Instituto Astronomico e Geofisico, Universidade de Sao Paulo, 3386, 01060-970, Brazil, email: rtrindad@iag.usp.br) Maria Irene B Raposo (Laboratório de Anisotropias Magneticas, Instituto deGeociencias, USP, Sao Paulo-SP, Brazil) Marcia Ernesto (Instituto Astronomico e Geofisico, Universidade de Sao Paulo-SP, 3386, 01060-970, Brazil)

The Tourao granite (Serido belt, NE Brazil) was emplaced along a set of NE and E-trending dextral strike-slip shear zones. Rock magnetism revealed that magnetite is the unique feromagnetic mineral in these rocks. Anisotropy of low-field magnetic susceptibility (AMS) was measured in 83 sites and showed a strong scatter for 20% of the sites. Anisotropy of partial anhysteretic remanence (pAAR) was determined for 29 sites in the 0-50 mT (pAAR0-50) and 19 sites in the 50-90 mT (pAAR50-90) windows to isolate the fabric contribution of the remanence bearing fine- and coarse-grained magnetites. The pAAR0-50 is related to coarse-grained early crystalized magnetites while the pAAR50-90 is interpreted as due to fine needle-shaped magnetites hosted in biotites. Although the intrusive body does not show any inprint of solid-state deformation, magnetic fabrics were able to record discrete kinematic events that affected the pluton. The AMS and pAAR0-50 fabrics for most sites seems to be correlated to the early NNE-trending magmatic fabric, whereas pAAR50-90 gives a new fabric probably related to late partitioning of strain along E-trending magmatic shear zones. The former fabrics are probably related to the NE-trending shear zones stress field and were partially overprinted by the E-trending fabric recorded by pAAR50-90 suggesting that the set of E-trending structures is slightly younger than the major NE-trending shear zones.

GA1.04/W/07-A4 Poster 0930-02

A CASE OF THERMAL ENHANCEMENT OF ANISOTROPY OF THE MAGNETIC SUSCEPTIBILITY IN THE NATURE

Silvia Singer, Juan VILAS, Claudia Prezzi and Ruben Somoza (Departamento de Geologia, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, e-mail: somoza@gl.fcen.uba.ar)

As part of a paleomagnetic study in northern Chile we sampled sedimentary rocks in both the limbs of a kilometer-scale, north-south trending syncline. Additional samples from postectonic dikes of andesite were taken in the eastern limb.
Most samples of sedimentary rocks from the eastern limb show a postectonic magnetic component of reverse polarity, with magnetite as the main carrier. The same component is observed in the dikes, suggesting that the postectonic component founded in the sedimentary rocks of this limb is related to the volcanism. In contrast, all the samples from the western limb show a pretectonic, normal-polarity magnetic component carried by hematite.
On the other hand, the sedimentary rocks of the eastern limb show a well defined, parallel-to-stratification magnetic foliation, whereas the magnetic susceptibility axes from sedimentary rocks of the western limb show a random distribution. However, these latter show a good clustering after thermal treatment, with the laboratory-induced magnetic foliation being parallel to the stratification. This suggests that the well-defined, natural magnetic fabric observed in the eastern limb is due to enhancement of the anisotropy of the magnetic susceptibility by heating during the volcanic activity.

GA1.04/L/06-A4 Poster 0930-03

PRELIMINARY PALAEOMAGNETIC DATA FROM PRECAMBRIAN, CAMBRIAN AND LATE ORDOVICIAN/EARLY SILURIAN ROCKS AROUND NUNEATON (MIDLAND PLATFORM OF THE UK)

VIZAN H.(1); Tomasso M.(1), Carney J.(2), Clarke P.(1), Turner P.(1) and Mullen R.(1). Schoolof Earth Sciences. University of Birmingham. Edgbaston. Birmingham B 15 2TT. (2) British Geological Survey. Keyworth. Nottingham NG12 5GG.

A collaborative study by the British Geological Survey and the University of Birmingham is being carried out on Precambrian (~603 Ma), Cambrian (?530-540 Ma) and late Ordovician/early Silurian (442 +/- 3 Ma) rocks around Nuneaton. The Precambrian rocks consist of crystal tuffs and a variety of tuffaceous lithologies, intruded by basaltic andesites and a granophyric diorite stock. These rocks display an increasing red colour and spheroidal weathering as the unconformity is approached and are overlain by red, lithic-rich granulestones and sandstones basal to the Lower Cambrian Hartshill Sandstone Formation. All of these rocks are in turn intruded by late Ordovician/early Silurian (Ashgill to Llandovery) lamprophyres. Preliminary palaeomagnetic data suggest that each of these three ages of rocks show a different characteristic remanent magnetization (ChRM). The mean ChRM in the Precambrian rocks pass a contact test and differ substantially from those previously published. In-situ, its steep inclination (I=+76_, Dec=123_) is quite close to that recorded in Precambrian rocks of the Church Stretton area (75 km to the west of Nuneaton). The mean ChRM in the Cambrian strata has a shallow inclination (I=-2_, Dec=170_) and, in-situ, is close to that recorded for various other parts of the UK during the Carboniferous. The mean ChRM of the Upper Ordovician dykes, in-situ, has an intermediate inclination (I=-41_, Dec=160_) between the other values. In order to determine the origin of these different magnetizations, we conducted follow-up palaeomagnetic studies and geological observation, including strain testing of rocks using anisotropy of magnetic susceptibility and tilt testing the ChRM.

IS THE PLATE MOVEMENT RANDOM?

Vsevolod N.VADKOVSKY (Department of Geology, Moscow State University, 119899 Vorobjevi gory, Moscow, Russia, email: vad@dynamo.geol.msu.ru)

On the face of it would seems that the plate movement is deterministic process at least latest 300 my (Cox, Hart,1985). Do any estimates of random wandering of litosheric plates exist? The characteristic of random (brownian) wandering of the particle is a root-mean displacement z which depends from time as square root: z=sqr(2*D*t), where D - diffusion coefficient (or mobility) of particle in the enviroment. This Einstein relation is the true for brownian wandering on a sphere surface too (Mardia,1972), but the displacement is an angle distance f between the start-point and point in any time. The analog of the root-mean displacement on a sphere is v=1-cos(f) (Fisher, 1953). There are analysed non-smoothed data of time-series of apparent palaeomagnetic pole positions for different plates on different time intervals. It has been found that non-smoothed palaeomagnetic data on Baltic shield for the period from 2850 to 600 my interval (Elming,1993) and the same data on East-European plate for the period from 430 to 34 my interval (Khramov,1991) correspond to brownian behaviour due to its v(t) dependences. The Global Palaeomagnetic Database (McElhinny, Lock,1995) was used for study of joint motion of the plates ensemble. The time period under study (2800 my - 0) was divide on non-

overlap intervals of different length (10,20,50,100..my). The empiric latitude and longitude distributions of palaeoposition of all continents were calculated for every temporal-window. This distributions were compared with theoretical distributions. The comparison of this distributions leads to the conclusion that plate motions has brownian type. Maybe somebody very exactly knows trajectory of a plate in the past, but nobody knows it in the future .. In what direction will propagate Red sea rift?

PALAEOMAGNETISM OF THE LOWER PALAEOZOIC VOLCANICS OF THE KACZAWA COMPLEX: EVIDENCE FOR VARISCAN MOBILISM IN THE POLISH SUDETES

Marek LEWANDOWSKI (Institute of Geophysics, Polish Academy of Sciences, Ks. Janusza 64, 01-452 Warsaw, Poland, email: lemar@igf.edu.pl); Ryszard Kryza (University of Wroclaw, Institute of Geological Sciences, Cybulskiego 30, 50-205 Wroclaw, Poland, email: rkryza@ing.uni.wroc.pl), Niels Abrahamsen (Department of Earth Sciences, Aarhus University, Finlandsgade 8, DK-8200 Aarhus N, Denmark; email: Abraham@geo.aau.dk)

Palaeomagnetic studies on Lower Palaeozoic metavolcanics from the Kaczawa Mts (West Sudetes, NE part of the Bohemian Massif) are reported. The rocks under study represent mostly bimodal within-plate volcanics with a U-Pb multigrain zircon age of 511±39 Ma, successively metamorphosed under blueschist and greenschist facies conditions. Samples for palaeomagnetic and mineralogic studies comprised some 140 oriented hand samples and cores, collected from 13 sites on area of 200 km2. The stable ChRMs are all of post-folding origin and may be divided into three groups: A, B, and C, according to their orientation. Group A show NNE declination with moderate downdip inclination, which probably represents an Alpine overprint. Group B shows W-to-SSW declination with shallow inclination, and is interpreted as acquired during a clockwise rotation of the Kaczawa unit during the Variscan orogeny. Group C display northern declination and a very steep inclination, similar to the remanence reported earlier from the Ordovician of Armorica. Lack of similarity of remanence C with known Phanerozoic palaeomagnetic directions from Baltica may indicate a possible separation of the Kaczawa Unit from Baltica at the time when this remanence was acquired. A resulting high latitude position of the Kaczawa Unit during the post-folding remagnetization, as suggested by the Group C, poses again a question upon the age and evolution of the Kaczawa structure, and a possible role of Caledonian movements within the area of Variscides.

GA1.04/W/09-A4 Poster **0930-06**

KINEMATIC RELATIONS BETWEEN MAGNETIC (AMS, AARM) AND TECTONIC FABRICS IN THE SHEAR ZONE (NIEMCZA FAULT ZONE, SUDETES FORELAND, SW POLAND)

Tomasz WERNER (Institute of Geophysics, Polish Academy of Sciences, ul. Ks. Janusza 64, 01- 452 Warszawa, Poland, Email: twerner@igf.edu.pl)

Anisotropy of magnetic susceptibility (AMS) and anisotropy of anhysteretic remanence (AARM) studies were performed for 22 sites with mylonites, gneisses, black shales, gabbros, serpentinite and granitoids within and in the vicinity of the Niemcza Fault Zone located in the Sudetic foreland in SW Poland. Some previous petrographic, structural and micro-tectonic studies in sites within the zone support the process of mylonitization of the Sowie Mountains gneisses in the strike-slip regional- scale sinistral shear zone developed along the eastern margin of the Sowie Mountains block.
Magnetic foliation (AMS kmin and AARM kmin axes) are in general closely correlated with tectonic foliation planes as well as magnetic (Kmax) with tectonic lineation on sample and site scale. Those relations were used as the kinematic indicators of non-coaxial deformation with a dominant sinistral shear component within the area.
The regional variability of the magnetic fabric (both direction and anisotropy parameters) was researched to test the postulated Sowie Mountains gneissic origin of the Niemcza zone mylonites. The relation of the magnetic fabric of late-tectonic gabbro, serpentinite and granitic bodies within the Niemcza zone with those of mylonites was also evaluated

GA1.04/E/09-A4 Poster **0930-07**

MAGNETIC FABRIC OF MESOPROTEROZOIC DIKE SWARMS FROM THE ILHÉUS, OLIVENÇA AND ITAJU DO COLÔNIA REGIONS, SE BAHIA STATE, BRAZIL

Maria Irene B. RAPOSO (Lab. de Anisotropias Magnéticas, Instituto de Geociências, Universidade de São Paulo, São Paulo, SP, 11348, 05422-970, Brazil, Email: irene@usp.br); Manoel S. D'Agrella-Filho (Instituto Astronômico e Geofísico, Universidade de São Paulo, São Paulo, SP, 3386, 01060-970, Brazil, Email: dagrella@iag.usp.br)

The anisotropy of low-field magnetic susceptibility (AMS) was employed in the Ilhéus (IL), Olivença (OL) and Itaju do Colônia (IT) dike swarms from the São Francisco Craton, to investigate the magnetic fabric of these dikes and to provide information on their mode of emplacement. Most dikes (69) show a normal fabric, i.e., K1-K2 parallel to the dike wall, representing magma flow within the dikes. In 7 dikes it was found an intermediate fabric, i.e., K1-K3 parallel to the dike wall, which can be interpreted as resulting from the vertical compactation of a static magma column with the minimum stress along the dike direction. In 10 dikes an inverse fabric (K1 perpendicular to dike plane) was found. This fabric is not related to an exchange of K1 and K3 axis since hysteresis parameters indicate magnetic grains in the PSD-MD state for all studied dikes. Anisotropy of anhysteretic remanence (AAR) performed in dikes with inverse fabric suggests that this fabric was acquired after dike emplacement. The normal fabric shows, generally, steep K1 inclinations (>40°) for the IT dikes, suggesting that they were fed by inclined up to vertical flow. The opposite is observed for the IL-dikes where shallow K1 (<20°) inclinations predominate suggesting distant magma source. However, the OL-dikes have both steep and shallow K1 inclinations. These data suggest that if a single magma source fed the 3 swarms it was probably close to Itaju do Colônia area. Our data could also suggest another source close to the Olivença area.

GA1.04/E/06-A4 Poster **0930-08**

THE PROBLEMS OF PALEOMAGNETIC RECONSTRUCTION OF THE EAST-EUROPEAN CONTINENT IN ORDOVICIAN

Ideya SVYAZHINA and Zifa Mezenina (Institute of Geophysics, Urals Branch of RAS, Amundsen Str., 100, Ekaterinburg, 620016, Russia, email: gloukhikh@igeoph.mplik.ru); Valerian Bachtadse and Jenny Tait (Institute fuer Allg. und Angew. Geophysik Ludwig- Maximillians Universitaet Muenchen, Theresienstrasse 41, 80333 Muenchen, Germany, email: jenny@magbakt.geophysik.uni-muenchen.de)

Shelf and slope deposits of the eastern edge of East-European continent were sampled within the structures of Southern, Middle and Northern Urals. According to the data received by the authors and other investigators, the continent in Early Ordovician was situated approximately between N 50 and S 200. Later in Middle and Late Ordovician it moved to the North (on modern geographical coordinates) and at the end of the period it was situated in equator-side zones of the Northern and Southern hemispheres.

According to the data received for Baltica (T.H.Torsvik and othres) the East-European continent was also situated in Southern hemispere in more high latitudes - between S 300 and S 600. During Ordovician it moved firstly to the South in Arenig-Llanvirn and later - to the North. As to polarity in Ordovician there are no differences in this problem. In Early Ordovician the polarity is supposed to be reverse and in Late – the normal one.

GA1.04/E/13-A4 Poster **0930-09**

PRELIMINARY PALEOMAGNETIC STUDY ON PALAEOZOIC SEDIMENTARY ROCKS FROM NORTHERN VIETNAM

N T K THOA (Institute of Geophysics Box 411 Buudien Boho, Hanoi Vietnam, email: thoa@igp.ncst.ac.vn)

Northern Vietnam is belonging to the South China block. Many tectonists believe that this block together with Southeast Asia were formerly part of Gonwanaland during early Paleozoic time. The late Proterozoi, Cambrian and Ordovician sedimentary sequences, exposed along Song Ma suture in Northern Vietnam. For preliminary paleomagnetic study, 340 oriented sampled from 35 sites were collected by using a portable gasoline-powered drill. Paleomagnetic treatments were carried out at the Institut f|r Angemeine und Allgewandt Geophysik in Munich, Germany. Samples were submitted to standard stepwise alternating field and thermal demagnetization. The principal component analysis showed that only a half part of samples yields useful paleomagnetic data. These samples were taken from limestones, sandstones and siltstones sequences. Additional magnetic measurements on IRM, Hc, Hcr, Mrs, Ms, Ist, Tc and hysteresic loops seem to confirm the content of primary mineral in these rocks (goethite and magnetite in limestones, hematite in sandstones and siltstones). The reversal test , fold test and conglomerate test were positive. The observed mean directions for paleozoic age of samples in North of Vietnam are follow: for Early Cambrian : D= 1807 I= -1002; for Midl Cambrian: D= 35504, I=-1409; for Late Cambrian: D= 18408, I= -1405 , for Early Ordovic: D= 20400, I= -1706. Local paleotectonic reconstruction of region is calculated as well as the comparison of these data with the expected directions for a reference point in Northern Vietnam (j = 220N, l = 1050E). These results appear to support the former southern paleolatitudes of these terraines, based on paleontological, stratigraphic, and structural relationships.

PALAEOMAGNETIC RECONSTRUCTION OF THE EARLY PALAEOZOIC METAIGNEOUS COMPLEX FROM THE WEST SUDETES (KARKONOSZE - IZERA MASSIF, SW POLAND) BASED ON THE MAGNETIC FABRIC STUDY

Maria JELENSKA, Tomasz Werner, Magdalena Kadzialko-Hofmokl (all at Institute of Geophysics, Polish Academy of Sciences, ul. Ks. Janusza 64, 01- 452 Warszawa, Poland, Email: bogna@igf.edu.pl) and Stanislaw Mazur (Institute of Geological Sciences, University of Wroclaw, Pl. M. Borna 9, 50-205 Wroclaw, Poland, Email: smazur@ing.uni.wroc.pl)

The southern and eastern margins of the Karkonosze-Izera massif in the Sudetes (northern Bohemian Massif) expose a nappe pile overthrust towards the NW onto the pre-Variscan continental basement of the Saxothuringian basin. The tectonically uppermost in the nappe pile is the Leszczyniec unit, composed of metaigneous Early Palaeozoic metabasites and gneisses. The isotopic age of protholith is about 500 Ma. The rocks underwent heterogeneous deformation accompanied by mostly epidote- amphibolite grade metamorphism of probably Late Devonian to Early Carboniferous age. Palaeomagnetic studies revealed several components of NRM of steep and intermediate normal inclinations and scattered declinations. Among them some Carboniferous remagnetizations were recognised. However, the paleopoles calculated for other palaeomagnetic directions lie far from the reference APWPs for Baltica or for terrains derived from Gondwana. Therefore, in situ palaeomagnetic directions were corrected to remove effects of superimposed tectonic evolution. Since the magnetic fabric (AMS) for Leszczyniec unit is characterised by approximately N-S trending almost vertical foliation planes, the rotation that brought Kmin axes close to the horizontal E-W attitude was performed. The same correction applied to NRM components rotated them towards the Early Palaeozoic segment of the APWP for Baltica.

VARISCAN REMAGNETIZATION AND TECTONIC ROTATIONS IN THE HOLY CROSS MOUNTAINS AND ARDENNES : PRELIMINARY CONCLUSIONS

Rafal SZANIAWSKI and Marek Lewandowski (Institute of Geophysics, P.A.S., Ks.Janusza 64,01-772 Warszawa, Poland, email: rafsz@igf.edu.pl); Olivier Averbuch, Jean-Louis Mansy and Juliette Lamarche (Sedimentologie et Geodynamique, U.F.R., Lille 1, Villeneuve d'Ascq, France, e-mail: Olivier.Averbuch@univ-lille1.fr)

Comparative palaeomagnetic studies have been undertaken on the Palaeozoic rocks of the Holy Cross Mts. (HCM, Poland) and Ardennes-Boulonnais (AB, northern France), aiming to point out differences and similarities in tectonic evolution during Variscan diastrophic cycle. HCM and AB are situated in the eastern and central segment of the northern Variscides, respectively. In both regions Devonian clastics and carbonates were analysed, concentrating mainly on the localities situated in the central and western branch of French Ardennes, places so far not investigated palaeomagnetically by previous teams. Main carrier of NRM in the early Devonian redbeds was hematite, while secondary magnetite and/or hematite dominate in the mid-upper Devonian carbonates. NRM display single to multicomponent structure. All components identified so far are of secondary origin and were acquired at various stages of tectonic development thus remanence acquisition is most probably related to (syn)orogenic Variscan movements. Reversed polarity is dominating except for Radkowice (southern unit of HCM) where normal polarity is observed. Common feature for the calculated VGPs in HCM and AB is their noticeable Northwest deviation from APWP for Baltica, a magnitude of the deviation varying from place to place. This is indicative for akin clockwise rotations in the distant parts of the Variscan fold belt, represented by structural units developed under different geotectonic setting.

YUKON-TANANA TERRANE: BACKSTOP FOR THE ACCRETED NORTH AMERICAN CORDILLERAN TERRANES

SYMONS, D.T.A., McCausland, P.J.A. (Earth Sciences, University of Windsor, Windsor, Ontario, Canada, N9B 3P4, ph: 519-253-3000, ext. 2493, e-mail: dsymons@uwindsor.ca); Hart, C.J.R. (Yukon Geology Program, Whitehorse, YT, Canada, Y1A2C6)

The Yukon-Tanana Terrane (YTT) underlies much of northern British Columbia, the Yukon and Alaska where it abuts against the North American craton. It is an enigmatic polymetamorphosed Phanerozoic terrane of either postulated far-traveled accreted or pericratonic origin. Preliminary paleomagnetic analysis of specimens collected by helicopter from 21 sites in the 190 +/- 5 Ma Jurassic Big Creek batholith (~500 km2), a coarse-grained quartz-hornblende syenite to monzonite pluton, and from 16 sites in the ~82 Ma Seymour

Creek stock (~4 km2), a granodiorite pluton, yields poles at 147°E, 68°N (dp=6°, dm=7°) and 195°E, 59°N (dp=11°, dm=11°), respectively. Al-in-hornblende geothermobarometry indicates Big Creek was emplaced at ~6 kbar, with uplift soon after intrusion, and Seymour Creek at ~3 kbar so that it froze on intrusion into the Big Creek batholith to provide a contact test in addition. Comparison of the YTT apparent polar wander path (APWP) segment given by these poles to the craton's APWP indicates that the YTT was formed alongside the craton with ~30° of subsequent counterclockwise rotation but no relative translation. This indicates that the YTT was formed next to the cratonic margin and that the accreted terranes impacted against it.

GEODYNAMIC MODEL FOR THE CENTRAL SECTOR OF ALPINE-HIMALAYA FOLD-BELT FOR RECENT TIME BASED ON PALAEOMAGNETIC DATA ANALYSIS

Yu. S. RZHEVSKY (St.Petersburg State University, 14th Line 29, V.O., 199178, St.Petersburg, Russia, email: yurkov@cape.nw.ru)

The conception offered is developed on the basis of the long-standing experience of palaeomagnetic data using in geodynamic investigations of the study region (Rzhevsky, 1964-1997). This conception uses the curves of migration of the instantaneous poles of rotation and synchronous curves of instantaneous rotation velocities for the different blocks of the Earth crust (Afgano-Tajik depression, North, Central, and Southeast Pamir, etc.). These curves are produced on the basis of palaeomagnetic data analysis for the recent time. Complex analysis of these curves allows us to make up the palaeogeographic reconstructions of the blocks for different time moments. Analysis of the palaeogeographic reconstructions obtained allows us to reconstruct the geodynamics of any part of the study area at any moment of recent time. Moreover, the model constructed lets to predict the character of geodynamic processes for any part of the studied area. Computer program, based on this model, may be used for evaluating of seismic potential of any area.

USING ROCK AND PALEOMAGNETIC METHODS TO ORIENT DRILL CORE: EXAMPLES FROM THE WESTERN CANADA SEDIMENTARY BASIN

Cioppa, M.T., SYMONS, D.T.A., (Earth Sciences, University of Windsor, Windsor, Ontario, Canada, N9B 3P4, ph: 519-253-3000, ext. 2502, email: mcioppa@uwindsor.ca), Lewchuk, M.T., (Institut de Physique du Globe, Paris, France), Gillen, K.P (Vox Terrae International, Calgary, AB)

Oriented core provides information on various directional properties in a reservoir, i.e. fracture orientation, anisotropy of permeability, and in-situ stress tensors. Paleomagnetism may be used to restore core to its in-situ position. The viscous remanent magnetization (VRM) method aligns the VRM to either the Earth's present or dipole-averaged magnetic field. However, in six dolomite hydrocarbon reservoir studies in the Western Canada Sedimentary Basin (WCSB), this technique worked wholly in only one, partially in three, but not at all in two reservoirs. The method failed due to the lack of a VRM and/or the presence of a drilling induced remanence (DIRM) that is correlated to pyrrhotite. Thus, alternative paleomagnetic methods of orientation were needed. In all six studies the characteristic remanent magnetization (ChRM) had a steep inclination, usually reversed, that was used to orient drill cores. In case 1 three sampled cores were drilled at very different angles, and the angle between the core and the ChRM inclination provided a unique solution to the true ChRM orientation. It could then be dated by using the reference apparent polar wander path (rAPWP). In case 2 the paleolatitude small circle determined from the ChRM intersected the rAPWP only once, thus dating its ChRM. In case 3, the presence of a high temperature component was suggested by remagnetization circles from the ChRM to a shallow inclination. Geochemical and petrologic data suggested that the host Mississippian carbonates were either unaltered or early diagenetic in origin. Assuming that the high temperature component was Mississippian resulted in a Late Cretaceous age for the ChRM. In all three cases, the known ChRM direction could then be used to orient the cores.

PALEOMAGNETIC ORIENTATION OF DRILL CORE IN THE WESTERN CANADA SEDIMENTARY BASIN: RESULTS FROM A WORST CASE SCENARIO

M.T. LEWCHUK (IPGP, Lab. de Géomagnetisme et Paléomagnetisme, 4 ave. du Neptune, 94107 St. Maur Cedex, France, email: mlewchuk@aol.com) D.T.A. Symons, I. S. Al Aasm (Dept. Earth Sci., Univ. Windsor, Windsor, Ontario, Canada, N9B 3P4) and K. P. Gillen, (Vox Terrae International, 40, 820-9a Street N.W. Calgary, Alberta, Canada, T2N 1V1)

Paleomagnetic analysis on drill cores is often done with the aid of external orienting tools such as well logs and fracture/bedding patterns to oreint the core. Alternatively the orientation can be obtained by rotating the remanent magnetization data about the azimuth of the core axis until the viscous remanence is aligned with the present Earth's magnetic field direction. We present paleomagnetic data from the Western Canada Sedimentary Basin for which there were no external references for core orientation and the viscous magnetization was absent or unstable. Further, the core was broken up and had been extensively handled so that even the true up direction was uncertain for several pieces. We used the inclination of the characteristic remanence magnetization (ChRM) to determine the uphole direction assuming a single polarity component. We then generated a mean core magnetization angle (CMA), defined as the specimen ChRM inclination with respect to the core azimuth, for three cores drilled in different directions (vertical, inclined and horizontal). Plotted as small circles around the borehole azimuth, the three CMA's intersected at a best fit point that defined a Laramide age for the magnetization. We interpret this as a remagnetization related to hydrocarbon migration which agrees well with several other studies of similar rock sequences in the region. Thus, despite a worst case scenario for paleomagnetic analysis we were able to conduct a complete study on these cores, providing both core orientation and age of magnetization.

A TEST OF ROTATION FOR MAGNETOSTRATIGRAPHIC DATA

S. J. SANGODE Wadia (Institute of Himalayan Geology Dehradun 248 001, INDIA)

Determination of vertical axis rotations of a tectonic block in an orogenically active terrain from magnetostratigraphic data pertains to several doubts. Some of the important problems in the conventional handling of such data are highlighted and a test of rotation is suggested to express the quality of data for such studies. Magnetic polarity stratigraphy provides sequential information on the palaeomagnetic directions of a given site over a stipulated time. Several authors used such data as a composite time to deduce vertical axis rotation of the site representing tectonic block. Here mean D and I (by PCA) are analyzed for a demagnetization spectrum of viscous component for post-depositional rotation and that of primary component for syn-depositional rotations over a red-bed sequence of Siwalik molasse dating 4 to 0.78 Ma. While the post depositional data is used compositly to test of reversal and fold test, the syn-depositional data is tilt corrected and separated into different time blocks characteristic of directional changes. A positive test of rotation is defined by clockwise/anticlockwise drift with time of normed declination in syn-depositional data and no drift in the post depositional data. Finally the data is assembled on a tectonic map of the area to infer the rotations with reference to present day tectonic elements to signify its application.

PALAEOMAGNETIC INVESTIGATION OF NEOTECTONIC CRUSTAL DEFORMATION IN CENTRAL-WEST TURKEY TURGAY ISSEVEN

John PIPER (Istanbul Technical University, Mining Faculty, Department of Geophysics, 80626 Maslak, ISTANBUL, Turkey); Orhan Tatar (Geomagnetism Laboratory, Department of Earth Sciences, University of Liverpool, LIVERPOOL L69 3BX, U.K.); Halil Gursoy (Department of Geology, Cumhuriyet University, 58140 SIVAS, Turkey.)

Present day Turkey is the site of collision between the Eurasian and Afro-Arabain Plates where a collage of accretionary belts comprising the Anatolian Block is being extruded laterally by tectonic escape. A widespread distribution of young volcanic rocks in this region provides a record of tectonic rotation during the Neotectonic Phase since termination of collision in Miocene times. Anticlockwise rotation averages about 30° in the eastern part of the Anatolian Block but increases to ~50 ° across the Ecemis Fault Zone, a major intracrustal strike slip belt cutting the south eastern sector of the Anatolian Block. This anticlockwise rotation is observed in young volcanic units attributed to the Quaternary and implies that rotation is a late feature of tectonic development of this region. In the Cappaddocian ignimbrite province (~12-2 Ma) in the south of the block comparable anticlockwise rotations are observed in the oldest and youngest units. This shows that rotation associated with escape has only occured late in the Neotectonic history presumably when strain release by crustal thickening consequent upon the continental collision could no longer be sustained. The rotations in Eocene volcanic units emplaced during the pre-collisional Palaeotectonic Phase are not markedly different from rotations found in much youger rocks and confirm that significant rotation has only characterised the last stage of the Neotectonic history. In northern Turkey the same ~30° anticlockwise rotation is observed in Eocene units on either side of the North Anatolian Fault Zone and indicates that this east-west lineament has been established as an intracontinental transform only at a late stage of the Neotectonic history. This general anticlockwise rotation is however, not uniform across Anatolia. Towards the southern margin of the Block it diminishes to near zero whilst in the north it changes westwards from anticlockwise to clockwise. Also towards the Aegean the strike slip regime gives way to an extensional province. In the vicinity of this transition in the Kutahya region clockwise rotations are observed in Miocene lavas and anticlockwise rotation in Pliocene rocks. Collectively these results show that the Anatolian Block is not a plate sensu stricto but is deforming in a distributed and differential manner. In the south west it is being extruded into…

OPENING HISTORY OF POWELL BASIN, ANTARCTIC PENISULA

EAGLES, G (University of Leeds, School of Earth Sciences Woodhouse Lane, Leeds. LS2 9JT UK); Roy A. Livermore (British Antarctic Survey, High Cross, Madingley Road, Cambridge, CB3 OET, UK)

The opening history of Powell basin, located at the northernmost Antarctic Peninsula, is modelled with constraint from its marginal and regional geology and newly-gridded magnetic data over the basin itself. Opening began with rifting of Mesozoic continental crust and breakup volcanism. This was followed by creation of oceanic crust at a slow spreading ridge oriented along N20W as a response to N55W relative plate motion of South America with respect to Antarctica during the Eocene and Oligocene. Models of the seafloor spreading anomalies suggest that the spreading phase of opening occurred between 32.1Ma and 23.3Ma. Microplate motions on the evolving Powell Basin's margins are assessed and presented using gridded magnetic data.

GRAIN-SIZE DEPENDENCE OF LOW-TEMPERATURE MEMORY IN MAGNETITE: POTENTIAL FOR GRANULOMETRY

David J. Dunlop (University of Toronto at Mississauga, Mississauga, Ont., Canada L5L 1C6; email: dunlop@physics.utoronto.ca) Ozden Ozdemir (same address) Masayuki Torii (Biosphere-Geosphere System Science, Okayama University of Science, 1-1 Ridai-cho, Okayama 700-0005, Japan; email: torii@big.ous.ac.jp)

We have measured the changes in saturation remanence (SIRM), produced either at 10 K or at 300 K, in 10-K intervals during zero-field warming-cooling or cooling-warming cycles between these endpoint temperatures. The first experiment is often used as a means of detecting magnetic minerals in rocks and soils by their characteristic remanence transitions (e.g., the magnetite Verwey transition around Tv = 120 K). The second experiment is the basis of low-temperature de-magnetization (LTD), a paleomagnetic cleaning technique. Neither has been seriously explored as a method of grain size determination in suites of rocks, sediments or soils with common mineralogy, but we find there is definite granulometric potential in both experiments. Our samples are natural crushed magnetites separated into narrow grain-size fractions with mean sizes of 0.6, 1, 3, 6, 9, 14, 20, 110 and 135 micrometers. Both unannealed and annealed samples were tested. A small fraction of low-temperature SIRM survives heating across the Verwey transition (first memory) with a very small recovery of the lost remanence in the second crossing of Tv during re-cooling (second memory). The transition is more sharply expressed in annealed samples, but un-annealed samples have larger first and second memories. Both memories increase steadily with decreasing grain size. Room-temperature

SIRM behaves in a comparable way except that most of the remanence loss and subsequent recovery occurs gradually between 300 K and the isotropic temperature, Ti = 130 K, rather than sharply at Tv. The second memory is much larger than for 10 K SIRM. Both memories increase in a general way with decreasing grain size, but the size dependencies are monotonic only in the range 1-20 micrometers.

GA1.05/E/12-A5 0850

XRD AND SEM ANALYSIS OF EXTRACTED MAGNETIC MINERALS IN RIVER SEDIMENTS AND IN BURNED TROPICAL SOILS

SATRIA BIJAKSANA (Department of Physics, Bandung Institute of Technology, Jalan Ganesa 10, Bandung 40132, INDONESIA, email: fisika@bdg.centrin.net.id) Eleonora Agustine (Applied Geophysics Graduate Program, Bandung Institute of Technology, Jalan Ganesa 10, Bandung 40132, INDONESIA, email: E.Agustine@hotmail.com); Ian Yulianti (Department of Physics, Bandung Institute of Technology, Jalan Ganesa 10, Bandung 40132, INDONESIA, email: Ianyuli@hotmail.com); Dini Fitriani (Department of Physics, Bandung Institute of Technology, Jalan Ganesa 10, Bandung 40132, INDONESIA)

Changes in environmental condition often reflect in changes in magnetic mineralogy and granulometry. We have studied magnetic mineralogy and granulometry of extracted magnetic grains from river sediments and burned tropical soils using X-ray diffraction (XRD) and scanning electron microscopy (SEM) methods. Magnetic grains were extracted using a bar magnet. The river sediments were taken along the Cikapundung River in West Java. The river originated from the relatively pristine Juanda national park, runs through Bandung, the city inhabited by three million people. Samples were taken from locations along the river to see whether pollution or other anthropogenic impacts can be identified through mineralogical, and visual and compound analysis of extracted magnetic grains. Results show that the shape of magnetic grains extracted from the river somewhat change during transportation processes while change in Fe/Ti ratio indicates new sources of magnetic grain. The river's morphology also plays a role in retaining certain forms of magnetic grains. Meanwhile, the tropical soils were analyzed to see the impact of burning on magnetic grains contained in the soils. Samples taken from Juanda National Park were burned for 4 hours, 12 hours, 24 hours, and 10 days to simulate forest fires. Natural, unburned, soils were also used for comparison. Results show that the Fe/Ti ratio does not change until the soils were burned for 12 hours after which the ratio does not vary with burning time. In some cases, burning also changes the texture of the grains. For both river sediments and tropical soils, magnetite is the main magnetic mineral.

GA1.05/W/08-A5 0910

COERCIVITY OF MULTIDOMAIN MAGNETITE AT LOW TEMPERATURES

Ozden OZDEMIR (University of Toronto at Mississauga, Mississauga, Ontario L5L 1C6, Canada, email: ozdemir@physics.utoronto.ca), David J. Dunlop (same address) Masayuki Torii (Biosphere-Geosphere System Science, Okayama University of Science, 1-1 Ridai-cho, Okayama 700-0005, Japan)

Hysteresis measurements were made on mm-size natural single crystals of magnetite at a series of 16 temperatures from 300 K to 10 K using a MPMS2 SQUID magnetometer. The coercive force Hc decreased gradually with cooling to the isotropic temperature, where the first magnetocrystalline anisotropy constant K1 becomes zero. The crystallographic phase transition Tv, is marked by a discontinuous increase in Hc at 119 K, where the cubic [001] hard direction suddenly becomes the monoclinic easy direction of magnetization. In crossing the Verwey transition, the coercive force increased more than two orders of magnitude, from 0.2 Oe to 24 Oe, which is more than an order of magnitude higher than Hc at 300 K. Between Tv and 10 K, Hc remained almost constant. As the crystal warmed from 10 K, Hc retraced the cooling curve, peaking just below Tv, and then decreased dramatically to 0.2 Oe in recrossing the Verwey transition. The abrupt changes in Hc in crossing Tv are mainly a result of large increases in K1, magnetostriction and magnetoelastic constants due to the switching of the easy directions of magnetization at Tv. Another factor controlling Hc below Tv is the presence of monoclinic twin boundaries, which interact strongly with the domain walls and tend to act as wall pinning sites.

GA1.05/W/12-A5 0930

EFFECT OF MANETITE OXIDATION ON THE HOPKINSON PEAK

J.G. KING (Dept. of Physics, P/bag 0022, Gaborone, Botswana, email: kingjg@noka.ub.bw)

To determine if magnetic particles in a rock sample are capable of storing paleomagnetic field faithfully over a long time period (geological time), one need to know their characteristics. Such characteristics include, the type of mineral, its particle size, shape and oxidation state. Since paleomagnetic useful particle sizes for the natural remant magnetisation major carrier mineral (magnetite) is in the micron to sub-micron range, it is not possible to use ordinary microscopes for viewing these particles. Even with high resolution specialised microscopes, it is not an easy task to identify these particles. Since there is no direct easy method of identifying magnetite particle characteristics from a rock sample, it is often necessary to infer these from indirect measurements such as hysteresis loop parameters. In this study an attempt was used to characterise magnetite particles using the Hopkinson peak. The main interest was to find if the Hopkinson peak characteristics could be used to infer the nature of magnetite particle oxidation state. The results show that apart from its use in determining particle size of magnetite samples, the Hopkinson peak can be used successfully to infer their oxidation state.

GA1.05/W/04-A5 0950

THREE-DIMENSIONAL MICROMAGNETIC MODELLING OF RANDOMLY ORIENTED SINGLE-DOMAIN AND PSEUDO-SINGLE-DOMAIN MAGNETITE (0.03-0.3 MICRON)

K. FUKUMA (Japan Marine Sci. Tech. Center, Yokosuka 237-0061, Japan,
email: fukuma@jamstec.go.jp) and D. J. Dunlop (Univ. Toronto, Mississauga L5L 1C6, Canada)

Three-dimensional micromagnetic structures were obtained for magnetite cubes with <100> edges in a size range from 0.03 to 0.3 micron. We employed the Metropolis algorithm (Monte Carlo method) to find equilibrium micromagnetic structures starting from initially uniformly magnetized states. Directions of initial magnetizations were chosen randomly to simulate a randomly oriented assemblage. Small grains (< 0.07 micron) exhibit single-domain structures parallel to a magnetic easy axis <111> irrespective of initial magnetization directions. Vortex structures represent pseudo-single domain grains above the single-domain threshold size. Axes of the vortices are parallel to <100> in the transitional size range, but become randomly oriented with increasing grain size. Neither lamellar domain structures nor multiple vortex structures were found for grains less than 0.03 micron. Reduced magnetization decreased gradually in a relatively narrow grain size range (0.07-0.15 micron) down to ~0.1 with increasing grain size. Such a grain-size variation of magnetization depends on vortex structures inside a single grain and the randomness of grain magnetization directions in an assemblage.

GA1.05/E/11-A5 1040

MICROWAVE MAGNETIZATION

DEREK WALTON (Dept. of Physics and Astronomy, McMaster University, Hamilton, Ont., L8S 4M1, Canada)

Microwave magnetization and demagnetization of ceramics has been shown to reduce any alteration effects to unobservable levels because the microwave energy is, essentially, only absorbed by the magnetic grains. In order for this to occur the microwave frequency must be high enough to generate spin waves, and the microwave magnetic field must exceed a threshold. Failure to satisfy these conditions doomed early attempts to use microwaves for magnetization to failure. If the conditions are satisfied the permeability of the magnetic grains becomes extremely high with the result that virtually all the energy is absorbed by the magnetic grains: for instance with the latest version of our apparatus at the University of Liverpool, a small sample of pottery, occupying 1/500 of the volume of a microwave cavity, and containing on the order of 0.1% magnetite, absorbed over 90% of the incident power. In order to achieve these efficiencies stringent conditions must be met, and these conditions will be discussed. The efficiency of the process is also strongly frequency dependent, which to a large extent determines whether or not the process will work. The reasons for this will be discussed in some detail.

GA1.05/W/02-A5 1100

A TEST OF THE THELLIER LAWS OF PARTIAL TRM FOR MULTIDOMAIN GRAINS OF MAGNETITE

David J. DUNLOP (University of Toronto at Mississauga, Mississauga Road North, Mississauga, Ontario, Canada L5L 1C6; email: dunlop@physics.utoronto.ca) Ozden Ozdemir (same address)

We have carried out Thellier double-heating experiments (simulated paleointensity determination) and stepwise thermal demagnetizations of individual partial TRM's for large grains of magnetite, in the size range 125-150 micrometers. The results allowed us to test to what extent the three Thellier laws of single-domain partial TRM apply to multidomain grains.The law of reciprocity, or equality of blocking and unblocking temperatures, was strongly violated. From the first steps of the Thellier experiment, unblocking temperatures of pTRM's were lower than their blocking temperatures, producing a sagging, convex-down curve on an NRM-pTRM plot. This non-linearity has serious consequences for paleointensity determination, leading to paleofield estimates that are high by as much as a factor 2.The law of independence of adjacent pTRM's was also violated. We tested adjacent pairs, pTRM (Tc, Ti) and pTRM (Ti, To), with Ti = 300, 400, 500, and 564˚C. For the lower-T pTRM of each pair, the pTRM intensity depended on initial state, as reported previously by Vinogradov and Markov (1989) and McClelland et al. (1996). For consistency, a thermally cooled initial state was used in thermal demagnetization experiments. Adjacent pTRM's are definitely not independent in their thermal demagnetization. At the boundary temperature Ti between them, 20-23% of the lower pTRM remains undemagnetized, while 8-15% of the higher pTRM has already been erased. The overlap of unblocking temperatures is not confined to a small range near Ti, but extends practically all the way from To to Tc. Therefore there is no temperature range where "primary" and "overprint" pTRM's of multidomain grains could be cleanly separated by thermal demagnetization.Surprisingly, the law of additivity of pTRM's was obeyed to within 2-3% for three of the pTRM pairs and to within 6% for the Ti = 564˚C pair. The additivity holds throughout the unblocking process: the sum of thermal demagnetization curves of pairs of adjacent pTRM's almost exactly matches the total TRM demagnetization curve, over the whole range from To to just below Tc.

GA1.05/W/11-A5 1120

ON THE ACQUISITION OF WEAK-FIELD THERMOREMANENT MAGNETIZATION IN MULTIDOMAIN PARTICLES

Karl FABIAN (FB Geowissenschaften, University of Bremen, Germany,
email: karl.fabian@uni-bremen.de)

At present there exist several physical descriptions of multidomain (MD) thermoremanent magnetization (TRM). Each of them has it's own merits and drawbacks. While up to now all hysteretic models of TRM acquisition assume a sharply defined blocking process after which the magnetization structure remains unchanged during cooling, the kinematic theories are physically justified only by a vague analogy between spin glasses and MD particles. A recent proposal to use renormalization group theory for the description of MD TRM acquisition seems to join both of the above disadvantages. Yet it offers a new physical approach to understand fluctuation processes in the vicinity of the Curie temperature.
Using thermodynamic arguments, here it will be shown from first principles that the equilibrium weak-field TRM is at all temperatures proportional to the external field. Physically based phenomenological arguments further extend this result to obtain a kinematic equation for TRM which substantiates the result of Shcherbakov et al. (1993) and at the same time restrict its validity to weak-field TRM. The presented results together with the new work on hysteretic and renormalization theories give hope that a physically based phenomenological model of weak-field TRM is within reach for rock magnetists.

GA1.05/E/20-A5 1140

TO THE THEORY OF MD PTRM

V.P. SHCHERBAKOV (Geophysical Observatory Borok, Borok, 152742, Russia,
email: shcherb@borok. adm.yar.ru)

Let pTRMa(T1,T2) be the pTRM acquired when the upper temperature T1 is reached by cooling from Tc and pTRMb(T1,T2) be the pTRM acquired by heating to T1 from room temperature Tr. Let tail of pTRMa(T1,T2) is the rest of pTRMa(T1,T2) after it was partially thermodemagnetized by heating to T1. As was shown experimentally by Shcherbakova et al., a relationship pTRMa(T1,T2)=pTRMb(T1,T2)+tail of pTRMa(T1,T2) (1) exists for the MD grains between these three variables. An aim of this report is to present a simple phenomenological scheme to explain this regularity based on the thermofluctuational MD Neel's model. This model was chosen particularly because of requirement that any theory of MD TRM should include thermofluctuational elements to account for the linear dependence of value of TRM on H in weak fields. To show the idea note let the equation (1) may be interpreted by such a way that the remanence carriers, which constitute tail of pTRMa(T1,T2), do not participate in creation of pTRMb(T1,T2). In terms of unblocking temperatures Tub appearance of the tail may be understood as a result of increase of Tub above T1 due to irreversible variations of the domain structure during thermal treatment. Increase of Tb leads to failure of the same grains to acquire pTRMb(T1,T1). Apparently, these simple arguments lead to the desired decomposition of pTRMa(T1,Tr) into two parts.

GA1.05/E/19-A5 1200

PROPERTIES OF PARTIAL THERMOREMANENT MGANETIZATION IN PSD AND MD MAGNETITE GRAINS

V.V. SHCHERBAKOVA, V.P. Shcherbakov (Geophysical Observatory 'Borok', Russian Academy of Sciences, Russia, email: shcherb@borok.adm.yar.ru), F.Heider (GeoForschungsZentrum, PB 3.3, Telegrafenberg, 14473 Potsdam, Germany)

An experimental study was carried out to investigate the thermal demagnetization properties of pTRM(T1,T2) imparted in different temperature intervals (T1,T2). Fifteen igneous rock samples and five synthetic specimens containing crushed and hydrothermally grown magnetite of different grain sizes were studied. The domain structures (DS) of the samples cover the range from SD to MD grains. Two different kinds of pTRM were considered: 1.) pTRMa(T1,T2) acquired when the upper temperature T1 is reached by cooling from the Curie temperature Tc and 2.) pTRMb(T1,T2) acquired by heating to T1 from room temperature. As was shown previously, the intensity of TRM(T1,T2) depends on the thermal pre-history of the sample, e.g. pTRMb(T1,T2) is not equal to pTRMa(T1,T2). Furthermore, any pTRM(T1,T2) has a tail that is not removed by thermal demagnetization to T1. The properties of pTRM(T1,T2) depend strongly on the temperature interval (T1,T2). Half of the natural samples under consideration have MD or PSD properties for the low-temperature pTRMs and typical SD-PSD behavior for the high-temperature pTRMs. A linear relation was found for MD samples where pTRMa(T1,T2)-pTRMb(T1,T2) = (intensity of the tail of pTRMa(T1,T2) after thermal demagnetization at T1). This relationship implies that the remanence carriers, which constitute the tail of pTRMa, do not contribute to pTRMb. The relative value of the tail is suggested as an independent means to evaluate the DS of a sample. The deviation in the Arai-Nagata plot from a straight line is proportional to the normalised value of the tail of pTRM(300,Tr), where Tr is room temperature. The presence and intensity of such a tail can be used as a test for suitability of a sample for paleointensity determinations with the Thellier method.

GA1.05/E/21-A5 1220

ROLE OF MAGNETOSTATIC INTERACTIONS IN ACQUISITION OF TRM AND VRM IN N ENSEMBLE OF SD GRAINS

V.P. SHCHERBAKOV and N.K. Sycheva (Geophysical Observatory Borok, Borok, 152742, Russia, email: shcherb@borok.adm.yar.ru), B.E. Lamash (Far East State University, Suhanova 8, Vladivostok 690600, Russia)

A direct numerical calculations of susceptibility k of small number N=(2-20) interacting uniaxial SD grains, randomly dispersed over space, are carried out using the Boltzmann's distribution. The results of the calculations were averaged over 10000 randomly chosen configurations. For moderate interactions (the volume concentration c=(0.5-2)%) the dependence k(N) shows saturation. As expected the interactions lead to decrease of k in comparison with the susceptibility of non-interacting ensemble but the decrease does not exceed 20%. Hence for the practical purposes it is admissible to neglect the magnetostatic interactions when k of SD grains is considered. As a consequence, TRM depends on the interactions through increase of the blocking temperatures Tb mainly but not due to change of k(c). Limit value of VRM only slightly depends on the interactions but they drastically change the spectrum of relaxation time Tr. This leads to quasilogarithmic increase of VRM with time t even for the ensemble of non-interacting SD grains

METHODS AND APPROACHES IN ROCK MAGNETISM

GA1.05/E/02-A5 1400

THE NEW THEORY OF THE RESIDUAL MAGNETISM OF MAGNETITE BEARING ROCKS

Vladislav GERNIK (Russian Geological Research Institute, Sredny pr. 74, 199106 St. Petersburg, Russia, email: gernik@mail.dux.ru)

This theory comprises the following theses:
1.Residual magnetization (RM) of magnetite is generated by the inclusions of ferrimagnetic minerals represented, mainly, by hemoilmenites or magnesioferrites. Inclusions-free magnetite matrix can not to acquire RM.
2These inclusions, as a rule, are consisted of products (phases) of solid solution decay. On the contact of the each magnetic phase with magnetite matrix exchange interaction appears. This process induces exchange anisotropy, which creates the space energetic barrier in a magnetite grain. The barrier prevents retrieving of magnetite domain boundaries into position corresponding to demagnetized state. Thus, in RM of a magnetite grain the magnetization of the phases of inclusions appears, but matrix plays role of powerful amplifier of their weak magnetic moment. 3. Hence, the state of residual magnetization of magnetite is determined by the properties of the solid solution, namely: - by the number of the products of its decay and by their magnetic interaction between one another; - by the relaxation time of decay-homogenization process of solid solution and by its tolerance to the temperature changes.
All these theses have been proved experimentally and repeatedly tested. The new theory explains really all the known effects: the physical essence of the Rayleigh law, the cause of the offence of the Thellier laws, mechanism of self-reverse thermoremanence, origin of multi-component NRM, and the cases of chaotic diversity of its directions, which can not be removed with magnetic cleaning, etc.

GA1.05/W/37-A5 1420

JUXTAPOSED AND SUPERIMPOSED REMANENT MAGNETIZATIONS IN TWO FORMATIONS OF THE TINDOUF BASIN (ALGERIA)

H. BOUABDALLAH, N. Merabet, and S. Maouche (CRAAG, BP 63, 16340 Bouzaréah, Algiers, Algeria, email: h.bouabdallah@lancaster.ac.uk). B. Henry (Paléomagnétisme et Géomagnétisme, CNRS and IPGP, 4 avenue de Neptune, 94107 Saint-Maur cedex, France,
email: henry@ipgp.jussieu.fr).

Two paleomagnetic studies in the West African Craton have been carried out in the Tindouf basin, in the Merkala red sandstones of the lower Stephanian age and in the Reouiana red sandstones of Namurian age. During thermal treatment, after elimination of a weak viscous magnetization A, two components B and C are clearly separated. B is isolated between 200-250°C and 550-580°C, and C at higher temperatures until 670°C. Rockmagnetic studies pointed out the presence of hematite and probably of magnetite.
On the one hand, the components B and C are well defined, with nice clustering and should represent a nice example of juxtaposed magnetizations. On the other hand, the angle between the mean directions of B and C appears remarkably constant, in value and in orientation, from one site to another. A strong relation exists therefore between B and C. B component is interpreted as resulting from the superimposition of the component C with an unknown component. To determine this component D, the intersection of great circles containing B and C directions has been studied. At Merkala, the component D has been obtained, and is a Permian overprint (paleomagnetic pole at 38.9°S and 60.0°E). At Reouina, the best intersection unfortunately corresponds to component C, which is therefore better grouped than D.
At Merkala, component C allows a lower Stephanian paleomagnetic pole to be defined: 32.4°S, 56.6°E. The Namurian pole determined with C at Reouiana is situated at 28.4°S, 56.9°E.

GA1.05/E/07-A5 1440

NATURE OF NATURAL REMANENT MAGNETISATION OF LOWER CRETACEOUS RED-BEDS OF AFGANO-TADJIK DEPRESSION (SOUTH TIEN-SHAN)

Yu. S. RZHEVSKY (St.Petersburg State University, 14th Line 29, V.O., 199178, St.Petersburg, Russia, email: yurkov@icape.nw.ru)

Natural remnant magnetisation of the rocks studied has chemical character, that is magnetic moments of the particles distributed in the rock have been oriented and fixed by the ancient magnetic field when the particles reach the some size. However, the other process affects the remnant magnetisation as well. This process appears as partial diagenetic transformation of hematite into maghemite, which lead to reversal magnetisation (in relation to original hematite) due to negative unidirect magnetic anisotropy. In the rocks studied this additional process lead to partial self-reversal remnant magnetising, and in some cases produces the full self-reversing of the magnetisation.

GA1.05/W/05-A5 1500

SECONDARILY ACQUIRED MAGNETIZATION OF CRETACEOUS GRANITIC ROCKS IN KITAKAMI MASSIF OF NORTHEAST JAPAN

Yo-ichiro OTOFUJi, Koji Uno, Takahiro Higashi, Tomomichi Ichikawa, and Tuyoshi Ueno (Department of Earth and Planetary Sciences, Faculty of Science, Kobe University, Kobe 657, Japan email: otofuji@kobe-u.ac.jp; unokoji@kobe-u.ac.jp)

Cretaceous granitic rocks of the Kitakami massif, whose K-Ar ages range between 107 and 120 Ma, are categorised into two types on the basis of paleomagnetic directions; (A) westerly direction with shallow inclination which is sub-parallel to the paleomagnetic direction of the Paleogene Heizaki volcanics and (B) northwesterly direction with moderate inclination which is sub-parallel to the paleomagnetic direction of the Early Miocene times for northeast Japan. Thermal demagnetization of the composite IRM shows that magnetite is carrier for hard and medium components in coercivity of both types. Alternating field demagnetization shows that Type A is characterised by low coercivity (less than 10 mT in MDF) whereas Type B reveals high median destructive field larger than 20 mT. Microscopic observation indicates that fairly large and euhedral magnetite occurs in neighbouring to biotites in Type A. In Type B, small grains of magnetites (less than 10 mm) are observed within alternating parts of hornblende where original green colour is bleached and becomes pale green. Studies by a scanning electron microscope equipped with a energy-dispersive analytical system show that a magnetite in Type A contains a small amount of Ti (the Fe/Ti ratio is 51.8) whereas a magnetite in Type B is free from Ti. The energy-dispersive analysis also shows that the bleached area in Type B reflects enrichment of Mg due to release of Fe. The pure magnetites within the bleached areas of Type B are originated from released Fe in hornblende, implying the secondary products. We conclude that origin of the remnant magnetization of Type B is CRM which is acquired by secondarily originated magnetites during alteration of rocks at about 20 to 30 Ma. Type A preserves primary magnetization, although its coercivity is low.

GA1.05/E/16-A5 1520

SIMULTANEOUS REMAGNETIZATION AND PB ISOTOPE RESETTING IN THE BAMBUÍ CARBONATES (BRAZIL)

Manoel S. D'AGRELLA-FILHO and Ricardo I.F. Trindade (Instituto Astronomico e Geofisico, Universidade de Sao Paulo (USP), SP, 3386, 01060-970, Brazil, email: dagrella@iag.usp.br, Marly Babinski (Instituto de Geociencias, USP, Sao Paulo, SP, Brazil) William R.Van Schmus (Department of Geology, University of Kansas, Lawrence, KS, USA)

Paleomagnetism, rock magnetism, U-Pb and Pb isotopic data on carbonates from the southern São Francisco basin support a close connection between a pervasive remagnetization and the resetting of the isotopic system of these rocks at 530-500 Ma, during the final stages of the Brasiliano/Pan-African orogeny. The post-depositional origin of the magnetization directions is strengthened by the following: (a) the rock magnetic properties, such as wasp-waisted hysteresis loops, anomalously high hysteresis ratios and contradictory Lowrie-Fuller and Cisowski tests, are typical of remagnetized carbonates; (b) thermomagnetic analysis and scanning electron microscopy suggest authigenic magnetite as the main magnetic carrier, and (c) paleomagnetic poles from carbonate sequences and adjacent Brasiliano metamorphic rocks are similar and coincide with high quality Gondwanan paleomagnetic poles for the 530-500 Ma interval. Most Pb-Pb and U-Pb ages from the carbonates coincides with ages of metamorphic rocks from marginal fold belts. In addition, undeformed carbonates containing radiogenic crustal Pb with an isotopic signature of the Archean/Paleoproterozoic basement suggest Pb incorporation through fluids which promoted the resetting of the isotopic system and the severe remagnetization in the carbonates. The similarity between paleomagnetic and isotopic resuts from the Bambuí and the 1000 km far Salitre carbonates implies a large scale event that simultaneously affected the whole basin.

GA1.05/W/09-A5 1540

INTERPRETATION OF MAGNETIC PROPERTIES OF ESTONIAN CARBONATE ROCKS USING FACTOR ANALYSIS

Alla SHOGENOVA (Institute of Geology at Tallinn Technical University, 7 Estonia Avenue, Tallinn, EE10143, Estonia, email: alla@gi.ee)

Magnetic susceptibility (k) and saturation isothermal remanent magnetization (SIRM) were studied together with bulk and grain density and chemical composition of Estonian Lower Palaeozoic carbonate rocks. Magnetic properties were analyzed on some 700 samples of argillaceous to varying degree limestones and dolomites of different genesis. The total database was subdivided into 6 data sets from Lower Ordovician up to Silurian age. To analyze together 17 parameters the R-mode factor analysis was applied. It permitted to determine the two principal factors controlling the alteration of magnetic properties and of two studied iron forms FeO and Fe2O3 . These factors are clay content and dolomitization. In the non-dolomitized carbonate formations magnetic susceptibility increases with increasing clay content, including both iron forms and in the rocks, which included impurities of iron oxides (Fe2O3). In the Lower and Middle Ordovician data sets with samples from widespread

dolomite layers, dolomitization is the first principal factor. It caused increase in magnetic susceptibility and both iron forms in Middle Ordovician dolomite layer and increase in FeO in Lower Ordovician layer. In the Middle Ordovician dolomites from the fracture zone dolomitization caused increase in k and both iron forms. In Silurian rocks clay content is the more important factor in rise of magnetic susceptibility and both iron forms. Dolomitization caused there less increase in k, and this is connected with increase in FeO. In Upper Ordovician sequence both clay content and dolomitization control increase in Fe2O3, but more influence were made there by clay content, which also controls alteration in SIRM in most of Ordovician rocks. Application of factor analysis helped in interpretation of magnetic properties and processes caused their alteration.

GA1.05/W/06-A5 1630

AGE DEPENDENCY OF MAGNETIC PROPERTIES IN OCEAN FLOOR BASALT

Juergen MATZKA and Nikolai Petersen (Inst. f. Pure a. Appl. Geophysics, University Munich, Theresienstr. 41, 80333 Muenchen, Germany, email: matzka@rockmag.geophysik.uni-muenchen.de), Thomas Kunzmann (Inst. f. Mineralogy a. Petrography, University Munich, Theresientr. 41, 80333 München, Germany, email: kunzmann@petro1.min.uni-muenchen.de)

Due to the gradual low temperature oxidation of titanomagnetites in ocean floor basalts, a corresponding age dependency of magnetic properties arises. This process, reflected for example by an increase in Curie temperature, is regarded as a two step process: rapid oxidation in the first 10 to 20 Ma and a slower oxidation rate thereafter. Coinciding with the transition from step one to two, a minimum is observed in both NRM intensity and amplitudes of the marine magnetic anomalies.
A rock magnetic study on a set of ocean floor basalts covering an age span from 0 Ma to more then 100 Ma, reveals also an age dependency of magnetic hysteresis properties. At room temperature, parameters reflecting magnetic hardness (e.g. coercivity) show an increase with age to a maximum at ca. 10 Ma and a decrease for older samples. For the samples younger than 10 Ma hysteresis parameters show distinctive differences depending upon whether they were measured at room temperature or at liquid nitrogen temperature. For samples about 10 Ma old, ratios of Hcr/Hc and Mrs/Ms approach extreme values typical for SD particles and the NRM is very stable against AF-demagnetization. It is, however, unlikely that this is a grain-size related phenomenon. The susceptibility normalised on saturation magnetization reaches a minimum for these same samples. These samples exhibit Neel's P-type characteristics in their thermomagnetic curves with a maximal saturation magnetization at around 100°C. All together, we will discuss a number of particular magnetic properties coinciding with the above mentioned minimum in NRM intensity, which seems to be of a rather intrinsic than paleofield related origin.

GA1.05/W/14-A5 1650

REMANENCE ACQUISITION OF OCEANIC GABBROS FROM HOLE 735B

H.-U. WORM (BGR, Hannover, Germany), J. Gee, E. Kikawa & ODP Leg 176 Scientific Party

The vertical structure of the sources of marine magnetic anomalies have remained poorly known ever since the recognition that the oceanic crust records reversals of the geomagnetic field. Inferences on the magnetization of lower crustal rocks from studies of dredged rocks are ambiguous because these surficial samples have been subjected to varying degrees of seawater alteration that may have significantly affected the magnetic properties. To date, ODP Hole 735B constitutes by far the deepest penetration into plutonic basement and thus arguably provides the best available information on the magnetization of oceanic gabbros. The high average NRM intensities of ~2.5 A/m, together with a large Q-Factor of 13.4 and high stability during af and thermal demagnetization suggests that gabbros constitute a significant source for lineated marine magnetic anomalies. The gabbros from Hole 735B may be considered to be typical for the lower crust generated at slowly spreading ridges, however, the observation that stable inclinations scatter by more than 10° within meter distances does not fit the model of a slowly cooling deep crust. Possible explanations are: (a) a fraction of the magnetite grains was formed below Tc and thus carry a CRM, (b) stress and strain deflected the NRM, (c) late intrusions reheated the gabbros locally, (d) magnetic anisotropy affected the primary TRM acquisition. (c) can probably be ruled out based on the petrographic description. (b) can hardly be investigated by experiment. Laboratory measurements of continuous thermal demagnetization, pTRM acquisition, AMS, and TRM anisotropy suggest that the NRM is a primary TRM that was strongly affected by anisotropy. TRMs acquired parallel kmax and kmin can vary in intensity by a factor of 3. Another question of interest is, up to which temperature a primary TRM can survive a subsequent polarity reversal. For that purpose thermoviscous measurements were also conducted with a 2G SQUID magnetometer equipped with a non-magnetic furnace inside.

GA1.05/E/14-A5 1710

MUD-FILLED CAVITIES IN SPELEOTHEM SAMPLES FROM TRENGGALEK, EAST JAVA AND REMANENCE ACQUISITION

SATRIA BIJAKSANA (Department of Physics, Bandung Institute of Technology, Jalan Ganesa 10, Bandung 40132, INDONESIA, email: fisika@bdg.centrin.net.id) Siti Zulaikah (Department of Physics, Banndung Institute of Technology Jalan Ganesa 10, Bandung 40132, INDONESIA)

Giving their continuous accumulation and relatively precise orientation, speleothems (such as stalagmites, stalagtites and flowstones) occasionally might be valuable for paleomagnetic studies especially for the Holocene. Low content of magnetic minerals, however, results in very low magnetic intensity requiring a very sensitive magnetic magnetometer to measure. While measuring anisotropy of magnetic susceptibility (AMS) of two stalagmites from a cave complex in Trenggalek, East Java, we find that the susceptibility of the samples varies greatly from one sample to another. Variations in both magnetic susceptibility and anisotropy apparently depend on the presence of small mud-filled cavities of about 2-5 mm in diameter. During occasional flooding, muds might be trapped inside the minute holes in the uneven surface of the stalagmites. Muds taken form the vicinity of the stalagmites is indeed rich in magnetic minerals. The presence of these mud-filled cavities, on one hand, will enhance the sample's magnetic intensity. On the other hand, they will mask the remanence carried by finer magnetic grains embedded in the calcite or aragonite matrix. If this so, instead of averaging the secular variation over longer period of time, the remanence in one stalagmite sample represents a rather implusive record of the Earth's magnetic field. Study on the stability of magnetic remanence in samples with such cavities is underway.

GA1.05/W/13-A5 1730

EFFECTS OF ALTERNATING FIELD DEMAGNETIZATION ON ANISOTOROPY OF MAGNETIC SUSCEPTIBILITY - A CASE STUDY ON MARINE SEDIMENTS

Hirokuni ODA (Marine Geology Department, Geological Survey of Japan, Higashi 1-1-3, Tsukuba, Ibaraki 305-8567, Japan, email: hoda@gsj.go.jp), Abdelaziz L. Abdeldayem (Institute of Geoscience, University of Tsukuba, Tsukuba 305-8571, Japan, email: dayem@gsj.go.jp)

Potter and Stephenson (1988, 1990a, b) have shown that static AFD shift the directions of AMS principal axes and increase the degree of anisotropy by using synthetic samples and basalts bearing magnetite. It is generally believed that the tumbling AFD would not impress the anisotropy and even in some cases (e.g. Park et al.,1988) it was recommended to be used to eliminate stress induced anisotropies. To our knowledge, no such experiments have been yet carried out in detail on natural samples. In this study, we demonstrate that tumbling AFD increases the lineation, changes the shape parameter, and changes the directions of principal axes of natural sediment samples.
Paleomagnetic cube samples were taken from a 3.5m-long silicesous sediment core from Bransfield Basin close to Antarctic Peninsula. According to the low-temperature magnetic phase transition and hysteresis analysis, the samples comprises mainly of multi-domain magnetite. The static AFD was confirmed to impress the anisotropy on AMS of the specimens. The daughter samples were AF demagnetized with a 3-axes tumbling system. With increasing tumbling AF, AMS shows gradual increase in average susceptibility up to 2% of the original values; Kmax and Kmin increases particularly resulting in increase of lineation, decrease of foliation and change in shape parameter from oblate to prolate. The concentration of principal axes increases with increasing AF, then minimum and intermediate axes interchange for the samples from 0.5-1.0m depth above 60 mT AFD. These lines of evidence suggest that not only static AFD but also tumbling AFD should be avoided before measurement of AMS particularly for sediments.

MAGNETIC PROPERTIES AS ENVIRONMENTAL PROXY PARAMETERS

GA1.05/W/36-A6 0830

SIMULATION OF MRS/MS AND HCR/HC VALUES (DAY PLOT) FOR MIXTURES OF SUPERPARAMAGNETIC, SINGLE-DOMAIN, MULTIDOMAIN AND PSD GRAINS

David J. Dunlop (University of Toronto at Mississauga, Mississauga, Ont., Canada L5L 1C6; email: dunlop@physics.utoronto.ca)

A plot of saturation remanence ratio Mrs/Ms versus coercivity ratio Hcr/Hc was proposed by Day et al. (1977) as a method of discriminating domain state (single-domain, SD; pseudo-single domain, PSD; multidomain, MD) and by implication, grain size. For Day et al.'s sized titanomagnetite grains, values of the two ratios trend along a single approximately hyperbolic curve for all four compositions (x = 0, 0.2, 0.4, 0.6). There is a monotonic trend with grain size, the finer grains approaching SD values and the coarser grains approaching MD values. However, different compositions trend along different sections of the hyperbola, and my data for annealed and unannealed magnetites show that different internal stress levels also shift points along the master curve. In order to use the Day plot to determine grain size, mineral composition and state of internal stress must be independently known. Data from suites of oceanic rocks (Dunlop, 1981; Geeand Kent, 1999) and continental limestones (Channell and McCabe, 1994) show that there is infact no single master curve. Jackson (1990) proposed that the different trends for remagnetized and unremagnetized limestones result from mixtures of superparamagnetic (SP) and SD grains inthe first case and SD-MD mixtures in the second case. Gee and Kent likewise propose SP-SD and SD-MD mixtures as the cause of different trends in suites of submarine titanomagnetites. Tauxe et al.(1996) numerically modelled SP-SD mixtures and were able to fit the trends displayed by submarine basaltic glasses. However, until the present study there has been no first-principlestheoretical treatment of the parameters Mrs, Hcr, Hc and their correlation in the Day plot for SP, SD, PSD, and MD grains, and their mixtures. The results indicate that MD grains have a separate trend that intersects the curve for SD-MD mixtures at a large angle. SP-SD mixtures generate a variety of trends. all lying well above the MD or SD-MD trends. A simple SD-MD mixture …

GA1.05/E/13-A6 0850

CAN WE MATHEMATICALLY UNMIX NATURAL MAGNETIC MIXTURES?

Roy THOMPSON (Geology and Geophysics Dept., University of Edinburgh,
email: egph08@holyrood.ed.ac.uk)

Natural materials such as soil, lake gyttja, marine clay and atmospheric dust are complex mixtures. Using hysteretic or laboratory- imparted remanence measurements as basic magnetopetrological data we wish to model these natural mixtures as linear combinations of known reference minerals. Extremely good mathematical fits (r2 > 0.99) can be generated from constrained regression or optimisation algorithms. Approaches to assessing the quality (skill) of such fits will be described. The magnetic properties of magnetite have been well known since the work of Parry (1965). Recently we have been able to characterise the properties of bacterial magnetosome chains, making them easy to recognise and to include in unmixing calculations. A key remaining question concerns the magnetic properties of additional end-members, not included in our models. Despite much laboratory and theoretical work, in recent decades, on the thermo- remanence properties of titanomagnetites and titanohaematites, the range of their hysteresis properties, in the natural environment, appears to remain surprisingly poorly known.

GA1.05/E/01-A6 0910

A NEW TECHNIQUE FOR CHARACTERIZING THE MAGNETIC PROPERTIES OF NATURAL SAMPLES

Christopher R. Pike (Dept. of Geology, University of California, Davis, California, 95616 USA) Andrew P. ROBERTS (School of Ocean and Earth Sciences, Southampton Oceanography Centre, University of Southampton, Southampton, UK) Kenneth L. Verosub (Dept. of Geology, University of California, Davis)

Environmental magnetic studies are commonly conducted on samples with mixtures of magnetic minerals and/or grain sizes. Such measurements are often ambiguous because they represent the composite response of all magnetic grains in the sample. Overcoming this ambiguity represents one of the most important challenges for environmental magnetism. We have developed a new method for studying the magnetic properties of natural samples using a class of partial hysteresis curves known as first order reversal curves (FORCs). These curves are transformed into contour plots (FORC diagrams) which look similar to Preisach diagrams, but which are not model-dependent. The shape and location of features on a FORC diagram can be used to obtain a qualitative estimate of the magnetic grain size distribution in a sample. FORC diagrams can be used to detect the presence of superparamagnetic grains and non-single-domain behaviour that result from domain wall nucleation and annihilation, as well as the effects of magnetic interactions. We have calibrated the FORC technique with well-characterised samples and our interpretations are consistent with FORC distributions obtained

from theoretical models. Preliminary results indicate that it is possible to characterise a wide range of natural samples and to clearly identify and discriminate between the different components that contribute to wasp-waisted hysteresis loops.

GA1.05/L/01-A6 0930

A NEW METHOD FOR THE CHARACTERIZATION OF MAGNETIC GRAIN SIZE DISTRIBUTIONS

Horst-Ulrich Worm (Federal Institute for Geosciences & Natural Resources, Hannover, Germany)

Measuring the frequency dependence of susceptibility (Xfd) is the commonly applied method for detecting superparamagnetic (SP) grains in rocks and soils. However, this method fails if the concentration of ferrimagnetic minerals is so low that their susceptibility contribution to the bulk susceptibility is comparable to the para- or diamagnetic contribution. Therefore, alternative methods have been explored using measurements of remanent magnetizations that were acquired at various time constants. As test specimens served a variety of natural and synthetic samples containing distinct grain size distributions of SP, stable single domain (SSD), multidomain (MD) magnetite, titanomagnetite, hematite and pyrrhotite grains, respectively. ARM acquisition and AF demagnetizations were performed in the frequency range 50 to 640 Hz. The results, however, are nearly frequency-independent. Differences are only noticable for samples with the highest Xfd. Much more revealing proved to be a second method where IRMs were acquired in time spans of 0.01 s and 10 s, respectively. Depending on the field intensity the IRM ratios can be as large as > 10 for SP samples. The IRM intensities of SSD grains also increase significantly with field exposure time, and the ratio is smallest for MD grains. Viscous decay following IRM acquisition is pronounced for SP grains while it is at least an order of magnitude smaller for SSD and MD grains.

GA1.05/W/30-A6 0950

THE VERWEY TRANSITION AS A REMARKABLY SENSITIVE INDICATOR OF MINOR AMOUNT OF MAGNETITE IN SEDIMENTS

M. Torii (Fac. Info., Okayama Univ. Sci., Okayama 700-0005, Japan, email: torii@big.ous.ac.jp), C.-S. Horng (Inst. Earth Sci., P.O Box 1-55, Taipei, Taiwan, email: cshorng@earth.sinica.edu.tw)

Magnetic mineralogy in sediments is generally complex. Not only magnetite and hematite, but also iron sulfides, such as greigite and pyrrhotite, have been increasingly reported from sediments. We should also be careful with goethite and other iron hydroxides. However, the presence of magnetite is still critical to understand magnetic property of samples. Magnetite has larger magnetization compare to the other minerals. Magnetite can survive as a detrital, chemical or biogenic particle in most sediments. It is thus crucial to detect magnetite in a target sample even if the concentration is very low.We found complex magnetic mineralogy having magnetite, pyrrhotite, and greigite in the marine sediment from Southwest Taiwan (Horng et al., 1998). Such a situation makes the NRM records very complicated. The characteristic remanent component was only revealed with applying thermal demagnetization of the moderate temperature, which corresponds to the decomposing temperature of greigite. We determined magnetic mineralogy first with an X-ray diffractometry. For the X-ray method, however, we have to separate significant amount of the magnetic minerals from the sediment of one kg or more. We also applied a low-temperature method using an MPMS. The sample for MPMS is only a scoop of about 10 mg from the sample for NRM measurement. We found the Verwey transition is very sensitive to suggest the presence of minor amount of magnetite.

GA1.05/W/35-A6 1010

MICROWAVE INDUCED SYNTHESIS OF MAGNETIC CRYSTALS

C. PETERS and A. G. Whittaker, (Department of Chemistry, University of Edinburgh, King's Buildings, West Mains Road, Edinburgh, EH9 3JJ, Scotland)

The growth and characterisation of synthetic magnetic crystals are important for attempting to identify magnetic components within natural, soils, sediments and rocks. A new technique using microwave radiation is currently being developed to synthesise magnetic crystals. Microwaves allow rapid, uniform heating of solutions under either pressure or reflux conditions. The overall size of the crystals can be controlled by the length of time the radiation is applied. Crystal morphology may be controlled by face-blocking agents e.g. the presence of phosphate ions yield needle-shaped particles. The resulting magnetic mineralogy of the crystals is dependent on the initial reactants. Microwave-hydrolysed ferric ions produce haematite, for example, whereas mixed ferric and ferrous ions initially yield goethite and ultimately magnetite. Under optimum conditions the microwave technique allows the direct synthesis of magnetite crystals. The resulting synthetic magnetic crystals are characterised using x-ray diffraction and scanning electron microscopy, in addition to magnetic studies.

MAGNETIC CHARACTERISTICS OF TREE NEEDLES AND HUMAN LUNG SPECIMEN AS AN INDICATOR OF ANTHROPOGENIC DUST IMMISSION

Viktor HOFFMANN, Mathis Knab, Carsten Leven (Institut fuer Geologie und Palaeontologie, Arbeitsbereich Geophysik, Universitaet Tuebingen; Sigwartstrasse 10, 72076 Tuebingen, Germany; email: viktor.hoffmann@uni-tuebingen.de). Manfred Wildner (Bavarian Public Health Research Center, University of Munich, School of Medicine, Tegernseer Landstrasse 243, 81549 Muenchen, Germany; email: wil@ibe.med.uni-muenchen.de)

Emission and deposition of aerosols and dusts often containing highly toxic substances can reduce significantly the quality of the environment and seriously affect human health. Forest decline e. g. in northern Bohemia or southern Poland is a consequence of the acid rain and the partly extremely high content of heavy metals in the soil. High rates of allergies or diseases of the respiratory system (e. g. lung cancer) are caused by polluted air or the uptake of potentially contaminated food or water. Since the pilot studies of Oldfield et al. (1985) we know that magnetic parameters can be used successfully for the discrimination of geogenic and anthropogenic aerosols and dusts. Here we present results of our investigations concerning the magnetic signature of the following sample sets: firtree and spruce needles were collected in various areas with different states of Imission including so-called clean-air areas without any local industrial emissions. Further on, pilot studies were done on human lung specimen. Hysteresis and backfield data as well as IRM-acquisition curves were measured by using the micromag (Geophysics group in Tuebingen and Physics Department, Univ. of Toronto, D. Dunlop). In general, we obtain a clear magnetic signal, which is dominated by a soft magnetic, maybe magnetite-like phase in various grain sizes. In addition, the magnetic signature of highly magnetic single spherules of various sources (grain-size 20-100 microns) was determined in order to be able to compare the magnetic signal on the emission as well as on the immission side. In this way, the reconstruction of the transport paths and the sources of toxic aerosols seem to be possible just by using magnetic proxies.

GA1.05/E/10-A6 1115

SOURCES OF FERRIMAGNETIC MINERALS IN CEMENT DUSTS

Beata Goluchowska (Institute of Biology and Environment Conservation, University of Opole, ul Kominka 4, 45-035 Opole, Poland, email: beska@uni.opole.pl) Zygmunt STRZYSZCZ (Institute of Environmental Engineering, Polish Academy of Sciences, ul. M. Sklodowskiej-Curie 34, 41-819Zabrze, Poland, email: zygmunt@ipis.zabrze.pl)

Former studies have shown a wide variation in magnetic susceptibility of cement dusts (90 - 1620 x10-8m3kg-1). It was because of additives using in clinker production and during a cement grinding. Still open is a question if any new ferrimagnetic minerals can be forming during the cement production as a result of mineralogical changes in existing iron compounds. The laboratory experiment based on firing of raw materials and additives in the same proportion in a presence of different amount of carbon monoxide proved that mineral changes leading to increase of magnetic susceptibility during the cement production are possible. Except a temperature the crucial factor in this process is CO content. The magnetic susceptibility of agglomerate obtain in presence of 1 % Co was 4 x10-8m3kg-1. Increase of CO content to 10 % caused an increase of magnetic susceptibility to 245 x10-8m3kg-1. In presence of 30 % CO the magnetic susceptibility increased to 330 x10-8m3kg-1 and ferrimagnetic forms made 73 % of total iron. During the firing in atmospheric air only 1 - 2 % of total iron were present in ferrimagnetic form. These data suggest that a wide variation of magnetic susceptibility in cement dusts can be not only a result of additives but also as a result of occurring new ferrimagnetic minerals during a process of cement production.

GA1.05/W/21-A6 1130

CHANGES OF MAGNETIC PARAMETERS OF POWER-PLANT FLY ASHES UNDER CONDITIONS OF DIFFERENT SOIL ENVIRONMENTS

Ales KAPICKA, Eduard Petrovsky and Neli Jordanova (Geophysical Institute, Acad.Sci., Prague 4, Czech Republic, email: kapicka@ig.cas.cz), Sergej Ustjak (Research Inst. of Crop Production, Chomutov, Czech Republic)

Areas of high and low levels of contamination due to atmospheric deposition of fly ashes from coal-burning power plant were determined on the basis of magnetic susceptibility mapping. Investigation of soil depth profiles showed that antropogenic ferrimagnetic minerals are concentrated in the depth between 5 and 10 cm. Magnetic parameters of contaminated soil layers as well as fly ashes collected from power plant were studied in detail (thermomagnetic curves, frequency dependent susceptibility, hysteresis parameters). In order to examine magnetic stability of fly ashes, samples were exposed to soil extracts for periods of 1 to 8 weeks. Soil extracts from typical soils around the power plant with pH=5.0 and pH=7.0 and distilled water as a control medium were used in experiments. Our results show that nonstoichiometric (maghemitised) phase dominates the ferrimagnetic fraction (about 10vol%) of fresh fly ashes, with Tc typically of 630deg.C. This phase could be identified only in the most polluted soil samples from close neighbourhood of the source. However, it seems to be quite unstable and upon exposure to soil extract it transforms to stable magnetite phase with Tc = 580deg.C. At the same time irreversible changes of k, Js, Jrs and Hcr were observed in dependence of increasing time exposition to soil extracts. Stable magnetite was also identified as a main ferrimagnetic phase in most of the contaminated soil layers around the power plant.

GA1.05/W/24-A6 1145

MONITORING OF HEAVY METALS POLLUTION FROM COPPER-SMELTING PLANT: APPLICATING MAGNETIC METHOD

Alla NULMAN, Rimma Kopteva and Alexandr Rytsk (Institute of Geophysics, UD RAS, Amundsen str.100, 620016 Yekaterinburg, Russia, email: nulm@igeoph.mplik.ru)

Considerable number of data about links between magnetic properties and quantities of various pollution in different environmental components has been obtained already. That allows magnetic proxy in the monitoring systems to be included. Some results of such a work for heavy metals aerogenic polluted zone by Middle Ural Copper-Smelting Plant (MUCP) is presented here. That zone contains several towns and a part of Yekaterinburg's drinking pond catchment, while the relief is rather intricate and the weather is quite variable. Therefore the thick monitoring network is necessary. But the cost of spectrochemical analysis is very high and that is just the case a magnetic proxy would be useful.
For working up the magnetic monitoring method a snow cover has been utilised as a natural accumulating plane. During 3 years 53 samples have been collected from 20 sites in the zone of influence of MUCP (the effect of another heavy metals sources was excluded). The samples have been selected and melted by different methods. The magnetic properties of the samples (solutions and solid fractions) have been studied. For 20 samples collected in 1998 the quantity of 10 heavy metals have been determined by usage of spectrochemical analysis. The quantities of Cu, Pb, Zn, As, Cd and the values of differential magnetic moments (dM/dH) of snow samples solid fractions obtained by standard methods of hydrometeorogical service has been found to be correlated. Calibration curves for calculation of heavy metals quantities in snow samples from dM/dH are shown here.

GA1.05/W/26-A6 1200

COMPARATIVE MAGNETIC MEASUREMENTS ON POLLUTED AND UNPOLLUTED SOILS FROM BUENOS AIRES PROVINCE (ARGENTINA)

Ana M. SINITO (CONICET-IFAS, Universidad Nacional del Centro, Pinto 399, 7000-Tandil, Argentina, email: asinito@ifas.exa.unicen.edu.ar)
Marcos A. Chaparro and Claudia S. G. Gogorza (IFAS, Universidad Nacional del Centro, Pinto 399, 7000-Tandil, Argentina, email: cgogorza@ifas.exa.unicen.edu.ar)

Magnetic measurements of soils exposed to pollution became one auxiliary tool of estimating contamination. In this study, magnetic properties of recent soils from Buenos Aires Province (Argentina), with special attention on magnetic enhancement on soils'superficial layers, are presented."In situ" susceptibility measurements on unpolluted and polluted (by metallurgical dust) sites were carried out. Hand samples coming from these sites were studied in laboratory. Results of susceptibility (K) at two different frequencies, Isothermal Remanent Magnetization (IRM), Saturation Isothermal Remanent Magnetization (SIRM), coercivity of remanence (Bcr), S ratio and relationship between SIRM and K are complemented with studies of changes of susceptibility with temperature (heating and cooling curves). These studies contribute to the knowledge of magnetic mineral composition, grain size, characteristics of the main carriers, concentration of heavy metals, etc.The comparison of the results between polluted and unpolluted soils shows significant differences, which are analysed.

GA1.05/E/05-A6 1215

SEASONAL CHANGES OF MAGNETIC SUSCEPTIBILITY IN SEDIMENTS FROM ZYWIECLAKE (SOUTH POLAND)

Tadeusz MAGIERA, Zygmunt Strzyszcz, Maciej Kostecki (Institute of Environmental Engineering, Polish Academy of Sciences, ul. M. Sklodowskiej-Curie 34, 41-819Zabrze, Poland,
email: magiera@ipis.zabrze.pl), Friedrich Heller (Institute of Geophysic, ETH Honggerberg, CH-8093, Switzerland, email: frieder@mag.ig.erdw.ethz.ch)

Lake Zywiec is a man-made lake constructed in 1965 on the river Sola in the Beskidy Mountains (South Poland). The lake is the largest one in a flood control reservoir system known as Sola Cascade. Its area is about 10 km2 and the average depth is 6.3 m. In May and in September 1970, separated by a big flood event in July, the lake was sampled twice for rock magnetic, chemical and granulometric studies. Low field specific magnetic susceptibility of very recent lake sediments is generally low (6 - 30 x10-8m3kg-1). The spatial variation of the susceptibility is rather low but higher values (27 - 30 x10-8m3kg-1) are observed near the eastern shore of the main basin of the lake. A susceptibility anomaly is observed in the most eastern part of the lake where the susceptibility rapidly increases to 70 x10-8m3kg-1. In 85 % of the September samples, susceptibility decreases by 10 - 40 % compared to the value measured in the May samples. In September 1970 the spatial variation of susceptibility was lower (15 - 25 x10-8m3kg-1) than in May with the only exception of the eastern lake anomaly where susceptibility increased by about 40 % above the May value. Granulometric studies showed that the average grain size varies between 2.7 and 2.9 m near the dam at the northern edge of the lake and 120 m at the southern edge near the town of Zywiec. In the September samples, grain size varies stronger. The maximal grain size increases to 340 m especially in southern and eastern lake parts and muddy areas were enlarged as a result of the big summer flood in July 1970. Seasonal changes are also observed in the total Fe content and some heavy metals. A general decrease in Zn, Pb, Cd, Cu and Cr content during the summer season was observed in the whole lake. The content of other metals such as Mn and Ni increased in samples taken in September.

GA1.05/W/23-A6 1230

ROCK MAGNETIC PARAMETERS EXPRESION OF SEDIMENTOLOGICAL AND DIAGENETIC CONTROLS OF CONTAMINANTS IN AN STUARINE-LIKE ENVIRONMENT

Daniel REY, Belen Rubio, M Nombela & F Vilas (Dpto. Geociencias Marinas, Universidad de Vigo, 36200 Vigo, Spain. email: danirey@uvigo.es)

This paper will presents the results of a preliminary study intended to investigate the application of environmental magnetism techniques in the study of the relationships between contaminant distribution, mobility and spatial variations in sediment character and diagenetic processes in stuarine-like deposits. Its interest relies in presenting a multidisciplinary analysis integrating rock magnetic, sedimentological and diagenetic parameters with contaminant profiles. The study is based in three 90 cm long gravity cores collected in July 1997 at three locations within the inner (1), middle (2) and outer (3) parts of the Ria de Pontevedra in NW Spain. The cores were cut into 3 cm slices in preparation for a range of textural, mineralogical, geochemical, and rock magnetic analyses.
The grain size, mineralogical and magnetic evidence suggests that sediment in the Ria is derived from two main sources: (a) terrestrial and (b) marine. At the Core 1 site terrestrial sediment is dominant, while at sites 2 and 3 marine derived sediment assumes greater importance. Susceptibility is very low in Core 1 as a result of the finer and clay-rich nature of the terrestrial-derived sediments, that have a greater capacity to transport and sorb contaminants after reduction of original oxides during early diagenesis. Cores 2 and 3 were different from Core 1. They showed a two orders of magnitude higher susceptibility values in the top 10-20 cm. This indicates that these sediments experience a higher rate of organic matter oxidation than in Core 1, and the sediments overall are less anoxic and higher in authigenic iron oxyhydroxides and iron silicate phases.

MAGNETIC PROPERTIES AS ENVIRONMENTAL PROXY PARAMETERS

GA1.05/W/34-A6 1430

A LATE QUATERNARY ROCK MAGNETIC RECORD OF CLIMATIC AND OCEANIC CHANGE; TANNER BASIN, CALIFORNIA BORDERLAND

Franz HEIDER (GeoForschungsZentrum, PB 3.3, Telegrafenberg, 14473 Potsdam, Germany), Ingrid Hendy and James P. Kennett (Dept. of Geological Sciences, UC Santa Barbara, CA, USA), Juliane M. Bock and Jürgen Matzka (Institut für Allgemeine und Angewandte Geophysik, Ludwig-Maximilians-Universität, Theresienstr. 41, 80333 München, Germany)

A high-resolution record of rock magnetic properties and oxygen isotopes was determined from marine isotope stage 6 to the Holocene (130 Ka to P.D.) for hemipelagic sediments (ODP Leg 167) from Tanner Basin. The sedimentation is 12 cm/kyr and sample spacing is 10 cm. Anhysteretic remanent magnetization (ARM) is taken as a measure for the concentration of magnetic minerals. The quantity of magnetic material increased during transitions from warm to cool periods, and resulted from increased shelf erosion during lower sea levels. During interglacials and inter-stadials a reduction in the quantity of magnetic material in the sediment occurred, decreasing magnetic susceptibility. This resulted from dilution of the magnetic fraction due to increased biogenic deposition during these warm intervals. The ratio of ARM to ARM after 15 mT AF demagneti-zation is used as a coercivity indicator. The magnetic properties of these sediments are largely determined by two climatically controlled fluxes of magnetic material. Large and magneti-cally softer hemoilmenite grains were deposited during times of decreasing sea level when the concentration of magnetic particles was elevated. Small magnetite grains (< 2 µm) control the magnetic properties during transgressing and high sea levels, when detrital hemo-ilmenite was low. The ARM ratio leads the delta18O curve by 0.8 m. This offset between the coerci-vity parameter and intervals of climatic change represents evidence for autigenic growth of magnetite grains near the Fe-redox boundary. Authigenic growth of magnetite is associated with rapid climate events as recorded by planktonic foraminiferal assemblage shifts. These relations may have resulted from changes in oxygen concentrations in intermediate waters.

GA1.05/W/29-A6 1445

ORGANIC CARBON FLUX CONTROLS THE MORPHOLOGY OF MAGNETOFOSSILS IN MARINE SEDIMENTS

Toshitsugu YAMAZAKI and Hodaka Kawahata (Geological Survey of Japan, Tsukuba 305-8567, Japan, email: yamazaki@gsj.go.jp)

Magnetotactic bacteria produce chains of magnetite crystals within a cell. Bacterial magnetites have characteristic morphologies and sizes under strict biological control. The morphologies of bacterial magnetites (hexagonal prism, octahedron, and teardrop shapes) appear to be species specific, but factors that control the morphology have not been understood. We examined morphologies of fossil bacterial magnetites (magnetofossils) preserved in deep-sea sediments and its relation to organic carbon fluxes (Corg). Magnetofossil morphology was determined under a TEM on magnetic extracts from Pacific deep-sea surface sediments at 13 sites obtained by box-corer or multiple corer. At 8 of 13 sites, Corg fluxes were determined from particulates collected by sediment traps moored for about 1 yr. Isotropic crystals dominate magnetofossils in sediments in a relatively oxidized condition (lower Corg flux), whereas proportion of anisotropic crystals increases in a more reduced condition (higher Corg flux). Geographically, the isotropic-dominant region corresponds to the low primary productivity province. Our finding has important implications for iomineralization processes, and demonstrates the potential of magnetofossil morphology as a paleoenvironmental indicator.

GA1.05/W/19-A6 1500

MAGNETIC STUDY OF CORE MD972151 FROM SOUTHWESTERN SOUTH CHINA SEA AND ITS PALEO-ENVIRONMENT IMPLICATIONS

T.Q. Lee (Inst Earth Sci., Acad. Sinica, Taipei, Taiwan; e-mail: tqlee@earth.sinica.edu.tw).

This study will present paleomagnetic and rock magnetic results of core MD972151 taken from Southwestern South China Sea during IMAGES III-IPHIS Cruise in 1997.
Paleomagnetic secular variation pattern indicated a reversed polarity event appeared at depth between 21.7 and 23.8 meters. It is recognized as the Blake event of about 130 ka in age. Results of the oxygen isotope dating and many well established time series of other proxies proposed that the boundary of stage 5-6 is located at about 21.5 m. These assignments are in very good consistency. In addition, a short event is also found at the bottom of the core. It is tentatively assigned to an excursion of intensity low which has an age interval of about 150-160 ka reported by Valet et al. (1993). Thus, the core MD972151 is thought to provide records for the last 160 ka.
To study the environment changes, several magnetic parameters are used, such as magnetic susceptibility, NRM, ARM, SIRM, soft and hard components of SIRM, S-ratio etc. Relative high peak values and quick variations were found at the depths below 21.5 m for all the studied magnetic proxies. This phenomenon suggests that a very important event of environment change should have happened at the time during the boundary of stage 5-6. The sediments of the core studied major came from its surrounding area, such as southeast Indochina peninsula at the western part, Sunda Shelf, Indonesia and Borneo at the southern part. From magnetic patterns, it is thought that some of the source areas might have stopped to supply sediments to the area studied since of about 120 ka. In addition, hard component of SIRM is found to vary at the opposite sense relative to those of the other proxies, such as UK'37 SST and carbonate abundance etc. Abundance of magnetic minerals correspond to contribute the hard component of SIRM, such as hematite, is thus considered to be one of the important proxies for paleo-environment change studies at least at the area studied.

GA1.05/W/01-A6 1515

MAGNETIC SIGNATURE OF BRIEF INTERSTADIAL EVENTS IN LAKE BIWA DURING THE PAST 40 KYRS

AKIRA HAYASHIDA (Doshisha University, Kyo-Tanabe, Kyoto 610-0321, Japan; email: ahay@doshisha.ac.jp), Y. Kuniko (Kyoto University), M. Ali (Geological Survey of Pakistan), M. Torii (Okayama University of Science), K. Yamada, H. Fukusawa (Tokyo Metropolitan University), H. Kitagawa (International Research Center for Japanese Studies), K. Takemura (Kyoto University)

Lake Biwa, situated in the central part of Japan, is a sedimentary basin that can provide continuous record of past environments since the Middle Pleistocene. Although the paleoclimatological data from previous core samples are correlated to major glacial and interglacial cycles during the last 430 kyrs, high-resolution studies on both paleomagnetism and paleoenvironment have not yet been attained. In 1995, seven piston cores of 10-15 m long were obtained at three localities in the northern part of Lake Biwa. Detailed studies of tephrochronology and AMS radiocarbon dating showed that two piston cores of about 15 m long, which were recovered on the margin of the deep depression, cover the time period of the last 40 kyrs. The total organic carbon content (TOC) data from this site show increased value in the post-glacial period, and also mimic millennial-scale climatic variations during the glacial period. Magnetic mineral concentration, represented by ARM or SIRM intensities, shows a remarkable correlation with the TOC data. In particular, the ARM variation from 40 to 30 kyrs BP is well correlated to the Dansgaard-Oeschger cycles recorded in Greenland ice cores. We interpret that flux of fine grained magnetite and organic carbon were both increased during interstadial periods, probably associated with greater precipitation. It is thus suggested that there were rapid changes in climate around Lake Biwa in response to the instability of the glacial climate. of AMS particularly for sediments.

GA1.05/E/08-A6 1545

MAGNETIC STUDIES OF MEXICAN LAKE SEDIMENTS AND SOILS

John D.J. BRAISBY (Geology and Geophysics Dept., University of Edinburgh), Roy Thompson (Geology and Geophysics Dept., University of Edinburgh, Sarah E. Metcalfe (Geography Dept., University of Edinburgh)

Magnetic techniques provide useful methods for the detection of environmental and climatic change as recorded in lake-sediment sequences. Lake-sediments can contain complex mixtures of magnetic minerals derived from a range of sources. We have explored a variety of parsimonious unmixing algorithms that can be used to identify the magnetic components. These include unmixing in terms of (1) catchment materials, (2) type horizons, (3) reference magnetic minerals and (4) combinations of (1), (2) and (3). Perturbation analyses are used to explore the propagation of errors through the models. At Babicora lake in northernmost Mexico clear variations in magnetic concentration closely parallel changes in diatom abundance. These reflect climatic changes associated with switches in the season of precipitation from summer to winter. Magnetic measurements also pick out 16 distinct, and yet previously unrecognised, horizons from the
last 61,300 years.

GA1.05/E/17-A6 1630

CONTRASTING MAGNETIC PROPERTIES FROM TWO LOESS/PALEOSOL SECTIONS IN GANSU PROVINCE, WEST CHINA

Toshiaki Mishima (Division of Earth and Planetary Sciences, Kyoto University, Kitashirakawa-Oiwakemachi, Sakyo, Kyoto 606-8502, Japan, email: mishima@kobe-u.ac.jp), M. Torii, H. Fukusawa, S. Tsukamoto, K. Ohi, T. Sasaki, Y. Ono, X.-M. Fang, B.-T. Pan, J.-J. Li

Loess/paleosol samples were taken from the two sections in the western part of the Chinese Loess Plateau: the Beiyuan section, Linxia City and the Shajinping section, Lanzhou City. Although the distance between these two localities is less than 100 km, contrasting magnetic properties are observed.
The magnetic properties of the Beiyuan section is controlled by the following two magnetic components. The background component does not change in mineralogy, grain size distribution and concentration throughout the loess/paleosol sequences. Amount of the enhanced component increases at paleosols, which results in enhancement of magnetic susceptibility. Grain size distribution of the enhanced component does not change with the degree of enhancement. On the contrary, the background component is identical to that of the Shajinping section where no enhanced component was found. The identical background component can be considered as of pristine loess in the westeRn part of the Loess Plateau .Soil formation process may not always included enhanced production of magnetic particles.

GA1.05/W/32-A6 1645

VARIABLY OXIDIZED MAGNETITE OF LOESS AND PALEOSOL FROM NORTHEAST CHINA

K. FUKUMA (Japan Marine Sci. Tech. Center, Yokosuka 237-0061, Japan,
email: fukuma@jamstec.go.jp), M. Torii (Okayama Univ. Sci., Okayama 700-0005, Japan), H. Fukusawa (Tokyo Metro. Univ., Hachioji 192-0397, JAPAN), Y.-H. Yin (Liaoning Normal Univ., Dalian 116029, China), and Y. Yasuda (International Research Center for Japanese Studies, Kyoto 610-1192, JAPAN)

Magnetic susceptibility variations of loess-paleosol sequences from the Chinese Loess Plateau provide excellent records of paleoclimate change for the last 2.5 m.y. Susceptibility is believed to be enhanced during pedogenesis and usually regarded as a proxy of precipitation. However, there is still no consensus on how precipitation induces such a susceptibility enhancement.We collected loess, Holocene and S1 paleosol samples from northeast China. The susceptibility and hysteresis properties are similar to those of Luochuan in the Chinese Loess Plateau. Temperature dependence of isothermal remanent magnetization imparted at 5 K were measured continuously using the RSO mode in which temperature is gradually changed with vibrating a sample. Three types of behaviors were observed for samples from northeast China; Holocene black paleosols exhibit distinct Verwey transitions near 115K, loess samples show gradual magnetization changes in a temperature range from 90 to 120K, but no transition is observed for S1 paleosols. These low temperature behaviors reflect different oxidation states of magnetite. The distinct Verwey transition points to non- or only slightly oxidized magnetite, the suppressed Verwey transition to partly oxidized magnetite, and the extincted Verwey transition to highly or completely oxidized magnetite (maghemite). Partly oxidized magnetite has been thought to be responsible to the susceptibility enhancement. Our low-temperature results suggest that non- or only slightly oxidized magnetite is primarily formed in soil layers and subsequently oxidized.

GA1.05/W/22-A6 1700

MAGNETIC MINERALOGY OF SANDS FROM TAKLIMAKAN DESERT, WESTERN CHINA: IMPLICATION FOR SOURCE OF CHINESE LOESS

M. Torii (Okayama Univ. Sci., Okayama 700-0005, Japan, email: torii@big.ous.ac.jp), T.-Q. Lee (Inst. Earth Sci., Taipei, Taiwan), H. Oda and T. Yamazaki (Geol. Surv. Japan, Tsukuba, Japan), N. Ishikawa (Kyoto Univ., Kyoto, Japan), and K. Fukuma (JAMSTEC, Yokosuka, Japan)

Surface sand samples collected across the Taklimakan Desert in the Tarim Basin, Xinjiang Uygur Autonomous Region, western China were examined with a rock magnetic method to elucidate magnetic mineralogy. We collected 19 samples along a route spanning about 1200 km in 1997. Magnetic mineralogy was determined based on high-temperature and low-temperature magnetic phase transitions. All samples clearly show the Verwey transition. The Curie temperature of 580¡C is also observed without exception. Some samples show minor Curie temperature at about 300¡C. Combined with the low-temperature analysis, we suggest coexistence of minor amount of titanomagnetite together with stoichiometric magnetite. Magnetic grain size suggested by the hysteresis parameters ranges from PSD to MD. It is now well established that the magnetic minerals in the Chinese loess/paleosol are either magnetite or maghemite. And even in the pristine loess, magnetite is oxidized to maghemite to some extent. However the magnetic mineral of the Taklimakan Desert samples shows the distinctive Verwey transition with relatively larger grain
size. These lines of evidence suggest that either the desert sands of Taklimakan was not major source of the Chinese loess, or the magnetic minerals in the loess were substantially changed from its aeolian origin even in the pristine loess.

GA1.05/W/17-A6 1715

PALAEOCLIMATIC SIGNIFICANCE OF MAGNETIC CHARACTERISTICS ALONG TWO LOESS/PALAEOSOL PROFILES FROM BULGARIA

JORDANOVA, DIANA (1) and J. Hus(2) (1) Geophysical Institute, Bulg. Acad. Sci., Acad.G. Bonchev Str., bl.3, 1113 Sofia, Bulgaria, email: vanedi@geophys.bas.bg (2) Centre de Physique du Globe, 5640 Dourbes, Belgium

Magnetic susceptibility variations along the two loess/palaeosol profiles in Bulgaria (profile Koriten with thickness of 34m and profile Viatovo with thickness of 26m) are used together with the ratio of susceptibility to saturation magnetization (X/Js) for palaeoenvironmental reconstructions and correlation with the global 18O record (ODP 677 core). The two susceptibility records show clear distinction between loess and palaeosoil horizons similar to the situation observed in China. Lateraly separated at about 120km sampling sites, the shape of the two-susceptibility records match in details. The one significant difference is the relative maximum susceptibility enhancement of the palaeosol horizons, which is an expression of peculiarities in the local environmental and soil-forming factors. On the basis of the proposed correlation between susceptibility variations and 18O record, a correction of the existing stratigraphy of the upper part of the loess complex in NE Bulgaria is proposed.

GA1.05/W/33-A6 1730

EVOLUTION OF MAGNETIC MINERALOGY IN QUATERNARY SOIL CHRONOSEQUENCES FROM THE CENTRE OF THE IBERIAN PLATE

Mari Fe Bógalo (Dpto. de Física, Universidad de Burgos, 09001, Burgos, Spain. email: mfbogalo@ubu.es); María Luisa Osete (Dpto. de Geofísica, Universidad Complutense, 28040 Madrid, Spain. email: mlosete@eucmax.sim.ucm.es); Friedrich Heller (Institut für Geophysik, ETH Hönggerberg, CH-8093, Zurich, Switzerland. email: frieder@mag.ig.erdw.ethz.ch); Alfredo Pérez-González (Dpto. de Geodinámica, Universidad Complutense, 28040 Madrid, Spain. email: alfredog@eucmax.sim.ucm.es)

Soil profiles from three systems of river terraces of Plio-Pleistocene to Holocene age in the centre of the Iberian plate have been investigated. Specifically, a study of the behaviour of magnetic parameters as a function of depth of each profile and age of the terraces has been carried out in several of the soil profiles. Magnetic-mineralogical properties are shown to be different in the distinct soil horizons (enhanced surface horizon, stable B and C horizon) of each profile, and also their pattern of variation with age has been established. Fine grained magnetite and/or maghemite are the dominant magnetic minerals in the enhanced surface horizon. In the stable B horizon the high contribution of goethite and hematite is proved by IRM measurements at different fields and temperatures and by "wasp-waisted" hysteresis loops. The contribution of different minerals in superparamagnetic state at room temperature is qualitatively determined. The behaviour with age of most magnetic soil parameters suggests a reduced activity of the pedogenic processes in the centre of the Iberian Peninsula during Early to Middle Pleistocene.

MAGNETIC PROPERTIES AS ENVIRONMENTAL PROXY PARAMETERS

GA1.05/E/15-A5 Poster 0900-01

ROCK MAGNETIC RECORDS FROM ITALIAN LAKE SEDIMENTS, PART 1: LAGO DI MEZZANO, CENTRAL ITALY

Ute BRANDT , Norbert R. Nowaczyk , and Jörg F.W. Negendank (GeoForschungsZentrum Potsdam, Telegrafenberg, D-14474 Potsdam, Germany, email: brandt@gfz potsdam.de) Antje Ramrath (Dept. of Geography, University of Western Australia, Nedlands, WA6907, Australia)

Detailed rock magnetic and sedimentological investigations were carried out on two sediment cores recovered from Lago di Mezzano, central Italy, yielding a continuous record of climate change for the last 31 ka. IRM acquisition experiments, hysteresis loop and backfield as well as thermomagnetic measurements revealed magnetite in the pseudo-single to multi-domain range as the main carrier of the remanence. Sedimentological investigation comprise dry density, total organic carbon, total sulphur and loss on ignition. All parameters investigated reflect the climatic controlled changes in the composition of the sediment due to the transition from the late Pleistocene to the Holocene. The variations in the concentration dependent parameters k, ARM and SIRM are linked to the increase/decrease of minerogenic influx, wheras the grain-size dependent parameters like ARM/SIRM, SIRM/k, kARM/k and the F-Factor reflect the dissolution of the fine grained magnetite fraction linked to a varying content of organic material. An apparent enrichment of high coercitivity minerals during intervals of high organic productivity, documented in the S-ratio and the MDFARM, is interpreted as a result of dissolution and dilution processes.

Ute BRANDT, Norbert R. Nowaczyk, Achim Brauer, Jens Mingram and Jörg F.W. Negendank (GeoForschungsZentrum Potsdam, Telegrafenberg, D-14474 Potsdam, Germany,
email: brandt@gfz potsdam.de)

A 65 m long sediment core from the crater lake of Lago Grande di Monticchio revealed a rock magnetic and sedimentary record of climatic change in the time interval from 20 to 105 kyr. Detailed rock magnetic investigations comprise magnetic susceptibility (k), ARM and IRM acquisition, hysteresis loops and backfield as well as thermomagnetic measurements. Sedimentological investigation includes dry density, total carbon, total sulphur and loss on ignition. Magnetite in the pseudo-single domain was identified as the main remanence carrier. Variations in the concentration dependend parameters k, ARM and SIRM are controlled by an increase/decrease of minerogenic influx due to climatic change as well as by an authigenic carbonate production and a varying organic productivity within the sediment profile. The variations in the content of organic material also controls the S-Ratio and the MDFARM, suggesting, that there is an increase of high coercitivity minerals during intervals of decreased minerogenic influx. In contrast, there is no relation between the variations in the grain size parameters ARM/SIRM, SIRM/k and kARM/k and the composition of the sediment as determined dry density and total organic carbon content.

ROCK-MAGNETIC PROPERTIES OF PLEISTOCENE-HOLOCENE SEDIMENTS FROM CUITZEO LAKE, CENTRAL MEXICO

Israde-Alcantara, I. (1), Urrutia-Fucugauchi, J. (2) & Garduño-monroy, V.H. (1) (1 Deapartamento de Geologia, Universidad Michoacana de San Nicolas Hidalgo, Morelia, Mexico and (2) Instituto de Geofisica, UNAM, Coyoacan 04510 D.F., Mexico)

Results of a paleoenvironmental study of the Plesitocene-Holocene sedimentary sequence of Cuitzeo Lake are reported. The lake, located in the Michoacan volcanic highland, has a tectono-volcanic origin and forms part of the extensive lake system that developed in central Mexico durint the Late Quaternary. This study is based on samples taken from a 27 meters long core drilled in the central sector of the lake. Preliminary chronological control is based on nine AMS radiocarbon dates for the shallow section of the core down to 9.1 m (42,000 yr BP). Results show that Cuitzeo Lake underwent several climatic and environmental changes, with more humid phases during the Late Pleistocene than during the Holocene. Sediment chemistry and diatom records suggest that before 50,000 yr BP the lake was a fresh water eutrophic system. There is evidence for two fairly humid intervals around 50,000 and 100,000 yr. From 42,400 yr to present, the lake experienced episodes of aridity and intense erosion, becoming a shallow alkaline saline water body. There is a hiatus between 8,830 and 17, 605 yr BP, which correlates with intense volcanic activity. From 2,000 yr BP to present, there is a

A

tendency to arid conditions, with Cuitzeo Lake becoming shallow, with saline and turbid waters. magnetic susceptibility shows an apparent cycliciy, with peaks every 3 m for the complete core, which may correlate with periods of increased detrital input. Spectral analysis of the susceptibility and NRM intensity records show evidence for several characteristic periods.

GA1.05/W/28-A5 Poster **0900-04**

LATE QUATERNARY ENVIRONMENTAL CHANGE IN SONORAN DESERT, MEXICO

Beatriz ORTEGA and Margarita Caballero (Instituto de Geofisica, Universidad Nacional A. de Mexico, 04510 DF, email: bortega@tonatiuh.igeofcu.unam.mx) Socorro Lozano (Instituto de Geologia, Universidad Nacional A. de Mexico, 04510 DF)

The research on climatic change during Late Quaternary has been scarce in the Mexican portions of Sonoran desert, particularly in Baja California, mainly due to the fact that the fossil record is poorly preserved in many stratigraphic sequences of this area. We have carried out a number of experiments in sediments collected in a 9.5 m long core, in a playa lake from Baja California (San Felipe), to characterise the magnetic fraction in terms of magnetic mineralogy, concentration of magnetic grains and grain-size distribution, and combined these data with palynological, organic content and particle size distribution data as a first approach to reconstruct the environmental history of the area. The sequence spans the last 70 kyr. Results from mineral magnetic analyses (including room- and low-temperature X and Xfd%, ARM, SIRM, Curie temperatures, hysteresis parameters and S ratios), and the other proxies analysed show highly contrasting environmental conditions between the glacial and the late glacial-Holocene. Very low magnetic concentrations are characteristic in late glacial. Pollen record is only present in the full glacial, between 40 and 15 kyr B.P. Arboreal and lacustrine elements indicate moist conditions and the presence of a steady lake. The late glacial-Holocene sediments display a 5-fold increment in the magnetic concentration parameters, in the abundance of finer SD and SPM magnetic grains, and in sedimentation rate. These changes are interpreted as an increment of erosion that cut through the mantle soil and rocks in the catchment. The onset of the present arid conditions is around 4 kyr B.P.

PALEOCLIMATIC AND DEPOSITIONAL CONTROLS OF LATE PLEISTOCENE LOESS/PALAEOSOL SEQUENCIES FROM SIBERIA

Galina MATASOVA, Alex Kazansky and Valentina Zykina (UIGGM, Siberian Division, Russian Acad. Sci., Akad. Koptug ave. 3, 630090 Novosibirsk, Russia, email: galina@ig.cas.cz), Neli Jordanova, Eduard Petrovsky and Ales Kapicka (Geophysical Institute, Acad. Sci. Czech Rep., Bocni II/1401, 141 31 Prague 4, Czech Republic, email: neli@ig.cas.cz)

Two loess/palaeosol sections in Southwestern Siberia (Bachat and Kurtak) have been studied magnetically. Rock-magnetic properties, as well as anisotropy of magnetic susceptibility were investigated in detail. The results obtained up to now suggest combination of "Alaskan" and "Chinese" models of deposition. While for one site, magnetic susceptibility distinguished well between loess and paleosol layers, the other site expressed practically constant susceptibility values for the whole profile. However, in the latter case, frequency-dependent susceptibility suggests enhancement of pedogenesis in paleosol layers.
Studies of anisotropy of magnetic susceptibility reveal well-defined sedimentary magnetic fabric for both sections. Different mechanisms of loess deposition (pure aeolian in Bachat and aeolian/colluvial/alluvial features for Kurtak) is reflected well by AMS pattern. The two sections showed also different magnetic-phase composition. While for the Bachat section only one type of thermomagnetic curves was found, the Kurtak one contains different minerals in loess and paleosol layers.
Magnetic properties of samples from the two sections will be discussed in terms of paleoclimatic and depositional conditions.

MINERAL MAGNETISM AND ARCHAEOLOGY AT GALSON ON THE ISLE OF LEWIS, SCOTLAND

C. PETERS(1), M.J. Church(2) and G. Coles(2) (1) Department of Chemistry, University of Edinburgh (2) Department of Archaeology, University of Edinburgh

Coastal erosion is cutting a section through a complex later prehistoric archaeological site at Galson. 168 samples from individual features e.g. middens and hearths, and also from several continuously sampled vertical profiles were collected from the site. A range of mineral magnetic measurements, including susceptibilities and laboratory induced remanent magnetisations, have been carried out on the samples. The strong magnetic signal of the hearth material can be traced in selected floors and middens giving an indication of the anthropogenic use within the dwellings. The magnetic data also highlight differences between visually similar soils. The variation of susceptibility with temperature, measured at 2cm intervals in a vertical profile through a hearth in one of the dwellings, has revealed two distinct magnetic mineralogies, with varying domain states, possibly reflecting different fuel sources.

THE MAGNETIC METHOD FOR SEARCHING OBJECTS

Victor Zemtsov (Institute of Geology, Karelian, Research Centre RAS, Pushkinskaya St., 11, Petrozavodsk 185610, RUSSIA, email: Klabukov@post.krc.karelia.ru, in the Subject: zem)

The method proposed can be used to search for various objects in geophysics and geology, for cosmic (the Moon, the Mars etc.) and archaeological investigations, for estimation of the quality of manufactured articles and measurement of low temperatures (T) in technology. The objects of search can be isotropic and anisotropic, solid, liquid and gaseous, re-covered by unconsolidated sediments, by water and can have various T. The method is especially indispensable for the study of planets that have no global magnetic field and for the analysis of atmospheric oxygen. The method comprises periodical pressing of permanent magnet to an object at frequency (f), measurement of altitude of inductive impulse (Emax), the calculation of mass of the magnetic (c) in the object from the correlation: (c)=b (Emax /f), where b is the constant obtained on an object with the known mass of magnetic. According to the last invention, an united geometric system of sensors consisting of n-pair identical sensors is composed. In each pair, the clearance of the first permanent magnet is oriented in the direction of searching and that of the second magnet at the right angle to it. Besides, the method can be used to estimate the magnetization (I) of the object, its I-anisotropy and the optimal direction of search. The system of sensors can be enlarged by adding a T-sensor. A paramagnetic standard is brought at frequency f into the clearance of the T-sensor. One should know the T-object to be able to accurately determine the mass of the T-dependent magnetic. The system can have one more f-sensor used to measure f in working sensors. Searching may be completely automated.

ORIGIN AND DISTRIBUTION OF MAGNETIC PARTICULATE MATTER ON TREE LEAVES IN THE URBAN ENVIRONMENT

Juergen MATZKA (Inst. f. Allg. u. Ang. Geophysik, Universität München, Theresienstr. 41, 80333 München, Germany, email: matzka@rockmag.geophysik.uni-muenchen.de), Barbara A. Maher (School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, UK, email: B.Maher@uea.ac.uk)

Our study on the distribution of magnetic particles in the urban atmosphere is based on measurements of the IRM(300 mT) of tree leaves collected in Norwich and in a coastal location in Norfolk, UK. The leaves provide an almost non-magnetic surface on which particulate matter can settle. Known anthropogenic sources of magnetic particles in the atmosphere are the combustion of fossil fuel in cars or power stations. For each sample, the IRM(300 mT) was normalised on the leaf area.
All birch leaves are characterised by very similar remanence coercivity spectra typical for PSD magnetite. Therefore, we assume a very homogenous magnetomineralogy for all our samples and a proportionality between the IRM and the amount of remanence carrying particles. Most of the particles can be removed by washing the leaves, indicating that the particles are in fact adhering to the leaf surface. In nature, rain was found to remove the particles to some extend, too, therefore wet deposition could be excluded. The IRM is strongly dependent on the sampling location's distance to road traffic. In general, IRM values are maximal nearby roads and decrease significantly within a few tens of meters. The signal is also dependent on the slope of the road, or in other words, on the fuel consumption of the traffic. This identifies automotive combustion to be the source of the particles. Individual trees show significant maxima in IRM proximal to streets, indicating the trees' ability to remove particulate matter from the atmosphere.

MAGNETIC SIGNATURE OF ROADSIDE SOILS AND SPECIMEN OF POTENTIAL EMISSION SOURCES OF VEHICLES

Carsten LEVEN, Mathis Knab, Viktor Hoffmann (Institut fuer Geologie und Palaeontologie, Arbeitsbereich Geophysik, Universitaet Tuebingen; Sigwartstrasse 10, 72076 Tuebingen, Germany: email: viktor.hoffmann@uni-tuebingen.de)

Emissions of vehicles represent a significant contribution to environmental pollution along roads and highways. Amongst toxic gases (NOx, CO, CO2, ...), solid components such as soot particles from the exhaust system, abrasion products from the brakes, smaller parts and particles from the car body as well as abrasion products from the asphalt are emitted in the environment and accumulated in soils or sediments or transported to surface and ground water. In this study the magnetic signature of roadside soils and of potential pollutants from the vehicles has been investigated in more detail. A series of magnetic measurements have been performed on a large sample set depending on distance from the highway and depth from the soil surface: susceptibility, hysteresis and backfield curves, thermo-magnetic runs (J(s) and) from -200 C to Curie temperatures, IRM acquisition and ARM. In addition, X-ray and microscopic observations were done on selected samples. A magnetite-like phase was found to be the dominating ferrimagnetic phase in the soil as well as in the emission products from the vehicles. In closer distances to the asphalt, many spherical magnetite particles with sizes of 10-150 microns were observed showing skeleton and dendritic structures, which are an indicator of a rapid cooling process. We believe that abrasion products from the braking system and from the asphalt could represent the main sources of the ferrimagnetic particles of anthropogenic origin in roadside soils and sediments. Therefore the distribution and the magnetic signal from these phases can be used as an excellent magnetic proxy for the detection and mapping of areas which are affected or contaminated by vehicle emissions.

AN EXPERIMENTAL STUDY OF ORIENTATIONAL MAGNETIC ANISOTROPY IN MAGNETITE-BEARING ARTIFICIAL SEDIMENTS

Andrei A. KOSTEROV and Vladimir A. Shashkanov (Earth Physics Department, Institute of Physics, Sanct-Petersburg University, 198904, Sanct-Petersburg, Russia; email: kosterov@snoopy.phys.spbu.ru)

Orientational magnetic anisotropy of sediments arises from an alignment of magnetic grains during deposition in an external field. Albeit weak in small fields, orientational anisotropy has some potential to provide insight into the intrinsic structure of ferrimagnetic grains contained in a sediment, being sensitive, in particular, to their intrinsic magnetic anisotropy. We present the results of an experimental study of field dependence of orientational magnetic anisotropy carried out on magnetite-bearing artificial sediments deposited in horizontal magnetic fields ranging from 0 to 4.8 mT, and in vertical fields up to 4 mT. Orientational magnetic anisotropy was defined as the ratio of anhysteretic remanences (ARM) acquired parallel and orthogonally to the sedimentation field respectively. Obtained experimental results may be summarized as follows:
1.For the sediments produced in horizontal field orientational anisotropy approached saturation values of about four in the maximum sedimentation field.
2.Shape of angular dependences of ARM direction suggests that the ferrimagnetic phase of studied sediments is mostly represented by uniaxial grains.
3.Sediments deposited in vertical magnetic field reveal rather surprising result: grains' alignment suppresses vertical anisotropy (which is due to the sediment compaction) but fails to induce orientational anisotropy even in the strongest sedimentation field used.

AN EXPERIMENTAL STUDY OF DRM INCLINATION ERRORS IN ARTIFICIAL SEDIMENTS DEPOSITED IN LARGE-SQUARE VESSELS

Andrei A. KOSTEROV, Vladimir A. Shashkanov, Igor' V. Samsonov and Elena V. Isupova (Earth Physics Department, Institute of Physics, Sanct-Petersburg University, 198904, Sanct-Petersburg, Russia; email: kosterov@snoopy.phys.spbu.ru)

Inclination error is a feature commonly observed in the laboratory experiments modelling the acquisition of detrital remanent magnetization (DRM). Such observations raised a problem of the possible occurrence of inclination errors in nature as well, and also prompted the search for the methods to correct them. To investigate in detail the origin of inclination errors occurring in laboratory redeposition experiments, we have prepared artificial sediments using large-square vessels (25 cm vs. 20 cm, height 25 cm). Slurry was deposited in the laboratory magnetic field (Ho = 54 μT, j = 72 degrees) with the horizontal component parallel to the long wall of a vessel. Study of surface distribution of DRM and of magnetic anisotropy of such large-

square sediments has shown that these quantities are essentially but regularly scattered over the sediments' area. Vessel walls appear to disturb the DRM acquisition even at the center of vessel. At the same time, we obtained a clear correlation between inclination errors and magnetic anisotropy. This yielded an experimental material for a throughout check of proposed earlier [Shashkanov et al., 1989] method of correction of inclination errors making use of sediment's magnetic anisotropy.

STABILITY OF ORIENTATIONAL MAGNETIC ANISOTROPY OF ARTIFICIAL SEDIMENTS AGAINST HEATING

Vladimir A. Shashkanov, Andrei A. KOSTEROV, Andrei A. Bachurin and Sergei I. Morshchikhin (Earth Physics Department, Institute of Physics, Sanct-Petersburg University, 198904, Sanct-Petersburg, Russia; email: kosterov@snoopy.phys.spbu.ru)

The orientational magnetic anisotropy is acquired in sediments during deposition through the alignment of ferrimagnetic grains in an ambient magnetic field. However, its magnitude depends not only on the sedimentation field intensity, but also on the grains' intrinsic anisotropy. So far the magnetic anisotropy has been considered as a very stable element of a magnetic state of natural samples, often even more stable than the natural remanent magnetization. The stability of orientational magnetic anisotropy to heatings has been studied for the artificial sediments, deposited in the magnetic fields ranging from 0 to 5 mT. The most striking result is that for strongly anisotropic sediments anisotropy factor (defined as the ratio of ARMs acquired parallel and orthogonally to the sedimentation field respectively) while initially approaching 4.5 - 4.7, decreases drastically with heating, reaching values about 1.6 - 1.8 after heating to 620°C. Possible mechanisms explaining this phenomenon are discussed.

TEMPORAL CHANGE OF ROCK MAGNETISM DURING 1991-1995 ERUPTION AT UNZEN

Naoko UENO (Natural Science Laboratory, Toyo University, Asakashi, Saitama 351-8510, Japan, email: ueno@hakusrv.toyo.ac.jp)

Twenty-five samples of dacitic lavas including bombs and pyroclastics from Mt.Unzen erupted during 1991-1995 were studied on the temporal change of rock magnetic properties during eruption. The ten samples were studied as pilot. The work included intensity measurement by the Thelliers' method, hysteresis analysis by vibrating sample magnetometer. In progress of time in eruption, natural remanent magnetization increased, initial susceptibility decreased, Curie temperature increased, coercive force and remanent coercive force increased, ratio of remanent saturation magnetization to saturation magnetization increased. Temperature dependence of hysteresis parameters was measured both during descent and ascent. The other fifteen samples collected by S. Nakada throughout the eruption are studied to find the correlation with other temporal petrological characters such as effusion pulsation, Fe-Ti oxide temperature and chemical composition of Fe-Ti oxide minerals reported by Nakada and Motomura (1999).

ACTIVATION ENERGY OF THE VISCOSITY MAGNETIZATION PROCESSES IN ROCKS

V.A.Bol'shakov (Geographical Department, Moscow State University, 119899, Moscow, Russia, email: pasha@nbz.ru)

The author proposed the original approach for calculation of temperature-time parameters for T-cleaning of a viscous magnetization. This approach is based on the experimental evaluation of the activation energy (Ea) of the magnetic viscosity. Ea knowing for the concrete samples make it possible to carry out T-cleaning in the most gently manner. In this case primary remanence would be affected in the least degree. The author developed some methods for Ea determination. They consist in measurement of the viscous magnetization curve displacement after a little changing of temperature. Anisotropy changes and conversion of some magnetic particles in super-paramagnetic phase after a little temperature increase were neglected from the beginning. However, the recent investigations of loess-soil samples have shown that such neglects lead to mistakes in Ea measurements. The methods of minimizing such mistakes were proposed.

ANISOTROPY RESULTS OF IGNIMBRITES FROM THE TRANSMEXICAN VOLCANIC BELT

A.M. SOLER-ARECHALDE, Caballero-Miranda, C., Rebolledo-Vieyra, M., Bautista A., and Urrutia-Fucugauchi, J. (Laboratorio de Paleomagnetismo y Geofísica Nuclear, Instituto de Geofísica, UNAM., Circuito Institutos s/n, 04510, Coyoacán, México, D.F., México. tel (5) 6 22 41 13, email: anesoler@tonatiuh.igeofcu.unam.mx)

Preliminary results of a study of anisotropy of magnetic susceptibility of ignimbrite units from four calderas in the TMVB, are presented. Amealco, Huichapan, Zitacuaro volcanic complex and the Las Americas Formation within the central sector of the TMVB were selected for this project. Detailed sampling was performed on several profiles of 3 to 8 mts high each (one sample every 10 cms) and at different distances from the ignimbrite source. Anisotropy parameters were employed to analyse and characterise the distinct flow conditions over the profile. In a similar way, these parameters were compared for different distances from the source and on different sources. The magnetic fabrics was compared with observed flow directions and used to determine these directions in the absence of other indicators.

MAGNETIC SUSCEPTIBILITY ANISOTROPY OF THE CANTERA IGNIMBRITE, SAN LUIS POTOSI VOLCANIC FIELD, MEXICO

Torres-Hernández J. Ramón. (Instituto de Geología de la UASLP and UACPyP, UNAM), C. I. Caballero-Miranda and L. Alva-Valdivia (both at Instituto Geofisica, UNAM, Coyoacán D.F. 04510, México; email: cecilia@tonatiuh.igeofcu.unam.mx; lalva@tonatiuh.igeofcu.unam.mx)

Magnetic Susceptibility Anisotropy (AMS) results from 168 specimens from 8 sites (5 sites with 25 specimens average each and 2 with 8), from La Cantera Ignimbrite, belonging to the San Luis Potosi Volcanic field, are presented. These results together with gravimetry data, geomorphologic analysis and available traditional geological indicators, are used in order to determine whether a linear or a central flow origin of the ignimbritic flow. The AMS results were measured with the JR5 instrument, structural corrected and computed with principal components statistics. AMS ellipsoids are mainly oblate with minimum susceptibility axes nearly vertical and maximum susceptibility axis near the horizontal, sometimes showing a very good imbrication. Flow direction may be inferred quite well in half of the sites. In the other sites other sort of data has to be used in order to determine the flow direction with confidence. Presently available results suggest a central flow origin, which may correspond to a caldera according with gravimetric and geomorphologic analyses

A METHOD OF PALEOMAGNETIC DETERMINATIONS USING THE CHARACTERISTICS OF MAGNETIC ANISOTROPY OF ROCKS

Juliya B. ROSANOVA and Vladimir A. Shashkanov (Earth Physics Department, Institute of Physics, Sanct-Petersburg University, 198904, Sanct-Petersburg, Russia; email: rosa@geo.phys.spbu.ru)

Theoretical possibility of subdivision of rocks' magnetic anisotropy into components in accord with their physical nature and detection of a paleomagnetic component, i.e. the component caused by primary remanent magnetization and therefore making possible paleomagnetic determinations, has been investigated. Magnetic torque method was used to measure magnetic anisotropy. The magnetic torque curves of samples has been interpreted in two ways: (1) by direct determination of the standard paleomagnetic direction (J, D) and (2) with method of spherical harmonic analysis of the energy of magnetic anisotropy. Results of experimental and theoretical studies of the magnetic anisotropy for a representative collection of igneous rocks have shown that the latter method is more stable with respect to the rocks' inhomogeneity.

GA1.05/W/15-A6 Poster **0900-09**

PHYSICAL MODELLING OF MAGNETIC ANISOTROPY OF ROCKS AND A POSSIBILITY OF PALAEOMAGNETIC DETERMINATIONS USING MAGNETIC ANISOTROPY

Pavel V. DUBROVIN and Vladimir A. Shashkanov (Earth Physics Department, Institute of Physics, Sanct-Petersburg University, 198904, Sanct-Petersburg, Russia; email: packo@geo.phys.spbu.ru)

Being the integral part of magnetic state of rocks, magnetic anisotropy is generally more stable than their natural remanent magnetization (NRM) both in time and with respect to various physical factors altering NRM. Taking into account that remanence acquisition often leads to the formation of a respective component of anisotropy (palaeoinformative component), one can assert that magnetic anisotropy itself contains palaeomagnetic information. Generally, magnetic anisotropy of rocks may have more than one component but these latter can be almost always considered as uniaxial. Therefore a palaeomagnetic determination using magnetic anisotropy should be a throughout investigation of magnetic anisotropy of the rock, with the ultimate goal of subdividing the anisotropy into uniaxial components and detecting a palaeomagnetic component which is due to primary magnetization. The magnetic anisotropy has been investigated using the magnetic torque method, which had been previously applied only to studies of magnetocrystalline anisotropy on single crystal ferromagnetics and for mineralogical analysis. A technique of measuring and interpretation of the torque curves has been developed that make it possible to determine the orientations of magnetic axes for the rock samples. This technique has been tested on the several model samples prepared to mimic both "pure" uniaxial (one easy axis - one hard plane or one easy plane - one hard axis) and biaxial (two different uniaxial components) magnetic anisotropy. Palaeomagnetic investigations of series of natural igneous rocks samples have been carried out with the developed method.

THE METHOD FOR DETERMINING THE MAGNETIZATION ANISOTROPY OF VARIOUS MAGNETICS OF ROCKS

Victor ZEMTSOV (Institute of Geology, Karelian Research Centre RAS, Pushkinskaya St., 11, Petrozavodsk 185610, RUSSIA, email: Klabukov@post.krc.karelia.ru, in the Subject: zem)

The orientation of particles in rock is not the result of chance accumulation. The origin of rocks determines the process of orientation. There are mechanical, physical and chemical orientating factors. As a result, plane and axial fabrics are formed in rocks. If in a sample there are two fabrics one of which is secondary, then magnetization (I) anisotropy tenzors can be determined separately by the method proposed. Calculations and experiments show that an individual magnetic fabric is characterised by the I-anisotropy tenzor over a wide range of magnetic fields (H) and temperatures (T). Ferromagnetics have different ranges in which spontaneous magnetization exists, and are magnetized to saturation in different fields (Hs), too. Paramagnetics and diamagnetics have the linear dependence I(H,T). In fields H>Hs the I-tenzor of ferromagnetic fabrics turns into a sphere. The I-anisotropy parameters of the "nonmagnetic" fabrics of rocks can be determined by choosing optimum H and T. The effect of another magnetic fabric can be minimised in the same manner. The major axis of the I-anisotropy tenzor of the fabric of interest can be determined as the direction of maximum growth of the magnetization vector by its derivative dI/dH or dI/dT in the three-dimensional co-ordinate system of the sample. The method proposed can be used to reveal the superposed rock fabrics, to make paleomagnetic data more reliable and to obtain the anisotropy parameters of paramagnetic and diamagnetic rocks. 1. MIDDLE AND UPPER ATMOSPHERE OBSERVATIONS AT POKER FLAT WITH RADIO AND OPTICAL TECHNIQUES INCLUDING 16X16 IMAGING RIOMETER

Y. MURAYAMA, H. Mori, K. Kato, S. Kainuma, K. Igarashi (Communications Research Laboratory, Koganei, Tokyo 184-8795 JAPAN, email: murayama@crl.go.jp); Hans Nielsen, Tom Hallinan (Geophysical Institute, University of Alaska Fairbanks, Fairbanks, AK 99775-7320 USA)

A program of comprehensive middle and upper atmosphere observation at Poker Flat, Alaska, is being promoted and proceeding by Communications Research Lab. (CRL) of Ministry of Posts and Telecommunications of Japan, in cooperation with Geophysical Institute of Univ. of Alaska Fairbanks (GI/UAF). The comprehensive observation stage starts in 1998- 1999, deploying the 16x16 imaging riometer (1995-), an MF radar (Oct. 1998-), two Fabry-Perot interferometers (1998-), two airglow imagers (to be in 1999), and a millimeter-wave radiometer (Jan. 1999-), for ionospheric, neutral dynamics, and chemical observations covering strato-/meso-/thermospheric heights. CNA and luminosity images by the imaging riometer and the GI all sky camera (ASC), respectively, with both time resolution of 2 sec are compared for a discrete aurora on 20 March 1996, which suggests that CNA variation shows delay (const. ~10 sec) perhaps causing changes of CNA and ASC arc shapes. CNA data and energy data of the DMSP spacecraft show that the power law does not seem satisfactory for their temporal/spatial correlation. Also CNA and other data such as winds will be compared.

GA2.01/W/03-A1 Invited 0925

RECENT RESULTS FROM IMAGING RIOMETER MEASUREMENTS COVERING A WIDE LATITUDE AND LONGITUDE RANGE

Allan WEATHERWAX, Ted Rosenberg (both at Institute for Physical Science and Technology, University of Maryland, College Park, MD 20742-2431 USA, email: allanw@ipst.umd.edu)

The University of Maryland operates imaging riometers in both polar regions for the purpose of studying the spatial and temporal structures of ionospheric disturbances over a wide range of locations from near the plasmapause to the magnetic pole. This presentation will focus on a few topics of recent interest. Included will be a study of the occurrence and nature of short-duration (~ a few minutes), intense (to10 dB) absorption spikes observed around the dusk meridian and near the plasmapause (L ~ 4-5). These events are accompanied by weak ionospheric current flow, as manifested by small variation of the local magnetic field. This suggests that the absorption may be caused by the precipitation of very energetic electrons depositing most of their energy in or below the lower D region. We will also describe the features of very weak (typically < 0.2-0.3 dB) absorption variations observed deep in the polar cap (> 85 degrees magnetic latitude).

GA2.01/E/05-A1 0950

A PECULIAR FEATURE OF RADIO WAVE ABSORPTION IN THE CUSP-LATITUDE DURING NORTHWARD IMF: A CASE STUDY

Masanori NISHINO (Solar-Terrestrial Environment Laboratory, Nagoya University, Toyokawa, Aichi, 442-8507, Japan, email: nishino@stelab.nagoya-u.ac.jp); Nozomu Nishitani (Solar-Terrestrial Environment Laboratory, Nagoya University, Toyokawa, Aichi, 442-8507, Japan, email: nisitani@stelab.nagoya-u.ac.jp); Natuo Sato, Hisao Yamagishi (National Institute of Polar Research, Itabashi-ku, Tokyo 173-8515, Japan, (email: nsato@nipr.ac.jp, yamagisi@nipr.ac.jp); Mark Lester (University of Leicester, University Road, Leicester, LRI 7RH, UK, e-mail: le@ion.le.ac.uk); Jan A Holtet (The University of Oslo, Blindern, Oslo, Norway)

An example of daytime radio wave absorption at 30 MHz observed by the imaging riometer (IRIS) at Ny-Alesund(76.1 invariant latitude), Svalbard in the cusp-latitude is presented. The absorption was observed during about 3.5 hours in the magnetic noon sector on February 28, 1996. The absorption intensity first increased up to 0.6 dB in the prenoon (near 10 MLT) with the increase of the IMF north-south component (Bz), thereafter varied within 0.6 dB intensity during subsequent weak northward and moderate southward IMF. A peculiar feature during the northward IMF is an intensity fluctuation of the absorption observed in the southern part of the IRIS field of view at: The fluctuating absorption showed a 'rectified response' to an abrupt change of the clock angle defined by the IMF north-south and east-west (By) components. The turning of the rectified response is approximately 45 degrees on the clock angle in the northward-dawnward plane. The plasma convection observed simultaneously by the Finnish HF radar showed antisunward drift associated with the abrupt IMF southward excursion, and immediately changed to a sunward drift associated with the subsequent IMF northward return. The gemagnetic X-component obtained by the ground magnetometer showed positive and negative deflections syncronized with abrupt IMF changes. The particle data from DMSP satellite identified the cusp crossing near Ny-Alesund and represented no precipitation of energetic electrons attributable to the observed absorption. These results indicate that the cusp-latitude absorption observed during the northward IMF is related to E-region electron heating by horizontal electric fields which is driven by the high-latitude magnetic merging at the dayside magnetopause and penetrate into the cusp-ionosphere through the magnetic field lines.

GA2.01/E/08-A1 1005

DETECTION OF FIELD-ALIGNED CURRENTS AND PARTICLE PRECIPITATION ASSOCIATED WITH SMALL-SCALE HIGH-LATITUDE CONVECTION DISTURBANCES

P. STAUNING (Solar-Terrestrial Physics Division, Danish Meteorological Institute, Lyngbyvej 100, DK-2100 Copenhagen, Denmark, email: pst@dmi.dk)

Small-scale disturbances like "twin convection vortices", "travelling convection vortices", "ionospheric FTE or PTE signatures", or simply "magnetic impulses" constitute a host of events that link processes in the outer magnetospheric regions to features in the high-latitude ionosphere. These features are observable from ground by radar methods like incoherent scatter radars or HF coherent radars or through the associated magnetic disturbances detectable from the existing array of magnetometer stations. The coupling between the outer magnetosphere and the high-latitude ionosphere is mainly accomplished through field-aligned current systems which are spatially more localized and temporally more transient than the more steady region 1 and 2 field-aligned currents. Hence they are difficult to detect by space-based observations. However, the combination of the mapping of these transient events from their ionospheric signatures detectable from ground and the high-precision magnetic measurements from Xrsted and other satellites provides a possible tool to resolve such events. In addition to the geomagnetic effects of currents and convection we have investigated the signatures in high-energy electron precipitation and related radiowave absorption features associated with such transient disturbances.

GA2.01/E/03-A1 1040

OPTICAL AURORAL FORMS AND RIOMETRIC IMAGING

P. H. STOKER, A. Wilson (Space Science Unit, Potchefstroom University for CHE, Potchefstroom 2520, South Africa, email: fskphs@puknet.puk.ac.za, burt.wilson@za.pwcglobal.com)

Digitized allsky images of auroral optical emissions, recorded by a low light level TV system at the new SANAE 4 antarctic base on Vesleskarvet (71x40'S, 2x51'W, L = 4.1), have been mapped onto the angular sensitivity functions of the 64-beam riometer. The two-dimensional spatial and temporal characteristics of discrete auroral forms and of riometric imagery of cosmic radiowave absorptions are examined and intercompared with better resolution than previously (J. Geophys. Res. 102, 7439, 1997). The tendency is confirmed that cosmic radio noise appears to be more strongly absorbed in regions adjacent to discrete auroral arcs than in the arc regions themselves. Furthermore, temporal changes in absorption appear to be delayed up to tens of seconds relative to changes in luminosity. The significance of these results are explored. The long delay times suggest that the observed differences in spatial and temporal characteristics should be of magnetospheric rather than ionospheric origin.

GA2.01/W/07-A1 1055

THE MORPHOLOGY OF AURORAL OPTICAL EMISSIONS, RIOMETER ABSORPTION AND RADAR BACKSCATTER: A CASE STUDY

M. J. KOSCH, E. Nielsen, M. Rietveld, T. Hagfors (Max Planck Institut für Aeronomie, 37191 Katlenburg-Lindau, Germany, email: kosch@linmpi.mpg.de), F. Honary, N. Stamatiou (Communications Research Centre, University of Lancaster, UK)

During the night of 9 November 1998 simultaneous recordings were made in a common field of view of auroral optical emissions by the Digital All-Sky Imager (DASI), riometer absorption patterns by the multi-beam Imaging Riometer for Ionospheric Studies (IRIS), coherent-backscatter by the Scandinavian Twin Auroral Radar Experiment (STARE) and incoherent-backscatter by the European Incoherent SCATter radar facility (EISCAT). In the period 15 - 24 UT there was strong substorm activity with Kp = 5+ - 7- and sigma-Kp = 46 for the day. DASI makes recordings of auroral optical emissions at 557.7 nm, for an assumed height of 100 km, within the area 67.6-72.6 deg. North and 13.5-26.0 deg. East. The images give estimates of the precipitating patterns of soft electrons. IRIS makes recordings of cosmic radio noise absorption at 38.2 MHz, for an assumed height of 90 km, within the area of 67.8-70.2 deg. North and 17.75-23.75 deg. East. The images give estimates of the precipitating patterns of hard electrons. STARE measures the Doppler shift and backscatter intensity at 140 MHz, for an assumed height of 105 km, within the same area as DASI. EISCAT, located at 69.6 deg. North and 19.2 deg. East, can measure various ionospheric parameters such as electron density and temperature and ion velocity and temperature. In this case recordings were made along the local magnetic field line in the altitude range 87-587 km. The interaction of the various parameters will be discussed.

GA2.01/E/01-A1 Invited 1110

INTERHEMISPHERIC CONJUGACY OF THE AURORAL POLEWARD EXPANSION OBSERVED WITH AN IMAGING RIOMETER NETWORK AND HF RADARS

Hisao YAMAGISHI (National Institute of Polar Research, Kaga 1 chome, Itabashi-ku, Tokyo 173-8515, Japan, email: yamagisi@nipr.ac.jp); Peter Stauning (Danish Meteorological Institute, Lyngbyvej 100, DK-2100 Copenhagen O, Denmark, email: pst@dmi.min.dk); Masanori Nishino (Solar Terrestrial Environment Laboratory, Nagoya University, 3-13, Honohara, Toyokawa 442-8507, Japan, email: nishino@stelab.nagoya-u.ac.jp); Liu Ruiyuan (Polar Research Institute of China, 451 Shangchuan road, Pudong, Shanghai 200129, China, email: uap@mail.pric.cn)

Auroral poleward expansion is a strong manifestation of the substorm expansion phase, and it can be observed by a riometer network as multiple-step progress of the absorption region into the polar cap (Stauning, 1995). Interhemispheric conjugacy of this phenomena was studied with a network of imaging riometers from east Greenland to Svalbard and in their conjugate region in Antarctica. We have analyzed the data from Danmarkshavn in East Greenland, Ny-Alesund and Longyearbyen in Svalbard, and Chinese Zhongshan Station in antarctica in the period of 1997-1998. For the poleward expanding CNA events observed in the northern hemisphere, more than half of them were observed simultaneously at Zhongshan Station. Local time dependense of the conjugate point latitude is discussed, making use of the longitudinal extent of the network. Poleward expansion sometimes show easterly, or westerly deflection as observed by the imaging riometers, and this feature is discussed in connection with the IMF By variations. The area of this imaging riometer network is covered by SuperDARN HF radars. The radar echo usually disappears when the poleward expansion takes place due to enhanced D-region absorption and/or reflection of the transmitted signal by sporadic auroral E-region. It is therefore difficult to know the electric field inside the poleward expansion from the radar data. However, the area of the echo disappearence can tell about the spatial extent of the absorption region, and this is directly compared with the absorption observed by the riometers.

GA2.01/W/06-A1 1135

A COMPARISON OF RIOMETER AND HF RADAR RESPONSES TO SUBSTORM-ASSOCIATED ENHANCED PARTICLE PRECIPITATION

Jonathan K. GAULD, T.K. Yeoman (Department of Physics and Astronomy, Leicester University, Leicester. LE1 7RH, UK); F.Honary (Lancaster Communications Research Centre, Engineering Department, Lancaster University, Lancaster, LA1 4YR, UK)

The common occurrence of an HF radar signal loss during strong auroral precipitation at the substorm expansion phase onset is examined, using radar data from the CUTLASS SuperDARN HF radar, and supported by riometer data from IRIS at Kilpisjarvi, within the CUTLASS field of view. The mechanism or mechanisms which could cause a radar signal loss are analysed from a theoretical standpoint, employing ray tracing techniques, and in relation to radar elevation angle data measured by the interferometer array, which has then been used as a constraint in producing models of the radar propagation. The implications of the results for both the electrodynamics of the ionosphere-magnetosphere system during the substorm

expansion phase and for radar operational constraints during this key dynamical process are discussed.

GA2.01/W/01-A1 1150

THE TEMPORAL FINE STRUCTURE OF NIGHT-TIME AURORAL ABSORPTION INVESTIGATED BY A WAVLET METHOD

Aarne RANTA (Sodankylä Geophysical Observatory, 99600 Sodankylä, Finland, email: Aarne.Ranta@sgo.fi); John K. Hargreaves (Engineering Department, University of Lancaster, Lancaster LA1 4YR, UK, email: j.hargreaves@lancaster.ac.uk); James D. Annan (Proudman Oceanographic Laboratory, Bidston Observatory, Birkenhead L43 7RA, UK, email: jdan@mail.nerc-bidston)

The onset of a substorm is often characterised by a burst of Pi2 magnetic pulsations. Another common feature is the occurrence of a short-duration spike evnent in auroral absorption monitored using a riometer. A wavelet approach, which can identify how the various periodicities develop during the event, has been applied to absorption spikes in the night sector, using observations from the imaging riometer at Kilpisjärvi (L=5.9) at 1 second resolution. It is found that the spike events, though only lasting for about 2 minutes, often show a fine structure with periodicity in the range 20-40 seconds. Some events are compared with the magnetic pulsations observed simultaneously at the same site.

GA2.01/E/11-A1 1205

STUDY OF SUBSTORM ACTIVITY FROM COMBINED IRIS, EISCAT AND DASI OBSERVATIONS

C.F. DEL POZO, F. Honary, N. Stamatiou (Ionosphere and Radio Propagation, Communications Res. Centre, Lancaster University, UK); M. Kosch (Max-Planck Institute für Aeronomie, Katlenburg-Lindau, Germany)

A number of simultaneous observations of substorm activity by the IRIS, EISCAT, and DASI systems is presented. The spatial extent and structure, as well as the temporal evolution of the localised 2-D absorption signatures, and their correspondence with digital all-sky optical measurements, during the various phases of substorm activity are discussed. EISCAT observations provide high-resolution time-series and altitude profiles of the various physical parameters defining the state of the ionosphere above Tromsø (electron density, electron and ion temperatures, electric field, etc.) and allow the estimation of the electron precipitation spectrum as well as the height and width of the absorption layer.
These features are studied from the point of view of the precipitation spectrum in the 1 to 400 keV energy range and the related phenomena in the D and E regions. The systematic analysis of the concurrency of auroral absorption and optical signatures allows the characterisation of cases when soft and hard precipitation may correspond to either the same or two different populations. The differential time of arrival between the higher and lower energy components of the precipitation at the late growth and onset phases is also studied.

GA2.01/E/12-A1 1220

SIMULTANEOUS IRIS/EISCAT OBSERVATIONS OF CME EVENT ON 10 JANUARY 1997

C.F. DEL POZO, F. Honary, H. Tao (Ionosphere and Radio Propagation, Communications Res. Centre, Lancaster University, UK); I. McCrea (EISCAT group, Rutherford Appleton Laboratory, Didcot, UK)

Simultaneous observations of the Coronal Mass Ejection event on 10 January 1997 by the IRIS and EISCAT systems are presented. The effects of this event on the lower ionosphere are investigated, namely the spatial extent and dynamics of the absorption patches, the changes in altitude and width of the absorption layer, and the evolution of the electron precipitation spectrum. These features are correlated and contrasted with the observations by a number of satellites at various locations in the interplanetary medium, the tail and inner magnetosphere.
This CME event was relatively weak with very low proton fluxes at energies > 1.6 MeV measured by the satellites. The flux of energetic electrons with energies greater than 400 keV measured by a number of geostationary and GPS satellites was also weak. The corresponding series of electron injections are clearly seen in the IRIS and EISCAT data. In particular those at 04:40 UT and 07:00 UT and subsequent injections over the period with IMF Bz < 0 associated with the first pressure pulse at ~ 01:00 UT, but not the enhancement fluxes near 11:00 UT reported by the satellites. EISCAT measurements show that the precipitation fluxes are generally too low to produce ionisation above the radar sensitivity level (> 5.109 el/m3). Only between 04:00 UT and 10:00 UT ionisation reach low enough to produce absorption in a narrow layer with variable height above 75 km, for precipitating electrons with energies smaller than 400 keV. Maximum absorption occurs around 04:40 UT and 07:00 UT, the precipitation spectrum normally extents up to 150 keV with the exception of a 30 min hardening at about 07:00 UT (up to 350 keV).

GA2.01/W/09-A1 1400

GUISDAP - PART OF THE EISCAT SVALBARD RADAR SOFTWARE PACKAGE

Markku LEHTINEN, Juha Pirttilä (both at Sodankylä Geophysical Observatory, 99600 Sodankylä, Finland, email: markku.lehtinen@sgo.fi, juha.pirttila@sgo.fi); Asko Huuskonen (Finnish Meteorological Institute, 00100 Helsinki, Finland, email: asko.huuskonen@fmi.fi); Pekka HIITOLA (Department of Physical Sciences, Oulu University, 90570 Oulu, Finland Email: Pekka.Hiitola@oulu.fi)

In 1986 was first GUISDAP (Grand Unified Incoherent Scatter Radar Data Analysis Package ver 1.0) demonstration in EISCAT Workshop in Sweden. After that some new version of GUISDAP were launched, but all of those were based purely on MATLAB scripts so-called m-files. In 1995 Finnish GUISDAP group started to create next generation GUISDAP program. First step was assess weaknesses of old version and after define new one. All time-consuming parts of GUISDAP had to be translate into C++ and other parts keep in same or almost same than into old versions. This programming period takes about three years. And nowadays EISCAT community has a new generation data analysis package. This talk compare some old data analysis programs and GUISDAP 2 and show some reasons of those differencies.

GA2.01/W/04-A1 Invited 1415

EISCAT OBSERVATIONS AND IMPLICATIONS CONCERNING MINOR SPECIES

Martin FRIEDRICH (Department of Communications and Wave Propagation, Technical University Graz, A-8010 Graz, Austria, e-mail: friedrich@inw.tu-graz.ac.at)

The ionosphere at auroral latitudes has been monitored for more than a solar cycle by the European incoherent scatter radar EISCAT; this instrument has probably yielded more data on electron density from one location than any other instrument. In addition there were about 100 rocket soundings from near the location of the EISCAT measurements which provide extensions to lower densities and altitudes. This impressive body of data allows to study the behaviour of the ionosphere not only for disturbed conditions - which are really "normal" at these latitudes - but also for undisturbed situations which are thus comparable to the conditions prevailing outside the auroral zone. The combined database will be used to investigate the solar controlled behaviour, the impact of solar activity and season, but also to study these variations at times of disturbances, primarily expressed in terms of locally measures riometer absorption. Tests will be presented in which the observed riometer values are contrasted to corresponding simulations. Of the neutral minor species which have a bearing on the lower ionosphere, nitric oxide and atomic oxygen are the most prominent. "Reasonable" limiting values will be derived for these species based on suitably averaged undisturbed electron density profiles. Finally an attempt will be shown in which the effective electron recombination rate from empirical data will be contrasted to theory.

GA2.01/E/06-A1 Invited 1440

ELECTRON DENSITY VARIATIONS IN THE POLAR D REGION FROM IN SITU MEASUREMENTS

A.D. DANILOV (Institute of Applied Geophysics, Rostokinskaya 9, Moscow 129 128, Russia, email: hciag@sunny.aha.ru)

A dataset of more than 500 in situ (probe method) measurements of the electron concentration in the D region on board M100B meteorological rockets at Heiss Island (Arctic) and Molodezhnaya station (Antarctic) is considered. Dependencies on season, solar zenith angle and magnetic activity are studied. Some asymmetry of the hemispheres is found. It is shown that the electron concentration behavior at Heiss Island depends on whether the station is in the sub-auroral zone, auroral oval or polar cap.

GA2.01/W/10-A1 1505

RAPID CHANGES IN BACKSCATTER RANGE IN QUIET MAGNETIC CONDITIONS

Erhard MRAVLAG (Space Physics Research Institute, University of Natal, Durban 4041, South Africa, email: mravlag@scifs1.und.ac.za)

Extremely rapid changes in backscatter range have been observed at the SHARE radar at SANAE. These changes usually tend to follow the pattern of diurnal changes in backscatter range, ie. usually away from the radar site in the morning and towards the radar site in the evening. This is not always true, however. The changes generally occur in magnetically quiet conditions, with |B| < 10nT and B_z small. Similar patterns were seen in the data recorded at Halley.

GA2.01/E/09-A1 Invited 1540

THE POTENTIAL OF COMBINED INCOHERENT SCATTER RADAR, MST RADAR AND IMAGING RIOMETER OBSERVATIONS ON SVALBARD

Juergen ROETTGER (Max-Planck-Institut fuer Aeronomie, D-37191 Katlenburg-Lindau, Germany, email: roettger@linmpi.mpg.de)

The middle atmosphere in high latitudes is the merging region of forcing from below and above. Gravity waves, created in the troposphere propagate to mesospheric altitudes, where they deposit energy and momentum. Electric fields and particles penetrate into the lower thermosphere and mesosphere, where they significantly influence the ionization structure. The combination of the EISCAT Svalbard Radar (ESR), the SOUSY-Svalbard-Radar (SSR) and the Imaging Riometer System (IRIS), all collocated near Longyearbyen, can excellently be used to study this merging region. Polar Mesosphere Summer Echoes (PMSE), detected with the SSR MST radar, are phenomena which reflect ionization structures, gravity waves and turbulence. The PMSE, thus, are most proper tracers of some dominant phenomena occurring in the merging region. We will discuss the potential of studies of PMSE, detected by the SSR, combined with observations of electron density profiles (and conceivably PMSE) measured with the ESR.The horizontal structure of ionization content, measured with IRIS, should be compared with the occurrence and structure of PMSE. Such combined studies will be exclusively valuable in the magnetospheric cusp region, which is passing over Svalbard. The orography of the Svalbard archipelago comprises an effective source region of mountain waves, which can propagate into the middle atmosphere. Their effect on mesosphere dynamics can be studied with PMSE observations. Finally we will debate the plausibility whether PMSE and their environment could affect the ionization structure measured with the ESR and IRIS.

GA2.01/W/11-A1 Invited 1605

VARIATIONS OF MESOSPHERIC ION AND NEUTRAL COMPOSITION AS DEDUCED FROM IMAGING RIOMETER DATA

ESA TURUNEN, Thomas Ulich Sodankyl_ Geophysical Observatory, Tahtelantie 112, FIN-99600 Sodankyl_, Finland; Pekka Verronen, Erkki Kyrola, Finnish Meteorological Institute, Geophysical Research, PO Box 503, FIN-00101 Helsinki, Finland

Using recent detailed ion chemistry models it is in principle possible to estimate the effect of precipitating high energy particles on the ion and neutral composition, if the spectrum of the precipitating particles is known. However, in practice the variations in concentrations of the constituents are not only determined by local processes, but to a large extent also governed by horizontal transport. Since imaging riometers can map both spatial and temporal variations of the ionization produced by precipitating particles, we would expect this data to be extremely useful as constraints in model studies of the effects of precipitation. An attempt is made to combine a detailed ion chemistry model, with coupled neutral chemistry, and data provided by imaging riometer, in order to study the spatial effects of local ionization enhancements.

GA2.01/W/08-A1 Invited 1640

ELECTRICAL EFFECTS ON THE MESOSPHERE AND LOWER IONOSPHERE FROM THUNDERSTORMS

Prof. Robert H.HOLZWORTH (University of Washington, USA)

The effects on the ionosphere and magnetosphere caused by ordinary cloud-to-ground (CG) lightning include conductivity enhancement, heating and plasma wave stimulation. These effects, have been observed directly from rockets and satellites in the mesosphere and ionosphere, give us a statistical picture of the electromagnetic energy input to the ionosphere

which is significant up to 2000 km from the point of the lightning. Individual case studies of CG and now even IC (intracloud) lightning provide evidence that orientation and dynamics of the lightning events within the clouds can have significant control over the resulting ionospheric waveform of the lightning pulse. Direct lightning related phenomena such as Red Sprites can also have a dramatic electromagnetic effect on the mesosphere and ionosphere. In this talk I will review the recent research on lightning, thunderstorms and related high altitude phenomena such as red sprites, as they affect the mesosphere and lower ionosphere.

GA2.01/W/05-A1 **1705**

THE APPLICATION OF IMAGING RIOMETERS FOR DETECTION OFTHIN METALLIC-ION LAYERS

B.J. WATKINS (Geophysical Institute, University of Alaska Fairbanks D.F.Bedey US Military Academy, West Point, NY, USA); T.J. Rosenberg, A.T. Weatherwax (University of Maryland at College Park, USA); P. Stauning (Danish Meteorological Institute, Copenhagen, Denmark)

The incoherent-scatter radar at Sondrestrom, Greenland has been used to study the morphology and occurrence of thin metallic-ion layers that occur in the lower ionosphere at altitudes from about 90 to 110km; these result from the accumulation of metals from meteor ablation. The structures are frequently limited in spatial extent and move horizontally in response to electric fields and neutral winds. We report on efforts to use the co-located imaging riometer at the radar site to detect the presence, spatial extent, and motion of metal-ion layers. The levels of cosmic noise absorption are typically about 0.1 dB and therefore the detection of these structures is limited to geomagnetically quiet periods in the absence of auroral ionospheric structures. Imaging riometer data, in conjunction with a number of radar-observed layer events, will be presented.

ARTIFICIAL PERIODIC INHOMOGENEITIES AND A MODEL OF THE D-REGION

V.V. BELIKOVICH, E.A.Benediktov, V.N.Bubukina, V.D.Vyakhirev (Radiophysical Research Institute, Niznhy Novgorod, Russia, email: belik@nirfi.sci-nnov.ru)

New studies of the D-region using API technique were carried out by means of SURA heating facility (56.13 N, 46.1E) in August 1996. The heating of the ionosphere was conducted by extraordinary mode with a frequency of 4.7 MHz and effective radiated power 60-100 MW beamed vertically upwards during 3 s followed by off period of 12 s. In pause the impulses having duration of 20 mks and a repetition frequency of 40 Hz were radiated. The quadratures of the scattered signals were recorded with a height resolution of 1.2 km and were encoded by 10-digit analogue-digital converter. The height dependencies of the relaxation time and the amplitude of the scattered signal are obtained. They are compared with the model of the API formation. The once are constructed on the basis of the balance of ionization using one negative ion model. The diffusion redistribution of plasma is slower at the D-region heights and more quick processes as attachment and detachment of electrons dominate. The main physical cause of API formation at the D-region heights is the temperature dependence of the rate of the electron attachment to the oxygen molecules in three bodies collisions. The model is in agreement with factual data well. Our studies show that the model profiles of the API amplitude and the relaxation time are sensitive to atmospheric density and to the atomic oxygen concentration. It seems upper boundary of the API in the D-region to depend on increase of the atomic oxygen concentration and can be an indicator of this process. It is a new method of the middle atmosphere study. The work is supported by RFBR-DFG under grant 96-05-00074.

HIGH-ENERGY ELECTRON PRECIPITATION AND FIELD-ALIGNED CURRENTS IN THE CUSP REGION MEASURED FROM XRSTED SATELLITE AND CORRELATED GROUND-BASED OBSERVATIONS OF IONOSPHERIC CONVECTION AND ABSORPTION

TINA CHRISTENSEN, Peter Stauning, Freddy Christiansen, Torsten Neubert, Vladimir Papitashvili, Jian-Guo Wu (all at Danish Meteorological Institute, Lyngbyvej 100, DK-2100, Copenhagen, Denmark, email: tic@dmi.dk)

The cusp region located at approximately 77-80 degrees invariant latitude close to local noon at the dayside of the polar cap is threaded by field-aligned currents arising from interactions of the solar wind with the outermost reaches of the Earth's magnetosphere. The field-aligned current systems can be detected through high-precision geomagnetic measurements from the Xrsted satellite. These currents affect the high-latitude ionospheric convection, which may be defined from ground magnetometer array observations augmented by incoherent scatter radar measurements. The cusp region also marks the high-latitude boundary of the high-energy electron precipitation from the trapped radiation population in the inner magnetosphere. The Xrsted charged partiÃ˜˜, (CPD) c'Z"Ã÷ectron preci'.tion, while the effects of the precipitation into the upper atmosphere are detectable from ground through radio wave absorption measurements (e.g., by imaging riometers). This presentation will focus on the correlation of satellite-based and ground-based detection of current systems and high- energy electron precipitation in the cusp region. Particular attention will be given to the detection of the relative location of the field-aligned currents with respect to the boundaries of the trapped and precipitated radiation in vicinity of the cusp/cleft region.

QUIET DAY CURVES RECORDED WITH 46 AND 64 ANTENNAE IN A 64-BEAM IMAGING RIOMETER ARRAY

A. WILSON, P. H. Stoker (Space Science Unit, Potchefstroom University for CHE, Potchefstroom 2520, South Africa, email: burt.wilson@za.pwcglobal.com, fskphs@puknet.puk.ac.za)

Since April 1997, a 64-beam 38.2 MHz imaging riometer has been in operation at SANAE 4. To test the operation of the riometer a 408 MHz continuum map of the radio sky brightness (Haslam et al. 1982) was digitized and was convolved with the directivity of the eight beams in a central north-south row of the riometer antenna array. These estimated diurnal variabilities are compared with the quiet day curves (QDC's) obtained from cosmic radio noise recordings by the eight beams concerned.
After functioning for several months a severe storm damaged 18 of the 64 crossed dipole antennae. The damaged antennae were removed from the array and their inputs were terminated at the Butler matrix, resulting in a change in the angular sensitivities of the 64 beams. The peaks of the 64 QDC's of the array operating with 46 antennae appeared to be a little flatter than those recorded by the original array of 64 antennae, indicating an increase by several degrees of the -3 dB beam width of 13x of the near vertical beams. Furthermore, the signals strengths recorded in the directions of the 64 beams were reduced by about 46/64.

GA2.01/E/02-A1 Poster **0900-04**

DAYTIME RIOMETRIC ABSORPTIONS DURING GEOMAGNETICALLY QUIET PERIODS

WILSON, P. H. Stoker (Space Science Unit, Potchefstroom University for CHE, Potchefstroom 2520, South Africa, email: burt.wilson@za.pwcglobal.com, fskphs@puknet.puk.ac.za)

On 16 May, 1997 from 1400 - 1630 UT and on 12 September, 1997 from 1200-1530 UT absorptions with maxima of about 1 dB have been observed by the 64 beam imaging riometer at SANAE 4 (71x40'S, 2x51'W, L = 4.1). Kp was around 2 for most of both days and increased to, respectively, 4- and 3x during the events. At SANAE 4 the local K-indices did not show any increase during the events from the low values of these days. The Bz component of the interplanetary magnetic field turned negative shortly before the start of these absorptions and returned positive again by the end of the absorptions. The solar wind velocities were moderate. The latitude angles of the flows were at zero degrees during the events, and at positive angles before and after. The geomagnetic field was active during the days preceding these events. Electrons trapped in the magnetosphere may have been accelerated to relativistic energies during preceding days. This is supported by the increases in intensity of several orders in magnitude of electrons with energy greater than 2 MeV as recorded by the GEOS geostationary satellite. Presumably these electrons were precipitated at SANAE 4 when Bz turned negative, expedited by SANAE 4's location at the southern edge of the South Atlantic Radiation Anomaly.

Characteristics of upflowing ionospheric ions (UFIs), plasma waves, precipitating solar wind components, and field-aligned currents (FACs) in the cusp/cleft at low altitudes are presented on the basis of the observational results by the thermal ion dynamics experiment (TIDE), the multichannel analyzer of the plasma wave instrument (PWI-MCA), the charged particle instrument (Hydra), and the magnetic field experiment (MFE) on board the POLAR satellite. We mainly focus on cusp/cleft conics and the other crucial phenomena causing transverse ion acceleration (TIA) in the topside ionosphere. Energy and pitch angle distributions of the conics observed by TIDE and their spatial distributions show that the TIA is a dominant process in the cusp/cleft to effectively supply ionospheric ions into the polar magnetosphere. Some of these outflowing ionospheric ions could be observed in the magnetotail after further acceleration, which we reported as cold ion flows observed in the lobe/mantle regions by the Geotail spacecraft. The energies and cone angles of the conics and their variations are different between H+ and O+. Namely, the energies and cone angles of O+ are generally larger than those of H+, and their latitudinal variations are slower for O+ than for H+. These features imply that acceleration rates of the ionospheric ions would be dependent on locations (altitude and latitude) and that they could be different between H+ and O+. It is also likely that the convection effect appears differently in fast H+ and slow O+ ions. Comparisons with the observational results by PWI, Hydra, and MFE support these ideas and bring further insights: The spatial distribution of the TIA in the cusp/cleft is latitudinally wide (>1 deg.); small-scale intense FACs are embedded in the larger-scale FAC system typically seen in the cusp/cleft and accompanied by broadband electrostatic plasma waves at low frequencies close to gyrofrequencies of H+ and O+ in the 5300-km altitude cusp/cleft. It is also noteworthy that multiple TIA regions are repeatedly observed during some of the cusp/cleft crossings and also well correlated with repetitive appearances of the plasma wave enhancements and the small-scale FACs.

IONOSPHERIC OUTFLOW AS A LOAD IN MAGNETOSPHERIC ENERGY TRANSFER PROCESSES

R. Lundin, Swedish Institute of Space Physics, Kiruna, Sweden

The outflow of ionospheric plasma is a direct consequence of the solar wind interaction with the terrestrial magnetosphere. However, unlike the direct solar wind interaction with the ionosphere for the planet Mars, the interaction with the Earth is indirect and coupled to the magnetospheric boundary layers and the magnetotail by field-aligned currents. The intrinsic magnetic field of the Earth serves as a guidance for the currents/charged particles as well as the waves, feeding energy into and heating the ionospheric plasma, subsequently leading to escape. The escape regions may therefore be rather localized, confined to small-scale or large-scale depletion regions.
The outflow, or excavation, of the ionospheric plasma occurs predominantly over the auroral region, but extends also into the polar cap. During large magnetospheric disturbances this erosion may also extend to subauroral latitudes.

It will be argued here that the heating/acceleration of ionospheric plasma, and the corresponding outflow, may be considered a loading of field-aligned and transverse currents in the ionosphere in such a way that plasma escape occurs for both upward and downward currents. The most efficient heating/acceleration appears to occur inside density cavities, effectively replenishing plasma at the edges of the cavities.

GA2.07/W/13-A1 0920

THERMAL ION HEATING AND OUTFLOW OBSERVED BY AKEBONO SATELLITE BETWEEN 1989 AND 1999

Shigeto Watanabe and M. Yamada (Department of Earth and Planetary Science, Hokkaido University, Sapporo, Japan, Email: shw@pspace.sci.hokudai.ac.jp) T. Abe (The Institute of Space and Astronautical Sciences, Sagamihara, Japan) E. Sagawa (Communications Research Laboratory, Koganei, Japan) A.W. Yau (University of Calgary, Calgary, Canada)

The data obtained by the suprathermal ion mass spectrometer (SMS) on Akebono during 10 years were analyzed to investigate the spatial and temporal distributions and the physical processes of thermal ion heating and outflow in the topside polar ionosphere. Akebono was launched on February 1989 from Kagoshima space center of the Institute of Space and Astronautical Science and continues to observe the polar ionosphere. An escape of polar ionospheric ions is important to a loss process of the earth's atmosphere as well as a source of magnetospheric plasma. The escape rate of 5-50 tons/day was already estimated on the basis of rocket and satellite observations. The data showed the ion outflow, transverse ion energization (TIE), and ion conics at altitude below 10000km. The energy and pitch angle distributions of conics and their spatial variations verified that the TIE is a dominant process in the cusp/cleft to effectively supply ionospheric ions into the magnetosphere. The TIE occurred near thepolar cap boundary and correlated with both low requency wave activity and upward field aligned currents in the cusp/cleft region.

GA2.07/W/11-A1 0940

AN INVESTIGATION OF THE IONOSPHERIC CONTRIBUTION TO MAGNETOSPHERIC PLASMA USING THE AKEBONO SUPRATHERMAL MASS SPECTROMETER (SMS) DATA SET: FIRST RESULTS

Donovan, E. F., G. G. Arkos, A. W Yau, and C. M. Cully

The importance of the ionosphere as a source of magnetospheric plasma (relative to the solar wind) has become evident in recent studies. The Suprathermal Mass Spectrometer (SMS) has been in continuous operation onboard the Akebono (EXOS-D) spacecraft since 1989. It regularly measures the distribution functions of H+, He+ and O+ ions in the satellite spin plane, at altitudes between one and two Earth radii above the auroral and polar ionosphere. This data has been used in studies of ion outflow, ion heating and the polar wind and is well suited for a comprehensive study of the ionospheric contribution to magnetospheric plasma. As a first step in this study, we have implemented a model of ion motion in the electric and magnetic fields in the Earth's magnetosphere. The field model is a combination of the IGRF and Tsyganenko (1987, 1989) magnetic field models and the Weimer electric potential model (Weimer, GRL, 1986). Particle trajectories are calculated by considering the guiding center drift in the direction perpendicular to the magnetic field and solving the equation of motion in the noninertial reference frame parallel to the magnetic field as described in Northrop (1963). In this paper, we outline aspects of the SMS data set relevant to this study. As well, we use information from distribution functions obtained by the instrument as initial conditions for particle trajectory tracings in the model fields. Finally, we discuss the results of these tracings with regard to the ionospheric contribution of ions to the magnetotail plasma.

GA2.07/W/14-A1 1000

ON A MECHANISM OF CONTROL OF SMALL SCALE AURORAL ACCELERATION BY IONOSPHERIC CONDUCTIVITY

E. V. MISHIN (Max-Planck-Institut für Aeronomie, e-mail: mishin@linmpi.mpg.de)

Satellite and ground observations of auroral acceleration events, including auroral displays, particle acceleration, and accompanied electromagnetic phenomena, have revealed the significant seasonal and local time variation. This points out the dependence of the acceleration mechanism(s) upon the ambient ionospheric conductivity in that most intense acceleration events favor low ambient conductivity. These results are probably the most convincing arguments in favor of an active role that the ionosphere plays in magnetospheric-ionospheric coupling.
Mishin and Banaszkiewicz [GRL, 25, 4309, 1998] have addressed the statistical results from Freja and Viking on the preference for the midnight to early morning period of the diverging electric field shocks, upward electron beams, and O+ conics in terms of the stratification instability of the plasma convection. Its development is favored by low ambient conductivity. In the region of downward Birkeland current and mainly equatorward convection electric field, this instability results in formation of diverging electric field shocks and average downward parallel electric field. In the present work, it is taken into consideration that in the region of upward Birkeland current and mainly poleward convection electric field generation of converging electric field shocks and upward parallel electric field is favored. Therefore, the statistical results on downward electron acceleration and upward ion acceleration can qualitatively be understood in terms of the convection stratification instability.

GA2.07/W/22-A1 1020

AURORAL THERMAL WAVE AS A SOURCE OF AURORAL ION UPFLOWS IN THE IONOSPHERIC F-REGION

G. O. ZHIZHKO, V.G. Vlasov (both at Department of Mathematics, Irkutsk State Technical University, Lermontov 83, Irkutsk, 664074, Russia, e-mail: zhizhko@math.istu.irk.ru)

An auroral thermal wave is the phenomenon results from the collective interaction of the auroral electron beams with the F-region ionospheric plasma. The auroral electron beams, which is a course of the auroral arcs, are stabilized by the large-scale inhomogeneity of the plasma density at their path from the acceleration region up to the E-region of the ionosphere. The collective dissipation of the electron beam energy is possible only in the area of the small plasma density gradients in the F2-region maximum. Because of the electron beam energy is dissipated at the area with the small spatial size ($\sim 10-100$ km), there are intensive plasma heating in this area (electron and ion temperature can reach 8000 K and 6000 K correspondly). This heating results in ion upflows with the velocity around 1000 cm s^{-1} and density 10^{14} cm^{-2} s^{-1}. The similar flows are repeatedly observed by the EISCAT radar and approximately 80 \% events are associated with either increased ion or electron temperatures. Thereby it is the strictly reason to believe that the auroral thermal wave is an important source of the upflows auroral beams in the ionospheric F-region.

GA2.07/W/25-A1 1100

INTERACTION OF THE DYNAMIC IONOSPHERE WITH ALFVÉN WAVES

ROBERT L. LYSAK and Yan Song, (University of Minnesota, 116 Church Street SE, Minneapolis, MN 55455, USA)

The field-aligned currents and the resulting precipitation associated with the propagation of shear Alfvén waves can produce narrow-scale structuring of the ionospheric conductivity and the production of secondary Alfvén waves at the conductivity gradients. These interactions can give rise to a positive feedback interaction, leading to strong, localized enhancement of the ionospheric conductivity. This feedback interaction is particularly effective when coupled with the dynamics of Alfvén waves above the ionosphere, where the sharp gradient of the Alfvén speed gives rise to a resonant cavity with frequencies in the 1 Hz range. The development of this conductivity and current structure may play an important role in the coupling of the ionosphere and magnetosphere, particularly during magnetospheric substorms, and can lead to the formation of narrow-scale auroral arcs. Numerical simulation of the dynamics of this feedback interaction will be presented.

GA2.07/W/12-A1 1120

MAGNETOSPHERE-IONOSPHERE STRUCTURING CAUSED BY IONOSPHERIC ALFVÉN WAVE GENERATION

J. J. Sojka and L. Zhu Center for Atmospheric and Space Sciences Utah State University Logan, UT 84322-4405

The conventional methods of carrying out M-I coupling are often no more than simple cases of a magnetospheric system driving an ionosphere load. Often even the load, the integrated Hall and Pedersen conductivity, is held fixed. However, even in the case where the Hall and Pedersen conductivities change at each time step, the M-I scheme still does not include the complete physics of M-I coupling.When an ionospheric conductivity changes in time, an "Alfvén wave" is generated. Such an Alfvén wave would exist in the presence of magnetospheric Alfvén waves as well as its reflected Alfvén wave from the ionospheric load. It is the Alfvén wave being generated in the ionosphere, along with the reflected Alfvén waves, that we argue are responsible for auroral structuring and even possibly the orientation of large scale features such as the Harang discontinuity.The M-I coupling MHD modelling work of Zhu et al. for both polar cap and auroral arcs is presented to highlight the significant role played by the ionosphere in M-I coupling. Emphasis is placed on the conditions under which an unstructured magnetospheric source reads to highly structured ionospheric auroral forms. The characteristic scales of these forms are shown to be commensurate with observed scale sizes of large scale auroral arcs. Observations from both ground and satellite instrumentation are presented in support of our suggestion.

GA2.07/W/07-A1 1140

FRAYING OF THE IONOSPHERIC RESPONSE OF A FLUX TRANSFER EVENT DUE TO CONDUCTIVITY STRUCTURES

HANS NILSSON (Swedish Institute of Space Physics, Box 812, 981 28 Kiruna, Sweden, email: hans.nilsson@irf.se); Alan Rodger (British Antarctic Survey, High Cross, Madingley Road, Cambridge CB3 OET, UK, email: A.Rodger@bas.ac.uk)

The time constant of the inductive circuit coupling the source at the magnetopause to the load (the ionosphere) is to first approximation only dependent on the distance between source and load and the Pedersen conductance of the ionosphere. In the cusp region, the field line geometry is relatively simple and the connection between source and load very direct. The aim of this talk is to examine to what extent conductivity structures (pre-existing or caused by spatial variations in the cusp particle precipitation) will affect the ionospheric (and therefore also magnetospheric) response to a flux transfer event.
If separate field-aligned currents are set up feeding energy into regions with different conductance, these regions will respond differently. Regions with low conductance will respond fast whereas regions with high conductance will respond slower. If the response is slow, the inductive circuit will seldom be in steady state, the rotation of the electric field inside the current loop connecting the source with the load will be non-zero and consequently there will be a slippage of the magnetospheric field lines. This will cause a fraying of the response to a flux transfer event, with different flows and different magnetopause mapping for different regions in the ionosphere. An alternative scenario is that instead of field-aligned currents setting up on the borders of conductivity structures a polarization charge build-up will keep the Pedersen current constant. The result is still a slower response to a flux transfer event in a region with higher conductance.
Furthermore, the non-zero curl of the electric field resulting from the long ionospheric response time may explain a number of "meso-scale" phenomena observed by satellites such as overlapping magnetosheath injections.

GA2.07/E/05-A1 1200

HF POWERFUL WAVE IMPACT ON MAGNETOSPHERIC-IONOSPHERIC COUPLING OBSERVED DURING TROMSOE HEATING CAMPAIGN OF FEBRUARY 1996

Nataly Blagoveshchenskaya, Victor KORNIENKO, Renata Lukianova, Oleg Troshichev (all at Arctic and Antarctic Research Institute, 38 Bering Str., St.Petersburg, 199397, Russia, email: vikkorn@aari.nw.ru), Asgeir Brekke (Auroral Observatory, University of Tromsoe, N-9037, Tromsoe, Norway, email: asgeir@phys.uit.no), Mike Kosch, Michael Rietveld (both at Max-Planck-Institut fuer Aeronomie, 37189 Katlenburg-Lindau, Germany, email: kosch@linax1.mpae.gwdg.de).

The complex study of the geophysical and radiophysical processes during the Heating campaign on 15-17 February, 1996, in the nocturnal auroral ionosphere has been carried out. The following instruments were involved in the study: IMAGE magnetometer network, HF Doppler multichannel equipment, Tromsoe Dynasonde, EISCAT UHF radar, all-sky imager (DASI), and sattelite data sets. The features of the processes imply the modification of the M-I coupling associated with the HF Heater action: (1) local ionospheric currents redistribution during heating cycles; (2) local field-aligned current modification; (3) possibly the Alfven wave excitation; (4) triggering of particle precipitation; (5) possibly field-aligned current sheet

development disturbance. As key parameters in geophysical conditions for the observed phenomena we outline: (1) the HF Heater affected on the current carrying E-layer; (2) the ionospheric modification (the HF pumping) was in the closest vicinity of field-aligned current sheet (indicated by the discrete auroral arc). The inferred scenario is the following: the HF Heater produces the ionospheric modification in the E-layer, artificial field-aligned irregularities are excited; ionospheric current system are locally changed; conditions for field-aligned currents shortening are changed; field-aligned potential change leads to electron precipitation; the auroral arc development changed.

GA2.07/W/23-A1 1220

AN INVESTIGATION OF THE TIME SCALE OF THE CONVECTION RESPONSE IN THE IONOSPHERE TO IMF VARIATIONS AT THE MAGNETOPAUSE

Yan Song and Robert L. Lysak (both at School of Physics and Astronomy, University of Minnesota, 116 Church St. SE, Minneapolis, MN 55455, USA, e-mail: yan@aurora.space.umn.edu & bob@aurora.space.umn.edu)

The response time of ionosphere convection to IMF transients depends on (1) the intrinsic parameters of the magnetosphere-ionosphere system; and (2) the external forcing by the solar wind. For a given electric field and/or a current, the ionospheric response is caused by the drag force due to the collisions between the ions, electron and the neutrals.
The characteristic times of the ions, electrons and neutrals at different ionospheric altitudies to a given electric field and/or a given current are investigated numerically by solving the eigenvalue problem of a set of equations for the ions, the electrons and the neutrals. The response at different altitudes is coupled by the passage of Alfvén waves.
The time scales of the ionospheric response to an electromagnetic perturbation in the form of MHD waves and in the form of convection are different. The time scale of the response of the ionospheric reconfigures to a sudden IMF change is usually not the Alfvén travel time. We will report results from a numerical model of the ionospheric response time to the different driving forces.

AURORAL FIELD-ALIGNED CURRENT DESTABILIZATION IN THE IONOSPHERE

Supriya B. Ganguli and V. V. Garishchaka

Our research has shown that multimoment, multispecies generalized fluid models with appropriate parameterization of important plasma instabilities via anomalous transport coefficients are a promising vehicle to study the effects of auroral filed-aligned current destabilization in the ionosphere. Our simulation results show that the presence of field-aligned currents in the ionosphere generate field-aligned current driven instabilities that alter ionospheric flow into the magnetosphere by producing plasma density cavities and energization processes. Recent observations indicate that the field-aligned flows often have transverse structures. A structured flow can generate spatial gradient driven instabilities that can result in cross-field transport in addition to plasma energization. Our 3D, multifluid, multispecies model solves the continuity, momentum and energy equations in dipole magnetic filed and allows self-consistent treatment of the cross-field transport. We have shown that the low-frequency D'Angelo instability, driven by the transverse inhomogeneity in the magnetic field-aligned ion flow, can be excited for the typical parameters in this region. The instability generates cross-field transport, which significantly modifies the field-aligned ionospheric outflow. In the non-linear stage of the instability, V-shaped potential structures with magnitude ~1kV are formed. The simulation results will quantify ionospheric outflow, provide insight into the dynamical evolution of D'Angelo instability in the auroral region, its effects on ionospheric outflow and formation of 3D potential structures. The results will be compared with recent observations.

GA2.07/W/26-A1 Invited 1425

IONOSPHERIC MASS LOADING OF THE MAGNETOSPHERE DURING MAGNETIC STORMS

Ioannis A DAGLIS (National Observatory of Athens, Institute of Ionospheric and Space Research, 15236 Penteli, Greece)

A variety of observations in the inner magnetosphere have shown that the terrestrial plasma (singly charged oxygen in particular) is an important part of the energetic ion population. In particular, measurements have demonstrated that during intense magnetic storms, the abundance of ionospheric oxygen increases dramatically. The result is a rapid intensification of the ring current and an ionospheric dominance in the inner magnetosphere around storm maximum. The mass loading of the magnetosphere and the compositional change in favor of oxygen affect, among other processes, the decay of the ring current through the species- and energy-dependent charge exchange and wave-particle scattering loss. We will present relevant observations and modelling results, and will discuss the importance of the ionospheric mass loading in terms of its consequences for magnetic storm dynamics.

GA2.07/W/18-A1 1450

NEW ALFVEN WAVE GENERATION MECHANISM ASSOCIATED WITH MAGNETOSONIC WAVE INCIDENCE

P. NENOVSKI, Geophysical Institute, Bulgarian Academy of Science, Sofia, Bulgaria

The well-known mechanism of Alfven wave resonances by magnetosonic waves usually takes places at regions with steep gradients, plasma sheet boundaries, plasmapause, etc. The Alfven resonances are however observable also on field lines where such resonance conditions cannot be matched. An alternative mechanism of Alfven wave generation should be responsible for such resonances. An Alfven wave generation mechanism of ionospheric origin is suggested. The initial incident disturbance is again a magnetosonic wave. We demonstrate a non-resonant Alfven wave generation mechanism due to polarization effects of the low-altitude ionosphere on the incident magnetosonic wave. Owing to polarization effects through the ionosphere-atmosphere system the magnetosonic wave dissipation process yields a non-zero amplitude Alfven-type wave transmitted in the magnetosphere. This new Alfven wave generation ionosphere mechanism emerges however under specific conditions. The mechanism is most effective under condition SH =(SP + Am)^0.5. Here SH, SP correspond to the Hall and Pedersen conductances in the low-ionosphere part and Am is proportional to (k^2)l/Vph,hor (k is the horizontal wavenumber of the incident magnetosonic wave, Vph,hor the horizontal phase velocity, and l the Hall region thickness). Hence, only magnetosonic waves with appropriate wave characteristics are able to initiate an Alfven

GA2.07/W/27-A1 1510

GEOMAGNETIC HISTORY AFTER A SUBSTORM: THE NEUTRAL WIND DYNAMO EFFECT

ANASUYA L. ARULIAH, Alan D. Aylward, Ingo C.F. Mueller-Wodarg (all at Atmospheric Physics Laboratory, University College London,67-73, Riding House St., London W1P 7PP, England; e-mail: anasuya@apg.ph.ucl.ac.uk)

The Neutral Wind Dynamo is known to be a significant source of electric fields at low- and mid-latitudes, thus creating the Sq current system. At high-latitudes the magnetospheric dynamo is so much larger that the neutral wind dynamo is generally ignored. However, there are certain conditions when this is not the case. These occur when Bz is small resulting in weak ionospheric convection, whilst the neutral convection is strong. The strong neutral convection may exist for two reasons, either owing to the pressure gradient or a residual high-speed flow left over from a previously active condition that has quickly become quiet. A particular example is the recovery stage of a substorm. Model simulations, using the UCL-Sheffield-SEL CTIP model, are compared with FPI average wind speeds to investigate the significance of the neutral wind dynamo in this circumstance. Individual periods are also examined where simultaneous observations are made by the EISCAT radars at Tromso and Longyearbyen together with FPIs at Kiruna and Longyearbyen. These provide measurements over a large region extending from the polar cap to the auroral oval.

GA2.07/W/30-A1 1530

SOME NEW FEATURES OF HIGH-ALTITUDE CURRENT SYSTEM POSSIBLY GENERATED BY IONOSPHERIC NEUTRAL WIND

Toshihiko IYEMORI (Graduate School of Science, Kyoto University, Kyoto 606-8512, Japan, email: iyemori@kugi.kyoto-u.ac.jp) Masahisa Sugiura(Research Institute of Science and Technology, Tokai University, Tokyo 151-0063, Japan: email: sugiura@jspan.kugi.kyoto-u.ac.jp) Ryoichi Nakashima (Sony Co., 1-7-4, Tokyo 108-0075, Japan, email: rnaka@shiba.sony.co.jp) James A. Slavin (Code 696, Godderd Space Flight Center, Greenbelt, MD20771, U.S.A.,
email: slavin@lepjas.gsfc.nasa.gov)

Using the magnetic field data from DE(Dynamics Explorer)-1 and -2, we have investigated the electric current structure over the ionosphere including the mid-latitude field-aligned currents. Firstly, we deduced the magnetic fields of external origin by subtracting a model field from the observed field, and then averaged the field data in each latitude-longitude mesh. From the DE-2 (low-altitude satellite) data, we found four vortices of horizontal magnetic field centered around (4MLT, 40N), (20MLT,40N), (4MLT,40S), and (20MLT,40S), which suggest the existence of mlatitude field-aligned currents connected to an inner magnetospheric transverse current. Another new feature, observed with the DE-1 (high-altitude satellite) magnetometer, is the altitude dependence of the disturbance field over the polar cap, which appears to indicate horizontal currents flowing at high-altitudes of several thouthand km in the dusk-to-dawn or dawn-to-dusk direction. We discuss the characteristics of these newly found current systems and their generation mechanism.

GA2.07/W//06-A1 1610

STATISTICAL CHARACTERISTICS OF THE MID-LATITUDE TROUGHS (LIT) AND LOW-LATITUDE SUBTROUGHS IN HE+ IONS DENSITY ON SEASON, LOCAL TIME AND MAGNETIC ACTIVITY

Larissa SIDOROVA and Alexander Karpachev (Institute of Terrestrial Magnetism, Ionosphere and Radiowave Propagation Russian Academy of Sciences, Troitsk, Moscow region, 142092, Russia, e-mail: golovkov@izmiran.rssi.ru)

Quantitative characteristics of the mid-latitude troughs (LIT) and the low-latitude subtroughs in He+ of the topside ionosphere (~1100 km) were obtained by statistical analysis of "ISS-b" satellite data set (~1100 orbits, F10.7~180). The trough occurrence probability variations on local time, season and magnetic activity have rather unexpected character. So, for a nighttime the LIT's occurrence probability is maximal in vernal equinox, by other hand, this probability in winter conditions, having being comparative with summer's one, is about 50% only. For a daytime the LITs, contrary to expectation, are rather frequent (~30%) in summer and occasionally in winter (5-10%). However the low-latitude subtrough characteristics have got more "correct" character. So, the subtrougs are more frequent in winter nighttime (30%). For a daytime the most of subtroughs are observed in summer only (~7-12%). The occurrence probability for the both troughs depends poorly on the magnetic activity. Their diurnal probability variations have the pre- and post-midnight maximums. It is shown that these ones are determined by the corresponding [He+] variations. The obtained results suggest the revision of the LIT's formation mechanism. It is shown, particularly, that the summer daytime LITs are formed by the competition between "winter bulge" in [He+] and polar wind. It is found also the strong [O+] effect on the [He+] behaviour. This influence is determined by the dynamics of the H+, He+ and O+ flows and increases with the latitude growth.

GA2.07/W/02-A1 1630

A MODEL STUDY OF THE MAIN IONOSPHERIC TROUGH AND PLASMAPAUSE RELATIONSHIP

A.V.Tashchilin and E.B.Romanova (both at Institute of Solar-Terrestrial Physics, Russian Academy of Science, 664033, Irkutsk, POBox 4026, Russia, e-mail: avt@iszf.irk.ru)

The main ionospheric trough (MIT) is a distinguishing structural feature of the subauroral ionospheric F2-layer. If the latitude range, in which MIT is located, is mapped along geomagnetic field lines into the equatorial plane, then the resulting set of values of the parameter L will also show an abrupt decrease in electron density which is called the plasmapause (PP). It was established that the formation of PP and MIT is dramatically affected by the magnetospheric convection electric field which leads to a spatial redistribution of thermal plasma in the ionospheric F-region and near the plane of the geomagnetic equator. This inevitably brings up the questions: Are these structures brought about by the operation of some general mechanism, and do other physical factors influence the observed characteristic properties of MIT and PP. In an effort to investigate the formation process of MIT and PP under quiet and disturbed conditions, a model has been developed for thermal plasma evolution at

heights over 150 km, applicable at middle, auroral and polar latitudes. The model calculates the density distributions of the O+, H+ and M+ ions and electrons, their temperatures, as well as charged particle and heat fluxes through a numerical integration of the magnetohydrodynamic equations of thermal plasma transport and the kinetic equation of photoelectron transport along the entire drifting dipole plasma tube, including both the northern and southern hemispheres. The model takes into account the production of ions as a result of photoionization and impact ionization by magnetospheric electrons, as well as the processes of interaction of charged particles with the thermosphere. We present and discuss the calculated latitudinal density and temperature profiles of charged particles in the subauroral F2-region, in the topside ionosphere, and in the geomagnetic equatorial plane, corresponding to 00, 06, 12 and 18 MLT for quiet conditions and during a disturbance such as a magnetic storm.

THE PERSISTENCE OF HIGH-LATITUDE CONVECTIVE FLOWS THROUGH NORTHWARD IMF TURNINGS AS EVIDENCE OF THE IONOSPHERIC DYNAMO

J. MICHAEL RUOHONIEMI and Raymond A. Greenwald (both at Johns Hopkins University, Applied Physics Laboratory, Johns Hopkins Rd., Laurel, MD, 20723, USA, email:mike_ruohoniemi@jhuapl.edu)

Convection in the magnetosphere is most often discussed in terms of the coupling of energy and momentum from the solar wind to the magnetosphere with the ionosphere acting as a more-or-less passive load. However, energy stored in the ionosphere-thermosphere system can be released through dynamo action resulting in an ionospheric driver for magnetospheric convection. One manifestation of this mechanism is the neutral flywheel effect, which, upon a change in the solar wind-magnetosphere coupling conditions, causes the pre-existing convective flows to exert an influence in the ensuing period. We have identified one particularly clear example of the neutral flywheel effect in SuperDARN HF radar observations of high-latitude convection, namely, the persistence of flows after IMF turnings from southward to northward at latitudes which are generally sub-auroral for IMF northward conditions. The coverage afforded by the combined radar fields of view approaches _ of the entire global convection pattern and the temporal resolution is usually 2 minutes. The convection is seen to evolve from an expanded pattern characteristic of Bz- to a contracted pattern characteristic of Bz+ with a gradual (~ tens of minutes) decay of velocity within the latitude interval that effectively loses its source for convection in the solar wind-magnetosphere coupling. We present several examples of this phenomenon and discuss the dependencies of the time constants that characterize the decay of convection. These can be interpreted in terms of the effectiveness of the ionospheric dynamo for driving magnetospheric convection.

GA2.07/W/15-A1 **1710**

THE RELATIONSHIP BETWEEN SUPERDARN DOPPLER VELOCITIES AND GROUND MAGNETOMETER DATA

C.L. Waters, M.D. Sciffer, I.S. Dunlop, F.W. Menk, F. Fenrich, and J.C. Samson

Doppler oscillations at ultra low frequencies (ULF) in HF signals that encounter the ionosphere have been observed and studied since the 1960s. Only recently has a suitably sophisticated theoretical treatment been developed to model these effects [Sutcliffe and Poole, 1989]. This model concerned Doppler oscillations in HF ionospheric propagation due to the shear Alfven ULF wave mode. In this paper we extend the treatment to include both the shear Alfven and fast mode ULF wave modes in the ionosphere. Given relevant ionospheric parameters and the ULF wave characteristics obtained from ground based magnetometers, the model predicts the associated Doppler oscillations as a function of altitude. These results are discussed within the context of SuperDARN Doppler data and ULF magnetometer data.

OBSERVATIONS OF ULF FIELD LINE OSCILLATIONS IN THE IONOSPHERE AND ON THE GROUND AT HIGH LATITUDES

Fred W. MENK (Department of Physics, CRC for Satellite Systems, University of Newcastle, Callaghan, NSW, 2308, Australia, email: hyspuls3@cc.newcastle.edu.au) Tim K. Yeoman, Darren M. Wright and Mark Lester (all at Department of Physics and Astronomy, Leicester University, Leicester, LE1 7RH, UK, email: dmw7@ion.le.ac.uk)

We examine an interval where Pc5 field line oscillations were recorded with the same frequency across the entire IMAGE and SAMNET magnetometer arrays, spanning 51 to 76 degrees latitude, and simultaneously in the high latitude ionosphere with the CUTLASS HF radar and an HF Doppler sounder experiment. A signature was also observed with a nearby imaging riometer. The event was triggered by a solar wind pressure pulse. This seems to have produced global mode oscillations in the magnetospheric cavity which coupled to field line resonances near the last closed field lines. The scale size and three-dimensional velocity vectors in the ionosphere are also determined.

GLOBAL APPEARANCE OF THE MHD SIGNALS INCIDENT TO THE HIGH-LATITUDE IONOSPHERE IN THE IONOSPHERE

Shigeru Fujita (Meteorological College, Kashiwa, Chiba, 277-0852, Japan, Email: sfujita@typhoon.mc-jma.ac.jp. Masahiro Itonaga, Department of Education, University of Yamaguchi, Yoshida, Yamaguchi, 753-8513, Japan, email: itonaga@po.cc.yamaguchi-u.ac.jp. Yutaka Ogawa, Kashiwa, Chiba, 277-0852, Japan, email: yogawa@tsunami.mc-jma.ac.jp.)

Pi2 and PRI are associated with the field-aligned current injected to the high- latitude ionosphere. Traditional theory on horizontal spread (transmission) of the ionospheric electric field has not considered the magnetosphere-ionosphere coupling. Therefore, we study again theoretically the horizontal spread of the ionospheric electric field.
There are two possible mechanisms of the horizontal spread. One is the Earth- ionosphere waveguide transmission that was first suggested by Kikuchi and Araki (1979). Another is the instantaneous spread of the ionospheric electric field within the ionosphere. Theoretical consideration revealed that the latter is effective in horizontal spread of the Pi2 and PRI signals.

SIMULATION OF THE KELVIN-HELMHOLTZ INSTABILITY IN THREE DIMENSIONS

Kristi KELLER and Robert Lysak (both at School of Physics and Astronomy, University of Minnesota, 116 Church St., Minneapolis, MN 55455, e-mail: kellerk@aurora.space.umn.edu)

The Kelvin-Helmholtz instability is a mechanism for transport at the magnetopause. The results from a compressible three-dimensional MHD simulation that is coupled to the ionosphere through the boundary conditions will be presented. We will examine the effect of time changing conductivities on the Kelvin-Helmholtz instability and current generation at the ionosphere. We will also explore how hemispheric asymmetries change the evolution of the Kelvin-Helmholtz instability. We will explore the relation between the formation of curl and spirals in the aurora with the Kelvin-Helmholtz instability and ionospheric boundary conditions. We will also examine the effect of ionospheric conductivity on field line resonance.

SEPARATION OF THE DIFFERENT TYPES OF THE [HE+] TROUGHS IN THE TOPSIDE IONOSPHERE

Larissa SIDOROVA and Alexander Karpachev (Institute of Terrestrial Magnetism, Ionosphere and Radiowave Propagation Russian Academy of Sciences, Troitsk, Moscow region, 142092, Russia, e-mail: golovkov@izmiran.troitsk.ru)

Mid-latitude light ion trough (LIT) and low-latitude subtrough characteristics, permitting to divide troughs precisely, are detected by the system analysis of the large "ISS-b" satellite data set. It is shown, particularly, that the LITs are more often observed in nighttime than in daytime and just a little more often -in winter than in summer. LITs locate close and rather equatorwards to the internal plasmapause during whole day. LITs together with internal plasmapause shift to the equator during geomagnetic activity increasing. More high-latitudinal LITs, connected with external plasmapause, are sometimes observed in summer day period. The subtroughs are observed in the wide belt of the invariant latitudes of ~25-55° practically independently from geomagnetic activity. In summer condition the subtroughs are usually detected in evening, in winter condition – after midnight. Averaged subtrough occurrence probability is higher in the Southern Hemisphere than in the Northern one. In general, the subtrough occurrence probability is less than that of LITs, but more than expected one. The subtrough characteristics and an appearance region have got complicated season-diurnal variations and depend on a hemisphere. All these variations determine an asymmetry of the Northern and Southern Hemispheres in inhomogeneous structure of the topside ionosphere.

ASYMMETRY EFFECT IN CHANGES OF PLASMA DENSITY AND TEMPERATURE AT THE MAIN IONOSPHERIC TROUGH LATITUDES IN CONJUGATED HEMISPHERES

STEPANOV A.E. Zikrach E.K., Khalipov V.L., Plotnikov I.Ya., Shestakova L.V. (Institute of Cosmophysical Research and Aeronomy, 677891 Yakutsk, Russia, email: ikfia@sci.yakutia.ru) Afonin V.V. (Space Research Institute, 117810 Moscow, Russia, email: vafonin@esoc1.bitnet)

On data of the "Cosmos-900" satellite the variations of electron density (Ne) and temperature (Te) at latitudes of a main ionospheric trough in conjugate hemispheres in different conditions of geomagnetic activity are investigated. The measurements are analysed during an equinox, when the conditions of light exposure are identical in both hemispheres. Is revealed that in quiet geomagnetic conditions the magnitude of Te in a minimum of a trough in northern hemisphere is higher, than in southern. The appropriate significance of Ne in northern hemisphere, on the contrary, is lower than Ne in a southern hemisphere. During geomagnetic disturbances the character of modifications of Ne and Te in a minimum of a trough in both hemispheres varies on opposite. The physical explanation of the observable phenomenon is offered.

GA2.07/E/04-A2 Poster **0930-05**

NIGHTTIME VARIATIONS OF THE IONIZATION IN F REGION

Bienvenido LAZO , Amada Toledo Ricardo Dmaz , Alexander Calzadilla Departamento de Geofmsica Espacial, IGA/CITMA, Calle 212 No 2906, La Lisa, C.P. 11600,C. de La Habana, Rep. de Cuba

Experimental evidences of nighttime seasonal anomaly in ionospheric observations of ground-based vertical sounding and Faraday rotation carried out in Havana (23,0 N; 82,5 W), are given. Favoring conditions for mechanisms of interhemispheric coupling to explain the enhancement of ionization during winter nighttime are subject to discussion. The results of physical modelling of the interhemispheric coupling in the American sector (L=1,5) during low solar activity, are shown The anomalous behavior of NmF2 in connection with solar activity was analyzed. It was established that seasonal anomaly is manifested only in night conditions for R12 values ranging from 5 and 16,i. e., in low solar activity conditions, favored by plasma fluxes directed in the winter season from the Southern to Northern hemisphere. For values of the R12 parameter larger than 35 thermospheric composition changes dominate and ion-drag effectivity increases, whish benefits the existence of winter foF2 values larger than those of the summer, in day conditions. The space distribution of the anomalous behaviour, both diurnal and nocturnal, of the electronic concentration was also studied and established. At the height of 250 Km, the electronic concentration displays an anomalous nocturnal behaviour for the studied five levels of solar activity, i.e., the winter values of foF2 are larger than those of the summer, which could suggest that the interhemispheric coupling through the protonosphere is the main physical mechanism responsible of the winter night-time anomaly for heights lower than hmF2 in a wider range of solar activity.

FIELD-ALIGNED CURRENT PATTERN ON THE IONOSPHERIC DATA

Alla M. LYATSKAYA (Institute of Physics, University of St.-Petersburg, St.-Petersburg 198904, Russia; e-mail: lyatsk@snoopy.phys.spbu.ru)

The small-scale spatial structure of the fieldaligned current (FAC) is known always present at high latitudes. Instantaneous FAC pattern occurred during substorm has constructed from ionospheric parameters obtained by means of ground-based observations. Such construction of the FAC structure by means of ionospheric data is confirmed by results of the carried out study of the connection between the time-spatial structures of the field-aligned current and the ionospheric blanketing frequency fBEs for both positive and negative IMF Bz and By components during quiet and active magnetic activity: 1) a coincidence of the regions of the upward and downward FAC with the regions of enhancements and decreases of fBEs; 2) the observed dawn-dusk asymmetry in the behavior of fBEs with the increase of the magnetic activity; 3) the existence of the sharp latitude gradient of the fBEs near midnight what may be

connected with the narrow sheet of the upward field-aligned current in the Harang discontinuity region; 4) the opposite behavior for By < 0 and By > 0.
Field-aligned current pattern over the sheets of high conductivity was obtained by means of the numerical modelling with taking into account the coupling with the ionospheric layers, and magnetosphere.

HF WAVES AS A TOOL TO DIAGNOSE IONOSPHERIC–MAGNETOSPHERIC COUPLING IN THE MAIN IONOSPHERIC TROUGH

H. Rothkaehl Space Research Centre PAS, Bartycka 18A, 00-716 Warsaw, Poland

The region of the main ionospheric trough acts like a lens focusing a variety of instabilities and disturbances from different re-gions of the Earth's environment. The theoretical approach and the satellite measurements at the vicinity of the plasmapause at the top-side ionosphere as well as more recent trough data derived from analysis of HF radio spectrometer located on the board of Magion-3 satellite confirmed that ionospheric trough and plasmopause lay very close to each other. The aim of this paper is present the evolution of plasmapause position and the minimum of the trough during strong geomagnetic disturbances and to analyse the physical mechanism responsible for the generation broad band HF emission over ionospheric trough area.

HIGH LATITUDE GEOMAGNETIC VARIATION REFERENCE FIELD MODELS FOR 20-22 SOLAR ACTIVITY CYCLES

Vladimir Papitashvili (Space Physics Research Laboratory, University of Michigan, Ann Arbor, MI 48109, USA, email: papita@umich.edu) Boris BELOV (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation, IZMIRAN, Troitsk, Moscow Region, 142092, Russia, email: bbelov@adonis.iasnet.ru) Natalia Papitashvili (Raytheon STX and NSSDC, NASA/Goddard Space Flight Center, Greenbelt, MD 20771, USA, email: natasha@nssdca.gsfc.nasa.gov)

We present a newly obtained set of linear regression models of the ground magnetic response on 1-nT changes in the corresponding interplanetary magnetic field (IMF) components for the 20-22 solar activity cycles (from 1965 to 1997). These models are obtained over both the northern and southern polar regions and for different seasons of a year (summer, winter, and equinox). Data from 116 magnetic observatories were collected and quality controlled. The hourly means of the IMF and ground geomagnetic field components are analyzed utilizing the linear "black box" approach. The spherical harmonic analysis is applied to obtain a set of harmonic coefficients capable of modelling the ground geomagnetic responses on changing IMF conditions for any time instance between 1965 and 1997. The new set of models is compared with similar models obtained during the development of IZMIRAN Electrodynamic Model for two solar activity maximums (1968-1969 and 1979-1983). It shown that generally there are little differences in the models harmonic coefficients through the solar activity cycles. This allows us to apply the obtained results beyond of the studied interval. Validation of the new linear regression models against magnetic observatory data is also presented and discussed.

GA2.07/W/31-A2 Poster **0930-09**

A MECHANISM OF ANTICORRELATION IN OCCURRENCE OF ULF ELECTROMAGNETIC NOISE RESONANCE STRUCTURE AND PC 1 OBSERVATIONS WITH THE SOLAR ACTIVITY CYCLE

V. Y. Trakhtengerts, A. G. DEMEKHOV (both at: Institute of Applied Physics, Nizhny Novgorod, Russia; email: andrei@appl.sci-nnov.ru) P. P. Belyaev, S. V. Polyakov, E. N. Ermakova, and S. V. Isaev (all at: Radiophysical Research Institute, Nizhny Novgorod, Russia)

The observed anticorrelation between the 11-year solar activity cycle and occurrence of Pc~1 geomagnetic pulsations as well as the resonance structure of the electromagnetic noise spectrum (RSS) in frequency range 0.1-10 Hz is explained based on the role of ionospheric Alfven resonator (IAR) in formation of both phenomena. The relfection coefficient R of Alfven waves from IAR determines the threshold of the ion cyclotron instability (CI) which is the cause of Pc~1 pulsations. At the same time the quality of IAR, which varies synchronously with R, controls the RSS modulation depth. It is shown that the decrease of |R| maximum value during the maximum phase of the solar activity cycle remarkably increases the CI threshold and sharply decreases the modulation depth of RSS, thus decreasing the occurrnece probability of both phenomena.

LONG-TIME TRENDS IN F2-LAYER OF SUBAURORAL IONOSPHERE

Smirnov V.F., Kobyakova S.E.(Institute of Cosmophysical Research and Aeronomy, 677891 Yakutsk, Russia, email: ikfia@sci.yakutia.ru)

On data of vertical sounding on an Yakutsk station are considered long-time variation of F2-layer parameters for period 1956-1995. Statistical analysis of time series of midday and midnight values of foF2 and h'F parameters is conducted with the purpose of determination maximum and minimum values of subauroral ionosphere parameters, their cyclical, annual and seasonal variations, parameter variability on different phases of a solar cycles. Is shown that for the last three cycle of solar activity there is a tendency of growth average values of height of a F-layer, increasing tendency of maximum values of critical frequencies of a F-layer within a maxima of solar activity and decreasing of critical frequencies within a minimum of activity. It is shown the close connection of height growth of a F-layer with growth of average value temperatures in near-earth atmospheric layer for winter conditions.

THE MAGNETOPAUSE AND ITS BOUNDARY LAYERS

T.G. ONSAGER

The magnetopause and its boundary layers have a critical role in controlling the coupling between the solar wind and the magnetosphere/ionosphere/thermosphere system. The magnetosheath boundary layer, the low latitude boundary layer, the cusp, and the mantle all are controlled directly by the processes occurring in the magnetopause as driven by the solar wind/magnetosheath conditions. An emphasis over the past two years has been on the properties of the magnetopause and its boundary layers at high latitudes and on the flanks of the magnetosphere. New satellite observations have provided many insights on the plasma transport processes in these regions, including reconnection and non-reconnection related mechanisms, and on the dependence of these processes on the orientation of the interplanetary magnetic field. Numerical simulations have given new results on the large-scale properties of the magnetopause and transport across it, as well as on the small-scale processes occurring within the magnetopause. Recent progress on magnetopause studies will be reviewed, and future directions of this research will be discussed.

REPORTER REVIEW: DYNAMICS OF THE GEOMAGNETIC TAIL

T. I. PULKKINEN (Finnish Meteorological Institute, Helsinki, Finland)

The ISTP program that became fully operational in1996 has now continued measurements through the solar minimum to the rising solar activity period. A substantial data set covering solar, solar wind, magnetospheric, and ionospheric observations now has been collected and partially analyzed. The past two years have brought the solar community together with the magnetospheric and ionospheric communities in an unprecedented manner with several analyses that have followed the detailed sequence of events from solar events to near-Earth geomagnetic activity. Simultaneously, a vast amount of new results have been obtained about the detailed structure of the magnetotail and its dynamics during geomagnetically active events.Recent results of the analysis of the Solar-Terrestrial chain of events especially from the magnetotail point of view are reviewed.

THE INNER MAGNETOSPHERE

J. U. KOZYRA (Space Physics Research Lab, University of Michigan, 2455 Hayward, Ann Arbor, Michigan 48109-2143 USA, email: jukozyra@engin.umich.edu)

The physics of the inner magnetosphere is key to our understanding of magnetic storm development and recovery. It is also the region where radiation belts are created and linger and thermal plasmas of ionospheric origin reach their highest densities in the magnetosphere. The perturbations to the inner magnetospheric plasmas and fields, associated with elevated magnetic activity, have served as a focal point for investigations into the dynamics of this region and its coupling to the solar wind, magnetotail and ionosphere. Intense interest exists in understanding: (1) the role of composition, importance of variations in the source populations, and impact of non- adiabatic processes and structured electric fields in the ring current development and decay, (2) the acceleration mechanisms, solar wind drivers and source populations for the radiation belts, (3) the electrodynamic and energetic processes that structure the thermal plasma, possibly preconditioning the inner magnetosphere and impacting storm development, and (4) the redistribution of energy by interactions between different plasma populations. All of these processes play a role in the global energy balance and its variation among storms with different characteristics and different solar wind drivers. A review of current research on these and other issues relevant to our developing understanding of inner magnetospheric physics will be presented.

LARGE-SCALE FIELDS AND FLOWS IN THE IONOSPHERE-MAGNETOSPHERE SYSTEM

R. A. WOLF (Rice University MS 108, P. O. Box 1892, Houston, TX 77251 U.S.A.)

An attempt will be made to review the progress of the last several years, refining our understanding of large-scale plasma flow, electric currents, and electromagnetic fields in the Earth's magnetosphere-ionosphere system. Geotail observations of the inner and middle plasma sheet have clarified crucial aspects of the substorm problem. Energetic neutral atom images of the inner magnetosphere, mainly from the Polar spacecraft, have begun to provide useful information on the injection of the ring current. Knowledge of the electric-field coupling between the inner and middle magnetosphere has improved as a result of careful analysis of older data from the CRRES spacecraft and incoherent-backscatter radars. On the theoretical side, global MHD models have continued to proliferate and to serve with increasingly effectiveness both as data-analysis tools and as sources of theoretical ideas. The connection between basic research and the effort to achieve improved space-weather forecasts continues to strengthen and to motivate areas of research. For years, many theorists have expressed the philosophical view that proper quantitative representation of the large-scale behavior of the entire magnetosphere-ionosphere system will require synthesis of theories and models that utilize different formalisms and operate on different regions and scales; in the last few years, modest but significant practical steps have been taken in the direction of theoretical synthesis.

WAVE PARTICLE INTERACTIONS

Yoshiharu OMURA (RASC, Kyoto University, Uji, Kyoto 611-0011, Japan, Email: omura@kurasc.kyoto-u.ac.jp)

Roles in wave growth/damping, particle heating and diffusion, and mesoscale phenomena such as magnetic reconnections through anomalous resistivity. Recent spacecraft observations have been yielding coordinated high-quality wave and particle data with finer resolution than those of the previous observations, making it possible to compare the observations with theory and simulations quantitatively. Computer simulations based on particle, hybrid and Vlasov codes have been performed to clarify nonlinear wave-particle interaction that are absent in MHD or multi-fluid description. Nonlinear ion dynamics have been followed self-consistently by hybrid codes in realistic open and nonuniform systems. With such simulations, the signatures of ions at different regions of the magnetosphere have been clarified. Much work still needs to be done in two and three-dimensional configurations, where different types of instabilities and processes compete or couple with each other. High-energy electrons can carry information concerning acceleration and heating processes occurring at a distant location along the magnetic field. However, the high energy electrons are also subject to strong wave-particle interactions and thus to nonlinear processes, whose evolution in space and time cannot be described by quasi-linear theory or simple simulations in a uniform system. Many more studies are necessary, along with more powerful computational capabilities, in order to clarify nonlinear electron dynamics in realistic nonuniform systems.

MAGNETOSPHERES OF OTHER PLANETS

Vytenis M. VASYLIUNAS (Max-Planck-Institut fuer Aeronomie, D-37191 Katlenburg-Lindau, Germany, e-mail: vasyliunas@linmpi.mpg.de)

Planets with well-defined magnetospheres include, in addition to Earth, Mercury, Jupiter, Saturn, Uranus, and Neptune. Most attention continues to be devoted to the magnetosphere of Jupiter, where data from the Galileo orbiter have possible systematic, extended-time-scale studies of the configuration and dynamics of the magnetosphere and have also revealed a great variety of different interactions between the magnetosphere and the moons of Jupiter, including the magnetosphere-within-magnetosphere case of Ganymede. Speculations about similarities or differences between the magnetospheres of Earth and of Jupiter can now, with the availability of orbiter data from both, rest on a firmer ground. Second in the amount of attention is the magnetosphere of Saturn, with the Cassini/Huygens orbiter/probe mission now on the way to the planet.

AURORAL PROCESSES AND MIT COUPLING - 1

GA3.06/W/19-A2 Invited **0930**

WHAT OBSERVATIONS BY THE FAST SATELLITE REVEAL ABOUT AURORAL MIT COUPLING

Charles W. Carlson (Space Sciences Lab, University of California at Berkeley, Berkeley CA 94720, USA, email: cwc@ssl.berkeley.edu)

The FAST satellite observes auroral processes relevant to MIT coupling on scales ranging from micro- to macroscale. The largest scale is organized around the major field-aligned current systems that connect the magnetosphere and ionosphere in the auroral zone. Magnetic field-aligned potential drops arise in both upward and downward current systems. Precipitating electrons carrying upward current deposit energy into the ionosphere, causing ionization and heating. In downward current regions, upward accelerated electrons and heated ions are a source of new populations of particles for the magnetosphere. Microphysical processes associated with the parallel potential drops are responsible for intense heating and outflow of ionosphericions, and these processes also accelerate escaping ionospheric electrons to energies of hundreds of eV. These parallel potential drops also decouple the magnetospheric and ionospheric flows in localized regions.

THE FREJA PERSPECTIVE ON THE AURORAL CURRENT CIRCUIT

GVRAN MARKLUND and Tomas Karlsson, Alfvin Laboratory, The Royal Institute of Technology, SE10044 Stockholm, Sweden e-mail: marklund@plasma.kth.se

The recent discovery that particle acceleration to keV-energies is a common feature not only on auroral field lines in the upward current region but also on 2black auroral field lines2 in the return current region makes it necessary to consider the entire auroral current circuit for understanding the auroral phenomenon. Assuming a current generator that drives the auroral currents, particle acceleration is necessary to maintain the current at times and regions of low plasma density. The altitude distribution and intensity of the acceleration region will thus depend strongly on the local ambient plasma conditions, and thus vary with local time, season and magnetic activity level. A lowering of the acceleration region and increase in acceleration energies are features characteristic of nightside and wintertime plasma conditions. Although much information has been obtained by various spacecraft at different altitudes on auroral electric field, current, particle and plasma characteristics, the results need to be combined in order to obtain a coherent picture on how the acceleration region is influenced by season, local time and activity level within the upward and downward current region. An effort of this kind has been initiated using relevant data from the Viking, Polar, Freja and FAST satellites supplemented by results from other satellites reported on in the literature. First results of this study will be reported.

FIELD-ALIGNED CURRENTS AS SEEN BY THE POLAR AND INTERBALL-2 DURING 11 JANUARY 1997 EVENT

A.Z. Bochev 1, Guan Le 2 , V.G. Petrov 3 , D.L. Danov 1 , Y.I. Feldstein 3, P.T. Newell 4 1 Solar - Terrestrial Influences Laboratory, BAS, Sofia, Bulgaria 2 Institute of Geophysics and Planetary Physics, Los Angeles, USA 3 Institute of Earth?s Magnetism and Radiowave Propagation (IZMIRAN), Moscow, Russia 4 Applied Physics Laboratory, The John Hopkins University, Laurel, USA

In this talk field-aligned currents (FAC) in the north auroral magnetosphere during the CME geomagnetic storm on January 11,1997 are examined by using data mainly from magnetic field experiments on board of INTERBALL-2 and POLAR satellites. During the event from 0300 to 0600 UT, the spacecrafts crossed the dusk side from low to high latitudes in the altitudinal range 12000 to 40000 km. FAC structures were identified for sure on both magnetograms. The measurements permitted to monitor two unusual FAC systems separated from each other. The equatorward system was a remarkable demonstration of intense oscillating fields during steady IMF Bz >>0, immediately after the end of the most dramatic compression of the magnetosphere. In contrast the poleward system appeared as irregular structures probably controlled by a strong unsteady IMF By. Correlations with double-theta aurora are discussed also.

GA3.06/W/42-A2 **1110**

POLAR OBSERVATIONS OF INTENSE ELECTRIC FIELDS AND POYNTING FLUX NEAR THE PLASMA SHEET-TAIL LOBE BOUNDARY AT HIGH ALTITUDE

A. KEILING, J.R. Wygant, C. Cattell, M. Johnson (School of Physics and Astronomy, University of Minnesota, Minneapolis, MN, USA, email: wygant@ham.space.umn.edu) M. Temerin, F.S. Mozer (Space Sciences Laboratory, University of California, Berkeley, CA, USA) C.A. Kletzing, J.D. Scudder (Department of Physics and Astronomy, University of Iowa, IA, USA) W. Peterson (Lockheed-Martin Palo Alto Laboratories, Palo Alto, CA, USA) C.T. Russell (IGPP, University of California, Los Angeles, CA, USA) G. Parks, M. Brittnacher (Geophysics Program, University of Washington, USA) W. Lotko (Dartmouth College, Thayer School of Engineering, Hanover, NH, USA)

In this talk, we present measurements from the Polar spacecraft of intense electric field structures near the outer boundary of the plasma sheet, at altitudes of 4-6 Re near local midnight. The electric field variations have maximum values exceeding 100 mV/m and are typically polarised approximately normal to the plasma sheet boundary. The electric field structures vary over time scales (in the spacecraft frame) ranging from 0.1 to 30 seconds. They are associated with strong magnetic field fluctuations. The Poynting flux measured at these altitudes is about 1-2 ergs/cm2s and is directed along the magnetic field towards the ionosphere. If the measured Poynting flux is mapped to ionospheric altitudes along converging magnetic field lines, the resulting energy flux can exceed 100 ergs/cm2s. Simultaneous UVI

images of aurora demonstrate that these structures occur during periods when the Polar spacecraft is magnetically conjugate (to within a one-degree-mapping accuracy) to intense auroral structures. The electron energy flux (averaged over a spatial resolution of 0.5 degrees) deposited in the ionosphere due to electron beams as estimated from UVI images is 20-30 ergs/cm2s. Thus, there is strong evidence that these electric field structures provide sufficient Poynting flux to power the acceleration of auroral electrons (as well as the energisation of up-flowing ions and joule heating of the ionosphere). The E/B ratios are about 4000-10000 km/s which is consistent with Alfvenic variations, but is an order of magnitude larger than those expected for the typical values of the height integrated conductivity of the ionosphere. Minimum variance analysis…

AUREOL-3 SATELLITE OBSERVATIONS OF MULTIPLE INVERTED-V STRUCTURESAND HOT PLASMA STRATIFICATION THEORY

M. V. STEPANOVA, O. Luizar (both at Universidad de Santiago de Chile, Ecuador 3493, Casilla 307, Santiago, Chile, email: mstepano@lauca.usach.cl, oluizar@lauca.usach.cl), E. E. Antonova, (Skobeltsyn Institute of Nuclear Physics, Moscow State University, Moscow 119899, Russia, email: antonova@taspd.npi.msu.su), J. M. Bosqued, (Centre d'Etude Spatiale des Rayonnements, CNRS/UPS, BP 4346, 31029 Toulose, France, email: Jean-Michel.Bosqued@cesr.fr), and R. A. Kovrazhkin (Space Research Institute, Academy of Sciences of Russia, Profsoyuznaya 84/32, Moscow 117810, Russia, email: kovrazkin@romance.iki.rssi.ru)

During the analysis of multiple inverted-V structure formation using AUREOL-3 satellite data, cases of formation of one, two, three and four structures are identified. This corresponds to the longitudinal stratification of the upward field-aligned current into extended in latitudinal direction multiple current sheets. This number is compared with the predicted by a hot plasma stratification theory. The theory is based on the suggestions, that plasma in the center of plasma sheet is in magnetostatic equilibrium, and plasma sheet ion motion is unmagnetized for the spatial scales in which the structures are formed. The solution of the magnetosphere-ionosphere interaction problem shows that upward field-aligned current may split into separate sheets. This number is determined by a parameter which depends on current density, current band width, hot magnetospheric ion temperature, and height-integrated Pedersen conductivity. It was found that in the majority of cases, the theory predicts well the number of observed structures.

GA3.06/W/01-A2 Invited 1150

THE AURORAL ACCELERATION REGION IN GLOBAL MHD SIMULATIONS

Joachim RAEDER (Institute of Geophysics and Planetary Physics, University of California, 405 Hilgard Ave, Los Angeles, CA 90095, USA, email: jraeder@igpp.ucla.edu)

The auroral acceleration region provides the interface between magnetospheric and ionospheric dynamics. Thus, any realistic global model of the magnetosphere - ionosphere system must include the acceleration region to some degree. For obvious reasons it is impossible to model the acceleration region down to microscales, or even mesoscales; therefore parameterizations of the microphysics in the auroral regions must be used. However, although the acceleration region is not treated with ab-initio calculations of the acceleration processes, global modelling is well suited to study the effects of different parameterizsations on the global magnetospheric dynamics. Because the parameterizations used in the global model embody our current understanding of the acceleration processes, the global model provides a means to test their validity. We present several case studies in which we compare the model predictions with in-situ observations and discuss what the model can tell us about the auroral acceleration processes.

GA3.06/W/03-A2 1220

PHASE-SPACE MAPPING SIMULATIONS OF STORMTIME DIFFUSE AURORAL (PLASMASHEET) ELECTRONS IN STRONG PITCH-ANGLE DIFFUSION

Margaret W Chen (Space & Environment Technology Center, The Aerospace Corporation, M2-260, P. O. Box 92957, Los Angeles, CA 90009, USA, e-mail: mchen@aero.org) Michael SCHULZ (Lockheed Martin Advanced Technology Center, O/H1-11, B/255, 3251 Hanover Street, Palo Alto, CA 94304, USA, e-mail: schulz@agena.spasci.com)

Strong pitch-angle diffusion so thoroughly randomises the first two adiabatic invariants of charged-particle motion that it conserves a phase-space volume Lambda, equal to the cube of the particle momentum p times the occupied flux-tube volume per unit magnetic flux. We trace drift shells of plasmasheet electrons with representative values of Lambda in a magnetic field model that consists of a dipole field plus a uniform southward field. Using the simulated drift shell results, we map phase-space densities from the neutral line according to Liouville's theorem (modified by attenuation due to particle precipitation) and compute corresponding rates of energy deposition into the auroral ionosphere along the trajectories and at the energies corresponding to the conservation of Lambda. In the past we have applied a time-independent Stern-Volland electric-field model with a 25-kV cross-tail potential drop to represent quiescent conditions. Our quiet-time simulation results show a paucity of precipitating energy flux in the afternoon sector, in qualitative agreement with the "darkness" of POLAR/PIXIE X-ray images of the diffuse aurora in that sector. In this work we apply a larger (storm-associated) cross-tail magnetospheric electric field enhanced by impulses to represent substorm effects. We compute the energy deposition rate and characteristic energy of the precipitating electron spectrum as functions of magnetic latitude and local time during a model storm for indirect comparison with observational data on precipitation-induced ionospheric conductivities and with spectral characteristics of X rays detected by PIXIE.

AURORAL PROCESSES AND MIT COUPLING - 2

GA3.06/W/15-A2 Invited 1400

AURORAL ARCS AND AURORAL STRUCTURES PRODUCED BY SHEAR ALFVEN FIELD LINE RESONANCES

John C. SAMSON, R. Rankin, and I. Voronkov (all at Department of Physics, University of Alberta, Edmonton, Alberta, Canada T6G 2J1, email: samson@space.ualberta.ca) V. Tikhonchuk (P. N. Lebedev Physics Institute, Russian Academy of Sciences, Moscow 117924, Russia)

Abundant experimental evidence now indicates that ULF (1-5 mHz), shear Alfven field line resonances produce some types of auroral arcs. Dispersive effects in the FLR, including electron inertia, can lead to parallel electric fields, and acceleration of electrons to form auroral arcs with overall latitudinal scale sizes of about 10 km, with 1 km scale discrete arcs embedded in the larger structure. Non-linear effects, including ponderomotive forces in the FLR, can lead to density cavity formation in the acceleration region, and an even more rapid onset of dispersive effects. In this talk, we will review observations, computational models, and recent non-linear theories of these FLRs and address the issue of magnetosphere ionosphere coupling through FLRs.

GA3.06/W/27-A2 1430

DEVELOPMENT OF SMALL-SCALE STRUCTURES IN AURORAL ARCS

Robert L. LYSAK (University of Minnesota, 116 Church Street SE, Minneapolis, MN 55455, USA)

Auroral currents and fields form on scales from 100 km to scales less than 1 km, the scale of individual auroral arcs. The formation of structure on such a variety of scales is examined through a model of auroral currents and fields involving the propagation of Alfvén waves along auroral field lines. Large-scale parallel electric fields can be involved in the larger scale structures, and can lead to decoupling of the magnetosphere and ionosphere on scales less than a few tens of kilometers. Smaller scale Alfvénic structures can be formed from non-linear effects, the interactions of Alfvén waves with perpendicular gradients in the density, or through ionospheric feedback. The roles of these phenomena in producing the spectrum of scales observed in auroral structures will be examined.

GA3.06/E/01-A2 1450

FIELD LINE RESONANCE INTERFERENCE MODEL FOR MULTIPLE AURORAL ARC GENERATION

Wladislav LYATSKY (Polar Geophysical Institute, Apatity, 184200, Russia, email: lyatsky@pgi-ksc.murmansk.su) R. D. Elphinstone, Q. Pao, and L. L. Cogger (all at Institute for Space Research, University of Calgary, Calgary, Alberta, Canada T2N 1N4, email: rob@hobbes.phys.ucalgary.ca)

A simple model for the generation of poleward moving multiple auroral structures in the nightside ionosphere is described. The model is based upon the premise that field line resonance oscillations are responsible for auroral arc generation. The auroral structures are considered to be a result of interference between Alfven field line resonance oscillations on different L shells. Because of the dependence of the Alfven resonance frequency on L shell, any two neighbouring L shells which oscillated initially with the same phase, after some time appear to be in opposite phase. that results in the appearance of counter- directed electric fields at these L shells and a large field-aligned current between them, which can produce the electron acceleration along the magnetic field and be responsible for auroral arc generation. The out of phasing between the oscillating L shells begins first at low latitudes and then propagates poleward producing poleward moving auroral arcs. The field line resonance interference model explains periodic behavior in such auroral activity having frequencies in the Pc5 range. The poleward propagation of the auroral arcs in this model is a result of the poleward propagation of interference maxima rather than any real plasma or wave propagation.

GA3.06/W/35-A2 1510

PARALLEL ELECTRIC FIELD GENERATION BY AN ALFVEN WAVE IN A MIRROR FIELD

Tadas K. NAKAMURA (Fukui Prefectural University, Fukui 910-1195, Japan, e-mail: tadas@fpu.ac.jp)

In a simple classical picture, the parallel (to B field) electric field of Alfven waves is negligibly small. This is because the high mobility of electrons enables this small electric field to cause enough field aligned current in the MHD scale. On the other hand, there are models that predict the existence of parallel electric field in a static limit. For example, the model by Knight (PSS, 1973) suggests that a finite parallel electric field is required to create a finite field aligned current in a mirror field. To solve this contradiction, it is proposed in this paper that an Alfven wave must have an parallel electric field due to the mirror effect. In a converging magnetic field, mobility of electrons is restricted by the mirror force and a parallel electric field must exist to carry a field aligned current associated with Alfven waves. The parallel electric field created by this mechanism can be much larger than that of a kinetic or inertial Alfven wave.

GA3.06/E/07-A2 Invited 1550

IONOSPHERIC ION OUTFLOWS AND THEIR EFFECTS ON THE MAGNETOSPHERE

Andrew W. Yau (Department of Physics and Astronomy, University of Calgary, Calgary, Alberta, Canada T2N1N4; and Herzberg Institute of Astrophysics, Dominion Astrophysical Observatory, Victoria, BC, Canada V8X4M6, e-mail: yau@space.phys.ucalgary.ca)

A number of ion flow and energisation processes contribute to the outflow of ionospheric ions to the magnetosphere. These include bulk ion flows such as the polar wind and auroral bulk upflows, and energisation processes such as upflowing ion beams, conics, and transversely accelerated ions. The overall rate of ion outflows is strongly dependent on magnetic and solar activity, and sometimes exceed 3 x 10^26 O+ ions/sec and 1 x 10^26 H+ ions/sec. We will review observations of ion outflow processes from both recent and earlier satellites, and discuss their morphological characteristics. In addition, we will assess their relative contributions to the overall outflow, and their effects on the composition and dynamics of the magnetosphere.

GA3.06/W/22-A2 1620

DOWNWARD ION ACCELERATION IN THE LARGE-SCALE DOWNWARD CURRENT REGION

D M KLUMPAR, M H Boehm (Lockheed Martin, Advanced Technology Center, Space Physics Laboratory, Palo Alto, CA 94304; e-mail: klump@sierra.spasci.com); C W Carlson, J P McFadden, M A Temerin (University of California at Berkeley, Space Sciences Laboratory, Berkeley, CA 94720); and R J Strangeway (University of California at Los Angeles, Institute of Geophysics and Planetary Physics, Los Angeles, CA 90095)

Using ion spectrometers on the FAST Auroral Snapshot Explorer we have observed striking field-aligned ion precipitation features imbedded in the auroral plasmasheet precipitation. The identification and cataloguing of dozens of events along with the detailed examination of specific events reveal the following characteristics. The ion precipitation structures occur within the large-scale downward current region and are frequently found in the pre-midnight MLT sector. In this MLT sector they are located well equatorward of the discrete aurora commonly associated with electron inverted-Vs and upward moving ion beams. Ion mass spectrometer measurements reveal that the ions are dominantly hydrogen. This new class of ion precipitation feature has a very characteristic energy-time profile. Individual events are narrowly confined in latitude (typically < 1 degree), and display a latitude profile similar to

electron inverted-Vs. The flux versus energy spectral distributions are peaked, with the peak energy first rising and then falling with increasing latitude. Peak characteristic energies often reach 1 keV. The phase space density distributions are ring-like, with an ionospheric loss cone, as would be expected for a population that has been accelerated downward into a converging magnetic field. The downward ion beams are easily distinguished from the more energetic precipitating plasmasheet ions observed on the same or adjacent flux tubes, and carry an order of magnitude or more greater differential energy flux. The observations are consistent with the downward acceleration of ions through a quasi-static, downward-directed, parallel potential structure lying above the satellite. It is likely that the quasi-static potentials that are commonly observed at FAST to be accelerating electrons upward can, at times, move to a location above the FAST orbit producing these downward moving ion beams.

GA3.06/W/37-A2 1640

PONDEROMOTIVE UPWARD ACCELERATION OF IONS UNDER THE ACTION OF ULF WAVES OVER THE POLAR REGIONS

R. LUNDIN, (Swedish Institute of Space Physics, Kiruna, Sweden) A. Guglielmi, (Institute of Physics of the Earth, Moskow, Russia)

A ponderomotive theory, describing the acceleration of magnetospheric ions along geomagnetic field lines, is developed and compared with Viking and Freja satellite observations. The theory is in agreement with observations of ULF electric field fluctuations correlating with the upward escape of ions. Attention is here focused on the non-resonant acceleration of the polar wind and the resonant acceleration of a small admixture of heavy ions under the action of Alfvén and ion cyclotron waves. We show that the critical point of supersonic transition shifts toward the Earth under the ponderomotive action of waves, and the velocity, as well as the acceleration of the flow at this point increase as the wave amplitude increases. The asymptotic behavior of the flow is also modified substantially under the action of waves. In particular high amplitude Alfvén waves results in field aligned small-scale plasma density depletions observed by polar orbiting satellites. We show that the gain in energy of heavy ions under favourable conditions increases as the power of one of the wave amplitude (*e = E) despite the fact that the ponderomotive force (magnetic moment "pumping") is proportional to the power of two of the wave amplitude (F = E^2).

GA3.06/E/11-A2 1700

HIGH- AND LOW-ALTITUDE OBSERVATIONS OF ADIABATIC PARAMETERS ASSOCIATED WITH AURORAL ELECTRON ACCELERATION

Kazuo SHIOKAWA (Solar-Terrestrial Environment Laboratory, Nagoya University, 3-13, Honohara, Toyokawa, Aichi 442-8507, Japan, email: shiokawa@stelab.nagoya-u.ac.jp) W. Baumjohann and G. Haerendel (Max-Planck-Institut fuer extraterrestrische Physik, 85740 Garching, Germany, Email: bj@mpe-garching.mpg.de) H. Fukunishi (Faculty of Science, Tohoku University, Sendai 980-0845, Japan, Email: fuku@pat.geophys.tohoku.ac.jp)

Electron density and temperature, adiabatic thermal current, and field-aligned conductivity have been estimated on the basis of observations by the DMSP satellites above the auroral oval and from measurement by the AMPTE/IRM satellite in the near-Earth plasma sheet. We found that the estimated densities are comparable between these two satellites, while the temperatures obtained from an accelerated Maxwellian fitting procedure used on the DMSP spectra are lower by a factor of 2-3 than those measured by IRM in the near-Earth plasma sheet. The DMSP data show that a large field-aligned potential difference, which accelerates auroral electrons downward, is formed in the region with low field-aligned conductivity. The AMPTE/IRM data show that the field-aligned conductivity decreases with increasing Xgsm-distance, increasing AE index, and after earthward high-speed flow passage. We suggest from these results that large field-aligned potential difference tend to be formed in higher latitudes of the auroral oval (which is connected to larger Xgsm-distances), during high magnetic activity, and in the newly dipolarized magnetic field region after the flow passage.

GA3.06/W/29-A2 1720

ON THE MASS DEPENDENCE OF TRANSVERSE ION ACCELERATION BY BROAD-BAND EXTREMELY LOW FREQUENCY WAVES

E MÖBIUS, E J Lund, K A Lynch (all at Space Science Center, Morse Hall, University of New Hampshire, Durham, NH 03824 USA; email: Eric.Lund@unh.edu, Eberhard.Moebius@unh.edu, Kristina.Lynch@unh.edu), D M Klumpar (Lockheed Martin Advanced Technology Center, 3251 Hanover St., Palo Alto, CA 94304 USA; email: klump@teams.spasci.com), R E Ergun, C W Carlson (both at Space Sciences Laboratory, University of California, Berkeley, CA 94720 USA; email: ree@ssl.berkeley.edu, cwc@ssl.berkeley.edu)

Recent data from the Fast Auroral Snapshot Explorer (FAST) and other satellites indicate that broad-band extremely low frequency (BBELF) waves account for the majority of the transverse ion acceleration in the aurora. These waves tend to accelerate ions of different masses to approximately the same energy. We analyse selected events from the FAST data set to assess the mass dependence, or lack thereof, of transverse ion acceleration by BBELF waves. We also examine the spectral shapes of the BBELF emissions in order to estimate heating rates for each ion species. The data will be compared with a simple model of transverse ion acceleration [Gorney et al., J. Geophys. Res. 90, 4205, 1985] in order to asses the roles that parallel electric fields and spectral shapes play in transverse ion acceleration.

GA3.06/W/23-A2 1740

IONOSPHERIC SHEAR FLOW SITUATIONS OBSERVED BY THE MIRACLE NETWORK, AND THE CONCEPT OF HARANG DISCONTINUITY

Olaf AMM, P. Janhunen, H. J. Opgenoorth #, T. I. Pulkkinen, and A. Viljanen (Finnish Meteorological Institute, Geophysical Research, P.O. Box 503, FIN - 00101 Helsinki, Finland, email: Olaf.Amm@fmi.fi, Pekka.Janhunen@fmi.fi, Hermann.Opgenoorth@fmi.fi, Tuija.Pulkkinen@fmi.fi, Ari.Viljanen@fmi.fi) ; (# also at: Swedish Institute of Space Physics, Uppsala Division, S - 75591 Uppsala, Sweden)

Ionospheric shear flow situations regularly occur at the edges of the ionospheric potential cells, one of the most prominent leading to the transition from positive to negative values of the H ground magnetic disturbance component in auroral latitudes around magnetic midnight, named as Harang discontinuity. We present observations of such shear flow situations made by the MIRACLE network in northern Fennoscandia. The network comprises an array of magnetometers and all sky cameras, as well as the STARE coherent scatter radar pair. Thus it provides two-dimensional data of the ground magnetic and ionospheric electric field (or, equivalently, electron flow velocities), and of the optical activity. Some of the most interesting shear flow situations are processed with the 'method of characteristics' to obtain distributions of ionospheric conductances, true ionospheric currents, and field-aligned currents (FACs). Our discussion focuses on the differences in the physical state of the ionosphere between shear flow regions that are governed by upward and downward FACs, respectively, and their different roles in the global magnetospheric current systems. Based on our observations, we point out that what is defined as the Harang discontinuity in the ground magnetic variation field can be caused by currents flowing in topologically different regions of the ionospheric potential cells, depending on the degree of activity. Therefore, a refined definition of terms is introduced to clearly distinguish the different shear flow situations. We show that shear flow situations in the auroral ionosphere are typically connected with ionospheric conductance minima, with the conductance increasing from the shear flow zone to the south. Hence, two latitudinally seperated layers of FACs of the same sign.

AURORAL PROCESSES AND MIT COUPLING - 3

GA3.06/W/40-A3 Invited 0830

PLASMA WAVE EFFECTS ON AURORAL MIT COUPLING

Raymond POTTELETTE

One of the main challenges of the space plasma community consists in the requirement to understand interacting global and microscopic nonlinear processes on a hierarchy of scales. Due to the high sampling and telemetry rates implemented on recent rocket and satellite experiments, and the subsequent development of new experimental techniques (such as wave-wave and wave-particle correlators), it has become possible to determine the role of transient non-linear structures - associated with large amplitude waves - in the basic microscopic processes taking place in the variety of plasmas characterizing the MIT coupling. We will show some observations performed in space plasmas related to the formation of non-linear coherent structures (solitons, cavitons). The main emphasis will be put on recent theoretical developments which focus on the relevance of these structures with regard to turbulence, generation of radiation, and particle acceleration.

GA3.06/P/01-A3 0900

DEVELOPMENT OF CURRENT DRIVEN INSTABILITIES AND RELATION TO AURORAL PRECIPITATIONS: OBSERVATONS FROM INTERBALL-2

Sylvaine PERRAUT, Alain Roux, Patrick Robert, Claude de Villedary (CETP/UVSQ, 10- 12 Av. de l'Europe 78140 VELIZY, France) Jean André Sauvaud, Daniel Popescu (CESR/CNRS, 9 Av. du Colonel Roche -31400 Toulouse, France) Nicolas Dubouloz (CETP/CNRS, 4 Av. Neptune, 94107 Saint-Maur-des-Fossés, France) François Lefeuvre (LPCE, 3A Av. de la Recherche Scientifique, 45071 ORLEANS Cedex-2) Mikhail Mogilevski (IKI, MOSCOW, Russia)

Electromagnetic fluctuations in the frequency range just below the proton gyrofrequency are commonly observed when the INTERBALL-2 s/c crosses the boundary between the polar cap and the auroral region, as well in the night and morning sectors. We study the main characteristics of these fluctuations: polarization, direction of propagation, E/B ratios... It leads to identify these waves as current driven instabilities which result from the differential velocity between ions and electrons in presence of a parallel electric field which develops at these boundaries. It will be shown that these waves which are driven unstable by electron drift provide energy to ions, thereby ensuring a collisionless dissipation of the current. It is suggested that this collisionless dissipation controls the development of larger scale processes such as surface waves at magnetospheric boundaries and interchanges/ballooning instabilities at substorms.

GA3.06/W/20-A3 0920

THE POLARIZATION, FREQUENCY STRUCTURE AND BANDWIDTH OF AURORAL KILOMETRIC RADIATION

R. J. STRANGEWAY (Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA 90095, USA, Email: strange@igpp.ucla.edu), P. L. Pritchett (Department of Physics and Astronomy, University of California, Los Angeles, CA 90095, USA, Email: pritchet@physics.ucla.edu), R. E. Ergun. C. W. Carlson, J. P. McFadden, and G. T. Delory (all at: Space Sciences Laboratory, University of California, Berkeley, CA 94720, USA)

The FAST spacecraft is able to make detailed observations of Auroral Kilometric Radiation (AKR), both inside and outside of the source region. These observations indicate that within the source region AKR can occur below the local cold electron gyro-frequency. Furthermore, the wave electric fields are polarised perpendicularly to the ambient magnetic field near the low frequency cut-off. The wave magnetic field is found to be polarised parallel to the ambient magnetic field. This polarisation is consistent with perpendicularly propagating X-mode waves, which together with the observation of a cut-off below the cold electron gyro-frequency indicates that the accelerated and mirroring auroral electrons are the primary energy source for AKR. This type of distribution is referred to as a "horseshoe" distribution. This electron population is being continuously re-energised by the parallel electric field in the auroral acceleration, and we might expect strong emission intensities for AKR, without invoking multiple transitions of the source region. Analysis of the waveforms acquired within the source region indicate a packet-like structure. This may be a signature of the reformation of the distribution. In addition, both inside and outside of the source region rapidly falling tones are observed roughly 50% of the time. These falling tones may be caused by ion beam modifications of the plasma density within the source region. The bandwidths of the emissions are usually ~ 200 Hz, both inside and outside of the source region. This bandwidth may be narrower than that expected from simple linear instability analysis, and propagation effects could be controlling the width of the emitted spectrum. However, we have yet to observe the very narrow tones that would indicate the presence of a feedback oscillator in the AKR source region.

GA3.06/W/14-A3 0940

THE BURSTY NATURE OF CYCLOTRON MASER EMISSIONS IN A DRIVEN MODEL OF THE AKR SOURCE CAVITY

P L PRITCHETT (Department of Physics and Astronomy, University of California, Los Angeles, CA 90095-1547, USA, email: pritchet@physics.ucla. edu), R J Strangeway (Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA 90095-1567, USA, email: strange@igpp.ucla.edu), C W Carlson, R E Ergun, J P McFadden, and G T Delory (all at Space Sciences Laboratory, University of California, Berkeley,CA 94720-7450, USA)

The Fast Auroral SnapshoT (FAST) satellite has made observations in the AKR source region with orders of magnitude higher time and frequency resolution than previous missions. Wave observations within the source region often showed highly structured spectra, and the particle distributions revealed clear signs of free energy associated with the primary inverted-V

electrons. We present the results of high resolution 2-D particle-in-cell simulations of the cyclotron maser emission process driven by a down going distribution of energetic magnetospheric electrons in the auroral cavity. The relative roles of the inherent bandwidth of the maser instability process and of the magnetic field inhomogeneity in determining the emission spectrum are contrasted, and the possible influence of transverse density variations on the emission process will be examined.

GA3.06/E/10-A3 1000

FINITE AMPLITUDE ELECTROSTATIC ION-CYCLOTRON WAVES IN AURORAL BEAM PLASMA SYSTEM

R. V. REDDY and G. S. Lakhina (both at Indian Institute of Geomagnetism, Dr. Nanabhoy Moos Road, Colaba, Mumbai - 400 005, India, email: vreddy@iig.iigm.res.in)

The low frequency finite amplitude electrostatic ion-cyclotron modes in a magnetised auroral beam-plasma system is studied. The dispersion relation is solved numerically and the growth rates and the real frequencies are calculated for the auroral plasma parameters. The non-linear evolution equation is derived using the reductive perturbation method. The numerical solutions of the non-linear evolution equation are obtained and the essential features of the waveform are compared with the observed waveform. Implications of these results for the generation of parallel electric fields in the auroral region are discussed.

GA3.06/E/02-A3 1020

PLASMA INSTABILITIES IN AURORAL REGION

A.A.Shaikh(C.U.Shah Science College,Ashram Road,Ahmedabad-3800014,India) A.C.Das(Physical Research Laboratory,Navrangpura,Ahmedabad-380009,India, email: acd@prl.ernet.in)

A plasma instability mechanism seeded by steep density and temperature gradients in a weakly ionized magnetoplasma is proposed with a view to understand some type of density irregularities in the auroral region of ionospheric plasma.Gradients are associated with auroral processes namely precipitated charged particles which are to be believed due to the transfer of solar wind energy into the magnetosphere.It is shown that the growth of proposed instability depends on collision between charged particle with neutrals as well as the ratio of density and temperature scale lengths.We have also studied the effects of recombination and loss process in our model.The potential candidacy of our results is set forth to explain some characteristics of echo received from auroral region.Furthermore,the model is supported by the electron density and temperature gradient measured with EISCAT in the auroral region.

GA3.06/W/05-A3 Invited 1100

ESTIMATES OF ENERGY TRANSFER BETWEEN THE MAGNETOSPHERE AND THE UPPER ATMOSPHERE USING THE AMIE PROCEDURE

Arthur D. RICHMOND and G. Lu (NCAR High Altitude Observatory, P.O. Box 3000, Boulder, CO 80302-3000, USA, email: richmond@ucar.edu)

Electromagnetic energy transfer between the magnetosphere and the upper atmosphere can be described either as a deposition of heat and kinetic energy into the upper atmosphere, or as a divergence of a Poynting flux that can be defined in a number of different ways. We use the Assimilative Mapping of Ionospheric Electrodynamics (AMIE) procedure to estimate the large-scale energy transfer during disturbed periods, and we use AMIE inputs to the NCAR Thermosphere-Ionosphere-Electrodynamics General Circulation Model to evaluate how thermospheric winds influence the energy transfer calculations.

GA3.06/L/08-A3 1130

INVESTIGATION OF AURORAL COUPLING BY CONJUGATE HEMISPHERE OBSERVATIONS.

S. B. Mende, H. U. Frey, Space Sciences Laboratory, University of California, Berkeley, CA 94720, email: mende@ssl.berkeley.edu J. H. Doolittle, Lockheed-Martin Palo Alto Research Laboratories, Palo Alto, CA 94304 J. A. Cumnock, Dept. of Physics, Univ. Texas Dallas, Richardson, TX, 75083.

The conjugate behavior of auroral processes is examined from optical observations from the large area array of ground based Automatic Geophysical Observatories (AGO-s) and simultaneous ultra-violet imaging data from the POLAR UVI experiment. The ground based optical data is available from the Austral winter (April-August) periods from 1996 to 1998. The ground-based stations provide a detailed view of the aurora, which is sometimes difficult to compare with the much larger scale global view seen from the POLAR satellite. The observations show that substorm expansions occur in conjugate pairs, however the onset regions are usually displaced to a small extent in latitude and often substantially more in longitude. Conjugate behavior of transpolar arcs was also studies. Current understanding of transpolar arcs would predict that arcs located in the dawn side on one hemisphere would have their conjugate counterparts on the opposite, dusk side on the other hemisphere. Although this situation is often observed, there are cases when a transpolar arc has a counter part in the conjugate hemisphere located on the same side of the noon midnight meridian. It should be noted that in our observations the conditions of the two conjugate ionospheres are quite different. Ground based optical images are always taken while the ionosphere is dark and there is no solar illumination on the atmosphere while the satellite images are mostly taken when the atmosphere/ionosphere is illuminated by the sun consequently having high conductivity.

GA3.06/W/06-A3 1150

POLAR CAP AURORAL ARCS OBSERVED FROM SCOTT BASE, ANTARCTICA

B. J. FRASER, I. M. Wright, and F. W. Menk (Physics Department, CRC for Satellite Systems, University of Newcastle, NSW, 2308, Australia, email: physpuls20@cc.newcastle.edu.au, phbjf@cc.newcastle.edu.au, physpuls3@cc.newcastle.edu.au)

The morphology and movement of auroral arcs observed at Scott Base, Antarctica by a dual wavelength allsky image intensified imager have been related to conditions prevailing in the upstream solar wind and interplanetary magnetic field (IMF). The wavelengths observed in the red 630 nm emissions and the blue 427.8 nm emissions correspond to electron reactions with atomic oxygen and nitrogen in the upper atmosphere, respectively. Data have been collected over three observation seasons, in the 1996, 1997, and 1998 Austral winters, mainly during quiet magnetic conditions, with 1998 data from more active times.
Observations from a fixed ground station are necessarily limited in extent, and modulated by viewing conditions, which means the examples examined are selected because definitive features are apparent. The useable field of view is about 500 km in diameter, which is only a small part of the polar cap. The polar cap arcs discussed are mostly relatively small-scale local events that are in some cases aligned with the cusp or the sun direction. The intensity and structure of arcs vary during their lifetime. Average lifetime is some tens of minutes, and occasionally longer than 1 hour. Wave-like intensity variations can propagate along the arcs. The relationship of the motion and other properties of these arcs to ionospheric plasma convection, solar wind and IMF conditions and the open/closed field line boundary will be discussed for a number of events.

GA3.06/W/08-A3 1210

STATISTIC CHARACTERISTICS OF THE AURORA OBSERVED AT ZHONGSHAN STATION, ANTARCTICA

Liu RUIYUAN (Polar Research Institute of China, 451 Jinqiao Rd, Shanghai 200129, China, email: pric@stn.sh.cn)Hu Hongqiao (Department of Space Physics, Wuhan University, Wuhan 430072, China, email: pric@stn.sh.cn)

Statistic analysis has been done with the auroral observation taking from an all-sky TV camera for the years of 1995 and 1997 at Zhongshan Station of Antarctica, which is located at 69.4S, 76.4E.
The invariant latitude of this station is 74.5S (L=13.9), and the dayside auroras are observable there during mid-winter .The diurnal variation of the aurora occurrence has two peaks. One peak locates in postnoon sector (1400~1800MLT), and the other in midnight (2200~0300MLT). It is shown that there are often gaps between dayside auroras and nightside auroras. Four types of aurora have been examined. They are corona aurora, band aurora, active surge and transpolar aurora arc. The corona aurora mainly occurs in postnoon and midnight sectors. The band aurora mainly occurs in postnoon sector, equatorward side of evening and equatorward of midnight. But the active surge mainly occurs in midnight and the transpolar arc in midnight too. It is revealed that 75% of aurora belongs to the band in postnoon sector and 52% belongs to the active surge in midnight sector.The relationship between the aurora occurrence and the geomagnetic activity is also studied by considering the conditions of Kp<=1, 1<Kp<=2 and Kp>2 respectively. It is quantitatively shown that the occurrence and luminosity of aurora are positively correlated with Kp index. On geomagnetic quiet days the postnoon aurora is mainly a week band one with a pole ward movement. On disturbance days there is corona aurora as well in postnoon sector and active surge is dominant in midnight although the band aurora and tanspolar arc sometimes occur.

AURORAL PROCESSES AND MIT COUPLING - 4

GA3.06/W/34-A3 Invited 1400

AURORAL PROCESSES STUDIED BY ALIS

Ake STEEN, Urban Brandstrom and Bjorn Gustavsson (Swedish Institute of Space Physics, Kiruna Sweden), Takehiko Aso and Masaki Ejiri (National Institute of Polar Research, Tokyo, Japan), Mikhail Pudovkin and Oleg Kornilov (University of St. Petersburg, St. Petersburg, Russia)

The optical aurora clearly illustrates the complexity of the MIT interaction processes. Three-dimensional (3-D) tomographic imaging of the optical auroral signal has a considerable potential for investigations of several of the MIT interaction processes. ALIS (Auroral Large Imaging System) is a multi-station (six stations currently) imaging system in the Kiruna-region using high-performance CCD-imaging (3-D), remote Internet operation, and in the future AI-operations. The presentation is mainly concentrating on the study of the development of auroral vortices using several of the methods available in ALIS and also in co-ordination with other measurements. Auroral vorticity is a characteristic auroral feature occurring on almost all scale sizes. Using ALIS auroral vorticity can be investigated from a few hundred metres up to a few hundred kilometres at the same time. ALIS 3-D imaging is carried out in individual auroral emissions, e.g. N2+ 427.8 nm and OI 846.6 nm. An example of the methods used is the technique of spectroscopic ratios. Spectroscopic ratio images can be used to study the 2-D temporal development of the energy characteristics of the precipitating particles, e.g. during the development of an auroral vortex structure.

GA3.06/E/06-A3 1430

RECENT OBSERVATIONS OF MOMENTUM COUPLING IN THE HIGH LATITUDE THERMOSPHERE AND IONOSPHERE BY DOPPLER IMAGING SYSTEMS.

David REES (CASS, Utah State Univ. Utah State University, Logan, UT 84322-4405, USA, email: walnut1@easynet.co.uk)

Within the Polar Cap and Auroral Oval, magnetospheric electric fields generate a large and highly variable, inflow of momentum for the thermosphere through momentum coupling from the rapidly-motion of ionospheric plasma to the neutral gas via ion drag. Two Doppler Imaging Systems,located, respectively, at Kiruna, Northern Sweden, and in Svalbard, have provided a series of graphic illustrations of the development of complex thermospheric flow patterns during a series of geomagnetic disturbances during the past two years of increasing solar activity.

GA3.06/W/18-A3 Invited 1450

HOW WELL CAN EMPIRICAL MODELS PREDICT IONOSPHERIC STORMS

Timothy FULLER-ROWELL, M.V. Codrescu, (both at NOAA Space Environment Center and CIRES, University of Colorado, Boulder, CO 80303, USA, email:tjfr@sec.noaa.gov; mcodrescu@sec.noaa.gov); E.A. Araujo-Pradere (Inst. de Geofisica, UNAM, Ciudad Universitaria, Coyoacan 04510, Mexico DF, email: earaujo@sec.noaa.gov)

Recent understanding of the physical processes responsible for ionospheric changes during a geomagnetic storm has led to the possibility of capturing part of the response in an empirical model. The model simulates the expected change in neutral composition during the evolution of an event by integrating the auroral power injected into the atmosphere over the previous 30 hours, weighted by a filter. The model is particularly well suited to the storm-time response in summer, when no feature boundaries are expected. In winter, where sharp discontinuities are expected, the empirical model is less accurate.

GA3.06/W/25-A3 1520

RESPONSE OF THE AURORAL AND POLAR THERMOSPHERE TO GEOMAGNETIC FORCING

M. J. KOSCH, K. Cierpka, M. Rietveld, T. Hagfors and K. Schlegel (Max Planck Institut für Aeronomie, 37191 Katlenburg-Lindau, Germany, email: kosch@linmpi.mpg.de), D. Rees (Utah State University, USA)

The upper atmosphere above ~ 80 km altitude consists of over 99% neutral gas (generally termed the thermosphere). The remainder is ionised, comprising the embedded ionosphere. At high latitudes the ionosphere is strongly controlled by the magnetospheric convection electric field which responds strongly to geomagnetic disturbances such as substorms and associated auroral events. Through ion-neutral collision processes, the dynamics, thermodynamics and composition of the high-latitude thermosphere can also be strongly influenced by geomagnetic disturbances. For example, increasing geomagnetic activity is accompanied by enhanced convection electric fields, which accelerate the ions, and auroral precipitation, which increases ionospheric Pedersen conductivity. The result of increased ion density, combined with their higher velocities, imparts increased momentum to the neutral gas by collisions (ion drag). The neutral gas may be accelerated to velocities of many 100s of m/s, whilst enhanced Joule heating increases both ion and neutral temperatures. Conversely, a strong horizontal neutral wind may change the ionospheric composition by driving ions up or down the magnetic field lines into a region of different recombination rates. It is clear that the ionosphere and thermosphere are closely coupled. Past work from models, satellite observations and ground-based instruments will be reviewed with emphasis on the effect of geomagnetic forcing on the thermosphere. A powerful experimental combination for thermospheric studies is the incoherent-backscatter radar co-located with a ground-based optical interferometer. The radar and the interferometer can measure velocities and temperatures of the ions and neutrals, respectively. Examples from northern Scandinavia from the EISCAT radar and the Skibotn Fabry-Perot interferometer will be discussed.

GA3.06/W/28-A3 1540

MIRACLE OBSERVATIONS OF MAGNETIC AND ELECTRIC FIELD VARIATIONS NEAR AURORAL ARCS

K. KAURISTIE, A. Viljanen, P. Janhunen, A. Pajunpaa, M.T. Syrjasuo, T.I. Pulkkinen, H.J.Opgenoorth, and P. Eglitis (all at Finnish Meteorological Institute, Geophysical Research, P.O.Box 503, FIN-00101 Helsinki, Finland, email: kirsti.kauristie@fmi.fi)

Auroral arcs can be classified to different categories according to the distribution of the electric field and ionospheric currents near the arc. For example, a narrow region of intensified horizontal electric field can be observed either equatorward (evening sector) or poleward (morning sector) of the arc. We assesse the generality of these findings using data of years 1997-1999 recorded by the Scandinavian MIRACLE network which is a two-dimensional array of magnetometers, ionospheric radars, and allsky cameras. The distribution of ionospheric Hall currents is estimated with equivalent current vectors derived from ground-based magnetic field data. Reliability of the vectors especially in the vicinity of the arcs where the conductivity gradient is large is tested with the radar observations. Long-term recordings provide us the possibility to get a view on how the arcs distribute in magnetic local time: Do they appear preferentially in the evening sector of the oval, like some arc theories predict?

GA3.06/W/10-A3 1620

OPTICAL OBSERVATIONS OF TOPSIDE MOLECULAR NITROGEN IONS IN THE POLAR CAP: ALTITUDE PROFILES OF THE VIBRATIONAL AND ROTATIONAL DISTRIBUTIONS

G. J. ROMICK, J. H. Yee, M.F. Morgan, D. Morrison (JHU/APL, Laurel, MD. 20723)

The Ballistic Missile Defense Organization's (BMDO) Midcourse Space Experiment (MSX) obtained optical observations of molecular ions at very high altitudes above the northern polar cap. MSX's Ultraviolet and Visible Imagers and Spectrographic Imagers (UVISI) instrument shows the presence of molecular nitrogen ions over the high latitude northern polar region (geomagnetic latitude 75° - 85°N, 12-06 MLT) at altitudes above 900 km on Nov.7, 1997 and only to 700 km on Nov.8, 1997. The contiguous wavelength coverage of UVISI allows us to unambiguously identify the N2+ First Negative Bands over a range of wavelengths from 330 to 471 nm. Transitions from the v = 0, 1, and 2 vibrational levels are identified in the observed spectrum. In addition, transitions from the v = 2, 3, 4, and 5 vibrational levels of the Meinel bands were also observed. The source must be solar resonance fluorescence of upward moving molecular nitrogen ions associated with the general morning-side polar ion outflow. If the source were particle impact excitation other emissions such as the N2 1st and 2nd Positive Bands and the atomic oxygen line at 557.7 nm would have been observed. The recorded spectra show the N2+ 1st Negative Bands with an integrated band intensity of 2.5 kR. This implies an N2+ number density of about 1x 103 ions/cm3 at 900 km. In order to understand the energy associated with these ions and possibly differentiate between ambient and energetic ions, the altitude profiles of the relative populations of the vibrational states of N2+ 1st Negative and Meinel bands as well as the effective rotational temperatures will be presented.

GA3.06/E/12-A3 1640

GEOMAGNETIC VARIATIONS AT EQUATORIAL AND AURORAL LOCATIONS, AND THEIR INTER-RELATIONSHIP DURING STORM AND SUBSTORM CONDITIONS

Girija RAJARAM, T. Arun, A.N. Hanchinal (Indian Institute of Geomagnetism, Colaba, Mumbai-400 005, India, email: girija@iig.iigm.res.in, tarun@iig.iigm.res.in, arun@iig.iigm.res.in), Jacques Vassal (Observatoire de St.Maur 4 avenue de Neptune 94107, St.Maur-Cedex,
email: jacques.vassal@cetp.ipsl.fr), M.Salam Ndiath (Observatoire ORSTOM, B.P. 50, M'BOUR, Senegal)

This work is an attempt to understand the elusive problem of electromagnetic coupling between the high and low latitudes of Earth, markedly during disturbed conditions. The stations selected are the French low-latitude location M'BOUR (geog.14.4N, 343.05E; geom.21.3N, 55E), and the Indian Antarctic location MAITRI (geog.70S, 12E; geom.66.8S, 56.3E), which lie more or less on the same flux tube. Any electromagnetic coupling between the two is thus sought to be understood in terms of field-aligned behaviour.
Selected magnetic storms of 1994 are chosen, and the X,Y,Z variations at the two stations are examined for substorm intervals. Power spectrum analysis is carried out for the two locations with frequency filters which select the Pi2 signal(6.66-25mHz) and the Ps6 signal(1-2mHz), both being typical features of the Substorm.
Preliminary analysis of the ssc storm of 28 May '94, and the gc storm of 2 April '94 indicate that while geomagnetic variations at these two locations can show positive, negative or even no correlation, depending on the phase of the storm, the typical frequencies associated with the Pi2 and the Ps6 pulsations show up strongly at both high and low latitudes during substorms. The implications of these are being understood by examining more storm cases during 1994.

GA3.06/W/17-A3 1700

POLAR ARCS AND LARGE-SCALE CONVECTION

A. E. LEVITIN, S. A. Golyshev, Y. I. Feldstein, Isaev N. V.(Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation, Troitsk, Moscow Region, 142092, Russia, email: lgromova@izmiran.troitsk.ru) Marklund G., Blomberg L. (Alfven Laboratory, Royal Institute of Technology, S-100 44 Stockholm S-100 44, Sweden, email: marklund@plasma.kth.se)

The influence of the polar arc appearance on the spatial convection pattern in the high latitude ionosphere, were analysed. Particular events of the polar arcs appearance were considered using Viking and DMSP data. The IZMEM model, which accepts variations of the interplanetary magnetic field and the solar wind parameters as input parameters (Feldstein and Levitin, J. Geomagn. Geoelectr., 38, 1143-1182, 1986) were used as a background model of the electric field and current systems. The currents connected with the polar acrs were put over the background distribution of the electric field and currents. The high latitude ionosphere conductivity variations were taken into account based on DMSP satelites data. The spatial-temperal distributions of the convection before and after the polar arcs appearance are presented. They show that polar arcs which appear in the polar cap have weakly influence on the large-scale convection system. The connected with polar arcs spatial scales and amplitudes of disturbances of the electric and magnetic fields and electiric currents have been calculated.

GA3.06/L/05-A3 1720

VELOCITIES OF AURORAL FORMS AND PROCESSES IN THE MAGNETOSPHERE

Oleg KORNILOV, Mikhail Pudovkin (both at Istitute of Physics, St.Retersburg State University, St. Petersburg, Petrodvorets, 198904, Russia, Email: mikhail.pudovkin@pobox.spbu.ru, pudovkin@snoopy.phys.spbu.ru)

Well known, that registration of aurora by video cameras allow us to receive a lot of new data about processes in the magnetosphere. In particular, velocities of moving auroral forms provides an unique information about electric fields, field-alligned currents, plasma instabilities etc. For these purposes algorithm of full automatic velocity calculation was proposed. Application of this routine to real auroral video data allowed us to determinate system of field-aligned currents that drifts westwards with a speed of some kilometers per second.

GA3.06/L/09-A3 1740

INTERPRETATION OF AURORAL ARC DYNAMICS BASED ON MODEL OF MAGNETIC RECONNECTION IN THE MAGNETOTAIL

Yulia BOGDANOVA and Vladimir Semenov (both at Institute of Physics, St.Petersburg State University, St.Petersburg, 198904, Russia, Email: julia@geo.phys.spbu.ru, sem@snoopy.phys.spbu.ru) Richard Rijnbeek and Maria Buchan (both at Space Science Centre, University of Sussex, Brighton, BN1 9QH, UK, Email: R.P.Rijnbeek@sussex.ac.uk, M.J.Buchan@sussex.ac.uk)

We present new results to predict the motion of nightside auroral arcs during the expansion phase of a magnetospheric substorm. The model is based on the hypothesis that reconnection in the magnetotail plays a central role in substorm development. We suppose that auroral arcs are interpreted as the ionospheric manifestation of upward field-aligned currents, induced by Alfven waves generated during reconnection pulse in the vicinity of an X-line in the magnetotail current sheet. The non-uniform plasma medium leads to dispersion of the waves, and in this case manifestation of magnetotail reconnection could correspond to both poleward and equatorward moving auroral arcs. Furthemore, we show that the morphology and location of the arcs depend on the dissipative electric field in the diffusion region, the plasma density distribution in the magnetotail, and the position of the X-line. Dynamics of auroral arcs deduced from our model is in a good agreement with experimental data.

MODEL STUDY OF IONOSPHERIC ELECTRODYNAMICS OF AURORAL SUBSTORMS

Lie ZHU, Jan Sojka, Robert Schunk, Mike Bowline (Center for Atmospheric and Space Sciences, Utah State University, Logan, UT 84322-4405, U.S.A., email: zhu@cc.usu.edu)

In the ionosphere, the theoretical models have been developed to an extent that the 3-D global as well as small-scale ionospheric features of substorms can be simulated within the model capability. But the inconsistency among available global time-varying magnetospheric drivers for the ionospheric models, especially the global convection and precipitation, or/and the coarse spatial and temporal resolutions of these drivers have been restricting the global ionospheric models from producing the observed small-scale auroral structures and dynamical features of substorms in the ionosphere. In this work, we used a set of magnetospheric drivers produced from a theoretical M-I coupling model as the inputs for the USU Time-Dependent Ionospheric Model (TDIM) to study the ionospheric electrodynamics during a representative substorm. The features of these theoretical magnetospheric drivers include the sharp convection reversals, the narrow precipitation channels, the self-consistency between convection and precipitation, and the high spatial and temporal resolutions. The simulation results revealed many interesting dynamical and small-scale features of the ionospheric electrodynamics during substorms. Specifically, the results showed that there were both electron and ion hot spots associated with the auroral substorm in the ionosphere, but these two spots were spatially separated. The temporal and 3-D spatial features of plasma structures in these hot spots will examined and the underlying physics will be discussed in this presentation.

AURORAL DENSITY CAVITIES AND ASSOCIATED ENERGETIC ION BEAMS

H L COLLIN and W K Peterson (Lockheed Martin ATC, Space Physics Laboratory) P D Craven (NASAMarshall Space Flight Center) M Andre (University of Umea SWEDEN) C A Kletzing (University of Iowa) T E Moore (NASA Goddard Space Flight Center)

Inverted V regions associated with ion beams and a field aligned potential drop are regions of reduced plasma density, density cavities. The nature of ion and electron acceleration process is strongly limited by details of the local ion velocity space distribution. In particular it is important to know the relative contribution of the thermal core and higher energy ion beams and if there are other significant plasma components in these cavities. POLAR/TIDE measures ions with energies below 300eV and estimates the thermal ion density in the cavities. Comparison with the POLAR/TIMAS measurements of high energy ion beams it is evident that

the thermal plasma is much lower inside the cavities than in adjacent regions and suggests that the contribution of the high energy part of the beams makes up at substantial part of the total density. In the archetypal auroral ion beam which has been accelerated through a field aligned potential all ions have roughly the same drift speed. Although heated by wave-particle interactions they are still relatively cool. It is therefore surprising that POLAR/TIMAS commonly sees ion beams which have a narrowly field aligned component extending down to tens of eV and persist through regions. The presence of such a low energy ion component is also supported by the simultaneous POLAR/TIDE observations.

GA3.06/L/03-A2 Poster **0930-03**

THE RELATIVE LOCATION OF AURORAL ION BEAMS AND FIELD ALIGNED CURRENTS

H L COLLIN (Lockheed Martin ATC, Space Physics Laboratory) W J Peria (University of California, Berkeley) W K Peterson (Lockheed Martin ATC, Space Physics Laboratory) P J Chi and C T Russell (IGPP University of California Los Angeles)

It is well established that, statistically, energetic ion beams occur in the same region of the auroral zone as do upward field-aligned currents. However, there have been few studies investigating the details of their spacial relationship in individual events. Upflowing energetic ion beams are detected by the POLAR ion mass spectrometer in the southern auroral zone near perigee. In order to identify feild-aligned current sheets we have adapted an automatic algorithm first developed for use with the FAST dataset. We will present the initial results of a survey of the spatial relationship of ion beams and current in a large number of auroral zone transits.

OCCURRENCE OF O-SHAPED POTENTIALS OVER AURORAL OVAL

Pekka JANHUNEN (Finnish Meteorological Institute, Geophysical Research, POB 503, FIN-00101, Helsinki, Finland, email: Pekka.Janhunen@fmi.fi)
Annika Olsson (Swedish Institute of Space Physics, Uppsala Division, S-75591 Uppsala, Sweden, email: ao@irfu.se)

Over stable auroral arcs, the absence of convergent perpendicular electric fields and energetic oxygen beams in POLAR satellite data at 25000-30000 km altitude has suggested that the potential pattern above stable arcs is O-shaped rather than U-shaped. This means that there is no net potential drop between the ionosphere and the magnetosphere, although there are parallel electric fields and the low-altitude electron spectra are of the inverted-V type. An O-shaped geometry can produce peaked "accelerated" electron spectra by filtering out the lower energy part of the magnetospheric thermal electron flux. A negative O-shaped potential well is supposed to be an ion and electron cavity, because it repels electrons and increases the speed of ions within itself.
We review our most recent findings about the O-shaped potential. Especially, we present a large statistical Freja satellite study (about 1700 km altitude) of more than 80 inverted-V events on different MLT sectors. In this study we determine the field-aligned current density and the apparent source plasma density, temperature and the peak potential for each data point. From the relationship between the peak potential and the field-aligned current density on different MLT sectors we can infer something about the occurrence frequency of O-shaped potentials as a function of MLT.

THE STATISTICAL X RAY AURORA AS OBSERVED BY PIXIE

S.M.PETRINEC, J.Mobilia, D.L.Chenette, W.L.Imhof

The Polar Ionospheric X ray Imaging Experiment (PIXIE) on board the NASA/GGS POLAR spacecraft has been making global observations of X rays from the Earth's auroral regions since March, 1996. PIXIE remotely senses the bremsstrahlung produced by the loss of multi-keV electrons from the magnetosphere into the ionosphere. In this study we examine more than two years of X ray observations of the northern auroral region from the PIXIE instrument. Emitted X ray flux is estimated from the PIXIE observations, which allows us to produce synoptic auroral maps representing the precipitation of energetic electrons as a function of geomagnetic activity as determined by various indices. Effects on the average and median auroral X ray flux are also examined as a function of solar wind parameters, including IMF clock angle.

AURORAL SUBSTORM AS SEEN IN INTERBALL-2 UV IMAGES

Wladislav LYATSKY (Polar Geophysical Institute, Apatity, 184200, Russia,
email: lyatsky@pgi-ksc.murmansk.su) and Leroy L. Cogger (Institute for Space Research, University of Calgary, Calgary, Alberta, Canada T2N 1N4, email: cogger@phys.ucalgary.ca)

The study of substorms from Interball UV measurements and ground-based magnetometer arrays, shows that a specific phase of a substorm is often observed between the expansive and recovery phases when the substorm stops in its progressing but the energy release remains to be very large, and it can be thought to be a result of a directly driven activity as was suggested earlier by Akasofu [1980]. A real recovery phase is observed in the end of this period. Interball UV images show also that the formation of a bright auroral border at the poleward edge of the auroral bulge seems to be the most remarkable and significant feature of all substorms observed. When reaching some latitude after the beginning of a substorm, this poleward auroral border can stop and remain there during a long time. Sometimes this border occupies a wide interval of local time forming an inner auroral ring described earlier by Elphinstone et al.[1995] as the double oval structure. Interball UV images show that the auroral distribution in the region occupied by auroral substorm forms often bubble or petal-like structures which seem to be growing from a bright protuberant region on the equatorward boundary of the auroral oval. Earlier the similar bubble-like structure of aurora during substorms as seen from Viking UV images was demonstrated by Lyatsky et al. [1998].

TIME AND SPACE CORRELATIONS BETWEEN PULSATING AURORA AND VLF CHORUS

Ilia KORNILOV (Polar Geophysical Institute, Apatity, Murmansk region,184200, Russia, Email: kornilov@pgi.kolasc.net.ru)

On the base of all-sky TV and VLF data aurora-chorus correlations for the different intervals of local time and geomagnetic positions of the recording stations have been studied. It was found that time interval about 22h.- 08h.LT can be separated into three intervals with the different pulsations characteristics. During the interval 20h.-02h.LT typical optical and VLF pulsations have a periods about 5-10 sec, VLF being represented by pulsating hiss. Correlation analyses reveals anticorrelation between optical and VLF pulsations, and anticorrelating auroral pulsations lead VLF for about 0.5-1.5 sec. Later, about 02h.-05h.LT high frequency component with periods about 0.5-2sec. Appears in aurora pulsations, though strong traces of previous periods of 5-10 seconds are still exist. Chorus elements are also became obvious in VLF emissions. Aurora - VLF correlation is positive, with time delays concentrating preferably around zero. Time interval of the late morning hours (05h.-08h.LT) corresponds to auroral pulsations in the form of week, low brightness fast flashers with a periods about 0.3-1sec., VLF emissions are intensive chorus. Integrated correlation function shows two maxima in delays distribution. VLF lead aurora for 2 seconds and aurora lead VLF for 1.5 sec., and these time delays between aurora and VLF are very well defined. The fact may denote that in the late morning hours aurora and VLF pulsations generating magnetosphere system involves in some global-scale self-synchronization. Study of pulsating aurora and chorus correlations for the different areas of TV screen has revealed, that independently on the position of the maximum of pulsating aurora intensity, the best correlation is achieved for the northern stations (L=5.9) at the south and for the southern station (L=5.2) preferably at the north. These data may point out the position of plasmopause.

OBSERVATIONS OF DAYSIDE AURORAL PULSATIONS BY THE INTERBALL UV IMAGER AND EISCAT RADAR

Alexander KOZLOVSKY (Dept. of Physical Sciences, University of Oulu, P.O. Box 3000, FIN-90401 Oulu, Finland, email: kozlovsky@skynet.oulu.fi), Jorma Kangas (Sodankyla Geophysical Observatory, FIN-99600 Sodankyla, Finland, email: Jorma.Kangas@sgo.fi), Leroy Cogger (Dept. of Physics and Astronomy, The University of Calgary, Calgary, Alberta, Canada, email: cogger@phys.ucalgary.ca) Antti Oikarinen, and Ritva Kuula (both at Dept. of Physical Sciences, University of Oulu, Oulu, Finland)

10 min pulsations in dayside Interball UV auroral measurements and in the magnetic and electric fields variations were studied. The pulsations were observed on 12 February 1997, during quiet geomagnetic conditions and stable IMF Bz = 2nT. Interball UV imager showed 10 min period pulsations of the dayside auroral arc brightness. Corresponding pulsations occurred in the northward electric field over Tromso as measured by EISCAT radar. However, the northward electric field variations over Tromso were in better agreement with the northward magnetic field variations at Svalbard (about 8 degrees northward from Tromso) than with those at Tromso. We believe that this phenomenon is due to inhomogeneous ionospheric conductivity in the vicinity of terminator.
At the Svalbard magnetometer network, northward propagation of the phase of pulsations was observed with a velocity of about 3 km/s, but there was not any visible phase delay along the geomagnetic parallel (Hopen Island - Jan Mayen).
Observed pulsations are discussed in terms of magnetic field line resonance oscillations.

GA3.06/W/13-A2 Poster **0930-09**

CROSS-SECTION OF AN AURORAL ARC INFERRED FROM EISCAT RADAR MEASUREMENTS

Alexander KOZLOVSKY, Timo Lakkala (both at Dept. of Physical Sciences, University of Oulu, P.O. Box 3000, FIN-90401 Oulu, Finland, email: kozlovsky@skynet.oulu.fi) Jorma Kangas (Sodankyla Geophysical Observatory, FIN-99600 Sodankyla, Finland, email: Jorma.Kangas@sgo.fi), Antti Oikarinen, and Ritva Kuula (both at Dept. of Physical Sciences, University of Oulu, Oulu, Finland)

Variations of the electric field and ionospheric plasma parameters were measured by the EISCAT incoherent scatter radar during 10 cases of auroral arcs passing through the radar beam. Optical observations of the arc brightness allowed us to separate temporal and east-west spatial variations and to derive a picture of electric fields, currents, electron precipitation, plasma density, electron and ion temperatures across the arc.
The following results are discussed in the light of existing theories of auroral arc formation:
a) relationship between the electron precipitation characteristics (energy flux and electron energy) and field-aligned current;
b) difference between the velocity of the arc and plasma convection velocity,
c) influence of the electric field and electron precipitation on the electron temperature in E and F regions.

GA3.06/W/11-A2 Poster **0930-10**

HIGH-ALTITUDE AURORAL CAVITIES AND THEIR GROUND SIGNATURES

MÄKELÄ,J.S., P. Janhunen, H. Laakso, and A. Viljanen (Finnish Meteorological Institute, PO Box 503, 00101 Helsinki, Finland. email: Jakke.Makela@fmi.fi. JM also at Physics Department, University of Helsinki, Finland)

We present observations of large-scale plasma cavities at 1 RE and above 4 RE made by the POLAR satellite. We compare the results to ground data from the IMAGE magnetometer chain and EISCAT radar, where applicable. We note that a large-scale cavity with well-defined boundaries can be identified at high altitudes under a wide variety of geomagnetic conditions. There is smaller-scale fine structure within these cavities that can be highlyvariable. We compare our findings to ground data at the POLAR footpoint. No specific ground signature is found to correspond exclusively to the high-altitude cavity.

DYNAMICS OF AURORAL ELECTRON ACCELERATION REGION AS REVEALED BY AURORAL HISS

E.E. Titova, A.G. YAHNIN (Polar Geophysical Institute, Apatity, Russia, email: titova@pgi.kolasc.net.ru), F. Jiricek, J. Smilauer, P. Triska (Institute of Atmospheric Physics, Prague, Czech Republic, email: fji@ufa.cas.cz) M.M. Mogilevsky, T.V. Romantsova, A.A. Rusanov (Institute of Space Research, Moscow, Russia, email: mogilevsky@romance.iki.rssi.ru) Smith (Geophysical Institute, University of Alaska, Fairbanks, Alaska, USA,
email: bblw@geewiz.gi.alaska.edu)

The Interball-2 satellite auroral hiss observations performed during November-December 1996 were compared with simultaneous observations of auroras. Auroral data were obtained from the ground-based observations on Kola peninsula and Svalbard. Auroral dynamics was used as indicator of the temporal and spatial behavior of the acceleration region. Main attention is paid to strong variations of auroral hiss intensity and frequency at latitudes poleward of the auroral oval, and their relation to auroral dynamics. The temporal intensifications of the hiss, which were observed well poleward from the auroral oval, correlate with both substorm onset and week intensification of a single aurora arc. The auroral hiss cutoff frequency likely depends on distance between auroras and satellite. The cutoff frequency of auroral hiss decreases when the distance between satellite footprint and auroras

decreases and vice versa. Thus the variations of intensity and cut-off frequency of auroral hiss observed by the satellite poleward of auroral oval are close related with both temporal and spatial dynamics of auroral electron acceleration region. Applicability of auroral hiss characteristics for diagnostic of acceleration region is discussed.

STUDY OF THE MORPHOLOGY OF LARGE SCALE INVERTED-V STRUCTURES

Oswaldo LUIZAR (Departamento de Fmsica, Universidad Nacional de San Antonio Abad del Cusco, Perz, email: oluizr@inti.unsaac.edu.pe) Marina Stepanova (Departamento de Fmsica, Universidad de Santiago de Chile, email: mstepano@lauca.usach.cl) Jean Michel Bosqued (Centre d'Etude Spatiale des Rayonnements, CNRS/UPS, France) Elizaveta Antonova (Skobeltsyn Institute of Nuclear Physics, Moscow State University, Russia) Rostislav Kovrazhkin (Space Research Institute, Academy of Sciences of Russia

The present work reports the morphological study of multiple inverted-V structures performed in base of the AUREOL-3 satellite data. The upward field-aligned current obtained by integrating of the precipitating electron fluxes often stratifies latitudinally forming multiple large-scale current sheets. Observed events have been classified considering the level of stratification, latitudinal asymmetry of individual current sheet, and increasing (or decreasing) of the current maxima with latitude. It was found that all evens show latitudinal asymmetry. The correlation study between the event morphology and the geomagnetic activity shows that the level of stratification increases with the AE-index, and that the mean slope of the structure's asymmetry is determined by the AO-index. The performed classification and the established dependencies can be useful for the development of the field aligned current generation theories.

IONOSPHERIC CONDITIONS DURING BRIGHTENINGS OF THE POLEWARD BORDER OF THE DIFFUSE AURORAL BAND

ARJA PAJUNP, Mikko Syrjsuo, Pekka Janhunen, Kirsti Kauristie, Ari Viljanen, and Tuija Pulkkinen (all at Finnish Meteorological Institute,Geophysical Research, P.O. Box 503, FIN-00101 Helsinki, Finland, email: arja.pajunpaa@fmi.fi)Erling Nielsen (Max Planck-Institute fur Aeronomie, D-37191 Katlenburg-Lindau, Germany, email: nielsen@mirage.mpae.gwdg.de)

During geomagnetically moderate and intense periods there are usually two or three substorm sequences associated with the westward electrojet. We will discuss the brightenings of the poleward border of the diffuse auroral band, which are seen in the vicinity of the latest substorms near the magnetic midnight or morning side. We consider their temporal and spatial occurrence with respect to the substorm expansion phase.
We use data of MIRACLE, which consists of the IMAGE magnetometer network, five all-sky auroral CCD cameras, and the STARE radar system. Events to be investigated are selected based on the magnetometer and all-sky data. Ionospheric equivalent currents are described by IMAGE, and the electric field and the plasma convection are determined by STARE. With the use of available satellite data, we obtain information of conditions in the solar wind and the magnetotail.

SIMULTANEOUS MEASUREMENTS OF AURORAL FINE STRUCTURE WITH RADARS, PHOTOMETERS, ALL-SKY CAMERAS AND TV-CAMERAS

J. JUSSILA, H. Holma and K. Kaila (Department of Physical Sciences, University of Oulu, P.O. Box 3000, FIN-90401 Oulu, Finland, email: Jouni.Jussila@oulu.fi)

In November 1998 an Finnish EISCAT measurement campaign was organized. During this EISCAT was supported with versatile ground-based instrumentation. High resolution optical equipment were installed in line at Tromso, Kilpisjarvi and Karesuvanto in northern Skandinavia. They included two wide-field-of-view real-speed TV-cameras and three photometers. The Tromso area was also covered with all-sky cameras at Kilpisjarvi (Finnish Meteorological Institute) and Skibotten (Max-Planck-Institut fuer Extraterrestrische Physik).
In evening 18.11.1998 an auroral substorm occurred at about 2000 UT. Substorm was mainly located north of Tromso. During the substorms break-up discrete auroral structure passed by the EISCAT radar beam and were clearly observed with optical equipment.
This paper deals with the results of movement of the auroral arc measured by different instruments.

UNUSUAL AURORAL STRUCTURES OVER THE KOLA PENINSULA

S.CHERNOUSS, A.Yahnin, A.Roldugin (Polar Geophysical Institute, Apatity, Russia, email: SergeyChernouss@hotmail.com)

Unusual space wave structures in the auroral luminosity (or nightglow) were observed by low light level TV camera from Lovozero station at the Kola Peninsula January 10, 1997 during about one hour in auroral disturbed day. Complete description of the pattern is done in the report and presents by the TV recordings. The periodical luminosity wave structure looks like auroral gravity waves pattern described before by K.Henriksen and M.Taylor (Gravity Wave Studies at Polar Lattitudes, in "The Electrmagnetic Coupling in the Polar Clefts and Cusps", NATO ASI Series, 1988, p.421.) but have other space and temporal scales and features. The question is a nature and source of the periodical luminosity structures event. Have they an auroral source or atmospheric one connected with thermospheric disturbances after the rocket launch from Plesetsk launch station several hours before the event. Both ideas are under consideration.

AURORAL ACTIVATIONS OVER KOLA PENINSULA AND X-RAYS MEASURED BY POLAR/PIXIE, ON FEBRUARY 9, 1997

G.STARKOV1, L.Lazutin1, J.Stadsnes2, J.Bronstad2, I.Kornilov1, , T. Kornilova1, L.Borovkov1, N. Ostgaard2, E.Thorsen2, S. Chernouss1 1)Polar Geophysical Institute, Academia, Apatity, Murmansk Region, 184200, Russia, email: lazutin@pgi.kolasc.net.ru 2)Department of Physics, University of Bergen, Allegt. 55, N-5007, Bergen, Norway, email: Johan.Stadsnes@fi.uib.no

During substorm onsets and intensifications acceleration and precipitation into the atmosphere of charged particles occur in a wide energy range from hundreds of eV to several MeV. Some types of active aurora are related to the enhancement of the low energy electrons alone, whereas other types are also accompanied by the increase of the electron flux with energy more than 20 keV. We have analysed four hours of continuous auroral activity on February 9, 1997, registered by TV cameras on the Kola peninsula and the X-ray imager PIXIE on the POLAR satellite to study visual aurora and X-ray aurora relation and to find different types of auroral activations. Comparison shows that aurora and enhanced X-rays in the midnight sector are observed in general within the same latitudinal boundaries. The main difference is related to the duration of the emission: aurora was observed continuously over Kola peninsula, whereas X-rays were recorded with considerable interruptions. Auroral activations can be divided into three groups by positive, moderate and negative correlation with the X-ray increases. X-rays have been recorded in three out of four substorm onsets with poleward expansion during the initial equatorial arc brightening and several first activations of the poleward expansion. One intense auroral activation with fast southward expansion was also accompanied by X-ray enhancement. Moderate cases include brightening of auroral arcs moving equatorward and active auroral forms in the evening sector. Auroral arcs observed between the substorm intensifications and active auroral forms occurring after first 10-15 minutes of substorm onset and expansion are not accompanied by X-rays enhancement.

IMPULSIVE CURRENT VORTICES IN THE EVENING SIDE IONOSPHERE

A. AIKIO (Department of Physical Sciences, University of Oulu, FIN-90570 Oulu, Finland, e mail: Anita.Aikio@oulu.fi), M. Persson, A. Olsson (both at Swedish Institute of Space Research, Uppsala Division, S-75590 Uppsala, Sweden), M. Lester (Radio and Space Plasma Physics, Department of Physics and Astronomy, University of Leicester, Leicester LE1 7RH, UK)

Short duration (1-2 min) impulsive events in the evening side ionosphere are studied. These events appear as intense short-lived spikes in magnetograms and when differential equivalent current vectors are examined, it appears that they are small-scale current vortices in the ionosphere. Since the vortices are associated with simultaneous bursts of short-period broadband magnetic pulsations (PiBs) it is likely that field-aligned currents accompany these vortices. Two time periods have been selected for a further analysis, the other one is measured by the EISCAT radar and the other by the CUTLASS radar. Relations to auroral features, magnetospheric convection and solar wind will be discussed.

LOWER IONOSPHERIC RADIO EMISSION AND THE ROLE OF MESOSCALE DENSITY STRUCTURE

A T WEATHERWAX, P H Yoon, and T. J. Rosenberg (Institute for Physical Science and Technology, University of Maryland, College Park, MD 20742 USA, email: allanw@ipst.umd.edu)

Recent observational and theoretical works on the medium-frequency (1-4 MHz) narrow-band auroral radio waves detected at the ground level, known as auroral roars, have revealed the importance of the mesoscale density cavity structure. Here the F- region density structure is modelled on the basis of measured density structure at the times of roar emissions. In this paper, the excitation of the Z- mode waves at 2 and 3 times the local electron cyclotron frequency inside a model density cavity is investigated, and the subsequent propagation of the Z-mode is studied together with the convective cyclotron growth/damping property as well as collisional damping. It is shown that, in order for the excited Z-mode waves to remain trapped inside the density cavity and continue to grow, the density cavity must be "deep enough." The linear mode conversion of Z-mode to O-mode is also studied by means of simple ray tracing technique, and the mode-converted O-mode rays are also followed to the ground. It is found that the Z-mode waves maintain sufficiently high wave intensities despite the cyclotron and collisional damping, owing to the spontaneously emitted Z-mode waves by the energetic electrons. It is also shown that the linear mode conversion of Z to O mode through the Ellis radio window is possible under broad circumstances, which include the initial wave normal angle and the source height.

AKR FINE FREQUENCY STRUCTURE AS A MESO-MICROSCLE COUPLING PROCESS

P H YOON (Institute for Physical Science and Technology, University of Maryland, College Park, MD 20742 USA, email: yoonp@ipst.umd.edu) A T Weatherwax (Institute for Physical Science and Technology, University of Maryland, College Park, MD 20742 USA, email: allanw@ipst.umd.edu)

A theory for the fine frequency structure (< 1 kHz) associated with auroral kilometric radiation (AKR) is presented. It is based upon a realistic model of electron distribution function inside the AKR source region, which is constructed on the basis of mesoscale constraints such as dipole magnetic field strength and parallel potential drop. The growth rate of the X-mode is determined from the local microscopic electron cyclotron maser instability calculation. The resulting normalised bandwidth associated with the X-mode instability growth rate is of the order 0.0001 to 0.001, which may naturally account for the AKR fine frequency structure. The results are quite different from those obtained in many previous calculations and simulations of AKR which relied on simple model electron distribution functions. The convective growth and saturation of individual wave packets can be discussed on the basis of quasi-linear theory combined with the ray trajectory calculations. The numerical results will also be discussed.

X-MODE RADIATION IN THE HOT NON-MAXWELLIAN AND INHOMOGENEOUS PLASMA

Alexey KUZNETSOV and Valerii Vlasov (both at Department of Mathematics, Irkutsk State Technical University, Lermontov str. 83, Irkutsk, Russia, email: vlasov@math.istu.irk.ru)

According to recent observations, the auroral kilometric radiation (AKR) is generated in small-scale sources where the propagation of electromagnetic waves is determined mainly by the hot component of plasma. Another feature of these cavities is the presence of sharp plasma density gradients. The dispersion equation for the case when electrons have a ring-like distribution is obtained. To take into account the plasma and magnetic field inhomogeneities, we use Hamiltonian equations. It is shown that inhomogeneities limit the time, during which the wave can be in resonance with particles in the positive slope region. This effect has to be taken into account when determining the amplification rate of the waves in the AKR source.

FRACTAL STRUCTURE OF AURORAL IMAGES AND SELF- ORGANISED CRITICALITY

KOZELOV B.V. (Polar Geophysical Institute, Apatity, Russia, email: kozelov@pgi.kolasc.net.ru) Jussila J. (University of Oulu, Oulu, Finland)

Auroral phenomena display the processes in the magnetospheric plasma. The spatial structure of aurora may be described by fractal geometry. We use the box-counting procedure to obtain fractal dimension of isoline as a function of intensity on digitised TV image. This

procedure has been applied to long set of images during substorm. Last decade the conception of self-organised criticality (SOC) as a manner of plasma existence in the magnetic field becomes very popular one. We compare the dynamics of fractal characteristics of auroral images with some features of clusters in the SOC model. The possible connections are discussed.

STATISTICAL HI-LATITUDE SURVEY OF THE RATIO OF THE WAVE TO STATIC CURRENT POWER USING E/B RATIOS AND A MODEL HI-LATITUDE IONOSPHERE

J.P.KEADY (Geoloc Coporation, 1601 N.Kent St., Suite 1102, Arlington Virginia 22209 USA, email: keady@geoloccorp.com)

Magnetic field lines are the communication link between the ionosphere and the magnetosphere. Energy deposition by plasma (Alfven) waves and static currents into and out of the ionosphere is an important consideration in modelling ionospheric and magnetospheric coupling, and are dependent on the ability to distinguish temporal and spatial signals in satellite E and B data. The following statistical study uses derived E/B ratios for transmitted, reflected, absorbed low frequency Alfven waves and static currents, and a realistic electron density profile for the D,E,F regions (from Geoloc's physics based ionospheric model) to interpret the ratio of wave to current power entering the high latitude regions as a function of various Kp ranges, IMF orientations, seasons and scale sizes.

IMF BZ ASSOCIATED VARIATIONS OF THE EQUATORIAL ELECTROJET

Lilia SIZOVA (Institute of terrestrial magnetism, ionosphere and radiowave propagation; 142092, Troitsk, Moscow region, Russia; email: sizov@izmiran.rssi.ru) Mikhail Pudovkin (St. Petersburg State University; 198904, Petrodvorets, Russia; email: pudovkin@snoopy.spbu.ru)

Interaction between solar wind, magnetosphere and equatorial ionosphere has been analysed. For this purpose the daytime characteristics of the equatorial F2 ionospheric layer observed during magnetic storms, and the H-component of the geomagnetic field variations at magnetic equator have been compared with the IMF Bz. The electric field produced by the cusp aligned currents is supposed to cause observed disturbances of the equatorial ionosphere and additional magnetic variations at magnetic equator. Decrease of the H-component (counterelectrojet effect) associated with the appearance of the westward electric field is produced by the field-aligned currents of the zone II. An additional increase of the H-component are associated with the appearance in the day side ionosphere of an eastward electric field produced there by the field-aligned currents of the zone I.

QUANTITATIVE PARAMETERS OF AURORA-SOUNDS AND OF RELATED ACTIVE ARC

E. TIMOFEEV, A. Roldugin, V. Kosolapenko (Polar Geophysical Institute of the Kola Science Center of the Russian Academy of Sciences, Murmansk, Russia) M. Syrjasuo, T. Tuomi (Finnish Meteorological Institute, Helsinki, Finland) H. Holme, K. Kaila (Physical Department of the University of Oulu, Finland)

A set of ground-based geophysical data is analyzed for Feb.9, 1997 event when being outdoors three PGI scientists have heard a noisy-like aurora-sound during about one minute when extremely bright rayed arc passed the Lovozero observatory zenith. The set includes data of two TV cameras, scanning photometer, VLF-emissions and ground-based magnetometer recordings at the Kola peninsula, the Tromso, Kiruna and Kilpisjarvi scanning photometer recordings, color Abisko all-sky camera film and variations of the low atmospheric currents recorded in the Sodankyla meteorological observatory. According to the witnesses the sounding rayed arc had red (pink) color at its lower edge and was accompanied by a luminosity streamer propagating down from the edge to non-usually low altitudes so that the luminosity was even visible at the background of the hills surrounding the observatory. The following quantitative parameters of the active arc and of the related sounds are estimated,: the Lovozero luminosity intensity was more than 100 kR, the Tromso luminosity time derivative was more than 100 kR/s, velocity of the polarward expansion was the same at the both meridians at distance more than about 500 km and equal to about 5.7 km/s, frequencies of the aurora sounds covered range from about 1 to 5 kHz. The sound phenomenon was not accompanied by any considerable variations of the low atmospheric currents at least by recordings made in Sodankyla at distance of about 300 km from the Lovozero observatory.
The results are discussed in terms of a nonlinear transformation of the natural electromagnetic waves and in the light of the contemporary theories of the electro-hydrodynamics of the low atmosphere.

IMF SCALE LENGTHS AND PREDICTABILITY

MICHAEL R. COLLIER, J. A. Slavkin, A. Szabo and R. P. Lepping (Laboratory for Extraterrestrial Physics, NASA/GSFC, Greenbelt, Maryland 20771, U.S.A.). Kokubun (Solar-Terrestrial Environment Laboratory, Nagoya University, 3-13 Honohara, Toyokawa, Aichi 442, Japan)

We discuss the results of a systematic study using simultaneous data from three spacecraft, WIND, IMP 8 and Geotail, to examine the properties of magnetic field structures in the typical solar wind. This represents a continuation of the work described in Collier et al. [1998]. Time periods were selected when the plane formed by the three spacecraft included the GSE x-direction so that, in the case of planar structures, the two adjacent spacecraft pairs would determine the same structure angles. Consequently, if effects such as the motion of the Earth relative to the interplanetary structures and deviations in the solar wind direction from GSE x-axis alignment are taken into account, differences in the measured structure angle between the two spacecraft pairs may be used to deduce structure curvature. Current results indicate typical radii of curvature of ~150-200 RE. This leads to the conclusion that there are two important IMF scale lengths relevant to predictability: (1) the (well-established) scale length over which correlations observed by two spacecraft decay along a given IMF structure, on the order of a few tens of Earth radii and (2) the scale length over which two spacecraft are unlikely to even observe the same structure because of structure curvature, on the order of a hundred Earth radii.

CORRELATIVE STUDIES OF THE SOLAR WIND MAGNETIC FIELD AT TWO NEAR-EARTH SPACECRAFT:IMP8 AND ISEE1

Zerefsan KAYMAZ (Istanbul Technical University, Faculty of Aronautics and Astronautics, Maslak, 80626, Istanbul, Turkey, Email: zerefsan@itu.edu.tr) David Sibeck (John Hpkins University, Applied Physics, 11100 John Hopkins Road, Laurel, Maryland, 20723, US, Email: sibeck@s1pvx9.jhuapl.edu)

Interplanetary magnetic field (IMF) at two near- Earth spacecraft are compared for the purposes of space weather program. For the magnetospheric studies, both spacecraft are often used as solar wind monitor of the IMF. Previous correlative studies with one spacecraft at the liberation point and the other near-Earth showed that the correlations were highly variable. Among the factors suggested that might effects the correlation are the spacecraft separation, IMF direction and variance, foreshock region, and solar wind parameters. In the present study, despite both the spacecraft are near-Earth orbiting, the correlations still show great variability. We search for parameters that effect the correlation between these two spacecraft. We find that in addition to the distance between spacecraft, foreshock region plays an important role in determining the degree of correlation. The correlation is found to be better if both spacecraft are outside the foreshock region and close to each other. While in the foreshock region, determined by the upstream waves in the magnetic field signature, our initial results show that the distance to the bow shock is important. The upstream waves are large and have high frequencies when spacecraft is close to the bow shock. The larger the amplitude of the waves the lower the correlation is found. While increasing IMF strength and variance result in lower correlation, no clear correlation is found with the solar wind velocity. These results suggest that one should be cautioned while using either of these spacecraft and be aware of the conditions under which they can be used.

HOT FLOW ANOMALIES REVISITED

Steven J. SCHWARTZ (CESR/CNRS, BP 4346, 9 Avenue du Colonel Roche, 31028 Toulouse Cedex 4, France, email: Steve.Schwartz@cesr.fr; permanent address: Astronomy Unit, Queen Mary and Westfield College, London E1 4NS, UK, email: S.J.Schwartz@qmw.ac.uk) Goetz Paschmann (MPI fuer Extraterresiche Physik, Postfach 1603, D-85740 Garching,Germany, email: gep@mpe.mpg.de) Malcolm Dunlop (Space and Atmospheric Physics, Imperial College, South Kensington, London SW7 2AZ, UK, email: m.dunlop@ic.ac.uk) Andrew Fazakerley (Mullard Space Science Laboratory, Holmbury St. Mary, Dorking, Surrey RH5 6NT, UK, email: anf@mssl.ucl.ac.uk) Michelle Thomsen (Space and Atmospheric Sciences (NIS-1), Los Alamos National Laboratory, Mail Stop D466, Los Alamos, NM 87545, USA, email: mthomsen@lanl.gov)

Hot Flow Anomalies (HFA) are events near the Earth's bow shock characterised by extremely hot ion temperatures and flow deceleration/deflections greatly in excess of those found in the nearby magnetosheath. Observations and numerical simulations suggest they are the result of an interaction between interplanetary tangential discontinuities and the bow shock. We have put together all studied examples to investigate the statistics of the underlying discontinuities and other apsects. These suggest that HFA formation is favoured by orientations perpendicular to the solar wind flow (resulting in long connection times). We also use multi-spacecraft techniques both to investigate the undisturbed interplanetary discontinuity, which in at least one case is a rotational discontinuity, and to investigate in detail the relative motions of the internal structures.

SMALL SCALE SOLAR WIND ION FLUX AND IMF CORRELATED STRUCTURES IN THE EARTH'S FORESHOCK REGION: INTERBALL-1 OBSERVATIONS

Pavel EIGES, Georgy Zastenker, Mihail Nozdrachev (Space Research Institute, Profsouznaya str. 84/32, Moscow, 117810, Russia, Email: eiges@iki.rssi.ru)

The foreshock phenomenon is an important part of solar wind-magnetosphere interaction. In our work long series (up to several hours) of high time resolution (up to 16 Hz) measurements of solar wind plasma and IMF made onboard INTERBALL-1 were used to study large and fast fluctuations in the Earth's foreshock region. Several types of fluctuations in the foreshock have been selected in consequence of statistical analysis. Comparison analysis was also applied in order to establish unique characteristics of each type. High positive correlation (correlation coefficient is about 0.7-0.8) between plasma and magnetic field ULF (3–30 mHz) variations during all the time of foreshock observations was found. Existence of such correlation is supposed as a typical foreshock feature. Many events of simultaneous nearly harmonic oscillations of solar wind ion flux and IMF magnitude with periods 1-3 seconds and duration of wave-packet up to 20 seconds were observed and case study of them was performed.

STATISTICAL BOW SHOCK MODELS: COMPARISON WITH NEW OBSERVATIONS

J. SAFRANKOVA, Z. Nemecek, M. Borak (Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic, Email: jana.safrankova@mff.cuni.cz)

During the time interval from August 1995 to August 1997, the MAGION-4 satellite (INTERBALL-1's subsatellite] observed more than 850 bow shock crossings. Due to the high inclination and temporal evolution of its elliptical orbit, the MAGION-4 data set covers mainly two latitudes - near the equatorial plane and around the $Z_{GSE} = \pm 10 R_E$. Both outbound and inbound crossings are spread from the subsolar region to the $X_{GSE} \sim -10 R_E$ and occurred under various upstream conditions: the solar wind dynamic pressure varied from 1 to 12 nPa and Alfv_nic Mach number from 4 to 50.
GEOTAIL bow shock crossings measured in the same time interval covered the equatorial plane near the terminator. These new data set provides an opportunity to test empirical models describing the bow shock position. We have tested influence of the solar wind and IMF fluctuations, solar wind aberration, and Mach number with motivation to find a direction for further development of models.

ON BOW SHOCK SURFACE WAVES NEAR SOLAR MINIMUM

R. L. KESSEL, NASA GSFC, Greenbelt, MD 20771, USA

Earth's bow shock represents the outermost boundary between that region of geospace which is influenced by Earth's magnetic field and the undisturbed interplanetary medium streaming from the Sun. This boundary is important because it is here that the streaming solar wind is slowed, heated, and partially deflected around the Earth's magnetosphere. From solar wind observations, we know there exist rotational and tangential discontinuities, current sheets, magnetic holes and clouds , many of which eventually impact the Earth's magnetosphere with first contact at the bow shock. There are also any number of small scale structures, inhomogeneities, or perturbations present in the solar wind which hit the bow shock. As solar wind structures or changes in the solar wind impinge on the bow shock, it moves in response. In this presentation we investigate under what conditions waves can form on the surface of the bow shock due to structures in the solar wind. We use Geotail data near solar minimum (1995-1997); concentrating on bow shock flank crossings because it is here that more motion and wave activity is expected - the nose is more tightly locked into place while the flanks can flap in the breeze. High speed solar wind streams are dominant during the descending phase of the solar cycle because the polar coronal holes producing the fast solar wind, reach their maximum latitudinal extent near sunspot minimum, confining the slow solar wind to a narrow equatorial belt. We correlate the high speed streams to times of large numbers of bow shock crossings with bow shock normals significantly different from model normals. We also explore increased fluxes of energetic electrons using SAMPEX data which have also been correlated with high speed streams. If the structures in the solar wind are responsible for exciting the magnetosphere, waves on the bow shock may be the first signal.

GA3.07/W/09-A3 1430

UNUSUAL SHAPE AND MOTIONS OF EARTH'S BOW SHOCK

ADAM SZABO (Laboratory for Extraterrestrial Physics, NASA Goddard SFC, Greenbelt, Maryland, 20771, USA, email: Adam.Szabo@gsfc.nasa.gov)

Multi-point observations of Earth's bow shock by WIND, IMP 8, Interball, and Geotail reveal unusual motions and/or distortions in the shock surface. The results of non-linear least squares, Rankine-Hugoniot fittings carried out for observations at each spacecraft will be presented. It has been established that the bow shock moves significantly even during relatively calm solar wind conditions without any apparent trigger disturbance. In partucular, one set of observations, when IMP 8 and Geotail crossed the bow shock within a few Re of each other and nearly simultaneously, indicate higly distorted bow shock shapes as both spacecraft encounter it multiple times. Possible physical sources of these distorted bow shock motions will be discussed.

SYNOPTIC MAPS OF EARTH'S MAGNETOSHEATH

J. D. RICHARDSON, K. I. Paularena, M. A. Kolpak, (M.I.T., Center for Space Research, Cambridge, MA, USA, 02139) and G. L. Siscoe (Center for Space Physics, Boston University, Boston, MA 02215).

We present results of a study of Earth's magnetosheath using data from 1977-1984 and 1994-1998. IMP 8 crosses the sheath twice every 12 days, and ISEE 1, ISEE 3, and WIND serve as upstream solar wind monitors. We transform coordinate systems to produce maps of plasma parameters in the magnetosheath. Previous work showed a dawn-dusk temperature and density asymmetry near solar maximum that was not present during solar minimum. We look at an additional five years of data to investigate this effect. The average plasma parameters are compared with those predicted by gasdynamic models. We also show that a poleward circulation is present in the plasma mantle and describe the properties of this region. Comparisons are made with published synoptic maps of the magnetic field in the magnetosheath and magnetotail.

GA3.07/E/08-A4 1000

SOLAR-WIND/MAGNETOSPHERE COUPLING: SPECULATIONS ABOUT THE ROLE OF THE MAGNETOSHEATH

Joseph E. BOROVSKY and John T. Gosling (both at Space and Atmospheric Sciences Group, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, email: jborovsky@lanl.gov)

Any coupling of the solar wind to the Earth's magnetosphere is mediated by the magnetosheath, which interposes. The known correlations between the solar wind and the magnetosphere are reviewed: these include (1) electrodynamic coupling wherein vBz of the solar wind is correlated with power outputs and substorm occurrences in the magnetosphere-ionosphere system and (2) mass coupling wherein the densities and velocities of the solar-wind plasma are correlated with the densities and temperatures of the hot magnetospheric plasma. Following the review, we will discuss these couplings in light of the changes that occur to the solar wind within the magnetosheath.

GA3.07/W/72-A4 1030

MODELLING THE LARGE-SCALE DYNAMICS OF THE MAGNETOSPHERIC BOUNDARY USING GLOBAL MHD SIMULATIONS

Jean Berchem (Institute of Geophysics and Planetary Physics, University of California, Los Angeles, California 90095-1567, USA, Email: jberchem@igpp.ucla.edu)

Understanding the large-scale dynamics of the magnetospheric boundary is an important step in assessing the global transport of plasma and energy through the geospace environment. In this talk we review the results from several case studies of the dynamics of the magnetospheric boundary based on three-dimensional magnetohydrodynamic (MHD) simulations of the solar wind-magnetosphere-ionosphere system. In these studies, interplanetary magnetic field (IMF) and plasma parameters upstream of the bow shock served as input to the global simulations; results reveal the large-scale response of the magnetospheric boundary including the dynamics of the magnetospheric cusp. The case studies presented encompass both typical and severe solar wind conditions, as well as different orientations of the IMF and upstream activities. After reviewing global configurations of the dayside magnetosphere for generic solar wind inputs to the simulations, we discuss the results from simulations that use real input from solar wind monitors. In particular, we use the comparison of the local data streams from the simulations with time series measured by spacecraft crossing the magnetospheric boundary to reconstruct the global geometry and dynamics of the magnetospheric boundary during the events.

POTENTIAL PROBLEMS IN THE INTERPRETATION AND TESTING OF LARGE SCALE MHD SIMULATIONS

T. D. ARBER (Mathematical Institute, University of St. Andrews, St. Andrews, Fife KY16 9SS, Scotland, UK, email: tda@dcs.st-and.ac.uk)

Over recent years there has been a rapid growth in the use of large scale numerical simulations to solve problems in MHD. This has been due not just to the increase in computing power but also to the shear number of different codes which are now available.
This paper presents a review of problems which can occur in such simulations and the tests which should be performed in order to avoid them. These potential problems should be well known to numerical specialists. However, large codes are now often being used as 'black box' research tools by scientist whose primary interest is not in numerical techniques. This paper is intended to clarify the problems one can expect when performing these simulations. At the simplest level this involves tests such as checking energy conservation and convergence. Following on from this are more complex and subtle issues which vary from potential problems with conservative codes (which guarantee exact conservation of total energy) to how one can be sure that the scheme converges to the correct physical solution.

WIND SURVEY OF MIXED MAGNETOSHEATH-PLASMA SHEET ION REGION EARTH-WARD OF XGSE= -20 RE: IMPLICATIONS FOR PLASMA TRANSFER

Tai PHAN (Space Sciences Lab, University of California, Berkeley, CA, 94720, USA, email: phan@ssl.berkeley.edu) and Masaki Fujimoto (Earth and Planetary Sciences, Tokyo Institute of Technology, 2-12-1 Ookayama, Meguro 152, Tokyo, Japan, email: fujimoto@geo.titech.ac.jp)

We have surveyed more than 20 WIND spacecraft perigee passes to investigate the occurrence of regions of mixed low-energy magnetosheath and high-energy plasma sheet ion populations and its possible dependence on the IMF. We found that at low magnetic latitudes, the mixed region is generally confined to the magnetopause and a thin boundary layer, which is simply the low-lati-tude boundary layer (LLBL) with its typical tailward plasma flow. At higher magnetic latitudes, however, we have found at least two examples of the mixed ion region deeper inside the magneto-sphere. In one case, which occurred during the first perigee pass of WIND's new high-inclination (45o) petal orbit, on Nov. 27, 1998, an extended region of mixed ions was detected. This region is located between the lobe and the hot plasma sheet, and occurred during an extended period of northward IMF. The two ion populations in the mixed region are remarkably similar (in tempera-ture) to the distributions detected in the magnetosheath and plasma sheet proper, respectively. But in contrast to the LLBL distributions, the plasma in this mixed region is nearly stagnant. The elec-tron distributions in the mixed ion region consist only of a single population with energy between those of the magnetosheath and the plasma sheet proper. Electron pitch angle information reveals that the entire mixed region is on closed field lines, unlike the LLBL. However, the absence of high-energy plasma sheet electrons in this region may suggest that the region was once on open field lines. The exact path of plasma entry to form the mixed region cannot be discern with single-point observations. But it is possible to rule out the mantle as a source for the plasma seen in this region. A possible path is along the boundary between the lobe/mantle and the plasma sheet. In essence, our survey raises the possibility of a latitude dependence of plasma transfer across the flank magnetopause. Finally, comparisons will be made with a Geotail survey of the mixed region in the -35 RE < Xgse < 0 RE range.

ORIGINS OF ENERGETIC IONS IN CEP EVENTS AND THEIR IMPLICATIONS

Jiasheng CHEN and Theodore A. Fritz (both at Center for Space Physics, Boston University, 725 Commonwealth Avenue, Boston, MA 02215 USA, http://buspace.bu.edu/EPG/jiasheng/chen.html, email: chen@buasta.bu.edu)

A new magnetospheric phenomenon called a cusp energetic particle (CEP) event has been discovered by the POLAR spacecraft in 1996 [Chen et al., GRL, 24, p.1447, 1997]. The events were detected in the dayside polar cusp near the apogee of POLAR and could last for hours, in which the measured helium ions had energies up to 8 MeV [Chen et al., JGR, 103, p.69, 1998]. A fundamental question is where do the cusp MeV ions come from? It was flound that all of these events were associated with a dramatic decrease in the magnitude of the local magnetic field, and that the charge state distribution of these ions was indicative of their source being recently the solar wind. Furthermore, the simultaneous observations indicated that the ion fluxes in the CEP events were higher than that in both the upstream and the downstream from the bow shock. Therefore, bow shock acceleration cannot explain the measured ion flux in the CEP events. We have determined the power spectra of the local magnetic field turbulence calculated over the CEP event periods for fluctuations in the ultra-low frequency (ULF) ranges, corresponding to periods of about 0.33-500 seconds. It is found that the integrated power of the turbulent spectra over the ULF ranges is correlated with the intensity of the MeV helium flux. These results provide the first
direct observation evidence that the high-altitude dayside cusp is a new acceleration region of the magnetosphere.

GA3.07/L/03-A4 1430

ELECTRIC FIELDS AND ULF/ELF PLASMA WAVES IN THE CUSP OBSERVED WITH THE POLAR AND FAST SPACECRAFT

R. Pfaff (Laboratory for Extraterrestrial Physics, NASA/Goddard Space 46 light Center Greenbelt, MD 20771), C. Carlson, R. Ergun, F. Mozer, J.McFadden (all at Space Sciences Laboratory, University of California, Berkeley, CA), R. Strangeway (IGPP, Univ. of Calif., Los Angeles, CA)

Both the FAST and Polar spacecraft have encountered the Earth's cusp on numerous occasions during their first years in orbit. Intense quasi-DC electric field structures and distinct plasma waves are consistent features of these cusp encounters which are identified primarily by their localized keV dispersed ion "injections". In the Polar electric field data set at altitudes of 5-7 RE, intense (5-10 mV/m, rms), localized ULF electric field structures are a consistent

feature of these cusp encounters. Distinct magnetic field perturbations, evident in the Polar magnetometer data, are also commonly associated with these cusp encounters, and reveal evidence for Alfv=C8nic wave structures and field-aligned and filamentary currents. By analyzing simultaneous measurements of the electric and the magnetic field components of the ULF plasma waves, we address the energy flow associated with the wave fields and provide important information concerning the source region of the waves. The FAST data, near 4000 km, also reveals intense ULF electric field turbulence but also several wave modes associated with localized acceleration processes have been identified thus far include: intense (>100 mV/m rms) ULF/ELF waves, emissions observed near the lower hybrid frequency and associated ion Bernstein modes. We examine several cusp encounters in detail in order to study the complex relation of the waveswith the DC electric fields, ambient plasma density, and the cusp energetic particle populations, and relate these to larger scale driving processes.

ULF WAVES IN THE MAGNETOSHEATH

Richard E. Denton (Department of Physics and Astronomy, 6127 Wilder Lab, Dartmouth College, Hanover, NH 03755-3528, USA, email: Richard.denton@dartmouth.edu)

The magnetosheath is both a conduit into the magnetosphere for upstream waves and a source region for new waves. Alfven and ion cyclotron waves are commonly observed just downstream of the bowshock. Velocity anisotropies generated at the bowshock and within the magnetosheath proper drive mirror and ion cyclotron waves; these waves can be significantly modified as they approach the magnetopause where the plasma beta decreases. The mirror modes can pile up in front of the magnetopause, thus acquiring a finite phase velocity relative to the flow. Waves previously identified as slow mode waves have now been shown to be best identified as the mirror mode (it is possible that there is some coupling between the two). Kinetic Alfven waves may also exist in the vicinity of the magnetopause. Waves recently identified as the quasi-parallel mirror mode (with wave vector roughly parallel to the background magnetic field) probably consist of a mixture of conventional mirror mode (quasi-perpendicular wave vector) and Alfven waves. Quasi-parallel shock conditions (interplanetary magnetic field roughly parallel to the shock normal) lead to high beta large amplitude fluctuations, the properties of which are only now beginning to be examined.

CAVITIES, WAVEGUIDES AND OTHER BEASTS: THE GLOBAL ULF RESPONSE OF THE MAGNETOSPHERE

W. ALLAN (National Institute of Water and Atmospheric Research, PO Box 14-901 Kilbirnie, Wellington, New Zealand, email: w.allan@niwa.cri.nz)

Virtually all the energy in the magnetosphere comes from outside. Some of this energy arrives by direct solar heating, but most of it comes from the solar wind through the magnetopause and the magnetospheric cusps.
Hydromagnetic waves, or ultra-low-frequency (ULF) waves, are basic modes of the magnetospheric system. Changes in the energy distribution of the magnetosphere must be accompanied by ULF waves to transmit the changes. The waves can therefore be used as diagnostics of the changing magnetosphere.
In the last two or three decades, a zoo of strange creatures has appeared in the literature. These beasts include field line resonances, global or cavity modes, flank waveguide modes, tail waveguide modes, and waveguide modes energized by over-reflection at the magnetopause.
I will conduct a relaxed tour of this zoo, giving a qualitative description of the animals' interesting features, and briefly discussing the observations that have called them into existence.

EXCITATION OF MAGNETOSPHERIC WAVEGUIDE MODES BY MAGNETOSHEATH FLOWS

I.R. MANN (Dept. of Physics, University of York, Heslington, York, YO10 5DD, U.K., email: ian@aurora.york.ac.uk) A.N. Wright, K.J. Mills, and V.M. Nakariakov (Mathematical Institute, University of St. Andrews, St. Andrews, Fife, Scotland, KY16 9SS, U.K.,
email andy@dcs.st-and.ac.uk, katie@dcs.st-and.ac.uk, valery@dcs.st-and.ac.uk)

Using a model incorporating a realistic free magnetopause boundary we show how the compressional fast mode oscillations excited by the solar wind and supported by the Earth's magnetosphere have characteristics which are strongly local time dependent. In regions of low magnetosheath flow speed, such as near local noon, the magnetosphere acts as a leaky cavity. Only at magnetosheath locations where the flow speed is sufficiently fast can modes become perfectly reflected at the magnetopause so that solar wind energy becomes trapped in the magnetosphere. Importantly, for faster flow speed conditions, magnetosheath flows can energise the magnetosphere through the development of magnetopause Kelvin-Helmholtz shear flow instabilities. The mechanism by which these magnetospheric waveguide modes are excited can be understood in terms of the over-reflection of waveguide modes at the magnetopause, over-reflection being more prevalent on the flanks where the magnetosheath flow speed is high. Field line resonances (FLRs), are believed to be driven by these waveguide modes. Our model for the interaction of MHD waves in the magnetosheath and in the magnetosphere can explain both the observed local time dependence of FLR wave power, and the observed correlation between high solar wind speeds and Pc5 wave power. Moreover, the over-reflection mechanism can excite a waveguide mode spectrum displaying preferred azimuthal wavenumbers. This provides an explanation for the observation that FLRs are driven with a particular azimuthal wave number. Finally, we show how a waveguide bounded by a free magnetopause supports quarter-wavelength modes which have lower frequencies than the standard (magnetopause velocity node) half-wavelength modes. This boundary condition may have more success in producing waveguide eigenmodes possessing the millihertz eigenfrequencies required to drive the FLRs which are observed at these frequencies by HF radars and ground-based magnetometers.

GA3.07/L/05-A5 1100

WAVE ENERGY TRANSFER IN COUNTERSTREAMING MHD MEDIA - ACTIVE BOUNDARIES OR NEGATIVE ENERGY WAVES

A. D. M. WALKER University of Natal, Durban

The plasmas in the magnetosheath and magnetosphere are in relative motion. This allows an MHD wave, incident on the magnetopause, to be amplified or attenuated by exchanging energy with the background flow. Conventional treatments of this problem use a definition of the wave energy in which energy is conserved at the boundary. An amplified reflected wave then leads to the requirement of a transmitted wave carrying negative energy. Such an approach, while producing correct results, assumes harmonic waves and obscures the nature and location of the energy interchange. The proper definition of energy density and flux in a moving plasma will be discussed and related to the group velocity. The mechanism of energy exchange between streaming plasma and wave is through the work done by the Maxwell and Reynolds stresses on the gradient of velocity at the boundary. The location of the energy exchange can be identified as the active boundary, with no need to invoke ideas of negative energy. The relationship between the two approaches will be
critically discussed.

GA3.07/W/38-A5 1130

WHY IS THERE A TERRESTRIAL MAGNETOPAUSE?

Katharine J. Mills, ANDREW N. WRIGHT, Michael R. Ruderman, and Aaron W. Longbottom (all at Mathematical Institute, University of St. Andrews, St. Andrews, Fife KY16 9SS, Scotland, U.K., email: andy@dcs.st-and.ac.uk)

The existence of the terrestrial magnetopause is extremely well established observationally, but its stability is understood theoretically to a limited extent. Indeed, normal mode stability calculations show that a typical magnetopause should be Kelvin-Helmholtz unstable. Field line tension introduces a threshold for instability, and nonlinear effects may saturate the instability. Nevertheless, there should be plenty of occasions when the magnetopause can be expected to blow itself up, but this is never seen in data. Why? We suggest the answer can be found in a more detailed classification of stability: Absolute instabilities grow exponentially at every point in space. Convective instabilities can be interpreted as a wavepacket that grows but also propagates rapidly enough that the amplitude at a fixed point does not grow exponentially but tends to zero at a large enough time. Our preliminary calculations indicate that the magnetopause is onlyconvectively unstable. As a result, disturbances on the flanks will propagate into the tail as they grow and not lead to the disruption of the flank magnetopause (which will have the appearance of a ``stable'' boundary).

MODELS OF FLUID FLOWS IN THE HIGH ALTITUDE CUSP

P.J. Cargill and M.G.G.T. Taylor (ImperialCollege, London, SW7 2BZ), UK, emailp.cargill@ic.ac.uk

A new model for the interaction of a supersonic magnetosheath flow with the high altitude cusp is proposed. Archival and recent observations have suggested that the cusp is a region of indentation, where solar wind plasma is found Earthward of the nominal magnetopause position. It is proposed that a supersonic solar wind flow interacts with such an indentation by being first accelerated through an expansion fan, and then decelerated by a shock. For most realistic parameters the shock cannot originate from the deepest part of the cusp, but must be detached. The rarefaction of the magnetosheath plasma leads to a rather shallow cusp (< 1 Re),and also implies that the cusp becomes less indented the more tailward it is located. Models will also be presented where a magnetosheath magnetic field is present.

GA3.07/E/07-A5 1430

CONSTITUTION OF DAYSIDE FIELD-ALIGNED CURRENT SYSTEMS

Masakazu WATANABE (National Institute of Polar Research, 1-9-10 Kaga, Itabashi-ku, Tokyo 173-8515, Japan, email: maskaz@nipr.ac.jp)

Morphology of dayside field-aligned current (FAC) systems is a classic but still stimulating topic because of its importance in magnetospheric physics. This paper provides characteristics of large-scale dayside FACs revealed by DMSP F7 observations, in particular, intensity balance between currents flowing into and away from the ionosphere. It is well known that dayside FACs are controlled by the interplanetary magnetic field (IMF). We deal with two specific IMF conditions: (1) Bz<0nT and |By|>4nT (strong By case), and (2) |By|<1.5nT and -0.5nT<Bz<1.5nT (extremely quiet magnetosphere). For periods of strong IMF By (IMF condition 1), By-dependent FACs are found in cusp/mantle regions, with the intensity of the poleward mantle current either counterbalancing or exceeding the intensity of the equatorward cusp current. This suggests that in addition to the coupling of the mantle and cusp currents themselves, another coupling exists in the magnetosphere. By comparing the current intensities of prenoon and postnoon region 1 currents, we infer that the extra part of the mantle current is connected with the boundary layer region 1 current located downstream of the By-dependent midday ionospheric convection. In contrast, FAC systems that persist even under the extremely quiet magnetosphere (IMF condition 2) are the prenoon/postnoon region 1 currents and the counter region 0 currents poleward of and adjacent to region 1. Both currents are collocated with boundary layer particles with their current intensities evenly balanced. This implies that the basic mode of the dayside FAC systems consists of the coupling of region 0 and region 1 in the magnetospheric boundary region(s).

IONOSPHERIC TURBULENCE OBSERVED WITH SUPERDARN RADARS, AND RELATIONSHIP TO THE DAYSIDE PROCESSES

Raphael ANDRE, Mike Pinnock and Alan Rodger (Upper Atmospheric Division, British Antartic Survey, High Cross, Madingley Road, Cambridge CB3 0ET, United Kingdom) Jean-Paul Villain (LPCE/CNRS, 3A, Av. de la Recherche Scientifique, 45071 Orleans cedex 2, France) Christian Hanuise (LSEET/CNRS, Universite de Toulon, BP 132, 83957 La Garde, France)

The SuperDARN radars use ionospheric irregularities (15 meters scale length) as tracers of

the plasma motion, and derive the average line of sight velocity from a complex autocorrelation function (ACF) obtained by the emission of a multipulse sequence. The characteristics of the associated velocity spectrum (spectral width, shape, ...) are directly linked to the properties of the ionospheric turbulence and of the larger-scale electric field projected from the magnetosphere.
These ACFs can be used to describe both micro-scale and macro-scale processes in the ionosphere, which can be linked to magnetospheric processes. A statistical survey of these characteristics over the whole polar ionosphere shows their relationship to magnetospheric processes such as that associated with soft electron precipitation.
The dayside observations show some characteristic features, spatially localized, which give usefull information on the solar wind-magnetosphere-ionosphere coupling. In this talk, we describe the ACFs characteristics associated with particular plasma regimes comment on them in some case studies of the dayside ionosphere.

GA3.07/W/30-A6 0930

OBSERVING THE GLOBAL STRUCTURE OF SUDDEN IMPULSE AND TRAVELING VORTEX EVENTS USING GROUND-BASED MAGNETOMETERS AND THE ASSIMILATIVE MAPPING OF IONOSPHERIC ELECTRODYNAMICS TECHNIQUE

AARON RIDLEY (Southwest Research Institute, San Antonio, TX 78228-0510, USA, email: ridley@zed.space.swri.edu)

Magnetic impulsive events (MIEs) have been observed at high and mid-latitude magnetometer stations for a number of years. With the availablity of global data sets, an understanding of the global characteristics of MIEs is developing. We present a study of two different types of MIEs: sudden impulse events and traveling vortex events. The assimilative mapping of ionospheric electrodynamics technique is used to invert the ground-based magnetometer data to show the global electric potential pattern for the different types of events. It is shown that while all traveling vortex events differ in some respect, they all occur at cusp latitudes, have a latitudinal with of approximately 10 degrees, and typically originate in the prenoon sector. The differences in the traveling vorticies include direction of travel, speed, and number of vorticies. No solar wind or interplanetary magnetic field driver has been verified for these type of events. The sudden impulse events are manifested as a reversed convection pattern superposed upon the already existing large-scale convection pattern. The superposed pattern lasts for 2-5 minutes, and are shown to follow a rapid change in the solar wind dynamic pressure.

GA3.07/W/24-A6 1000

GROUND OBSERVATIONS OF CUSP ASSOCIATED FLOWS AND TRANSIENTS: RECENT RESULTS FROM THE MACCS MAGNETOMETER ARRAY

David MURR and W. J. Hughes (Center for Space Physics, Boston University, Boston, MA 02215, USA, email: murr@bu.edu) Mark Engebretson (Augsburg College, Minneapolis, MN 55454, USA, email: engebret@augsburg.edu)

Combining the MACCS array with magnetometers from CANOPUS, Greenland, and the MAGIC chains provides a unique opportunity to investigate cusp related flows. The combined network provides a large field of view, 10 hours in local time by 20 degrees in latitude, and a high time resolution of 20 seconds. We have used this array to study the dynamic nature of ionospheric flows as they are driven by the IMF and solar wind. By correlating the IMF and ground magnetograms we find that the ionosphere responds to IMF changes with time scales longer than approximately 15 minutes with a delay of several minutes. These driven flows are punctuated by transients (such as traveling convection vortices) as the ionosphere-magnetosphere system responds to discontinuities in the IMF and solar wind. Using data from solar wind monitors we have identified separate categories of ionospheric transients that appear to be in response to specific types of changes in the IMF and solar wind.

GA3.07/W/69-A6 1100

RECENT RESULTS FROM RADAR OBSERVATIONS OF PULSED IONOSPHERIC FLOWS IN THE DAYSIDE AURORAL ZONE

T. K. YEOMAN, S. W. H. Cowley, M. Lester, S. E. Milan, D. A. Neudegg, and G. Provan (Department of Physics and Astronomy, University of Leicester, University Road, Leicester, LE1 7RH, U.K.)

The use of special high temporal and spatial resolution scan modes run on the SuperDARN HF radars has provided a wealth of new experimental information about the ionospheric footprint of the cusp. Coordinated experiments with the Equator-S satellite have led to the first convincing simultaneous observations in space and from the ground of the effects of individual pulses of transient reconnection at the magnetopause. The dynamics of such pulsed antisunward ionospheric flows induced on newly opened field lines, and the resulting plasma flows in the return flow on closed field lines have been characterised. The influence of the IMF By component on these pulsed ionospheric flows has been investigated, on both a case study and a statistical basis, as has the latitude, MLT extent and seasonal variation. Comparisons have been possible between radar and optical data, and have shown a very close relationship between the radar backscatter and cusp precipitation. These new observations directly confirm many theoretical predictions of the spatial and temporal development of ionospheric flows in response to transient magnetopause reconnection.

GA3.07/W/01-A6 1130

MULTI-INSTRUMENT GROUND AND SATELLITE OBSERVATIONS OF DYNAMICAL FEATURES IN THE CUSP/CLEFT AURORAL IONOSPHERE

J. Moen (Air Force Research Laboratory/ VSB (Space), Hanscom AFB, MA-01731-3010, USA. On sabbatical leave from Arctic Geophysics, University Courses on Svalbard, N-9170 Longyearbyen, Norway, Email: jmoen@unis.no)

The complex chain of mechanisms involved in the transfer of solar wind energy, momentum and particles into magnetosphere-ionosphere system manifests itself in the aurora as a rich spectrum of activities. Systematic work on cusp/cleft auroral morphology, however, has provided us a rather comprehensive description of one particular class of activity. That is the poleward moving forms near magnetic noon of which location and motion pattern are strongly regulated by the IMF orientation. Since it was first suggested in the mid-eighties it has been an ongoing debate on whether or not this event class actually is a footprint of pulsed magnetopause reconnection. Ambiguity problems pertain mainly due to the suffer of a limited longitudinal coverage of optical observations. Multi-instrument data from Svalbard and Greenland will be presented to illustrate the IMF By effect on the occurrence probability of poleward moving auroral transients on either side of noon, the IMF By effect on the cusp location, and the relationship between moving auroral forms and excitation of polar cap flow.

GA3.07/W/25-A3 Poster 0900-01

FIELD-ALIGNED CURRENTS BETWEEN BOW SHOCK AND MAGNETOPAUSE

Igor ALEXEEV (Institute of Nuclear Physics, Moscow State University, Russia, 119899, email: alexeev@dec1.npi.msu.su)

The bow shock and magnetopause are two current surfaces where perpendicular to magnetic field current density is large. The magnetic field jump is a main marker of these surfaces. The bow shock currents system and the tangential to bow shock electric field rigid connected with IMF direction. In opposite magnetopause currents determined by mutual orientation of the geomagnetic dipole and IMF vector. Electric field tangential to magnetopause and magnetopause currents differ for southward and northward IMF. As consequence of this difference the field-aligned currents between bow shock and magnetopause generated. These field-aligned currents was calculated as function of IMF direction. The possibility of the experimental discovery of these currents was discussed.

GA3.07/W/49-A3 Poster 0900-02

COMPOSITION OF MAGNETOSHEATH TURBULENCE

I. BATES (e-mail: bates@acse.sheffield.ac.uk), M.A. Balikhin, H.St.C.K. Alleyne (all three at:Department of Automatic Control and SystemsEngineering, University of Sheffield, Mappin Street, Sheffield, S1 3JD, UK.), M. Dunlop (Department of Physics, Imperial College of Science, Technology and Medicine, UK.)

The dynamics of turbulence in the magnetosheath is complicated and often there is more than one wave mode observed at the same frequency. The determination of the wave propagation directionsat this frequency by standard application ofminimum variance analysis is impossible. A method was developed to filter wave data both in frequency and wave number domains to allow the separation of the wave modes. This enables the propagation direction for each separate wave to be determined by minimum variance analysis. Thus the wave mode for each of the observed waves can be determined. Such a technique was applied to the magnetic field data obtained by AMPTE-UKS and AMPTE-IRM satellites in the terrestrial magnetosheath. The wave mode composition of the turbulence for a number of magnetosheath observations have been determined. The results are compared with previous findings based on dimensionless ratios and with the theory of plasma instabilities in the magnetosheath. It is shown that the mirror waves in the turbulence are present to a lesser degree than suggested by the previous findings based on dimensionless ratios.

ON THE SPATIAL STRUCTURE OF MIRROR MODE FLUCTUATIONS IN THE DAYSIDE MAGNETOSHEATH

G. ERDOS and M. Tatrallyay (both at KFKI Research Insitute for Particle and Nuclear Physics, 1525 Budapest P.O. Box 49, Hungary, email: erdos@rmki.kfki.hu)

Magnetohydrodynamic waves generated by the mirror instability are analyzed in this presentation based on magnetic field data collected aboard ISEE-1 and ISEE-2 in the terrestrial magnetosheath. In many cases the time profiles of quasi-periodic mirror mode oscillations are practically the same as observed by the two satellites. However, in the special case discussed here ISEE-1 and ISEE-2 detected long lasting antiphased irregular fluctuations of periods 20 - 50 s close to the magnetopause in spite of the small distance (700 - 800 km) between them. This unique observation helped us to impose some constraints on the geometrical characteristics of the instability, in particular on the longitudinal and lateral size of the structures. Further, the event was associated with multiple quasi-perpendicular bow shock and magnetopause crossings suggesting that the variations of interplanetary parameters might have contributed to the development of the instability.

UNTYPICAL MAGNETOSHEATH PROPERTIES OBSERVED BY ISEE ON OCTOBER 30-31, 1978

C J FARRUGIA (Space Science Center, University of New Hampshire, NH 03824, USA, Email: farrugia@monet.sr.unh.edu), D Vogl, H K Biernat, S Muehlbachler (all at Space Research Institute, Austrian Academy of Sciences, A-8042, Graz, Austria), R J Fitzenreiter, K W Ogilvie (both at NASA Goddard Space Flight Center, Greenbelt, MD 20771, USA), N V Erkaev (Institute of Computational Modelling, Russian Academy of Sciences, 660036 Krasnoyarsk 36, Russia), G Le, C T Russell (both at Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA 90024, USA)

We examine a long crossing of the dawnside magnetosheath made by ISEE 2 on October 30-31, 1978, focussing on proton temperature anisotropies but discussing also electron data from the nearby ISEE 1 spacecraft. The observations show a number of unusual features among which are the following. The magnetosheath is mirror stable throughout. No left hand polarized ion cyclotron waves are excited. We find no relation between the proton temperature anisotropies and the proton beta parallel to the magnetic field, and only a weak relation with the proton beta perpendicular to the magnetic field. Following Hau et al. [1993], we study double-polytropic relations. Though polytropic relations fit the data best, the proton thermal behaviour may nonetheless be approximated by an isothermal law.

TRANSIENT DENSITY EVENTS IN THE MAGNETOSHEATH AND PLASMA IMPULSIVE PENETRATION IN THE DAYSIDE MAGNETOSPHERE

Daniel HUBERT (Departement de Recherche spatiale, Observatoire de Paris, 92195 Meudon CEDEX, France) Christopher T. Russell (Institute of Geophysics and Planetary Physics, University of California, Los Angeles)

This study uses ISEE-3 observations at the L1 Lagrangian point and ISEE 1-2 observations in the subsolar magnetosheath along an outbound crossing. Thanks to fortunate occurence a same phenomenon is successively observed in the solar wind, in the inner magnetosheath and in the dayside magnetosphere near the magnetopause. First we discuss the formation of transient density events (TDE) in the inner magnetosheath which are related to rotationnal discontinuities in the solar wind. The duration of the TDE varies from tens of seconds to about a minute. The density of the TDE in the magnetosheath can exceed background level by a factor of 40%, while the modulus magnetic field in the TDE is only 30% of the field in the surrounding regions. Then we discuss the interaction of the TDE's with the magnetopause. It is shown that this interaction can be analyzed in terms of impulsive penetration of a plasma element. Thanks to the high time resolution of the electron density and magnetic field data, the filamentary structure of the element of plasma observed in the magnetosphere is analyzed.

THE MAGNETIC FIELD STRUCTURE IN THE MAGNETOSHEATH

V.V. Kalegaev; Institute of Nuclear Physics, Moscow State University, 119899 Moscow, Russia

The magnetic field structure in the magnetosheath is considered using new dynamic model of supersonic solar wind - Earth's magnetosphere coupling. The magnetopause and bow shock are assumed to be represented as paraboloids of revolution. The supersonic solar wind flow past the parabolic magnetopause is calculated, taking into account changing of the magnetopause and bow shock location and flaring due to solar wind variations. Magnetosphere is presented by the paraboloid model. The condition of magnetic field continuity was held on the magnetopause. The MHD equations in the magnetosheath, where the ohmic conducting solar wind plasma flow past the magnetosphere, are solved analytically as a singularly perturbed system with two independent small parameters, which are inversely proportional to Mach-Alfven and magnetic Reynolds numbers.
It is found that the magnetic field enchancement on the bow shock is determined by plasma compression. Taking into account plasma conductivity near the magnetopause allows us to describe the magnetic field and energy transport into the magnetosphere and estimate the reconnection efficiency, potential difference across the polar cap, energy input rate into the magnetosphere by IMF and solar wind parameters. For the typical magnetosheath conditions, magnetopause thickness is about of 100 times less than stand-off distance. The magnetic field near the magnetopause is formed due to mutual diffusion of the magnetospheric magnetic field in the solar wind and IMF into the magnetosphere. It allows us to explain the difference between magnetic field structures near the magnetopause for the cases of high and low magnetic shears. The magnetic field and plasma flow in the magnetosheath are calculated and compared with those measured by AMPTE/IRM satellite during magnetosheath passes on 24 October 1985 (low magnetic shear) and 28 August 1984 (high magnetic shear).

A TWO-DIMENSIONAL NUMERICAL STUDY OF STRUCTURE WITHIN QUASI PERPENDICULAR COLLISIONLESS SHOCKS

ROBERT LOWE and David Burgess (both at Astronomy Unit, Queen Mary and Westfield College, Mile End Road, London E1 4NS, UK email: R.Lowe@qmw.ac.uk)

Two-dimensional hybrid simulations of quasi perpendicular collisionless shocks reveal structure in the magnetic field along the shock front. This structure manifests itself as ripples of magnetic field moving along the shock ramp. The ripples are particularly pronounced in the component of magnetic field perpendicular to the shock front. A physical mechanism for the production of this structure has yet to be satisfactorily determined. We present the results of a numerical study of these ripples using a two-dimensional implementation of the CAM-CL scheme. Our results show that the ripples have a dispersion relation which would be consistent with the presence of MHD-like modes. We investigate how instabilities at the shock front may drive the ripples. In particular, we look at processes driven by downstream waves. We also examine the possibility of trapping MHD-like modes within the shock ramp. Collisionless shocks are observed to be a source of relativistic electrons, although the exact acceleration mechanism remains poorly understood. One-dimensional simulations show that shock drift acceleration is insufficient unless the shock is nearly perpendicular. We examine how ripples might provide additional acceleration by reflecting electrons within the shock structure.

PROPAGATION AND EVOLUTION OF SOLAR WIND DISCONTINUITIES THROUGH THE MAGNETOSHEATH

Z. NEMECEK, J. Safrankova (Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic, Email: zdenek.nemecek@mff.cuni.cz) G. N. Zastenker (Space Research Institute, Moscow, Russia) K. I. Paularena (MIT, Cambridge, USA)

Abrupt changes of the solar wind dynamic pressure and the IMF magnitude or direction are a dominant factor controlling the magnetospheric dynamics. However, all discontinuities should pass the magnetosheath before they reach the magnetopause. The steady magnetosheath flow can be described by the gasdynamic model but the problem of the propagation of transient phenomena through the magnetosheath is very complicated. In quasisteady state, it should involve the spatial profile of magnetosheath parameters as well as the changing magnetopause geometry and magnetosheath thickness but the transformation of the discontinuities at the bow shock makes the investigation even more difficult.

Our study is based on the simultaneous measurements of the INTERBALL-1 and MAGION-4 satellites in the magnetosheath supported by the WIND data monitoring of the solar wind and IMF. The data from other spacecraft (GEOTAIL, IMP-8) are used whenever available. We have chosen disturbed solar wind intervals, often connected with the magnetic clouds, and traced the propagation of distinct features through the magnetosheath.

POLAR OBSERVATIONS OF ELECTRIC AND MAGNETIC FIELD BOW SHOCK STRUCTURE

J. A. NEWBURY, C. T. Russell (both at the Inst. of Geophysics and Planetary Physics, University of California Los Angeles, 405 Hilgard Ave., Los Angeles, CA 90095-1567 USA; email: newbury@igpp.ucla.edu and ctrussell@igpp.ucla.edu), M. Gedalin (at Dept. of Physics, Ben-Gurion University, Beer-Sheva, 84105 Israel), A. J. Hull and F. S. Mozer (both at Space Sciences Laboratory, Univ. of California Berkeley, Berkeley, CA 94720 USA), and J. Wygant (School of Physics and Astronomy, Univ. of MInnesota, Minneapolis, MN 55455 USA).

On May 4, 1998 the dynamic pressure of the solar wind was great enough to push the magnetosphere in to the point where the POLAR spacecraft observed six crossings of the Earth's bow shock (GSE coordinates: X ~ 6 RE, Y ~ 0 RE, Z ~ 6 RE). This provided the opportunity to examine the structure of both the electric and magnetic fields in collisionless shocks with very high magnetosonic Mach number (4.8 - 9.1), with high plasma beta (2.1 - 4.8), and with quasi-parallel and quasi-perpendicular orientation of the upstream magnetic field to the shock normal (20 - 66 degrees). Large-scale electric field structure is observed when the convective E-field is oriented within the spin axis of POLAR (where measurements from POLAR's Electric Field Instrument are most accurate). Integrating the electric field across the shock ramp and assuming that the ramp thickness is in the range of 0.2 - 0.6 ion inertial lengths, the cross-shock potential is roughly estimated to be in the range of 2000 - 6000 V. This is on par with the ~3 keV change in kinetic energy of an ion across this shock (as expected from the Rankine-Hugoniot shock jump relations).
When the convective electric field is primarily out of the spin plane, the large electric field fluctuations were examined (amplitudes up to 50 mV/m and frequencies of 1 - 20 Hz. The orientation and polarization of these fluctuations are analyzed with respect to the magnetic shock profile and the implications of these observations on shock heating are explored.

MIRROR INSTABILITY WITH FINITE ELECTRON TEMPERATURE EFFECTS

O.POKHOTELOV,(Institute of Physics of the Earth, Moscow, Russia, Email: pokh@uipe-ras.scgis.ru); M. Balikhin and H. Alleyne (both ACSE , The University of Sheffield, Mappin Street, Sheffield, UK, Email: m.balikhin@sheffield.ac.uk, H.Alleyne@sheffield.ac.uk)

A theory of mirror instability accounting for the finite electron temperature effects is developed. Using the standard approach to the analysis of this instability we have derived an expression for the growth rate and analyzed the modifications of the instability due to the presence of finite electron temperature and arbitrary electron anisotropy. In comparison with earlier analyses which were limited to isotropic electron distributions, consideration of the general case of arbitrary electron anisotropy allows the application of the results obtained to various regions such as the terrestrial magnetosheath or ring current. In the particular case of isotropic electron distribution comparison with the previous results have been made. It is shown that the earlier analysis is inadequate, because some important resonance terms have been overlooked. This led to the incorrect expression for the growth rate of the mirror instability in a finite electron temperature plasma.

CALCULATIONS OF PLASMA FLOW IN THE DAYSIDE MAGNETOSHEATH BASED ON THE BOUNDED ANISOTROPY MODEL

A.A SAMSONOV and M.I.PUDOVKIN

Experimental data show existence of the proton temperature anisotropy in the dayside magnetosheath. The adiabatic MHD model for an anisotropic plasma is known as the CGL equations. But exploitations of the CGL equations for the magnetosheath modelling overestimate the temperature anisotropy values. To improve this situation the CGL model has been developed into the bounded anisotropy model. The last model takes into account the proton pitch-angle diffusion resulting from a plasma instability growth. We calculate a 3D MHD flow around a sphere based on the bounded anisotropy model and compare the results with experimental data. We conclude that the model can describe the observed anisotropy values. Also we compare results of the isotropic and anisotropic models. The calculated magnetosheath width is bigger for the anisotropic model.

THE KINETIC MIRROR MODE: POLARISATION AND PROPERTIES

Steven J. SCHWARTZ* and Christian Mazelle (CESR/CNRS, BP 4346, 9 Avenue du Colonel Roche, 31028 Toulouse Cedex 4, France, email: Steve.Schwartz@cesr.fr; *permanent address: Astronomy Unit, Queen Mary and Westfield College, London E1 4NS, UK, email: S.J.Schwartz@qmw.ac.uk)

According to anisotropic MHD theory, the mirror mode is a non-propagating fluctuation with magnetic field magnitude and plasma density in anti-phase. The mode, derived in MHD theory from the magnetosonic branch, can grow in regions of perpendicular temperature anisotropies, especially in regions of high plasma beta such as the Earth's magnetosheath. More recently, kinetic aspects have been highlighted which reveal the curious role of the "resonant" particles and the co-existence of the mirror mode with the low frequency magnetosonic modes. All of this work, however, suggests that the mode is polarised in the traditional coplanar magnetosonic sense, i.e., that the fluctuations in magnetic field lie in the plane defined by the wavevector and background field. In numerical simulations, and in spacecraft data, however, a non-coplanar component is seen during the nonlinear phase. We show that such a non-coplanar component can, in fact, be present even in linear kinetic treatments, though it is not clear whether this component is responsible for that seen in the simulations. We explore other aspects of the mirror mode characteristics for such non-coplanar cases.

FORESHOCK PRECONDITIONING

D. G. SIBECK (JHU/APL, Laurel, MD 20723 USA, Email: david.sibeck@jhuapl.edu); T. D. Phan and R. P. Lin (both at Space Science Laboratory, UCB, Berkeley, CA, email: phan@ssl.berkeley.edu)

Kinetic processes within the foreshock can greatly modify the incoming solar wind shortly prior to the time when it encounters the bow shock and the magnetosphere, perhaps resulting in pressure pulses or hot flow anomalies. The multipoint observations provided by the ISTP program allow us to better determine the extent of this preconditioning. We begin by presenting a case study of simultaneous Wind, Geotail, Interball-1, and IMP-8 foreshock observations on April 19, 1996 which indicate that bursts of backstreaming ions in the foreshock can create diamagnetic cavities in the solar wind in which densities and magnetic field strengths are depressed by a factor of two. The multispacecraft observations allow us to demonstrate that the dimensions of these cavities are smaller than those of the magnetospheric obstacle, and to demonstrate that the extent of the diamagnetic effect decreases with distance from the bow shock. We then present the results of a survey of Wind perigee passes designed to determine the dependence of the diamagnetic effect on solar wind conditions and spacecraft distance from the bow shock.

INTERBALL TAIL OBSERVATIONS OF HOT FLOW ANOMALIES

Oleg Vaisberg Alexander Skalsky, Valery Smirnov, and Levon Avanov (Space Research Institute, 84/32, Moscow, 117810 Russia, email: olegv@iki.rssi.ru) James Burch, J.Hunter Waite, Jr. (Southwest Research Institute, San Antonio, TX 78228, USA, email: jburch@hal.space.swri.edu)

Several Hot Flow Anomalies in front of the bow shock were identified in 1996 in the data of fast 3-D ion measurements of the SCA-1 ion spectrometer on the Interball Tail Probe. We use

ion and magnetic data to analyze the structure of these HFAs and the magnetic conditions favorable to their development. We also use WIND data to tentatively identify interplanetary discontinuities responsible for these HFAs. We report two new findings compared to previous investigation of HFAs with AMPTE and ISEE spacecraft. One is distinct double structure of HFAs in the solar wind with the trailing (sunward) part being more isotropized. Another is a clear evidence of two ion components within HFA: modified solar wind beam and non-gyrotropic reflected ion beam(s). We present detailed development of interaction of two ion components within HFAs and the magnetic structures within these HFAs. A number of very strong flow anomalies within the magnetosheath, including ones quite close to the magnetopause, are identified. We present evidence that these flow anomalies, apparently associated with the propagation of interplanetary discontinuities through the magnetosheath, lead to the development of wave motions of the magnetopause.

TURBULENCE GENERATION UPSTREAM OF A QUASIPERPENDICULAR SUPERCRITICAL BOW SHOCK

S. Walker, M. Balikhin University of Sheffield, UK (University of Sheffield, ACSE, Mappin Street, Sheffield, S1 3JD UK. Email: simon.walker@sheffield.ac.uk); M. N. Nozdrachev, KI, Moscow, Russia

Nonlinear dynamics of the magnetic field turbulence observed upstream of a quasiperpendicular, supercritical bow shock by AMPTE-IRM and Interball are studied using high order spectral analysis techniques. Such an analysis provides evidence in favour of the generation of this turbulence by the internal macrodynamics of the shock front itself, rather than plasma micro instabilities.

MAGNETOSHEATH STRUCTURE JUST UPSTREAM OF THE MAGNETOPAUSE: DUAL SPACECRAFT ANALYSIS

T. I. WOODWARD and M. W. Dunlop Space and Atmospheric Physics, Imperial College, London SW7 2BZ, England, UK S. J. Schwartz Astronomy Unit, Queen Mary and Westfield College, London, England, UK. A. N. Fazakerley, Mullard Space Science Laboratory, Holmbury St. Mary, Dorking, Surrey, UK N. Sckopke Max-Plank-Institute fur Extraterrestrische Physik, Garching, Germany.

It is well known that the flow of the magnetised solar wind over the Earth's magnetosphere establishes an intricate system of upstream wave-fronts and shocks. In the framework of MHD theory, the bow shock is formed by the fast mode, while physical conditions for the Alfven and slow mode waves to stand in the flow behind the bow shock (but upstream of the magnetopause) exist. It is the purpose of the current study to use data from the dual spacecraft AMPTE IRM/UKS mission to identify and analyse the motion and structure of low frequency, wave-like structures recorded in the data from regions upstream, but adjacent to, the magnetopause. Evidence for a plasma depletion layer, slow/Alfven mode standing front, as well as mirror mode-like compressional structures in the local noon region has been reported previously. Here we find evidence for variation in composition between the noon and dawn-side regions and further investigate structural features by inter-comparison of the dual spacecraft data. These wave structures are discussed in the context of the local magnetosheath flow and magnetic field conditions and their occurrence in local time.

INTERACTIONS OF DISCONTINUITIES WITH THE BOW SHOCK

XIAOXIN ZHANG(Center for space science and applied research,Chinese academy of sciences, P.O.Box 8701,Beijing 100080, email: zhangxx@center.cssar.ac.cn and Yu Lin (Physics department,Auburn University, Auburn, AL 36849, email: ylin@physics.auburn.edu)

Recent theoretical studies have shown that the interaction of a solar wind discontinuity with the bow shock will produce a more complicated structure in the magnetosheath than that by a simple convection. We are searching for the observational evidences for such an interaction. In this study, we investigate the response of the plasma and magnetic field in the magnetosheath to the variations in the interplanetary magnetic field(IMF) direction. The correlation of the magnetosheath observations with the solar wind plasma and the IMF is studied by using magnetosheath data from ISEE-1, ISEE-2 and IRM and the solar wind data from ISEE-3 and IMP-8. We use the solar wind and the IMF measurements as input to the gasdynamic convected field model, as implemented in a new space weather forecast model,and get the relatively accurate timeshift from the solar wind monitor to the magnetosheath and also obtain the prediction properties of the plasma and magnetic field in the magnetosheath. Comparing the magnetosheath observations and predictions with the solar wind and IMF can discern the effectsof the variation of the IMF direction on the plasma and magnetic field properties in this process from a simple convection process.

THE PARABOLIC MAGNETOPAUSE FORM AND LOCATION VERSUS SOLAR WIND PRESSURE AND IMF

I.I. Alexeev, V.V. Kalegaev, Yu.G. Lyutov ; Institute of Nuclear Physics, Moscow State University, 119899 Moscow, Russia

The new parabolic approximation of the magnetopause is presented using magnetopause crossings data set. The main aim of this study is to provide a more "realistic" magnetopause for the paraboloid model of the magnetosphere which form and location depends on the IMF and solar wind dynamic pressure. This approach allows us to carry out the pressure balance on the magnetopause and provides more accurate calculations of the magnetospheric magnetic field in the framework of paraboloid model. The magnetopause subsolar distance and tail flaring identifying completely the parabolic magnetopause are obtained using crossings of ISEE, Prognoz, Explorer and IMP series satellites. The average values of these parameters are calculated separately for positive and negative Bz component of IMF. It was shown that magnetopause subsolar distance is larger and flaring is smaller for a positive Bz than those for negative one. The dependence of the magnetopause subsolar distance normalized to the average solar wind dynamic pressure on IMF Bz is found. It is less sensitive to positive IMF Bz variation than negative ones. The paraboloid model of the magnetosphere is presented in the form taking into account the magnetopause shape dependence on Bz IMF direction.

INTERACTION BETWEEN THE MAGNETOSHEATH AND MAGNETOSPHERIC PLASMAS AT THE DAYSIDE MAGNETOPAUSE

Elena BELENKAYA (Institute of Nuclear Physics, Moscow State University, Moscow, 119899, Russia, Email: Elena@dec1.npi.msu.su)

The structure of the magnetopause is one of the extensively studied questions in the recent years. Investigation of motions of the two sorts of collisionless plasma (magnetosheath and magnetospheric) with frozen-in strong magnetic fields allow to construct a self-consistent model. Low-latitude dayside magnetopause is a double-current layer. For southward IMF, both currents flow from noon to dusk. This is a metastable configuration, in which reconnection may occur. For northward IMF, the current created by the magnetosheath ions is directed to dusk, and the current generated by the magnetospheric ions is directed to dawn. A mechanism of a double-current layer generation at the dayside low-latitude magnetopause is connected with the difference of plasma parameters and magnetic fields in the magnetosheath and magnetosphere. The direction of charged particles gyration at the magnetopause is such that the magnetic field generated by each boundary current creates diamagnetic effect.

STATISTICAL STUDY OF MAGNETOPAUSE AND IT'S BOUNDARY LAYERS. INTERBALL-1 OBSERVATIONS.

N.L.BORODKOVA (Space Research Institute Russian Academy of Sciences, Moscow, Russia, Email: nbor@afed.iki.rssi.ru), D.G.Sibeck (Johns Hopkins University Applied Physics Lab., Email: david.sibeck@jhuapl.edu), S.A.Romanov (Space Research Institute Russian Academy of Sciences, Moscow,Russia, Email: sroman@mx.iki.rssi.ru),J.-A.Sauvaud (Centre d'Etude Spatiale des Rayonnements, Toulouse, France, Email: sauvaud@cesr.cnes.fr)

Magnetopause and its boundary layers play an important role in the transport of magnetosheath mass, momentum and energy into the magnetosphere. Interball-1 spacecraft crossed the magnetopause and boundary layers in a wide range of local times and latitudes. In this paper magnetopause results obtained from electron and magnetic field measurements from Interball-1 during 1995-1998 are reviewed. INTERBALL-1 observations have revealed the existence of very extensive low-latitude boundary layer(LLBL) at the flanks of the magnetopause. The dependence of LLBL encounter on IMF direction is presented. Electron measurements indicate that LLBL is located inside closed magnetospheric field lines.

SIGNATURES OF MAGNETOTAIL RECONNECTION DERIVED BY NUMERICAL SIMULATIONS AND VERIFIED IN SPACE

JOERG BUECHNER, B. Nikutowski (Max-Planck-Institut fuer Aeronomie, Max-Planck-Str. 2, D-37191 Katlenburg-Lindau, Germany); W. Baumjohann, G. Haerendel (Max-Planck-Institut fuer extraterrestrische Physik, D-85740 Garching, Germany); H.-U. Auster, K.-H. Fornacon (Technische Universitaet Braunschweig, Braunschweig, Germany); E. Georgescu(ISS, Bucharest, Romania}

We present EQUATOR-S magnetic field observations of low-latitude dayside reconnection signatures between December 1997 and February 1998.
All clear cut reconnection cases were obtained during periods of large magnetic field shear angles between the ambient solar wind (magnetosheath) and magnetospheric fields. At the same time when the reconnection signatures were found the observations additionally show strong magnetic field excursions in the current direction. We interprete this field behavior in terms of three-dimensional kinetic reconnection. We illustrate the latter by results of kinetic plasma simulations of magnetopause reconnection and compare observations and simulation results in an appropriate magnetopause normal coordinate system.

A FIRST APPROACH TO THE DYNAMICS OF THE SOLAR WIND MAGNETOSPHERE INTERACTION

Ricardo Dmaz, Bienvenido Lazo, Alexander CALZADILLA and Ricardo Mansilla Departamento de Geofmsica Espacial, IGA/CITMA, Calle 212 No 2906, La Lisa, C.P. 11600,C. de La Habana, Rep. de Cuba. *Universidad de la Habana,Facultad de Matematica, San Lazaro esq. 29

In this work, we study the predictability of the time evolution of the magnetic activity index Dst, using the methods of the theory of non linear dynamics. The Lyapunov exponents and the correlation dimension were estimated for different sets of Dst data corresponding to the years 1978, 1979, 1980, 1985, 1986, 1995 and 1996; as well as their variation with the embedding dimension. We also performed calculations of autocorrelation functions, probability distributions, and IFS clumpiness tests. Evidences were found of the presence of sensitive dependence of initial conditions, as well as a complicated dynamics of high dimensionality and tough prediction.

3D ANN DAYSIDE MAGNETOPAUSE MODEL: APPLICATION FOR SUB-SOLAR POINT AND CUSP DYNAMICS

A.V. DMITRIEV and A.V. Suvorova (Institute of Nuclear Physics, Moscow State University, 119899, Moscow, Russia, email: dalex@srdlan.npi.msu.su)

The code of 3D Artificial Neural Network Model of Dayside Magnetopause is used to describe the dynamics of subsolar point and cusp region under different solar wind and interplanetary magnetic field conditions. The dependence of the subsolar point location on the dynamic pressure and IMF Bz- and By- components is expressed in the form of modified logistic function which permits to describe three different regimes of magnetopause formation controlled by IMF Bz-component. The dynamics of the cusp region extension in longitudes and latitudes is presented. Effects of "dimple" formation in the region of the subsolar point and the cusp disappearance under strong negative Bz (<-10nT) are described.

DUAL SPACECRAFT VERIFICATION OF MAGNETOPAUSE MOTION DETERMINED BY METHODS BASED ON SINGLE SPACECRAFT DATA

M. W. DUNLOP Space and Atmospheric Physics, Imperial College, London SW7 2BZ, England T. M. Bauer and N. Sckopke Max-Plank-Institute fur Extraterrestrische Physik, Garching, Germany. A. V. Khrabrov and B. U. O. Sonnerup Thayer School of Engineering, Dartmouth College, Hanover, NH 03755, USA A. N. Fazakerley, Mullard Space Science Laboratory, Holmbury St. Mary, Dorking, Surrey, UK.

We attempt to validate results from multi-instrument, single spacecraft, methods for the determination of magnetopause speed and orientation by use of dual spacecraft data, including position and timing. Among these methods, which utilise measured plasma velocity and magnetic field, time series data, are: (1) the determination of the deHoffmann-Teller frame velocity, giving, in combination with the boundary (MVA) normal, the magnetopause speed along the normal, (2) Minimum-Faraday-Residue analysis, which yields both the magnetopause normal and speed and (3) for tangential discontinuities, use of the average measured plasma velocity in combination with the boundary normal to yield magnetopause speed. These techniques rely on certain assumptions, whose validity can be tested, concerning boundary structure and stationarity, and therefore can differ in result. They determine most closely the local properties sampled by a particular spacecraft. The results of such analysis can be verified by comparison with timings of boundary crossings between two or more closely separated spacecraft. We undertake such validation using a range of crossings taken from the AMPTE UKS/IRM data set, which exhibit different boundary characteristics and occur for different spacecraft configurations with respect to the boundary. If the spacecraft separation is small, the local conditions measured by each spacecraft are likely to be similar. But timing differences are then typically small, so that the analysis becomes sensitive to both data calibration effects and to uncertainties in relative spacecraft position and timing. If the spacecraft separation is large, the spacecraft may sample different magnetopause properties, but analysis and measurement errors are then less significant, unless the spacecraft separation vector is nearly perpendicular to the boundary normal. Our results indicate that, under favourable conditions, the aforementioned single spacecraft methods yield magnetopause velocities that agree well with those derived from dual-spacecraft time shifts.

PROPERTIES OF THE DAWN-SIDE MAGNETOPAUSE AND ADJACENT MAGNETOSHEATH OBSERVED BY EQUATOR-S

M. W. DUNLOP, E. A. Lucek, P. J. Cargill and A. Balogh, Space and Atmospheric Physics Group, Imperial College, London SW7 2BZ, England. G. Haerendel, W. Baumjohann, E. Georgescu1 and H. U. Auster Max-Plank-Institute für extraterrestrische Physik, Garching, Germany. 1Institute of Space Sciences, Bucharest, Romania. K.-H. Fornacon Institut für Geophysik und Meteorologie, TUB, Braunschweig, Germany.

A large number (more than 100) of magnetopause crossings in the low latitude, morning sector of the magnetosphere were observed by the German, Equator-S satellite between December 1997 and the end of March 1998. We review briefly the magnetopause locations, as observed in the magnetometer data (MAM experiment), and relate them to both solar wind and geomagnetic conditions, as well as routinely comparing the magnetospheric field to geomagnetic field models. The apogee of the spacecraft, at a height of 67,000 km, allowed long duration coverage (between 6:00 and 10:40 LT) of the magnetopause and adjacent magnetosheath for medium to high pressure solar wind conditions. Both crossing position and boundary normals compare well to predicted magnetopause location and orientation, but suggest a blunter magnetopause shape than in current magnetopause models. Little evidence is found for large deviations in local boundary normals, as would occur for a wavy boundary. This is consistent with the additional observation of a well ordered, draped magnetosheath field, typically under conditions of high magnetic shear at the magnetopause. The orbit of Equator-S was particularly suited to sample magnetosheath waves. During twelve of the orbits where the spacecraft crossed into the magnetosheath, intervals of intense compressional signatures, suggestive of mirror-mode structures, were observed, often immediately adjacent to the magnetopause. By contrast, no evidence for ion cyclotron waves in the magnetosheath has been found, suggesting the absence of a plasma depletion layer, extending into this dawn-side region. Spectral analysis of the mirror mode structures shows a characteristically shaped shoulder, well defined in the power spectral density, at about 0.05 Hz. The main features of the spectrum appear to be stable, despite significant changes in the temporal distribution and shape of the structures. We discuss the occurrence and characteristics of the observed mirror structures and the crossings associated with them.

GA3.07/W/28-A4 Poster **0930-09**

STATISTICAL STUDY OF THE FLANK LLBL LOCATION AND PROPERTIES UNDER DIFFERENT IMF CONDITIONS. INTERBALL-TAIL OBSERVATIONS.

Andrei FEDOROV, Elena Budnick (both at Space Research Institute, 34/82, Profsouznaja st., Moscow, Russia, email: af@afed.iki.rssi.ru), Jean-Andre Sauvaud, Helene Renault-Stenuit (both at CESR-CNES, 9, avenue de Colonel-Roche, Toulouse, France, email: sauvaud@cesr.cnes.fr)

The Low Latitude Boundary Layer (LLBL) is one of the important plasma and energy transition region between magnetosheath and magnetosphere. The characteristics of LLBL strongly depend on IMF direction and of magnetosheath plasma conditions, however the coupling processes remain unclear. Interball-Tail Probe was surveying the LLBL regions during 1995-1998. Four types of LLBL-type plasma were distinquished for this study. Every pass was divided in several zones according to different plasma regimes. Spacecraft position was projected along model field lines onto XY GSM plane and normalized to average magnetopause position. About fifty boundary layer crossings were investigated. It is shown that different LLBL regimes appear at the magnetospheric flanks depending on IMF direction. Based on this statistical study some assumptions on LLBL formation are presented. The evidence of appearance of ionospheric ions at the plasmasheet edge of LLBL is presented and discussed.

ORDERING OF ELECTRON ANISOTROPY IN THE LOW-LATITUDE BOUNDARY LAYER

Mike Hapgood and Mike Lockwood, (CLRC Rutherford Appleton Laboratory, Chilton, Didcot, Oxfordshire, OX11 0QX, UK, Email: M.Hapgood@rl.ac.uk)

Enhanced fluxes of 100 eV to 1 keV electrons parallel and anti-parallel to the magnetic field are observed during most crossings of the low-latitude boundary layer (LLBL). We show that these "counter-streaming electrons" are well-ordered by the magnetopause transition parameter of Hapgood and Bryant (1992), which also orders other independent quantities such as the magnetic field and ion bulk velocity. These results will be discussed in the context of a reconnection model of the LLBL.

TWO DIMENSIONAL STRUCTURES IN THE MAGNETOPAUSE RECOVERED FROM SINGLE-SPACECRAFT DATA

L.-N. Hau (Institute of Space Science, National Central University, Chung-Li, Taiwan 320, email: lnhau@jupiter.ss.ncu.edu.tw); Q. Hu and B.U.Ö. SONNERUP, (both at Thayer School of Engineering, Dartmouth College, Hanover NH 03755, USA, e-mail: qiang.hu@dartmouth.edu, sonnerup@dartmouth.edu)

A technique for recovering magnetic field maps that describe two-dimensional, coherent field structures observed in space is documented, benchmarked, and applied to magnetopause crossings by the spacecraft AMPTE in which the basic observed signatures were those associated with a tangential discontinuity. The calculations consist of the numerical solution of the plane Grad-Shafranov equation, using as initial values magnetic field and plasma data collected by a single spacecraft along a straight-line trajectory, produced when structures are convected past it. The integration proceeds in small spatial steps in both directions away from the trajectory. The method offers a substantial field of view of the region surrounding the trajectory, within which the map accuracy is a few percent. For the magnetopause events examined, it is found that the simple tangential-discontinuity structure is modified by embedded strings of magnetic islands, separated by X-type nulls in the transverse field. These configurations are a manifestation of the tearing mode, after it has reached its saturated state. Two or more islands contained within larger islands are observed, indicating that, during the active phase of the tearing mode, the reconnection rate was not the same at all X points. The possibility exists that one dominating X point produces a pair of narrow channels of open flux, connecting the magnetosphere to the magnetosheath. Even without such open flux, the presence of the islands should allow flow of plasma along magnetic fieldlines, from the outermost (magnetosheath) to the innermost (magnetosphere) parts of the magnetopause current layer, thus facilitating the overall plasma transport across the layer.

OBSERVATIONAL STUDY OF MODE CONVERSION OF LOW FREQUENCY MHD WAVES AT THE MAGNETOPAUSE: DEPENDENCE ON MAGNETIC ROTATION

Jay R. JOHNSON and C. Z. Cheng (Princeton University, Plasma Physics Laboratory, Princeton, NJ 08543, Email: jrj@pppl.gov, fcheng@pppl.gov)

At the magnetopause, large amplitude, low frequency, transverse MHD waves are nearly always observed. These waves are likely the result of mode conversion of compressional MHD waves observed in the magnetosheath. Mode conversion readily occurs at the magnetopause because there is a steep gradient in Alfven velocity [Johnson and Cheng, Geophys. Res. Lett., 24, 1423, (1997)]. A number of observational features support this scenario: a dramatic change in polarization is typically observed from longitudinal in the magnetosheath to transverse at the magnetopause, an increase in wave amplitude at the magnetopause, a change in Poynting flux from cross-field in the magnetosheath to field-aligned at the magnetopause, and a steepening in the wave power spectrum at the magnetopause. In this paper, we explore the dependence of the mode conversion process as a function of magnetic shear. In particular, we shall compare relative wave amplitudes in the magnetosheath and magnetopause; wave polarizations; and spectral slope as functions of magnetic rotation across the magnetopause boundary. The res ults of this data survey will be compared with theoretical predictions, and implications for transport processes at the magnetopause will be discussed.

ANALYTICAL MAGNETOSHEATH-MAGNETOSPHERE INTERACTION MODEL WITH EMPIRICALLY DETERMINED FREE PARAMETERS

Esa J. Kallio and HANNU E. J. KOSKINEN* (Finnish Meteorological Institute, Geophysical Research, P.O.Box 503, FIN-00101 Helsinki, Finland, e-mail: Esa.Kallio@fmi.fi; *also at University of Helsinki, Department of Physics)

We describe a new analytical model for studies of solar wind-magnetosphere interaction. Our aim has been to develop a computationally simple model with a small number of free parameters that can be varied to give the best possible fit to one or more satellite observations of the upstream plasma flow and the estimated position of the magnetopause. The magnetic field in the agnetosheath is derived from an analytical model of the plasma flow assuming that the magnetic field is frozen into the flow. The magnetosheath flow is parameterized by a small number of constants. The internal magnetic field model consists of dipole and ring current contributions with a variable dipole tilt. The field is confined inside a parabolic magnetopause. The subsolar point and the width of the parabola can be varied according to bservationally or theoretically derived shape of the magnetopause. We can simulate the interconnection of the external and internal fields by letting the two regions overlap within a boundary layer of variable thickness. Although the model does not describe the local physics of the interconnection, it can be used to investigate, e.g., the favorable regions for reconnection under arbitrary direction of the upstream magnetic field after it has passed the bow shock and become wrapped around the magnetopause. The advantages of the model are its numerical simplicity and its adjustability to actual observations. We illustrate the effects of variation of the model parameters using observations of solar wind magnetosphere interaction.

CHARACTERISTICS OF FTES OBSERVED B GEOTAIL AND INTERBALL SPACECRAFT

G.I.Korotova(1),D.G.Sibeck(2),S.Kokubun(3),K.Kudela(4),T.Mukai(5),V.P.Petrov(1), J.Safrankova (6),B.Styazkin(1),K.Takahashi (2) 1.IZMIRAN,Troitsk,Moscow Region,Russia, 2.JHU/APL ,Laurel,MD,USA 3.STEL,Toyokawa,Japan; 4.IEF in Cosice,Slovakia; 5.ISAS in Sagamihara,Japan; 6.KEVF MFF UK,Prague,Czech Republic

We present results from case and statistical studies of FTEs,observed by the Geotail and Interball spacecraft on the dayside and flank magnetopause. Magnetic field data acquired with Geotail constitute the main date base in this study. We used classical classification scheme and created data base that covers period from 1992 to 1997 and includes more than 1000 FTEs with their characteristics and values and orientation of ambient magnetic field in the magnetosheath and magnetosphere. We study FTE occurrence and recurrence patterns as a function of latitude,local time and solar wind parameters. The equatorial events show a marked tendency to occur for southward IMF orientation,consistent with the merging interpretation. We compare the characteristics of the events with recent numerical simulations of bursty merging at a patch, along a single x-line, and along multiple x-lines.

ANALYSIS OF THE PRESSURE BALANCE EQUATION ALONG THE MAGNETOPAUSE UNDER DIFFERENT CONDITIONS IN INTERPLANETARY MEDIUM

S.N.KUZNETSOV and B.Yu.Yushkov (both at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, 119899, Moscow, Russia, e-mail: kuznets@srdlan.npi.msu.su)

Analysis of the available data set, containing numerous intersections of the magnetopause by different satellites over more than 30 years leads to the conclusion, thay the form of the magnetopause should be approximated by a more complicated surface than those of the 2 order (ellipsoid, paraboloid). The form of this surface is not only a function of pressure but also of the Bz IMF component. We used real data for calculation of the pressure balance equation under different conditions in interplanetary medium and for comparison with model values. Results of this comparison are discussed.

RECONNECTION PROCESSES ON LOW LATITUDE DAYSIDE MAGNETOPAUSE AND HIGH LATITUDE GEOPHYSICAL PHENOMENA DURING 24 JULY, 1996 EVENT

Tamara Kuznetsova (IZMIRAN, Russian Academy of Sciences), Troitsk, Moscow region, 142092, Russia, email: tvkuz@izmiran.rssi.ru David SIBECK (APL/Johns Hopkins University), Rd., Laurel, MD 20723, USA, email: david.sibeck@jhuapl.edu

The IMF and the magnetosphere are strongly coupled by the magnetic field lines connecting boundary layers of the magnetosphere with the auroral ionosphere. We present our analysis of earlier reported event of dayside magnetopause deformation (24 July, 1996) detected by Interball-1 based on multi-instrument observations. Magnetosphere had a quiet state before event (DMSP F13). Parameters of the solar wind had not sharp changes before and during the event. Study of the geomagnetic data of the stations that allow to determine a sign of the IMF structure shows that sector structure changed sharply (from Bx >0, By <0 to Bx <0, By >0), data in the solar wind (Wind, IMP-8) confirm this changes and show Bz change (to Bz>0). Constructed current system DP4 depending from a sign of By IMF explains observed regularities in geomagnetic variations in the cusp and cap and dawn-dusk asymmetry in the Polar UVI images. Reconnection with By>0 IMF on the magnetopause leads to the dawnward convection of magnetic force lines on the dayside boundary of the polar cap concentrating at the cusp. This leads to field-aligned currents and transverse magnetic disturbances under the cusp that are seen at vector diagrams of the relevant stations. Current system DP3 depending from sign of Bz IMF explains additional regularities in the geomagnetic variations. Calculated orientations of reconnection line, intensities of Ey and Ez electric fields on the low latitude magnetopause caused by IMF orientation changes projecting on the polar ionosphere explain geomagnetic variations in the cusp and cap, strong electric fields observed by incoherent scatter radar, movements of the low latitude boundary layer at Interball-1.

RECONNECTION CONFIGURATION AT THE MAGNETOPAUSE BOUNDARY LAYER

Zhenxing LIU, Tao Chen, and Chao Shen (all at Center for Space Science and Applied Research, Chinese Academy of Sciences, Beijing 100080, China, e-mail: liu@sun20.cssar.ac.cn) Zuyin Pu (Department of Geophysics, Peking University, Beijing 100871, China, email: pzy@pku.edu.cn)

We have investigated the reconnection configuration in the subsolar region of dayside magnetopause boundary layer and high latitude boundary layer (HLBL) by using two-dimensional compressible MHD model. It is supposed that the local and transient magnetic reconnection in the subsolar region can be caused by the impact and sudden stop of a single directional transverse shear flow. It is found that the state of a flow and its lasting period play an important role in reconnection processes. When the inflow is a sheared one, magnetic reconnection always occurs in the magnetopause region. If the impact switches off, the system changes drastically, many kinds of reconnection configurations and fluid vortices are generated in the current sheet region. It is pointed that the sudden stop of external flow impact may be an important triggering mechanism of energy transformation and magnetic reconnection in the plasma boundary layer.
We have also studied the transient reconnection processes caused by the field-aligned shear flow at the high latitude boundary layer for different interplanetary magnetic field. A model of global reconnection configurations for IMF BZ~0 and IMF BZ is northward are proposed. We supposed that the flux transfer events might occur in the HLBL region when IMF is northward.

TRANSMISSION OF MAGNETOHYDRODYNAMIC WAVES THROUGH THE ROTATIONAL DISCONTINUITY AT THE EARTH'S MAGNETOPAUSE

A.A. Lubchich (Polar Geophysical Institute, Apatity, Russia; E-mail: lubchich@pgi.kolasc.net.ru)

Reflection and transmission of small amplitude magnetohydrodynamic (MHD) waves of solar-wind origin through the Earth's open magnetopause are studied. The open magnetopause with a nonzero normal component of magnetic field is assumed to be a rotational discontinuity. Transmission of MHD waves through the rotational discontinuity has been considered earlier. For instance, L.C.Lee (Planet. Space Sci., V.30, 1127, 1982) has studied the transmission of Alfvén waves for a rotational discontinuity in which the magnetic field rotates by 180° across the boundary. Y.C.Kwok and L.C.Lee (J. Geophys. Res., V.89, 10697, 1984) have studied the transmission of any of the incident waves for any rotational discontinuity. However, correctness of the results obtained in the last paper (for example, existing of the very high amplification regions and non-zero amplitude of transmission entropy wave for the case of an incident non-entropy wave) is doubtful. We performed the more accurate consideration and got different results. We also found that for any incident wave, there is one reflected wave (usually, it is a fast magnetosonic wave, but under some specific conditions it can be a slow magnetosonic wave) and five transmitted waves (one fast magnetosonic wave, two slow magnetosonic waves, one Alfvén wave and one entropy wave). The transmitted entropy wave appears only in the case of the incident entropy wave. Dependence of the transmission and reflection coefficients on the type of incident wave, the incident angle (all possible angles are included into the consideration), the orientation and strength of the ambient magnetic field is studied. In contrast to the result of Kwok and Lee, it is found that maximal amplitude of the emanating waves differs only by factor 1.5 in comparison with amplitude of the incident waves.

SIMULATION AND VERIFICATION OF THE SELF ORGANIZATION IN THE MAGNETOPAUSE KELVIN HELMHOLTZ INSTABILITY

Akira Miura (Department of Earth and Planetary Physics, University of Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo 113-0033, Japan, email: miura@sunep1.geoph.s.u-tokyo.ac.jp)

It is shown by using two-dimensional MHD simulations that the successive pairings of vortices occurring in the nonlinear stage of the Kelvin-Helmholtz instability is a self-organization process, in which the small-scale vortices excited by the instability near the dayside magnetopause evolve into global-scale vortices in the tail of the magnetosphere. The self-organization arises because of the inverse cascade. The total kinetic energy remains almost constant, but the enstrophy decreases rapidly owing to the selective dissipation by the numerical viscosity during the self-organization. Both the kinetic energy, the enstrophy, and the magnetic energy form power law spectra in the wavenumber space in the well developed nonlinear stage. A current eddy is associated with each flow vortex. The simulation results are tested against observations of the magnetopause oscillation. The linear relationships obtained by the simulations between the period of the magnetopause oscillation and the distance along the magnetopause from the subsolar point are in good agreement with the observed period vs. distance relationship. The comparison of the simulation results and the observations gives a thickness of the velocity shear layer near the subsolar point, which is slightly larger than the thickness of the magnetopause.

CRITERIA FOR FIELD-ALIGNED CURRENT-CARRYING SURFACE WAVES GROWTH AT RECONNECTION

P. NENOVSKI Geophysical Institute, Bulgarian Academy of Sciences, Sofia, Bulgaria

A surface wave model of field-aligned current (FAC) generation at reconnection has been suggested. The FAC associated with the surface waves flows along the separatrices which devide the unperturbed inflow region from the outflow. These separatrices confine the reconnection region of finite conductivity where the surface wave generation process is initiated. A simple model of velocity dependent conductivity is introduced and an associated reactive-diffusive equation scheme is constructed. The solution found yields the magnitude of the field-aligned currents depending on three parameters - the magnetic Reynolds number, the Mach number and the magnetic field-plasma density ratio. The associated solution has a periodicity trend of relaxation of the perpendicular current which feeds the FAC. When this current evolves to its final state the surface wave FAC process stops. The region of parameters under which the surface waves are marginally stable is examined. Consideration is made for magnetopause conditions.

USE OF HIGH CHARGE STATE ION COMPOSITION AS A TRACER FOR SOLAR WIND ENTRY INTO THE MAGNETOSPHERE

C.H., M. Grande and B. Kellett, S. Hefti and T. H. Zurbuchen, G. Gloeckler J.F. Fennell, B. Wilken and T. Fritz

Using data from Polar and ACE during the 1-3 May 1998 CME event we present a comparison of high charge state ion composition measurements from Polar in the magnetosphere with ACE near L1. The solar wind frozen-in charge state distribution for Fe ions was observed to undergo several abrupt changes during this period with the average charge state varying between +4 and +15. These abrupt changes have been used to demonstrate the connectivity between the observations at L1 and those made in the LLBL/Cusp region. They indicate direct entry of solar wind material during periods of southward IMF and provide some evidence for prompt entry of these ions into the plasma sheet though not in this case to below geostationary altitude. Having demonstrated that magnetospheric observations of high charge state ions provide a good means of tracing solar wind entry, we use a statistical survey of these measurements taken by Polar over a three-year period, to investigate the entry and transport of solar wind material in the magnetosphere as a function of location and geomagnetic conditions.

DIRECT DETERMINATION OF CUSP CURRENT SYSTEMS USING SUPERDARN RADAR AND GROUND MAGNETOMETER DATA - A LINK TO THEORY ON CUSP CURRENT ORIGIN

Olaf AMM (Finnish Meteorological Institute, Geophysical Research, P.O. Box 503, FIN - 00101 Helsinki, Finland, email: Olaf.Amm@fmi.fi); M. J. Engebretson (Augsburg College, 2211 Riverside Avenue, Minneapolis, MN 55454, USA, email: engebret@augsburg.edu), R. A. Greenwald (Johns Hopkins University, Applied Physics Laboratory, Johns Hopkins Road, Laurel, Maryland 20723-6099, USA, email: ray_greenwald@jhuapl.edu), H. Luehr (Geoforschungszentrum Potsdam, Telegrafenberg, D-14473 Potsdam, Germany, email: hluehr@gfz-potsdam.de), and T. Moretto (Danish Space Research Institute, Juliane Maries Vej 30, DK-2100 Copenhagen, Denmark, email: moretto@dsri.dk)

We analyse an ionospheric 'enhanced convection event' in the cusp on November 13, 1996, at 1900 UT, using data of the SuperDARN radar, of the IMAGE, Greenland, MACCS and CANOPUS magnetometer arrays, and from other magnetometer stations. The event occurs about 20 minutes after a transition of the IMF By component from positive to negative and an according reconfiguration of the ionospheric electric potential pattern. The data allows a two-dimensional instantaneous view of the event in terms of the ionospheric electric and ground magnetic field. The 'method of characteristics' is used to obtain distributions of ionospheric conductances, true ionospheric currents, and field-aligned currents (FACs) for the interval under study. Our results show that the region of enhanced convection observed by the radar corresponds to an area of low conductances, ranging only slightly above the UV conductance values. However, due to the strongly enhanced electric field, it is governed by enhanced westward flowing Hall and southward flowing Pedersen currents. At the northern and southern borders of the enhanced convection region, sheets of downward and upward FACs are observed, respectively, with magnitudes around 1 A/sqkm. We call this situation an 'inversed Cowling channel' since the resulting current system is similar to a Cowling channel, but the roles of the electric field and the conductance in producing the enhancement of the current are reversed. The geometry of the current system resembles the earlier introduced DPY current system. With our results, we test alternative theories on cusp current origin that lead to different predictions of the relative location of the cusp current system with respect to the open / closed fieldline boundary. The location of this boundary is inferred from DMSP satellite data.

HIGH ENERGETIC PARTICLES AS A CAUSE OF VLF PLASMA WAVES MEASURED ONBOARD MAGION 4 IN THE OUTER POLAR CUSP

J.Blecki1, K.Kudela6, J.Slominski1, R.Wronowski1, Z.Nemecek4, J.Safrankowa4, S.Savin2, J.A.Sauvaud5, P.Triska3. 1 Space Research Centre PAS 00-716 Warsaw, Bartycka 18A, Poland, 2 Space Research Institute RAS, Moscow, Russia, 3 Institute of Atmospheric Physics ASC, Prague, Czech Republic, 4 Charles University, Prague, Czech Republic, 5 CESR, Toulouse, France 6 Institute of Experimental Physics, Slovak Academy of Sciences, Kosice, Slovak Republic.
email: jblecki@cbk.waw.pl/

The satellite Interball Tail probe and Magion-4 -its subsatellite with their orbits with apogee about 30 RE and an inclination of 650 crossed the polar cusps many times at different altitudes. In this presentation we discuss results of measurements of the spectra of magnetic field fluctuations in the frequency range 30-2000Hz registered onboard Magion-4 and onboard Interball 1 in frequency range 0.1-200Hz. Presented in this paper results of wave measurements in the polar cusps shown, that in this region the wave are a good indicator of the dynamic processes. The most characteristic features of the wave spectra are the broad band emissions and maxima at the lower hybrid, electron cyclotron frequency and sometimes its harmonics. These waves correlate with strong fluxes of the high energetic electrons often observed within the polar cusp by Interball and Magion 4 satellites. The mechanism of the generation of the VLF waves by high energetic electrons will be briefly discussed.

EXTERIOR CUSP STRUCTURE UNDER DIFFERENT IMF CONDITIONS: THE EVIDENCE FOR THE OPEN MAGNETOSPHERIC TOPOLOGY

Andrei Fedorov, Elena BUDNICK (both at Space Research Institute, 34/82, Profsouznaja st., Moscow, Russia, email: af@afed.iki.rssi.ru), Eduard Dubinin (Max-Planck Institite fur Aeronomie, Katlenburg-Lindau, Germany, email: dubinin@helene.mpae.gwdg.de), Paul Song (Space Physics Research Laboratory, The University of Michigan, USA, email: psong@sprl.umich.edu), Jean-Andre Sauvaud (CESR-CNES, 9, avenue de Colonel-Roche, Toulouse, France, e-mail: sauvaud@cesr.cnes.fr)

We present observations of plasma flow in the exterior cusp in the vicinity of the magnetopause made onboard the Interball-Tail satellite for different directions of IMF. Under southward IMF three types of ion distribution function are observed in the magnetospheric parts of magnetic field lines (torus-like, pancake and D-shaped). They display a gradually decreasing ion entry along 'old' reconnected magnetic field lines. Under northward IMF D-shaped distributions with varying cutoff velocity parallel to the magnetic field are observed. Such distributions are typical for particles injected along recently reconnected magnetic field lines. We also present results of a simulation that uses the Toffoletto-Hill model of the open magnetosphere to trace the particles from the magnetosheath to magnetospheric locations of Interball. The simulation successfully reproduces the main features of measured distribution functions. Study of plasma behavior shows that the entry of magnetosheath plasma into the magnetosphere can be described in terms of reconnection leading to open topology of field lines near the exterior cusp.

GA3.07/W/17-A5 Poster **0900-04**

A SEMI-QUALITATIVE MODEL OF REGION 0 CUSP CURRENTS AND MOVING ARCS

Galperin Yuri, Space Research Institute of RAS

A simple model of cusp Region 0 FA currents is suggested. It is based on the well known GVBT formula (Grad, 1964; Vasyliunas, 1972; Bostrom, 1975; Tverskoy, 1982) aplied to the region of enhanced plasma pressure within the outer cusp plasma flux tubes as observed by the INTERBALL-1 and MAGION-4 closely-spaced satellites. A pair of Region 0 FA currents with the proper sign is generated at the sides of the outer cusp. A wave-like pressure variation in the outer cusp moving downward with about ion sound velocity will distort the Region 0 current pattern in a way that can lead to a double-sheet FAC formation and excitation of a transient poleward moving arc. The available data on the plasma pressure and magnetic field gradients at the outer cusp edges do not allow to calculate the FAC densities from the GVBT formula. So for quantitative comparisons of this simple model with experimental data we must await the CLUSTER-2 multi-point measurements.

THE MAGNETOSPHERIC MAGNETIC FIELD IN THE HIGH-ALTITUDE CUSP REGION. THE COMPARISON OF INTERBALL-TAIL MEASUREMENTS AND TSYGANENKO96 MODEL

Alexander Grigoriev, Andrei FEDOROV, Elena Budnick, Mikhail Nozdrachev, (Space Research Institute, 34/82, Profsouznaja st., Moscow, Russia, email: af@afed.iki.rssi.ru), Nickolai Tsyganenko (Raytheon STX Corporation NASA/Goddard Space Flight Center, Greenbelt, Maryland, USA)

It is well-known, that Tsyganenko96 model fails to describe the topology of magnetic field in the exterior cusp region. Recent observations of Polar spacecraft allowed to adjust the model at the middle altitudes. We performed the comparison of T96 model and Interball measurements in the cusp region adjacent to the magnetopause. The observations show the significant deviation of model from real magnetic field. The attempt to find an additional current responsible for this deviation was made.

GA3.07/W//62-A5 Poster **0900-06**

FLOWS AND CURRENTS OBSERVED IN AND NEAR THE CUSP BY POLAR AND MACCS

W.J. HUGHES, K.A. Walker, and D.L. Murr (Center for Space Physics, Boston University, Boston, MA 02215, USA; e-mail: hughes@bu.edu), N. Maynard (Mission Research Corporation, Nashua, NH, USA), W.K. Peterson (Lockheed Martin Space Physics Laboratory, Palo Alto, CA, USA), J.D. Scudder (Department of Physics, University of Iowa, Iowa City, IA, USA)

Flows in and around the magnetospheric cusp, as observed in the ionosphere, respond quickly to changes in the solar wind and IMF, presumably in response to changes in the location and rate of magnetic reconnection as well as to changes in the size and shape of the magnetopause. These changes also manifest themselves in observations made in the high altitude cusp by, for example, POLAR. We correlate observations made in and near the cusp by the field and plasma instruments on the POLAR spacecraft with IMF and solar wind observations, and with ionospheric convection flows deduced from magnetometer observations made around the foot of the POLAR field line. The fast, irregular, very radiply varying flows observed at POLAR altitudes in the cusp completely mask any signature of the the slower flows seen in the ionosphere. But the plasma signatures observed by POLAR vary in step with the changes in convection flow seen in the ionosphere and with IMF changes.

CHARGED PARTICLES TRAPPING IN THE REGION OF LOCAL MAGNETIC FIELD MINIMUM IN THE EXTERIOR CUSP

Igor Kirpichev, Andrei Fedorov, Elena BUDNICK, Volt Lutsenko (Space Research Institute, 34/82, Profsouznaja st., Moscow, Russia, email: af@afed.iki.rssi.ru), Jean-Andre Sauvaud (CESR-CNES, 9, avenue de Colonel-Roche, Toulouse, France, email: sauvaud@cesr.cnes.fr)

The models of magnetospheric magnetic field predict a local field minimum along the field lines passing through the exterior cusp near the magnetopause. The bouncing motion of quasi-trapped particles should thus be observed in this region. The Interball-Tail spacecraft was crossing this region during 1995 - 1998. To indentify trapping region we investigated the pitch-angle anisotropy of suprathermal ions and electrons in the energy range, 10 - 25 keV and of high-energy electrons (30 - 300 keV). The intensification of 90 degrees pitch-angle population is observed in the region predicted by Tsyganenko96 model. We discuss the possible origin of observed particles and the dependence of their appearance on the cusp configuration.

THE MORPHOLOGY OF UP-GOING O+ IONS IN RELATION TO INJECTED H+ IONS IN THE MID-ALTITUDE CUSP

IAN KRAUKLIS, Alan Johnstone, Mullard space science laboratory, Department of space and climate physics, University college London, Dorking, England. Bill Peterson, Lockheed-Martin Palo Alto res. lab. CA 94304, USA.

A common observation by the Polar/TIMAS instrument during cusp crossings is the close association of the energy of the up-going ionospheric O+ with the injected H+ populations. We present a survey of 14 cusp crossings where the interplanetary magnetic field (IMF) was south. A common feature is the rapid acceleration of the O+ co-incident with the onset of the injected H+ population. The average kinetic energy ratio, O+/H+, is approximately 5. There was no significant difference in this ratio for cusp crossings with the IMF northward. No time lag was observed between variations in the energy of the H+ and O+ populations. In the polar cap the parallel component of the bulk velocity of the H+ exceeded the O+ velocity by approximately 30 km/s. The rapid acceleration is inconsistent with centrifugal acceleration mechanism, resulting from convecting field lines, being responsible for the motion of the O+. However the observed velocity difference is consistent with a two stream instability.

DETERMINATION OF FIELD-ALIGNED CURRENT STRUCTURE ALONG SPACECRAFT TRAJECTORY WITH REGARD FOR EDGE EFFECTS OF CURRENT SHEETS

R.Yu. LUKIANOVA and O.A. Troshichev (Arctic and Antarctic Research Institute, St.Petersburg, Bering str. 38, Russia, email: renata@geophys.spb.su) Yu.I. Galperin and N.V. Jorjio (Institute of Space Research, Moscow, Profsouznay 108, Russia email: ygalperin@iki.rssi.ru)

Numerical method of determination of the field-aligned current patterns taking into account both, zonaland meridional, components of magnetic disturbances observed along the spacecraft trajectory has been developed. While the zonal component of magnetic field testifies to number and latitude location of the field-aligned current sheets, the meridional component is evidence of edges of the current sheets. The last circumstance is impotant for the day-time cusp region where Region 1 FAC are terminated in the vicinity of noon meridian whereas the current sheets located poleward of Region 1 (i.e. cusp currents) are evidently confined to limited MLT sector. Method of model simulation has been used to derive general regularities in latitudinal variation of zonal and meridional components in cases of one, two, three and four longitudinally limited current sheets, two-dimentional equation for vector magnetic potential being solved numerically in spherical coordinates. Latitudinal variations observed by spacecraft are compared with model ones and parameters of the current model are so designed that both curves match best. The optimal current sheet parameters providing similarity of observed and model variations for zonal and meridional components are determined by method of gradient decent in solving of equations for local minimums for each parameter. Magnetic field perturbations observed by AUREOL-3 spacecraft in the day-time region in vicinity of noon meridian have been used as experimental basis. The current patterns consisting with observed features of magnetic perturbations for IMF conditions Bz0 and By<0 involves the following main structures: sheet of upward current at latitudes 70-75 deg., sheet of downward current at latitudes 78-80 deg., and the third current sheet at latitudes above 80 deg. First two sheets are extended from dusk and terminated near the noon meridian, the third sheet consists of downward current in the pastnoon sector and upward current in the prenoon sector. These current sheets can be identified as FAC Region 2, Region 1, and Region 0 (cusp), correspondently. It implies availability of only one additional current sheet poleward of Region 1 under condition of northward IMF.

THE EXTERIOR CUSP: TWO-POINT OBSERVATIONS

J. MERKA, Z. Nemecek, J. Safrankova, O. Santolik, L. Prech (Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic, Email: merka@aurora.troja.mff.cuni.cz) S. Savin, A. Skalsky (Space Research Institute, Moscow, Russia)

The cusp is a part of the Earth's magnetosphere, where geomagnetic field lines are directly interconnected with IMF. Since the IMF lines are draped around the magnetopause and blown tailward with the magnetosheath flow, a permanent reconnection took place at the cusp-magnetosheath boundary. Reconnection produces accelerated plasma populations which excite different kinds of plasma waves. As a result, the region adjacent to the magnetopause is highly turbulent and occupied by the heated magnetosheath-like plasma with a low-drift velocity. This region is called turbulent boundary layer, stagnation region or exterior cusp in different papers and it seems to be a proper source of the cusp precipitation.
We have used two closely spaced (INTERBALL-1 and MAGION-4) satellites orbiting in the mentioned region with motivation to determine its structure under different upstream conditions monitored by WIND. The topology of the exterior cusp is determined by a direction of the magnetosheath magnetic field just above the cusp. The plasma entry shifts tailward when the magnetosheath magnetic field turns northward and the amount of the plasma entering the exterior cusp is controlled by the magnetosheath fluctuations.

A SIMPLE MODEL OF PLASMA MANTLE PARTICLE DISTRIBUTIONS DURING PERIODS OF HIGH-LATITUDE RECONNECTION WITH A COMPARISON TO GEOTAIL OBSERVATIONS

R. T. Mist, and C. J. Owen, Rosalind Mist, Astronomy Unit, Queen Mary and Westfield College, London E1 4NS, E-mail: R.T.Mist@qmw.ac.uk

Hirahara et al. (1997) have previously reported observations of double ion beams close to the magnetopause in the geomagnetic tail. These observations were interpreted as evidence for the occurence of high-latitude reconnection poleward of the cusp. We test this conclusion by presenting a simple, time-dependent model of the structure of the lobe magnetopause and plasma mantle during the switch from southward IMF/dayside reconnection to northward IMF/high-latitude reconnection. In particular, we address the motion of the plasma entering the magnetosphere from the magnetosheath, along field lines that may have been opened as a result of either subsolar or high-latitude reconnection, or both. We use the model to make predictions of the velocity distributions of these particles within the entry layer just inside the magnetopause. We compare these results to the observations made by Geotail close to the distant tail magnetopause, and show that the model successfully predicts the bulk velocities and densities of the observed plasma populations. Hence, on the basis of this model, the observed double ion beams do indeed appear consistent with the occurence of high-latitude reconnection.

DC AND WAVE ELECTRIC FIELDS AND OTHER PLASMA PARAMETERS OBSERVED ON TWOSOUNDING ROCKETS IN THE DARK CUSP DURING IMF BZ NORTH AND SOUTH CONDITIONS

R. F. Pfaff, S. Bounds, M. Acu=D2a (all at NASA Goddard Space Flight Center, Greenbelt, MD), N. C. Maynard (Mission Research Corporation, Nashua, NH), J. Moen (UNIS, Longyearbyen, Norway), A. Egeland, J. Holtet, K. Maseide, P. E. Sandholt (all at University of Oslo, Norway), F. Soraas(University of Bergen, Norway), J. Sharber (Southwest Research Institute,San Antonio, TX), M. Coplan, J. Moore (both at Univ. of Maryland, CollegePark, MD), W. Burke, D. Hardy, P. Ning, E. Weber (), J. Clemmons (M. Lockwood, M. Grande), A. Van Eiken (), M. Lester, S. Milan ()

Two Black Brant IX sounding rockets were launched into the dark, dayside cusp near magnetic noon on December 2 and 3, 1997, from Ny Alesund, Spitzbergen at 79 degrees N reaching altitudes of approx. 450 km. Real-time ground-based and Wind IMF data were used to determine the launch conditions. The first launch, with Bz north conditions, crossed into and back out of an open field region with merging poleward of the projected trajectory. The second flight, into Bz south conditions, was timed to coincide with an enhancement in the merging rate from a increase in the negative Bz, while the DMSP F13 satellite was situated slightly to the north of the rocket trajectory. Each payload returned DC electric and magnetic fields, plasma waves, energetic particles, photometer data, and thermal plasma data. Data from both flights will be shown, with an emphasis on the DC electric field results. In particular, the data gathered on December 2, 1997 will be used to discuss ionospheric signatures of merging and the open/closed character of the the cusp/low latitude boundary layer. In contrast, the data gathered on December 3, 1997 shows evidence of pulsed electric field structures which will be examined in the context of cusp plasma entry rocesses. Both data sets returned a rich variety of plasma waves, as well as optical emissions and thermal plasma data.

WAVES OBSERVED IN THE OUTER CUSP AND THEIRSIGNIFICANCE IN CUSP PROCESSES

J. S. PICKETT, J. D. Menietti, W. S. Kurth, D. A. Gurnett, and J. D. Scudder (all at: Department of Physics and Astronomy, The University of Iowa, Iowa City, IA 52242, email: pickett@uiowa.edu) S. Savin and S. Romanov (Space Research Institute, Russian Academy of Sciences, Profsoyuznaya 84/32, GSP-7, Moscow, 117810, Russia, email: ssavin@iki.rssi.ru)

A multitude of waves (ULF-VLF) have recently been observed by the Polar and Interball-1 satellites in the turbulent outer cusp region at 7-9 Re. Although many of these waves have been observed previously, we are gaining more insight into them due to the sophisticated instrumentation contained on both spacecraft. Most of the advances have come through the simultaneous capture of six components (three electric, three magnetic) of the waveform in the time domain at high resolution. From this, we have discovered that many of the broadbanded wave features observed in the past in the frequency domain are actually a numerical artifact of Fourier transformation of pulse-type and nonsinusoidal waveforms. Many of these waveforms have been associated with structures and nonlinear wave packets, rather than classical wave trains. We will discuss the potential of these structures to heat and accelerate particles in the cusp, and comment on their existence in this turbulent area of the cusp. We will also discuss the significance of more typical types of waveforms and Poynting vector distributions observed in the outer cusp, such as those associated with short bursts of whistler mode waves and of electron cyclotron harmonic waves. Examples of the different waveforms will be presented along with the discussion of their significance in the outer cusp.

PENETRATION OF THE MAGNETOSHEATH-LIKE PLASMA INTO LOBES

L. PRECH, J. Safrankova, Z. Nemecek, O. Santolik (Charles University, Prague, Czech Republic, Email: lubomir.prech@mff.cuni.cz) D. G. Sibeck (JHU, APL, Laurel, Maryland, USA)

Magnetospheric lobes are bounded by the plasma sheet and high-latitude magnetopause. Satellites orbiting in this region generally measure a low plasma density but sometimes the cavities filled with the magnetosheath-like plasma are encountered. As a rule, the frequency of their occurrence rises in the vicinity of the magnetopause suggesting their magnetosheath origin. A lot of phenomena have been proposed to explain such observations: flux ropes connecting the magnetosheath with ionosphere, surface magnetopause waves of large amplitudes, detached plasma vortexes, etc.
Two point observations of the closely spaced INTERBALL-1 and MAGION-4 spacecraft allow us to determine the motion and spatial extent of the observed plasma structures. We have used both statistical approach and case studies to determine a probability of different sources of these events.

OBSERVATIONS OF THE TIME-VARYING CUSP BY POLAR

J. RAE, M. Lester (at Leicester University, Leicester. LE1 7RH. U.K), M. Grande (at Rutherford Appleton Laboratory, Chilton, Didcot, Oxon. U.K), T. A. Fritz (at Boston University, Boston, Massachusetts, U.S.A), J. Scudder(at University of Iowa, Iowa City, U.S.A), C.T. Russell (at University of California, Los Angeles, U.S.A).

We present a multi-instrument study of the signatures associated with the cusp observed by the Polar satellite. Particle fluxes in the 1-50 keV range are found to pulse on a time-scale of between 12 and 20 minutes, while also pulsing on a shorter time-scale of 2-4 minutes. These pulsed particle populations on cusp field lines are dominated by He++ ions (of solar wind origin). Closed field line populations are of higher energy (50-200 keV), and dominated by protons. Dispersed ion fluxes are observed close to the boundary between open and closed flux. The pulse-within-a-pulse observations are discussed in terms of possible flux transfer events occurring at the magnetopause.

HF-VLF PLASMA EMISSION DETECTED IN THE CUSP REGION AT IONOSPHERIC ALTITUDE

H. Rothkaehl (1), J. Blecki (1), K. Stasiewicz (2), A. Eriksson (2). (1) Space Research Centre PAS, Bartycka 18A, 00-716 Warsaw, Poland (2) Swedish Institute for Space Physics , Uppsala, Sweden

Despite the long history of the observations and theoretical approach to the topside ionosphere at day-side sector still our knowledge in question about instability in cusp area during strong geomagnetic disturbances is not sufficient. HF waves measurements performed in the cusp area on board the ionospheric altitude orbiting satellite Freja reveal the existence of two types of emission: whistler mode waves and Langmuir emissions. The HF and VLF emissions restricted to the cusp region, provide a spatial picture of generation instability in cusp region during strong geomagnetic disturbances. The aim of this paper is presented nature of waves excited during recovery phase of geomagnetic storm in the cusp area.

FACTORS CONTROLLING THE LOCATION OF THE POLAR CUSP: DIPOLE TILT, IMF ORIENTATION AND SOLAR WIND PRESSURE

C. T. RUSSELL, X-W. Zhou and Guan Le (All at Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA, USA, email: ctrussell@igpp.ucla.edu) S. Fuselier (Lockheed Martin, Palo Alto, CA, USA); J. Scudder (University of Iowa, Iowa City, IA, USA)

Nearly 500 crossings of the polar cusp by the POLAR spacecraft at high altitudes over the northern polar cap have been used to examine the statistical behavior of the location of the polar cusp. The tilt of the polar cusp toward the sun moves the invariant latitude of the cusp poleward by 1 degree for every 14 degrees of tilt. Southward IMF causes the cusp foot points to move equatorward but northward IMF has almost no effect on the latitude of the cusp. The cusp also thickens in invariant latitude as the IMF becomes increasingly northward. The eastwest component of the IMF causes the local time of the cusp to move away from local noon inferring that the reconnection site has moved away from the subsolar point, much as foreseen by Crooker and Luhmann. Increasing solar wind pressure thickens the cusp in latitude and widens it in longitude. These results are consistent with those seen by the DMSP satellite when allowance is made for the hourly averaged IMF data used in their work.

TWO-POINT STUDY OF PLASMA STRUCTURES IN THE NEAR-EARTH MAGNETOTAIL

O. SANTOLIK, J. Safrankova, Z. Nemecek (Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic, Email: ondrej.santolik@mff.cuni.cz) A. Fedorov, A. Skalsky (Space Research Institute, Moscow, Russia) J.-A. Sauvaud (CESR, CNRS/University of Toulouse, France)

The data of the INTERBALL project alow to study the motion of plasma stuctures observed in the near-Earth magnetotail at distances up to 30 Earth's radii and in the wide range of latitudes. Near the boundaries of the magnetotail lobes, the INTERBALL 1 - MAGION 4 satellite pair sporadically encountered plasma structures with temperatures fromseveral hundreds eV to several keV. They move with velocities ranging from several km/s to several tens of km/s and their size is comparable with the Earth's radius. Our statistical study shows that their occurence rates and positions depend on the external conditions. We discuss possible sources of these plasma structures.

THE FINGERPRINT OF COLLISIONLESS RECONNECTION

J. D. SCUDDER and P. Puhl-Quinn (Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa, USA, email: jack-scudder@uiowa.edu) F. S. Mozer (Department of Physics, SSL, UC Berkeley, Berkeley, CA, USA, email: fmozer@sunspot.ssl.berkeley.edu) N.C. Maynard (Mission Research Corp., Nashua, NH, USA, email: nmaynard@mrcnh.com) C. T. Russell (IGGP, Department of Earth and Space Science, UCLA, Los Angeles, CA, USA, email: ctrussell@igpp.ucla.edu)

A protracted 4 hour immersion of the GGS-Polar spacecraft in the current carrying region of the cusp magnetopause during a distended northward IMF pass on May 29, 1996 has been analyzed to demonstrate with hithertofore unseen precision the following necessary fingerprints of collisionless magnetic reconnection: 1) non-zero tangential electric field measured in the required geometry of the normals of the rotational discontinuities; 2) 44 quantitatively successful Walen test for Alfvenic structures on both sides of the diffusion region; 3) a protracted interval of large (10mV/m) parallel electric fields measured with three axis electric field measurements with the preponderance of signal from long spin plane antennae; 4) parallel electric current density measured by direct cancellation of numerically integrated electron and ion fluxes; 5) regions of systematically positive J(parallel)E(parallel) required for field erosion; 6) non-gyrotropy sensed in the electron distribution function and the pressure tensor; 7) detection of all the relevant scales predicted from the collisionless Generalized Ohm's law have been observed including: electron beta modified ion inertial lengths and electron inertial length scales; 8) firm lower bounds of the scales for the electron pressure divergence parallel and perpendicular to B and electrical current densityare organized by the observed strength of field erosion; 9) independent cross checks on the scales perpendicular to the magnetic field of the currents from Ampere's equatio and the measured currents and the Generalized Ohm's law; 10) ambipolar electricfield identified observationally as supporting the parallel electric field; 11) super Alfvenic mach number electron flow sheets observed in agreement with simulations near the separatrix; 12) inflow speeds are sub Alfvenic while reconnected tubes moving at nearly Alfven mach number unity. A three dimensional pictorial overview of the four hour period will be shown to be consistent with the layer being an example of quasi-stationary, anti-parallel collisonless reconnection with very weak or non-existent guide field and that the spacecraft was on both sides of the separatrix as evidenced by the signs of the Walen proportionality constants and penetrated the region of flux erosion.

COMPARISON OF THE CUSP/CLEFT DPY CURRENTS OBTAINED FROM THE ØRSTED SATELLITE AND FROM GROUND-BASED INSTRUMENTS

Peter STAUNING, Freddy Christiansen, Tina Christensen, Vladimir Papitashvili*, and Ole Rasmussen (all at Danish Meteorological Institute, Lyngbyvej 100, DK-2100, Copenhagen, Denmark, email: pst@dmi.dk; *also at SPRL, University of Michigan)

The DPY current system associated with the azimuthal component of the interplanetary

magnetic field (IMF) is located in the cusp/cleft region, at approximately 75-80 degrees invariant latitude at the dayside of the polar cap. It appears that the DPY currents comprise the oppositely directed field-aligned current sheets bordering the cusp/cleft region. These currents close in the ionosphere through the horizontal, north-south-directed Pedersen currents, while the potential structure imposed by these currents drives the transverse, east-west-directed convection flows and associated Hall currents. The Hall currents are detectable from ground through their magnetic effects. During the intervals of northward or weak southward IMF these currents appear to be located in the cusp region, while during the strongly southward IMF conditions they appear to progress into the polar cap. The presentation will focus on the correlation of the satellite-based detection of the field-aligned currents, located inside and poleward of the cusp region, and the ground-based detection of the ionospheric DPY currents. These systems, in turn, will be correlated with the strength and direction of the interplanetary magnetic field and other solar wind parameters.

SPATIAL AND TEMPORAL STRUCTURES IN THE CUSP

K.J. TRATTNER, S.A. Fuselier, W.K. Peterson, D. Klumpar, M. Boehm (Lockheed Martin ATC, 3251 Hanover Str., B255, H1-11, Palo Alto, CA 94304, USA, e-mail: trattner@mojave.spasci.com), N. Dubouloz (Ctr. d'Etude des Environ. Terrestre et Planetaire, Saint-Maur Cedex, France), J.-A. Sauvaud (Ctr.d'Etude Spatiale des Rayonnerments, Toulouse, France), Y. Galperin, D. Chugunin (Space Research Institute IKI, Russian Federation)

Single point measurements of downward precipitating ions in the cusp suffer from the ambiguity of distinguishing between temporal and spatial effects. Therefore, combined observations from ISTP satellites, e.g. Polar, Fast and Interball together with upstream information from Wind or IMP-8, provide an unprecedented opportunity to examine plasma entry into the magnetosphere and structural properties of the cusp to resolve this fundamental ambiguity.
We have identified a series of magnetic conjunctions and close encounters of polar orbiting satellites to investigate cusp features including flux variations and sudden changes in the energy of cusp precipitating ions. Such variations and changes are generally interpreted as signatures of variations in the reconnection rate and/or changes in the de Hoffman-Teller velocity at the magnetopause. They are expected to be temporal features which move poleward with convecting field lines. However, our analysis showed that series of cusp features observed at one satellite are remarkable similar to cusp features observed up to 1.5 hours later by a second satellite, suggesting that these features are the result of spatial structures and not temporal variation in reconnection parameters.

MODEL STUDY OF IONOSPHERIC CONDUCTIVITY DISCONTINUITY EFFECT ON OBSERVED LATITUDINAL POSITIONS OF TRAVELLING CONVECTION VORTICES

Leonid BENKEVICH (Polar Geophysical Institute, Apatity, 184200, Russia, email:Ben@PGI.KolaSC.Net.RU W. Lyatsky (Institute for Space Research, University of Calgary, Calgary, AB T2N 1N4 Canada, email: Lyatsky@Phys.Ucalgary.CA)

Our aim was to model the ground magnetic effect of mesoscale high latitude ionospheric travelling convection vortices (TCVs). We took into account secondary interhemispheric field aligned currents that emerge if there are some conductivity discontinuities, e.g. at the terminator line. We have developed two models, analytical and numeric ones, each permitting calculation of the equivalent ionospheric current systems resulted from some incident magnetospheric currents. While the analytical model only allows constant though different conductivity magnitudes on either side of the discontinuity line and point current sources to be specified, the numeric one lets obtaining the equivalent currents under any arbitrary distributions of both the conductivity and the incident field-aligned currents. A good conformity is observed between the outcomes from both of the models under the same boundary and initial conditions. Results of modelling under the ionospheric conductivity conditions close to the real ones are shown. The experiments on either model give evidence for the fact that despite high-latitude incident current position (conceivably in the cusp/cleft region) the resulting vortex focus may be located at lower latitudes of 75°-80°, namely, on the terminator line. As an application, our work suggests the explanation why the TCVs are observed in so low latitudes that it is in contradiction with the magnetopause-surface-wave theories of their origin. This work has been supported by the RFBR grant 97-05-65894.

HIGH-TIME RESOLUTION SUPERDARN RADAR OBSERVATIONS OF THE DAYSIDE CONVECTION RESPONSE TO CHANGES IN IMF

G.CHISHAM and M.Pinnock (British Antarctic Survey, Cambridge, UK) A.D.M.Walker (Department of Physics, University of Natal, Durban, South Africa)

We present data from two of the southern hemisphere SuperDARN radars describing the high-latitude ionosphere's response to a change in the IMF By direction during a period of steady IMF Bz southward. Data from the WIND and GEOTAIL spacecraft describe the solar wind while the FAST satellite provides a snapshot of the convection reversal boundary region in the radars' field-of-view. Data from the northern hemisphere SuperDARN radars provide a conjugate view of the event. The radars were operating in a special mode which gave high time resolution data (30 s) on 3 beams with a full scan every 3 minutes. The location of the radars in the noon time sector gave a detailed observation of the change in the ionospheric convection pattern as IMF By changed from negative to positive. In particular the development of the westward edge of the afternoon convection cell is observed in the radars' field-of-view. Detailed study of the phase velocity of the changes in the ionospheric convection pattern will be presented. The plasma flow burst behaviour around the event is also studied and found to confirm the results of previous work which shows such bursts originating well equatorward of the convection reversal boundary. The observations are examined in the context of current ideas about the mapping of the magnetopause merging line to the ionosphere and the causes of plasma flow bursts.

INVESTIGATIONS OF IMF BY DRIVEN CONVECTION AND CONVECTION REVERSAL BOUNDARY TURBULENCE

C. R. Clauer, J. B. Baker, C. P. T. Groth, D. L. DeZeeuw T. I. Gombosi (all at Space Physics Research Laboratory, University of Michigan, Ann Arbor, MI 48109-2143, USA, email: rclauer@umich.edu); K. G. Powell (Department of Aerospace Engineering, University of Michigan, Ann Arbor, MI 48109, USA, email: ken_powell@umich.edu) A. J. Ridley (Southwest Research Institute, 6220 Culebra Rd., San Antonio, TX 78238-5166, USA, email: ridley@worf.space.swri.edu)

Dayside ionospheric convection patterns have been investigated using high latitude measurements by incoherent scatter radar and arrays of magnetometers. Particular focus has been placed on conditions where the interplanetary magnetic field (IMF) By component is large compared to the Bz component. During these conditions, a convection pattern develops which shows asymmetry between dawn and dusk, and between the northern and southern polar regions. The convection cells observed in the ionosphere under such conditions generally show 2 cells (a dusk cell and a dawn cell), with one banana shaped cell and another more round shaped cell. As the value of IMF By increases, the shear across the convection reversal boundary in the banana shaped cell increases and sometimes becomes very turbulent. The turbulence which develops at the convection reversal boundary appear in the ionospheric plasma convection as a series of traveling convection vortices centered on the boundary. We believe these waves to be generated through a Kelvin-Helmholtz instability initiated at the shear near the inner edge of the magnetospheric boundary layer. We report here on these observations and the relationship between the ionospheric convection and magnetospheric convection. This relationship is investigated using an advanced adaptive-grid MHD simulation code which enables us to resolve phenomena across 9 orders of magnitude. Thus, it is possible to investigate the magnetospheric configuration for IMF By conditions and to obtain the mapping from the outer dayside magnetosphere to the ionosphere. While the MHD simulation cannot resolve the Kelvin-Helmholtz instability, it does show, in three dimensions, the large scale convection and locations of strong velocity shear.

IONOSPHERIC FOOTPRINT OF THE MAGNEOPAUSE MERGING LINE AS PREDICTED BY THE ANTI-PARALLEL MERGING HYPOTHESIS

I J Coleman, M Pinnock and A S Rodger

The anti-parallel merging hypothesis holds that reconnection takes place on the dayside magnetopause where the solar and geomagnetic fields are oppositely directed. We have mapped the predicted merging regions to the ionosphere (using the Tsyganenko 96 magnetic field model). We will present the resulting shape, width and latitude of the ionospheric dayside merging region in both hemispheres, showing its seasonal and diurnal dependence as well as its conditioning by the IMF clock angle and other solar wind parameters. These predictions have implications for the conjugate electric fields in the northern and southern cusps, as measured by the SuperDARN HF radars for example. The relationship to cusp definitions derived from satellite data will also be examined. We will show to what extent this data supports the anti-parallel hypothesis.

DAYSIDE TRANSIENT PRECIPITATION STRUCTURES DURING CONDITIONS OF LARGE NEGATIVE BY AND POSITIVE BZ

O DE LA BEAUJARDIERE, (Air Force Research Laboratory, Hanscom Air Force Base, MA 01731, USA, Email: odelabe@plh.af.mil); M Ruohoniemi (Applied Physics Laboratory, Laurel, MD 20723, USA, Email: mike.ruohoniemi@jhuapl.edu; T Mukai (ISAS, Sagamihara, Japan, Email: mukai@jtl.isas.ac.jp)

The Sondrestrom Incoherent Scatter Radar, the Goose Bay SuperDARN Radar and the Akebono Satellite observed weak auroral features associated with plasma velocity increase and oppositely oriented field-aligned currents (FAC), around 1400 MLT, on January 27, 1992. The observations took place during stable solar wind conditions (Bz = + 5 nT, By = - 20 nT). The Sondrestrom Radar saw repeated quasi-periodic (20 min.) instances of auroral arcs that emanated close to a 75 degree invariant latitude boundary and that appeared to drift equatorward. The apparent equatorward motion is unexpected at this local time. The Sondrestrom as well as the Goose Bay radar data show that increases in poleward plasma velocity and vorticity were associated with these arc structures. A close Akebono satellite overpass of the Sondrestrom Radar showed that these soft arcs were within the Low Latitude Boundary Layer, were associated with a narrow FAC pair, and were near the region-1 region-2 FAC boundary. The data are consistent with elongated weak arcs that are slightly inclined with respect to the L shell direction and that drift westward (toward dusk). For this IMF, merging is expected in the northern hemisphere dawn flank and in the southern hemisphere dusk flank. We advance the hypothesis that the observed arc structures are the conjugate footprint of southern hemisphere newly-merged magnetic field lines.

HYDROMAGNETIC EMISSIONS OF INTERPLANETARY PLASMA AND DIAGNOSTICS OF GEOEFFECTIVE STREAMS OF SOLAR WIND

B. V. Dovbnya, E. T. Matveyeva, V. F. Ruban, R. V. Shchepetnov (Geophysical observatory Borok of United institute of Physics of the Earth RAS, 152742, Russia, email: dov@borok.adm.yar.ru) V. A. Parkhomov (Irkutsk State Economic Academy, Irkutsk, 664003, Russia)

A new type of hydromagnetic emissions of varying frequency in a range 0.5-4.0 Hz is discovered and investigated at latitudes of dayside polar cusp. On a totality of features it is possible to make a conclusion the appearance of this phenomenon is connected with the flare streams.According to morphological features the emissions are divided on two groups - "singlets" characterized by one frequent band of emission and "doublets" - with two bands of emission. A ratio of central frequencies at "doublets" is as a rule 1:2. Typical amplitudes of emission is about 10 nT with several times prevalence of a signal in a H-component. The comparison with parameters of a solar wind has shown that the emission arises at increased velocity and proton density (no less than a threshold value) of a solar wind that indicates the threshold character of their excitation. The modulation of emission frequency strictly follows a change in proton concentration in a solar wind. The bottom band in "doublets" is presumably excitated by helium ions. Various hypotheses of physical mechanisms of discovered emissions are considered. According to established relanions between emission parameters and parameters of a solar wind the technique of hydromagnetic diagnostics of the main characteristics of a solar wind such as density and its variations, breaks and waves, inhomogeneities and ion composition is suggested on the basis of the ground observational data under extreme conditions in the outer space. The recommendations for system of emission observation for continuous tracking of interplanetary medium state are presented.

UPSTREAM WAVES AS AN ENERGY SOURCE OF NARROWBAND PC 3 WAVES OBSERVED IN THE POLAR CAP REGION

Hiroshi Fukunishi_$B!"_(JAtsushi Shono_$B!"_(JMitsuteru Sato (Department of Geophysics, Graduate School of Science, Tohoku University, Sendai 980-8578, Japan, email: fuku@pat.geophys.tohoku.ac.jp) L. J. Lanzerotti and C. G. Maclennan (Bell Laboratories, Lucent Technologies, Murray Hill, NJ 07974, USA, email: ljl@bell-labs.com)

Automatic Geophysical Observatories (AGOs) are the first large-scale network of stations in Antarctica and cover the region mapped to the cusp, cleft, LLBL, plasma mantle and magnetotail lobe. At present this network consists of six sites, P1 - P6, located from 70 to 87 degree magnetic latitude. ULF waves are observed by search coil and fluxgate magnetometers installed at these AGO sites. Using the ULF data obtained from the AGO network and South Pole station at 74 degree magnetic latitude, we have investigated the spectral characteristics of Pc 3 waves in the frequency range of 0.02 - 0.1 Hz and the dependences of Pc 3 activity on IMF. It is found that the occurrence probability of Pc 3 waves with a narrowband structure is very high at these latitudes, and that the frequencies of Pc 3 spectral peaks coincide with the expected frequencies of upstream waves calculated by the relation given by Russell et al.(1983), f (mHz) = 5.81 x B(nT) where B is the magnitude of the interplanetary magnetic field. This result suggests that these Pc 3 waves are originated from upstream waves. It is also found that Pc 3 waves occur both in small and large cone angle conditions of IMF. This fact indicates that upstream waves can penetrate into the magnetosphere not only across the subsolar magnetopause but also across the flankside magnetopause.

AN INCREASE OF THE PC1 WAVE ACTIVITY PRIOR TO THE MAGNETIC SUDDEN IMPULSES SI

Anatoly Guglielmi (United Institute of the Physics of the Earth, Moscow, Russia, email: gugl@scgis.fisgeos.iitp.ru) Jorma KANGAS and Johannes Kultima (both at Sodankylä Geophysical Observatory, FIN-99600, Finland, email: jorma.kangas@sgo.fi) Alexander Potapov (Institute of Solar-Terrestrial Physics, Irkutsk, Russia, email: potapov@iszf.irk.ru)

The occurrence of Pc1 magnetic pulsations prior to the magnetic sudden impulses SI has been studied statistically by using midlatitude ground based observations. Totally, 11 years of Pc1 data and 280 SI events were analysed. It has been discovered that there is a tendency for an increase in Pc1 activity as the time gets closer to the SI. The phenomenon is interpreted as an impact of the upstream regions of the interplanetary shocks on the magnetosphere.

SUPER-DARN RADAR OBSERVATION OF FLOW BURSTS IN THE CUSP IONOSPHERE CAUSED BY SOLAR WIND DYNAMIC PRESSURE PULSE

Takashi KIKUCHI, Kumiko Hashimoto (Communications Research Laboratory, Koganei, Tokyo 184, Japan, e-mail: kikuchi@crl.go.jp), Mike Pinnock, Alan Rodger (British Antarctic Survey, UK), Masukazu Watanabe (NIPR, Japan), Jean-Paul Villain (CNRS, France), Mike Ruohoniemi (JHU/APL, USA)

Super DARN radar observed an abrupt increase in the ionospheric plasma flow velocity around the cusp when an impulsive ground magnetic increase (Si) was recorded at 1350 UT, July 16, 1995. WIND measured an abrupt increase in the solar wind plasma density; the dynamic pressure increased from 9.8 to 12.2 nPa under conditions of By=-10 nT and Bz=-10 nT. The plasma flow at the cusp was north-eastward with a speed of 600 m/s before the Si, while an intensified flow region appeared at the equatorward border of the cusp with a speed of 1200 m/s at the arrival of the pressure pulse. There occurred another impulsive cusp flow burst due to the pressure pulse on April 21, 1997. Radar scattering with high flow speed (up to 1000 m/s) abruptly occurred at 1634 UT in a spot region around the cusp where no scattering was observed before the arrival of the pressure pulse. The scatter region expanded poleward and azimuthally with keeping high flow speed. These observations suggest that the dayside reconnection was intensified by the abrupt increase in the solar wind dynamic pressure during Bz<0.

LATITUDINAL DEPENDENCE FOR THE AZIMUTH PROPAGATION VELOCITY OF GEOMAGNETIC SUDDEN IMPULSES

G.A. Makarov, S.I. SOLOVYEV, and D.G. Baishev (all at: Institute of Cosmophysical Research and Aeronomy, 677891 Yakutsk, Russia, Email: g.a.makarov@sci.yakutia.ru) M.J. Engebretson and J. Posch (both at: Department of Physics, Augsburg College, Minneapolis, MN 55454, USA, email: engebret@augsburg.edu) W.J. Hughes (Boston University, Center for Space Physics, Boston, MA 02215, USA, email: hughes@buasta.bu.edu) K. Yumoto (Kyushu University 33, Fukuoka 812-81, Japan, email: yumoto@geo.kyushu-u.ac.jp) V.A. Pilipenko (Institute of Physics of the Earth, 123810 Moscow, Russia; email: pilip@iephys.msk.ru)

Propagation of the geomagnetic sudden impulse (SI) in the high-latitude regions of the Earth has been studied by using ground-based magnetic station data. SI in the winter period caused by sharp decreases of the solar wind plasma density which are accompanied by abrupt changes of the IMF By and Bz components have been considered.
It is obtained that SIs are propagated from the dayside to the nightside of the polar cap with the velocities of 5-40 km/s. The latitude-dependence of the azimuth SI propagation velocity is found: the velocity decreases as geomagnetic latitude from 65 deg to 78 deg increases.

GA3.07/W/19-A6 Poster 0900-11

A STATISTICAL STUDY OF THE OCCURRENCE RATES AND REPETITION FREQUENCIES OF PULSED IONOSPHERIC FLOWS IN THE DAYSIDE AURORAL ZONE

K. A. MCWILLIAMS, T. K. Yeoman, G. Provan (Department of Physics and Astronomy, University of Leicester, University Road, Leicester, LE1 7RH, U.K.)

A study has been performed on the occurrence of pulsed ionospheric flows (PIFs) as detected by the SuperDARN HF radars. These flows have been suggested as being created at the ionospheric footprint of newly-reconnected field lines, during episodes of magnetic flux transfer into the terrestrial magnetosphere (flux transfer events or FTEs). Two years of both high-time resolution and normal scan data have been analysed in order to perform a statistical study of the occurrence rate and repetition frequency of the PIFs. These statistical results obtained from ionospheric flows are compared to occurrence rates and repetition frequencies of FTEs derived from in situ spacecraft data.

GA3.07/W/42-A6 Poster 0900-12

POST-NOON TWO-MINUTE PERIOD PULSATING AURORA AND THEIR RELATIONSHIP TO THE DAYSIDE CONVECTION PATTERN

S E MILAN, T K Yeoman, M Lester (All at Department of Physics and Astronomy, Leicester University, Leicester LE1 7RH, UK. Email: Steve.Milan@ion.le.ac.uk) J Moen (UNIS, P.O.Box 156, N-9170 Longyearbyen, Norway) P E Sandholt (Department of Physics, University of Oslo, P.O.Box 1048 Blindern, N-0316 Oslo, Norway)

Poleward-moving auroral forms in the vicinity of the cusp region are generally assumed to be the optical signature of flux transfer events. Another class of quasi-continuous, short-period (1-2 minutes) wave-like auroral emission has been identified, closely co-located with the convection reversal boundary in the post-noon sector, which is otherwise similar in appearence to cusp aurora. It is suggested that such auroral emissions are associated with ULF magnetohydrodynamic wave activity, which is observed simultaneously by ground magnetometer stations. This association with ULF wave activity is strengthened by the observation of several harmonic frequencies in the pulsation spectrum, each an overtone of the fundamental standing wave.

Using the Equator-S spacecraft and SuperDARN HF radars, observations have been made of processes at the magnetopause and associated flows in the polar ionosphere. The magnetopause processes include interactions with the IMF and solar wind such as transient reconnection/merging (FTEs) and pressure pulse effects. Appropriate geomagnetic field mappings to the fields of view of SuperDARN radars were performed to observe the effects presumed transmitted by FACs to the polar ionosphere. Cases of 'pulsed ionospheric flows' (PIFs) observed with a range of instrumentation and associated with different magnetopause processes will be presented. The strong correlation between reconnection/merging and the observationally established ionospheric 'flow channel events' (FCEs) will be shown.

GA3.07/E/19-A6 Poster 0900-14

COUPLING BETWEEN MAGNETIC IMPULSE EVENTS AND PI1 NOISE BURSTS AT CUSP LATITUDES

Viacheslav PILIPENKO, Sergey Shalimov (Institute of the Physics of the Earth, Moscow, Russia; e-mail: vpilipenko@uipe-ras.scgis.ru) Mark Engebretson (Augsburg College, Minneapolis, MN55454, USA; e-mail: engebret@augsburg.edu)

The estimated densities of local field-aligned currents related to nighttime substorm onset or magnetic impulse events at cusp latitudes may exceed the threshold for the excitation of high-frequency turbulence in the topside ionosphere. The evolution of an ion-acoustic instability is shown to lead to quasi-oscillations around the saturation level. Consequent variations in anomalous conductivity will result in pulsed electron precipitation and noise generation in the Pi1 band. This proposed mechanism gives a natural interpretation to the experimentally observed coupling between localized magnetic disturbances, electron precipitation/acceleration, and bursts of high-frequency ULF noise. The alternative interpretations based on mechanisms of ion-cyclotron instability stimulation and ionospheric Alfven resonator excitation can be applied only under specific plasma conditions. Several seemingly uncoupled geophysical phenomena (long period magnetic impulses, electron precipitation/acceleration, bursts of auroral brightness, and splashes of intensity of high-frequency ULF waves) find a natural interpretation as related consequences of the mechanism proposed.

ON THE ORIGIN AND PROPAGATION MECHANISMS OF CUSP REGION PC3 PULSATIONS

Pavlo PONOMARENKO, Brian J Fraser, Sean T Ables, and Fred W Menk (all in Department of Physics, CRC for Satellite Systems, University of Newcastle, Callaghan, NSW, 2308 Australia, Email: phpp@alinga.newcastle.edu.au), Ray J Morris (Australian Antarctic Division, Channel Hwy, Kingston, TAS, 7050 Australia); Liu Ruiyuan (Polar Research Institute of China, Shanghai 200129, China)

Ground-based investigations of pulsation activity at the magnetospheric cusp region have shown two pronounced spectral component in Pc5 and Pc3 ranges. The first peak is believed to be a signature of field line resonances, but the second one is more puzzling. Several mechanisms have been proposed including Kelvin-Helmholtz and ion-cyclotron instabilities as well as particle precipitation. In an attempt to solve the problem, we have assumed that different generation and propagation mechanisms could produce different seasonal and diurnal dependencies. The generation mechanisms can be identified through their relationship to the interplanetary magnetic field and plasma parameters. Also, the polarization structure and spatial coherency on the ground should depend on the propagation mode. Relative contributions of the different mechanisms can be found by comparison between data obtained from regions lying poleward and equatorward of the cusp. We investigated the statistical characteristics of Pc3 pulsations using induction magnetometer data from Antarctic cusp stations Davis (Australia) and Zhong Shan (PRC). Data from other Australian Antarctic stations, Casey (polar cap) and Mawson (auroral region), were used for comparative studies. Analysis suggests that the principal generation mechanism is the ion-cyclotron instability of solar wind protons upstream of the bow shock. The main mode seems to be a compressional wave propagating isotropically through the magnetosphere, but other mechanisms may give substantial contribution around local magnetic noon.

ARE PULSED IONOSPHERIC CUSP FLOWS DRIVEN BY SOLAR WIND ALFVEN WAVES?

P. PRIKRYL (Communications Research Centre, P.O.Box 11490, Station "H", Ottawa, ON K2H 8S2,Canada, email: prikryl@cancrc.dgrc.crc.ca); G. Provan, K.A. McWilliams and T.K. Yeoman (Department of Physics and Astronomy University of Leicester, Leicester LE1 7RH, UK, email: gp3@ion.le.ac.uk)

Ionospheric signatures of flux transfer events (FTEs) in the cusp footprint have been observed by the CUTLASS SuperDARN radar in high resolution modes. The ionospheric flow in the cusp footprint, which is believed to be a consequence of magnetic reconnection at the dayside magnetopause, was pulsed with periods from a few to several minutes. Here the quasiperiodic FTE signatures are correlated with Alfvenic fluctuations that were observed by ISTP satellites in solar wind. It is concluded that on these occasions the FTEs may be driven by Alfven waves

coupling to the dayside magnetosphere. Case studies will be presented in which the dawn-dusk component of the Alfven wave electric field appears to modulate the reconnection rate as evidenced by the radar observations of the ionospheric cusp flows. In addition, the multifrequency MHD waves generated in the magnetosheath through the interaction between the solar wind Alfven waves and the bow shock may excite field line resonances (FLRs) deeper in the magnetosphere. In this composite picture, the inter-FTE periodicity may be influenced by the FLR period on the last closed field line that is subsequently reconnected with the IMF.

WHERE ARE THE IONOSPHERIC SIGNATURES OF POST-TERMINATOR FLUX TRANSFER EVENTS?

A S RODGER, M Pinnock, G Chisham and I J Coleman British Antarctic Survey, Madingley Road Cambridge CB3 0ET, UK (email: A.Rodger@bas.ac.uk)

Flux transfer events (FTEs) are arguably the most important process by which energy is transferred from the magnetosheath into the magnetosphere. The manifestation of FTEs in the ionosphere near magnetic noon has been extensively reported over the last decade in terms of plasma velocity transients, optical auroral forms and magnetometer perturbations, though as yet no unified theory is forthcoming, and several key questions remain.
Perhaps what is more puzzling is the fact that FTEs at the magnetopause show little magnetic local time dependence along the magnetopause from ~04 to 20 MLT. To date there have been few reports of ionospheric signatures of FTEs well away from noon. In this paper, we will address the physics of why the ionospheric signatures of near-terminator reconnection have not yet been clearly identified. The critical physics involves both the current carrying capacity of the magnetosphere and the local Alfven speed. The extent to which the magnetosphere and ionosphere become decoupled will be discussed. Furthermore we will consider the relationship between the ionospheric location of these reconnection events with respect to the convection reversal boundary, a feature that is often, but erroneously taken to be the ionospheric signature of the polar cap. We will support our hypotheses using data from rockets, satellites and a variety of ground-based instrumentation.

THE ONSET TIME OF MAGNETIC RECONNECTION

Simon Shepherd, Raymond A. GREENWALD, and J. Michael Ruohoniemi (all at Johns Hopkins University, Applied Physics Laboratory, Johns Hopkins Rd., Laurel, MD, 20723, USA, email: Simon.Shepherd@jhuapl.edu)

One of the most important processes in space plasma physics is that of magnetic reconnection. It is important because this process is generally thought to be responsible for the transfer of mass, energy, and momentum from the solar wind to the Earth's dayside magnetosphere. While the precise nature of the reconnection process is still unknown, one topic that may be attacked with existing sets of satellite and ground-based data is the growth time of the reconnection process. Recently, Ruohoniemi and Greenwald [1998] have shown that enhancements in ionospheric convection in response to a southward turning of the IMF are observed at all local times within two minutes of the time that they are first observed near the noon meridian. In their study, they did not attempt to identify the time that the southward directed IMF actually impacted the magnetopause. In the present study, we have attempted to resolve this issue by using data from the Geotail spacecraft when it was located in the subsolar magnetosheath within a few Re of the dayside magnetopause. Under these conditions, the delay time between the observation of an IMF transition at Geotail and its impact on the magnetopause will typically be less than one minute. There will be an additional delay of 2 minutes for the magnetic signature of the freshly reconnected field line to propagate to the ionosphere. Any delay beyond these three minutes must correspond to the growth time of the reconnection process. In our study, we have found typical delay times of 10-12 minutes indicating that the growth time of the reconnection process at the magnetopause is ~7-9 minutes.

SOLAR WIND TANGENTIAL DISCONTINUITIES: TRIGGERS FOR IMPULSIVE GROUND MAGNETIC SIGNATURES?

R. J. SITAR and C. R. Clauer (both at Space Physics Research Laboratory, The University of Michigan, 2455 Hayward, Ann Arbor, MI 48109, USA, email: sitar@umich.edu, rclauer@umich.edu)

Magnetic impulse events (MIEs) have been associated with impulsive deformations of the magnetopause produced by sudden changes in the solar wind dynamic pressure. Other observations suggest that MIEs can be produced in the absence of pressure changes when there is a sudden change in the IMF orientation. Using data from the IMP 8 satellite, we have identified 121 IMF orientation changes which occur during intervals of steady solar wind dynamic pressure. The relationship between IMF orientation changes and MIEs are studied using Greenland magnetometer data. Preliminary analysis shows that the occurrence of MIEs produced by IMF orientation changes exhibits a weak dependence on the orientation of the motional electric field on both sides of the current sheet responsible for the orientation change. The motional electric field has also been shown to contribute to the production of hot flow anomalies (HFAs), suggesting that HFAs might play an intermediary role in MIE production.

GA3.07/W/44-A6 Poster **0900-20**

THE MORPHOLOGY AND DYNAMICS OF MAGNETIC IMPULSE EVENTS: SHIRE IMAGING RIOMETER RESULTS

M.B.Terkildsen, B.J.Fraser, and F.W.MENK, (Physics Department, CRC for Satellite Systems, University of Newcastle, NSW, 2308, Australia, email: phmbt@alinga.newcastle.edu.au) T.J.Rosenberg (IPST, University of Maryland, College Park, MD 20742, USA) R.J.Morris (Australian Antarctic Division, Kingston, TAS, Australia)

The SHIRE imaging riometer at Australia's Davis Antarctic station is located under the magnetospheric cusp region and is being used to study the morphology and dynamics of regions of enhanced electron density in the high-latitude ionosphere. Those regions of enhanced density associated with magnetic impulse events (MIEs) are being specifically investigated. MIEs are a possible ionospheric signature of magnetic reconnection (FTEs) on the dayside magnetopause. MIEs commonly appear as a bipolar spike in the geomagnetic field at the ground at high latitudes, most often with an associated patch of enhanced electron density detectable with a riometer. The imaging riometer enables a 2-dimensional spatial "image" to be made of the electron density structures associated with such impulsive events. The dynamics and morphology of a large number of impulse events, detected using a co-located fluxgate magnetometer, have been studied in this way and the results provide some insight into MIE generation and propagation mechanisms. Of particular interest is the ionospheric motion of MIEs in the vicinity of the southern polar cusp region.

DAYSIDE AURORAL TRANSIENT EVENTS OBSERVED BY POLAR ULTRAVIOLET IMAGERY.=20

V.G. Vorobjev, O.I. Yagodkina (Polar Geophysical Institute, Apatity, Murmansk region, Russia), D. Sibeck (Applied Physics Laboratory, Johns Hopkins University, Laurel, Maryland)

We have analyzed mophological features of dayside auroral transient events (ATE) using images acquired from the ultraviolet imager (UVI) on board the Polar satellite. The UVI data set used for the investigation covers a time of about 5 winter months, from Dec. 3, 1996 to Feb. 28, 1997 and from Oct. 19 to Dec. 23 in 1997. During period under investigation we found 31 cases of the auroral transient events in the pre noon sector while only 12 events of auroral transients were registered in the after noon sector. Pre noon ATEs generally appear as the bright "spot" of auroral luminosity in 09-11 MLT sector at the latitudes about 740 CGL. Bright aurorae then quickly shifted westward and the poleward part of the bright spot contained the discrete aurorae moved poleward as well. Afternoon ATEs usually appear like a sudden intensification of aurorae in the 13-16 MLT sector at 750-760 CGL. Bright band of luminosity quickly extended eastward achieving in 15-20 min the longitude of 20-21 MLT at 700-720 CGL. Global features of auroral luminosity evolution during 5 SSC events have been investigated as well. We have analyzed the interplanetary medium conditions during the pre noon ATEs, the after noon ATEs and the SSCs registrations. In the paper the comparative characteristics both of morphological features of three auroral phenomena and the interplanetary magnetic field and solar wind plasma changes associated with different auroral events are presented.

THE MAGNETOPAUSE DYNAMICS ACCORDING OF INTERBALL-1/MAGION-4 DATA AND ITS CONNECTION WITH GEOMAGNETIC DISTURBANCES

Alexander ZAITZEV (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation, Troitsk, Moscow Region, 142092, RUSSIA, e-mail: zaitzev@izmiran.rssi.ru) Nadya Nikolaeva, Georgii Zastenker (both of Space Research Institute RAN, Profsouznaya 84, GSP-7, Moscow, 117810, RUSSIA, e-mail: nnikolae@vml.iki.rssi.ru)Jana Safrankova, Zdenek Nemecek (both of Charles University, Y Holesovickach 2, 180 00 Praha 8 - Troya, Czech Republic,
e-mail: Jana.Safrankova@mff.cuni.cz)

The INTERBALL-1/MAGION-4 data base was analyzed to find the events of multiple magnetopause crossings. It was chosen the crossings near the X-Y plane after dawn-dusk meridian. Each case was analyzed and the relative amplitude and periodicity of magnetopause motion was estimated and summarized as a regular pattern of magnetopause dynamics. Further analyses was pointed toward the search of the connection between magnetopause motion and geomagnetic disturbances. Ground-based geomagnetic data from high latitude stations was used to infer the state of magnetosphere. It was suggested that large-scale magnetopause movements correlate with the level of geomagnetic disturbances. The connection of such processes might be considered in favor of a boundary layer model for magnetospheric substorms.

THE RESPONSE OF THE MAGNETOSPHERE TO AN INTERPLANETARY SHOCK: THE MAGNETOSPHERIC COMPRESSION ON SEPTEMBER 24, 1998

C. T. RUSSELL, P. Chi, Guan Le, J. Raeder and R. J. Strangeway (All at Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA 90095-1567, USA,
email: ctrussell@igpp.ucla.edu); H. J. Singer (Space Environment Center, NOAA, Boulder, CO, USA); H. Kawano (Kyushu University, Fukuoka, Japan); T. E. Moore (Goddard Space Flight Center, Greenbelt, MD, USA); W. K. Peterson (Lockheed Martin, Palo Alto, CA, USA)

At approximately 2344 UT on September 24, 1998 the nose of the magnetosphere was suddenly compressed by a strong interplanetary shock wave. As evidenced by successive compressions of the magnetic field at GOES 10, POLAR and GOES 8, the compressional wave moved rapidly through the magnetosphere. At POLAR the compression caused the magnetopause to move closer to the spacecraft, causing rapid cross field flows and altering the location of the conjugate point in the ionosphere. The pre-existing flows were heated locally only slightly by betatron acceleration because the flows were mainly field aligned. Waves also did not lead to much heating because they were small in amplitude. Centrifugal heating may have been a more important local process. Some of the observed change in the plasma observed at POLAR was associated with the motion of the non-uniform polar cap outflow across POLAR. Snapshots of the polar cap by FAST confirm that the outward polar cap flows are non-uniform at this time but also show that strong heating is present and subsequently is very important in determining the outflow of plasma. Ground station recordings, synchronized with GPS signals, enable the disturbance to be followed through the magnetosphere from high latitudes to low. This event teaches us much about how the ionosphere is coupled to the magnetosphere and demonstrates the symbiosis of ground based, ionospheric and magnetospheric observations with modelling in magnetospheric studies.

POLAR IONOSPHERIC OUTFLOW RESPONSE TO SOLAR WIND CONDITIONS AT 2-9 RE

Moore, T.E. and B.L. GILES (both at NASA Goddard Space Flight Center, Greenbelt, MD 20771 USA, Email: thomas.e.moore@gsfc.nasa.gov), M.O. Chandler (NASA Marshall Space Flight Center, Huntsville, AL 35812 USA), M.R. Collier (NASA Goddard Space Flight Center, Greenbelt, MD 20771 USA), H.L. Collin (Lockheed Martin Advanced Technology Center, Palo Alto, CA, 94304 USA), R. Fitzenreiter (NASA Goddard Space Flight Center, Greenbelt, MD 20771 USA), W.K. Peterson (Lockheed Martin Advanced Technology Center, Palo Alto, CA, 94304 USA), C.J. Pollock (Southwest

Research Institute, San Antonio, TX 78228 USA), C.T. Russell and R.J. Strangeway(both at University of California, Los Angeles, CA 90024 USA)

We report observations of direct ionospheric plasma outflow response to the incidence of an interplanetary shock and associated coronal mass ejection upon the earth's magnetosphere. Data from the WIND spacecraft, 185 RE upstream of Earth, document the passage of an interplanetary shock at 23:20 UT on 24 Sept. 1998, traveling at 860 km/s. The polar cap plasma environment sampled by the POLAR spacecraft changed abruptly at 23:45 UT, reflecting a displacement of the previously remote plasma mantle to the vicinity of the spacecraft, as the shock propagated through the polar magnetosphere. At about 02:00 UT, POLAR reentered the lobe and polar wind, finding it had changed to a colder, slower, and denser outflow dominated by O+ plasma. The O+-dominated outflow continued as the spacecraft passed through the northern cleft at ~4.5 RE and then the southern cleft at 1.8 RE (geocentric). Such a direct response of the ionosphere to solar wind pressure disturbances is of potential significance to the dynamics of the magnetotail.

GA3.08/W/17-A6 0940

CENTRIFUGAL ACCELERATION OF IONS OBSERVED ON POLAR SPACECRAFT NEAR 9 RE OVER POLAR CAP UPON ARRIVAL OF CME-DRIVEN SHOCK

John B. CLADIS, Harry L. Collin, and William K. Peterson (all at Lockheed Martin Advanced Tech. Center, 3251 Hanover Street, B 255, Palo Alto, CA 94304, USA, email: cladis@spasci.com) Thomas E. Moore (NASA Goddard SFC, Code 692, Bldg. 2, Greenbelt, MD 20771-1000, USA, email: thomas.e.moore@gsfc.gov) Christopher T. Russell (Inst. of Geophysics and Planetary Physics, UCLA, Los Angeles, CA 90095-1567, USA, email: ctrussel@igpp.ucla.edu)

A shock driven by a coronal mass ejection struck the magnetosphere about 2344 UT on September 24, 1998. The POLAR spacecraft was near apogee over the northern polar cap, at (X,Y,Z)GSM = (-2.3803, -2.7148, 8.1450) in RE. During the following 144 s, from 2345:18 UT to 2347:42 UT, (i) the magnetic field measured on-board with the UCLA magnetometer increased sharply from126.16 nT to 182.00 nT; (ii) the field components changed from (BX,BY,BZ)GSM = (84.91, 32.55, -87.45) to (151.11, 50.655, -87.867); (iii) the full rotation of B was 19.87o; and (iv) the velocity components of both the H+ and O+ ions increased by about 75 km/s antiparallel to B. We suggest the ions were flung along -B by the "motion" of the magnetic field, according to the centrifugal-acceleration process first described by Cladis [GRL, 13, 893,1986]. A parallel-velocity increase of 35 km/s was computed by integrating the term $dv_{||}/dt = vE \cdot d\hat{e}/dt$, using the local values of vE (the drift velocity) implied by the ion-velocity components perpendicular to the magnetic field and the measured values of $\hat{e}(t) = B(t)/B(t)$. The higher acceleration of the ions was confirmed by a computer simulation of the process along the ion paths.

FAST OBSERVATIONS DURING THE SEPTEMBER 24TH AND 25TH 1998 MAGNETIC STORM

R. J. STRANGEWAY, C. T. Russell (both at: Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA 90095, USA, Email: strange@igpp.ucla.edu), D. M. Klumpar (Lockheed Martin Advanced Technology Center, 3251 Hanover St., Palo Alto, CA 94304, USA), C. W. Carlson, J. P. McFadden, R. E. Ergun (all at: Space Sciences Laboratory, University of California, Berkeley, CA 94720, USA), T. E. Moore (NASA Goddard Space Flight Center, Greenbelt, MD 20771, USA), and W. K. Peterson (Lockheed Martin Advanced Technology Center, 3251 Hanover St., Palo Alto, CA 94304, USA)

During September 24th and 25th 1998 the FAST spacecraft acquired data over the Northern Polar Cap in the noon-midnight local time sector. This allowed for detailed observations of the dayside cusp at ~ 4000 km altitude. The spacecraft was therefore ideally suited for monitoring the outflow of ionospheric plasma which was also observed at the higher altitude POLAR spacecraft. The interval around the Sudden Impulse (SI) at 23:45 UT on September 24th is characterized by enhanced field-aligned currents in the cusp region. Because the FAST orbital period is ~ 135 minutes, we can provide snapshots of the cusp region, and FAST passes through the cusp at ~ 00:10 UT on September 25th, some 35 minutes after the SI. The field-aligned currents at this time are sig ificantly larger than on the previous orbit. Large fluxes of 100 eV oxygen ions are also observed to be flowing out of the ionosphere, with decreasing energy for increasing latitude. These ions form a conic in pitch angle, consistent with the "pressure cooker" model of ion acceleration, where transverse heating overcomes a downward electric field. As already noted the field-aligned currents are weaker on the previous orbit, and a weaker oxygen conic is also observed. This suggests that the main effect of the increased solar wind dynamic pressure is to enhance already existing ion outflow through an increase in the field-aligned currents and the associated parallel electric fields and ion heating in the cusp ionosphere.

GA3.08/W/05-A6 1040

THE RESPONSE OF THE MAGNETOSPHERE TO AN INTERPLANETARY SHOCK: GROUNDBASED OBSERVATIONS OF THE SUDDEN IMPULSE ON SEPTEMBER 24, 1998

P. Chi, Guan Le, J. Raeder, C. T. RUSSELL and E. Zesta (All at Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA, USA, email: pchi@igpp.ucla.edu); K. Yumoto, H. Kawano and K. Kitamura (All at Kyushu University, Fukuoka, Japan); V. Angelopoulos (University of California, Berkeley, CA, USA); M. Moldwin (Florida Institute of Technology, FL, USA)

The strong interplanetary shock wave that intersected the front of the magnetosphere at about 2344 UT on Sept. 24, 1998, launched a compression of the magnetosphere that was followed around the globe by a new generation of magnetometers with rapid sampling and precise GPS-synchronized timing. Magnetometers of these chains included those in the Circum Pan Pacific Magnetometer Network, those in the IGPP/LANL array, those in the MEASURE array and those in the MACCS array. The event exhibited all the classical signatures of an SI including the preliminary decrease before the main increase in the H-component. The ability to model this event and its induced ionospheric currents using an MHD code allows us to compare the compression as it is seen in the magnetosphere with the response of the ionospheric currents.

GA3.08/W/02-A6 Invited 1100

RECENT ADVANCES IN MAPPING MAGNETOTAIL BOUNDARIES USING SUPERDARN HF RADARS

Mervyn P FREEMAN (British Antarctic Survey, High Cross, Madingley Road, Cambridge, CB3 0ET, U.K, email: M.P.Freeman@bas.ac.uk)

We review and discuss recent publications which have shown how HF radars can remotely sense magnetotail boundaries and thereby measure how these boundaries respond to changes in the IMF and to substorms. Specifically, we present the following: (1) Evidence for a relationship between the boundary plasma sheet/central plasma sheet (bps/cps) interface in the magnetotail and the equatorward edge of HF radar backscatter from the ionosphere or a latitudinal gradient in the Doppler spectral width of the backscatter. (2) Examples using this empirical relationship to track both rapid (of order 1 min) and slow (of order 1 h) changes in the ionospheric projection of the bps/cps interface. (3) Comparison of the time-varying location of the bps/cps interface observed in these examples with that predicted by a magnetic reconnection-based magnetospheric model using concurrent solar wind observations.

GA3.08/W/25-A6 1130

ELECTRON PRECIPITATION AS A FUNCTION OF MAGNETOTAIL STRETCHING

THOMAS SOTIRELIS and Patrick T. Newell, The Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, 20723

A model for the differential energy flux of precipitating electrons from 32 eV to 30 keV is presented. The model spectra are keyed to the degree of magnetotail stretching as inferred from the precipitation itself. The result is less smeared and more flexible than previous work because a given portion of the oval— such as from the structured/unstructured boundary to the poleward edge of the oval— is averaged only with the appropriate precipitation. Data from twelve years and eight DMSP spacecraft are used. Extensive variations in the energy flux, average energy, and spatial extent of the precipitation are seen for different degrees of magnetotail stretching.

GA3.08/W/31-A6 1150

AURORAL PRECIPITATION BOUNDARIES AND THE MAGNETOSPHERIC TAIL ENERGITICS FOR VARIOUS LEVEL OF THE MAGNETIC ACTIVITY

YA. I. FELDSTEIN, L. I. Gromova (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation, Troitsk, Moscow Region, 142092, Russia, email: lgromova@izmiran.troitsk.ru) B. V. Rezhenov, G. V. Starkov, V. G. Vorobjev (Polar Geophysical Institute, Apatity, Murmansk region, 184200, Russia, email: vorobjev@pgi.kolasc.net.ru)

luminosity structure allow to suggest physically substantiated method of the plasma regimes boundaries identification (Newell et al.,1996; Feldstein and Galperin,1996).The interrelationship between these high-latitude plasma regimes in the nightside to dawnside sectors and plasma domains of the distant magnetosphere has been demonstrated. DMSP satellites data have been used for statistical investigation of the plasma regimes boundaries dynamics depending on the magnetic activity level. Boundaries determining the polar cap location (b6) and characteristic break of latitudinal variation of the electron energy (b2e) have been used to define the magnetic flux dynamics and to calculate the magnetic energy in the magnetospheric tail during the transition period from the quiet conditions to the very disturbed ones. P.Newell, Y. Feldstein, Y. Galperin, C.-I. Meng, JGR, 101,A5,10737-10748, 1996; Y. Feldstein, Y. Galperin, Cosmic Research,34, N3, 209-227, 1996.

GA3.08/W/22-A6 1210

ENERGETIC IONS FROM THE POLAR SATELLITE AS TRACERS FOR PLASMA SHEET CONDITIONS

P. K. Toivanen, D. N. Baker, W. K. Peterson (LASP, University of Colorado at Boulder, Boulder, CO, USA, Email: petri.toivanen@lasp.colorado.edu) T. I. Pulkkinen (Finnish Meteorological Institute,Helsinki, Finland)

Observations from the POLAR satellite obtained by the Toroidal Imaging Mass-Angle Spegtrograph (TIMAS) and by the MICS sensor of the Charge and Mass Magnetospheric Ion Composition experiment (CAMMICE) frequently show multible peaked distributions in energetic H+ and O+ ions (12--120 keV) in the dusk side magnetosphere. These ions are on open drift paths and thus drift from the tail plasma sheet to the dusk side geostationary region. Our earlier results suggest that, under certain geomagnetic conditions, these observations can be used to determine remotely charactheristics of the plasma sheet over a large portion of the tail. In this study, we mainly address the large-scale electric field, which is responsible for the acceleration of these ions during their drift from the plasma sheet. To trace back the observed distributions, we use an ionospheric electric field model mapped to the plasma sheet together with a modified version of the T89 model in our drift model. These traced-back distributions are then linked to GEOTAIL observations, which show frequently pristine field-aligned O+ beams on energy range up to a few keV originating from the ionosphere. Thus our final aim is to form a coherent picture of O+ flow from the ionosphere to the plasma sheet and of consequent earthward transport and related
acceleration of O+ ions.

OBSERVATIONS PERTAINING TO THE LOCATION OF THE SUBSTORM ONSET INSTABILITY

L. A. FRANK, J. B. Sigwarth and W. R. Paterson (All at: Department of Physics and Astronomy, The University of Iowa, Iowa City, IA, USA, email: frank@iowasp.physics.uiowa.edu) S. Kokubun (Solar-Terrestrial Environment Laboratory, Nagoya University, 3-13 Honohara, Toyokawa, Aichi 442, Japan)

Recent observations of the initially brightened auroral arc at substorm onset provide considerable evidence that the instability is located at geocentric radial distances in the range of about 6 to 12 Re. These findings are based upon unique, high-resolution images from a camera for visible wavelengths on board the Polar spacecraft. The location of the onset instability is particularly important for theoretical analysis and modelling of magnetospheric substorms in that the plasma and magnetic field parameters are significantly different at the above radial distances compared to those for radial distances in the range of 20 to 30 Re which are used for several current theory efforts. Simultaneous measurements of plasmas and magnetic fields at the relevant radial distances in the equatorial magnetotail are used to search for the position of the onset instability. It is found that the onset instability is initially confined to a narrow range of longitudes (local time) and rapidly expands in longitude and to greater radial distances.

GA3.08/E/01-A6 1430

COMPARISON OF AURORAL ARCS OBSERVED WITH POLAR/VIS MEDIUM-RESOLUTION CAMERA AND FINNISH ALL-SKY CAMERAS AND THEIR MAPPING TO THE MAGNETOTAIL

T. I. PULKKINEN, K. Kauristie, and M. T. Syrjasuo (Finnish Meteorological Institute, PO Box 503, FIN-00101 Helsinki, Finland, tel. 358-9-19294654, fax 358-9-19294603,
e-mail: tuija.pulkkinen@fmi.fi) D. N. Baker, N. E. Turner (Laboratory for Atmospheric and Space Physics, University of Colorado, Boulder, CO 80309-0590) L. A. Frank and J.B. Sigwarth (Department of Physics and Astronomy, University of Iowa, Iowa City, IA 52242) T. Mukai, Institute of Space and Astronautical Science, Sagamihara, Japan) S. Kokubun (Solar Terrestrial Environment Laboratory, Nagoya University, Toyokawa, Japan) L. Zelenyi (Space Research Institute, Moscow, Russia)

The POLAR/VIS medium-resolution camera can resolve auroral arcs to a scale of a few km. The camera observations show individual arcs embedded within a diffuse band of luminosity, allowing for detailed examination of the auroral breakups and their relation to other substorm onset-associated processes. Observations from the POLAR/VIS medium-resolution camera, Earth camera, Finnish all-sky camera network, and ISTP spacecraft are utilized to examine details of auroral arc breakups and their mapping to the magnetotail during several substorm events in late 1997 and early 1998. In particular, an isolated substorm of about 400-nT intensity occurred on Dec 17, 1997, after almost 20 hours of quiescence. The POLAR/VIS medium resolution camera observed two intensifications in the auroras at 2051 UT and at 2221 UT. The all-sky camera data from Kilpisjarvi showed that auroral activity intensified at 2050 UT, the auroras moved quatorward between 2140 and 2230 UT, after which a strong breakup and poleward motion of auroras followed. Magnetic field modelling techniques are utilized to obtain an accurate mapping between the auroral observations and the magnetotail substorm signatures as observed by GEOTAIL and INTERBALL Tail Probe, both in the nightside magnetotail. The results are used to discuss the processes prior to the global instability onset and their associationto the processes creating auroral breakups.

GA3.08/W/03-A6 1450

THE EXPLOSIVE PHASE OF THE SUBSTORM

John C. SAMSON, R. Rankin, and I. Voronkov (all at Department of Physics, University of Alberta, Edmonton, Alberta, Canada T6G 2J1, email: samson@space.ualberta.ca)

The explosive phase of the substorm, with time scales of 10s of second to minutes, follows the initial brightening of an arc on field lines threading the inner edge of the plasma sheet. Optical data from the Canadian CANOPUS array indicate that the initial brightening is followed within 10s of seconds by enhanced cross tail currents in the inner plasmasheet, and then by dipolarization. Lobe flux reconnection begins within three minutes of the initial arc brightening, indicating an extremely dynamic process with Alfvenic time scales. We argue that the Alfvenic time scales indicate that the explosive phase requires a nonlinear instability. We discuss a hybrid model in which the explosive phase is triggered by shear flow ballooning followed by tearing and reconnection. Ultimately, lobe flux reconnection begins at about 25-30 RE down the magnetotail.

GA3.08/W/19-A6 1520

SHARE RADAR OBSERVATIONS OF INTENSE FLOW BURSTS IN THE MAGNETOTAIL

A. D. M. WALKER and J P S Rash (University of Natal, Durban) K B Baker (The Johns Hopkins University Applied Physics Laboratory) M Pinnock and J R Dudeney (British Antarctic Survey)

Observations are presented of a very unusual event on March 10 1997. At this time, the solar wind conditions were extremely quiet. On the night side the SHARE and Halley radars observed a succession of flow bursts in the ionosphere with velocities exceeding 2 km per s. The poster presents a variety of observations including data from satellites in the solar wind, low altitude satellites passing over the radar field of view, and ground based instrumentation from unmanned ground instruments under the field of view in Antarctica. The event shows some of the characteristics of a substorm, but occurs in the absence of any external driving mechanism. It may be that this is an observation of a fundamental mode of magnetospheric oscillation, uncontaminated by external driving mechanisms.

GA3.08/W/32-A6 Invited 1600

HF RADAR OBSERVATIONS OF IONOSPHERIC CONVECTION IN THE NIGHTSIDE AURORAL ZONE DURING SUBSTORMS

T. K. Yeoman (Department of Physics and Astronomy, University of Leicester, University Road, Leicester, LE1 7RH, U.K.)

High time resolution data from HF radars reveal short-lived convection signatures in the auroral ionosphere during the three phases of the magnetospheric substorm. For example, transient modulations of the electrojet currents during the substorm expansion phase have reported in data from HF radars. The features typically show an interval of suppressed electric field, characterised by large equivalent currents deduced from ground magnetometers, presumably as a consequence of enhanced ionospheric conductivity due to energetic particle precipitation. Following this an enhanced electric field causes a vortical flow. Ground magnetometer data has suggested that the flow vortices propagate azimuthally at up to 6 km s-1, and are typically characterised by equatorward flow enhancements of order 600 m s-1. Recent data from high time resolution HF scans parallel to the L-shell have provided direct measurements of the azimuthal propagation and plasma velocity during such impulsive convection features. The features are not usually accompanied by Pi2 pulsations and in one case study there is some evidence from Geotail spacecraft data of a relationship a dawnward perturbation and dipolarisation of the magnetic field and dawnward plasma flow in the magnetotail, perhaps related to bursty bulk flows. The possible implications of these observations for the substorm process will be discussed.

GA3.08/W/07-A6 1630

CUTLASS HF RADAR OBSERVATIONS OF HIGH LATITUDE AZIMUTHALLY PROPAGATING CONVECTION FEATURES DURING MAGNETOSPHERIC SUBSTORMS

J.A. WILD and T.K. Yeoman (both at Radio & Space Plasma Physics Group, Dept. of Physics and Astronomy, Leicester University, University Road, Leicester, UK, LE1 7RH.
Email: jaw11@ion.le.ac.uk)

Previous observations have identified transient high latitude convection features in the substorm electrojets associated with the expansion phase which were inferred to propagate azimuthally from ground magnetometer data. In addition, during the substorm recovery phase, high time resolution radar modes have been used to study omega bands propagating in an eastward direction. The high time resolution and multi-point nature of the observations leads to a refinement of the previous models of omega band structure. This study combines new data from the CUTLASS radars with observations from the IMAGE, SAMNET, NIPR and Greenland magnetometer networks and the STARE VHF radar in order to look at the zonal flows within the CUTLASS radar field of view. Intervals have been identified in which regions of pulsed flow propagating eastwards are observed directly by the radar and also demonstrate characteristic magnetic behaviour. By directly combining measurements of magnetic field strength and line of sight velocity it is possible to estimate the height integrated ionospheric conductivities at several points within the fields of view of the radars. The continuous nature of the multi-instrumental observations allows the study of the occurrence of azimuthally propagating convection features with respect to substorm phase as well as yielding information regarding the bulk properties and structure of the features themselves.

GA3.08/E/09-A6 1650

THE ELECTRICAL COUPLING OF MAGNETOSPHERIC FLOW VORTEXES AND FLOW CHANNELS TO THE RESISTIVE IONOSPHERE

John W. Bonnell and Joseph E. BOROVSKY (both at Space and Atmospheric Sciences Group, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, email: jborovsky@lanl.gov)

Owing to their polarization electric fields, flows in the magnetosphere drive field-aligned currents that electrically couple to the ionosphere. The details of d.c. current systems driven by flow vortexes in the magnetosphere are examined. It is found that the current systems driven by positive (angular velocity antiparallel to B) and negative (angular velocity parallel to B) vortexes differ greatly. Positive vortexes drive stronger current systems, dissipate more power, and spread across B whereas negative vortexes drive weaker currents, dissipate less power, and do not spread across B.
The signatures above the ionosphere of the two types of vortexes also differ. The details of d.c. current systems driven by flow channels in the magnetosphere are examined. A flow channel in the magnetosphere will exhibit an asymmetry when it couples to the ionosphere; this asymmetric coupling is explored. Extrapolating these studies to flow turbulence in the plasma sheet, predictions are made about the statistics of electric-field divergence at low altitudes and flow vorticity at high altitudes.

GA3.08/W/26-A6 1710

PLASMA SHEET VARIATIONS DURING SUBSTORM ACTIVITY: OBSERVATIONS ON 17TH MAY 1996

J.STOREY, M. Lester (Both at Radio & Space Plasma Physics Group, University of Leicester, Leicester, United Kingdom) T. A. Fritz (Dept. of Astronomy, Boston University, Boston, USA) C. T. Russell (Institute of Geophysics and Planetary Physics / UCLA, Los Angeles, USA) M. Brittnacher (University of Washington Geophysics Program, Seattle, USA) J. B. Blake (The Aerospace Corporation, Los Angeles, USA) J. Scudder (Department of Physics & Astronomy, University of Iowa, Iowa City, USA)

This presentation details the initial results obtained from a study of an interval of substorm activity observed in the high-latitude plasma sheet by the Polar spacecraft, during a pass over the Scandinavian sector on 17th May 1996. The study makes use of the CAMMICE and MFE instruments on board the Polar spacecraft, specifically to investigate any substorm related plasma flows and associated magnetic field variations. Other Polar instruments from which data have been used include two other particle instruments, Hydra and CEPPAD, and the Ultra-Violet Imager (UVI), which provides images of the auroral zone throughout the interval and hence shows ground signatures of the plasma flows observed in situ. Other instrumentation includes the WIND magnetometer and the IMAGE and SAMNET magnetometer chains. These instruments provide background data sets that are used to confirm the presence of substorm activity and give the timing of the onset of any such activity. The particle instruments observePSBL signatures twice during this interval. The first entry into the PSBL is due to a slight re-configuration of the field geometry caused by pseudobreakups occurring at 20:48 and 21:00 UT. The continuing growth phase causes the tail field lines to become more tail-like resulting in the spacecraft exiting the plasma sheet, before the expansion phase onset results in the spacecraft observing CPS ions at 21:45UT.

GA3.08/E/08-A6 Invited 1730

ON THE ROLE OF RESONANCES IN THE TRANSPORT IN THE MAGNETOSPHERE

ENNIO R. SANCHEZ, SRI International, 333 Ravenswood Ave.,Menlo Park, CA 94025

The Sun-Earth connection produces magnetospheric boundaries, cavities, and waveguides where ULF resonances and instabilities can be excited. A combination of simultaneous measurements from high-, low-, and ground-altitude instruments has been used to identify how ULF resonances influence transport in the magnetosphere and onset and evolution of substorms. Intervals were selected for which ISTP spacecraft were appropriately positioned in conjugate positions to ground-based magnetometer and radar chains. Spectral analysis of the observations for the first time establishes a direct relationship between Pc-5 pulsations measured on the ground and the periodicity of dipolarizations and particle injections at geosynchronous altitude, discrete westward electrojet intensifications, plasma and magnetic field oscillations of the plasma sheet and lobes, plasma and magnetic field oscillations in the magnetosheath, and plasma density, convection, and magnetic field pulsations in the plasma sheet. These observations strongly suggest a coupling of resonant cavity modes, which involve energy transfer from compressional oscillations propagating from the outer magnetosphere into the near-Earth closed field lines, with other wave modes in different parts of the magnetosphere. Those modes include waveguide modes originated in the high-latitude open field line regions of the magnetosphere, and waveguide modes in the low-latitude closed field line regions of the magnetosphere encompassed by the low-latitude boundary layers and the plasma sheet. The coupled response of different magnetospheric regions to solar wind input defines a measure of coherence of the magnetosphere-ionosphere system. The coherence of the system defines a correlation between periodicities in reconnection and bursty plasma transport in the magnetotail and periodicities in magnetic flux buildup and particle injection in the near-Earth region.

THE GLOBAL IONOSPHERIC CONVECTION RESPONSE TO CHANGES IN THE SOLAR WIND AND INTERPLANETARY MAGNETIC FIELD ORIENTATION

AARON RIDLEY (Southwest Research Institute, San Antonio, TX 78228-0510, USA, email: ridley@zed.space.swri.edu)

It has been shown that the ionospheric convection is closely coupled to the interplanetary magnetic field (IMF) orientation and more loosely coupled to the solar wind speed and density. Most studies of the convection have investigated the statistical steady state conditions. Recently, a number of studies have focused on the how the convection changes in response to IMF reorientations. The first studies of this kind showed localized observations of how the convection changed with time. More recently, studies have focused upon how the global convection changes. One result of the global studies is that the global convection pattern is shown to change as a whole, instead of the change in convection spreading slowly over the polar cap. Examples of such simultaneous changes are shown to occur for both IMF orientation changes and sudden changes in the dynamic pressure of the solar wind. We present arguments on the interpretation of the convection data, showing the simultaneous change in convection in the noon, dawn, and dust sectors. We present ground-based magnetometer data to verify these arguments. In addition, we discuss the ramifications of these observations on the dynamics of the magnetosphere-ionosphere system.

GA3.08/E/03-B1 1000

DYNAMICS OF HIGH-LATITUDE IONOSPHERIC CONVECTION AND CURRENT SYSTEM FOLLOWING A SUDDEN SOUTHWARD TURNING OF THE IMF

Nozomu NISHITANI and Tadahiko Ogawa (Solar-Terrestrial Environment Laboratory, Nagoya University, 3-13 Honohara, Toyokawa, Aichi 442-8507, Japan, e-mail: nisitani@stelab.nagoya-u.ac.jp) Natsuo Sato and Hisao Yamagishi (National Institute of Polar Research, 1-9-10 Kaga, Itabashi, Tokyo 173-8515, Japan) Mike Pinnock (British Antarctic Survey, High Cross, Madingley Road, Cambridge CB3 OET, England) Jean-Paul Villain (LPCE/CNRS, 3A Av. de la Recherche Scientifique, 45071 Oeleans Cedex 2, France) George Sofko (Department of Physics & Engineering Physics, University of Saskatchewan, 116 Science Place, Saskatoon, SK., S7N 5E2 Canada)

One example of the global dynamics of ionospheric convection and current system has been studied by using the SuperDARN radar network and high-latitude magnetograms when the IMF changed stepwise from northward to strongly southward. There were two-step changes in the ionospheric flow pattern. The first change of the convection pattern can be characterized by a sudden formation of a large flow vortex in the afternoon sector. This change propagated from the noon sector to the evening sector within 2 to 4 minutes. The second change, which occurred twenty minutes later, can be characterized by a sudden antisunward shift of the flow vortex. The ionospheric current system observed by the high-latitude magnetograms showed gradual formation of the DP2 current system. The formation began simultaneously with the first response of the convection flow and completed a few minutes after the second response. Distortion of the DP2 current system, that is, antisunward shift of the center of the two vortices, occurred simultaneously with the second response of the ionospheric convection pattern. From these observations, we speculate that the first response is associated with the propagation of magnetosonic waves, and that the second response is due to the configuration change of the magnetosphere after the solar wind discontinuity arrived in the magnetotail region.

GA3.08/W/27-B1 Invited 1040

ION AND ELECTRON HEATING IN MAGNETIC RECONNECTION

M. Hoshino (The University of Tokyo, Tokyo, 113-0033 Japan, email: hoshino@geophy.s.u-tokyo.ac.jp)

The origin of hot and dense plasma in the Earth's plasma sheet has been a long- standing problem. Observations have established that the ion temperature is the order of several keV, and the ion temperature in the plasma sheet is always about several times larger than the electron temperature. Many microscopic and macroscopic plasma processes are thought to be involved in the plasma heating: magnetic reconnection plays an important role on energy conversion process from magnetic into kinetic energy, and provides the preferential plasma heating of ions. Current-driven instabilities around the plasma sheet boundary layer are believed to be substantial for the electron heating. Strong turbulence of waves in the plasma sheet is probably important for understanding the hot plasmas as well. These effects are undoubtedly important for various stages of magnetotail evolution associated with magnetic reconnection. We have started to investigate the self-consistent plasma heating and acceleration processes in association with the kinetic magnetic reconnection by using a three-dimensional, electromagnetic, particle-in-cell simulation, in which both the current-driven instabilities and the collisionless reconnection process are described. We have studied where and when ions and electrons gain their energy during reconnection evolution. The results are discussed in terms of the GEOTAIL observations.

GA3.08/E/02-B1 1110

SIGNATURES OF MAGNETOTAIL VARIABILITY IN THE AURORAL ZONE

VAHE PEROOMIAN, Maha Ashour-Abdalla (Both at UCLA-IGPP, Box 951567, Los Angeles, CA 90095-1567, USA, e-mail: vahe@igpp.ucla.edu) Lev M. Zelenyi (Space Research Institute, Academy of Sciences, Moscow, Russia, e-mail: lzelenyi@iki.rssi.ru)

We use a self-consistent, large-scale kinetic model to investigate the formation of the magnetotail and the auroral manifestations of the complicated temporal dynamics that occur there during quiet periods. In our model, the magnetotail's current is calculated by following ion trajectories in a magnetic field that is made up of ion currents calculated at the previous time step. The model takes into account both the local inductive and global dawn-dusk electric fields. We find that the magnetotail is quite variable: magnetic islands are formed, then decay and merge. This process appears to be quasi-periodic, and results from the cycles of loss and replenishment that current-carrying particles undergo in the current sheet; these cycles are themselves caused by the rapid and non-adiabatic energization of ions in the vicinity of the x-lines that form in the model. Ion intertia determines the characteristic time scale for this periodicity, which is on the order of 5 - 10 minutes. The magnitude of the dawn-dusk electric field also influences the time scale. In our model, ion acceleration near the temporally variable location of the x-line stimulates the formation of quasi-periodic, velocity-dispersed ion structures in the ion precipitation profile. Many polar-orbiting spacecraft have observed structures such as these. we will compare our results with these observations.

GA3.08/W/33-B1 1130

WIND OBSERVATIONS OF THE NEAR-EARTH PLASMA SHEET: SOLAR WIND AND GEOMAGNETIC ACTIVITY DEPENDENCE

M. OIEROSET, T. D. Phan, L. Chan, and R. P. Lin (Space Sciences Laboratory, University of California, Berkeley, CA 94720, E-mail: oieroset@ssl.berkeley.edu)

We have studied 20 WIND perigee passes through the plasma sheet earthward of 24 Re. The plasma sheet observations are sorted according to region, interplanetary magnetic field values, solar wind plasma parameters, and Kp values, in an attempt to increase our understanding for the causes of the variations in the plasma sheet plasma parameters. Preliminary results indicate a cold and dense plasma sheet for low Kp values while the plasma sheet gradually becomes heated and less dense with increasing Kp. Our findings are also in agreement with GEOTAIL observations by Terasawa et al. (GRL, 24, 935-938, 1997), showing a cold and dense plasma sheet for northward IMF when the IMF is averaged over several hours prior to the plasma sheet observations. We also survey the interrelationship between the thermal and flow parameters in the plasma sheet in order to investigate the structure and dynamics of the plasma sheet.

GA3.08/E/12-B1 1150

IS THE MHD APPROACH VALID IN THE DISTANT PLASMA SHEET?

Oleg TROSHICHEV (Arctic and Antarctic Research Institute, St.Petersburg, 199397, Russia, email: olegtro@aari.nw.ru); Elizabeth Antonova (Scobeltsin Institute of Nuclear Physics, Moscow State University, Moscow, 119899, Russia, email antonova@orearm.msk.ru); Yohsuke Kamide (Solar Terrestrial Environment Laboratory, Nagoya University, Toyokawa, Aichi, 442, Japan, email: kamide@stelab.nagoya-u.ac.jp)

Measurements of the magnetic field and low energy plasma by the GEOTAIL spacecraft were utilized to study correspondence between the plasma velocity and magnetic oscillations in the distant plasma sheet at X = -(79-200) RE. A total of 14 extremely quiet days from available GEOTAIL data in 1993-1994 (12-s averages of the magnetic field and plasma parameters) were chosen for the analysis, identification of the plasma sheet and estimation of the magnetic activity being realized according to Troshichev et al. [JGR, in press]. Case study of behavior of magnetic field and plasma velocity shows that correspondence between the changes in these parameters often is not carried out. The Fourier analysis also sometimes shows striking discrepancy in the frequent spectra for magnetic and plasma parameters when powerful oscillations of plasma velocity (usually VY or/and VZ components) in range 3-8 min occurs against the almost calm magnetic field and vice versa. These results suggest that MHD approach is often violated in the distant plasma sheet even under the extremely quiet conditions.

GA3.08/W/24-B1 1210

OBSERVATION OF PROLONGED, STEADY RECONNECTION IN THE MAGNETOTAIL BY THE GEOTAIL SPACECRAFT

R. T. Mist and C. J. OWEN (Astronomy Unit, Queen Mary and Westfield College, London, UK), T. Mukai (Institute of Space and Astronautical Science, Sagamihara, Japan), S. Kokubun (Solar Terrestrial Environment Laboratory, Nagoya University, Toyokawa, Japan)

It is relatively unusual for conditions in the distant tail to allow a spacecraft to remain in the central plasma sheet continuously for a prolonged period. However, on October 27, 1994, when the Geotail spacecraft was situated in the deep tail (X=-170 RE, Y=20 RE and Z=0 RE), the spacecraft crossed from the north to the south lobe, and spent about 4 hours continuously in the plasma sheet. The magnetic field and plasma moment data throughout this period are consistent with the plasma sheet being formed by quasi-steady reconnection. The level of geomagnetic activity during this period is steady and moderate, with no obvious enhancements due to substorms. We analyse the two-dimensional ion distributions from the LEP instrument during this interval, and study the plasma populations in the north and south lobes, the PSBL and the plasma sheet. We compare these observed distributions with the predictions of reconnection models based on the balance of magnetic field and plasma stresses at the central, cross-tail current sheet. In these models, the plasma sheet population is formed by both heating and acceleration of the inflowing lobe plasma during its interaction with the current sheet. We show that the observed ion distributions are consistent with the expectations of these reconnection models.

GA3.08/W/14-B1 Invited 1400

THE EARTH'S DYNAMIC MAGNETOTAIL

A. Nishida (Institute of Space and Astronautical Science, Sagamihara, 229-8510, Japan, email: nishida@gtl.isas.ac.jp)

Following the first comprehensive study of the magnetotail conducted with the IMP 1 satellite, Ness [1969] reviewed the latest findings on the physics of the Earth's magnetotail. It is impressive that most of the fundamental concepts were already established in that review. At the end of the paper he listed outstanding problems which future studies should be directed to resolve. In the present paper we shall summarize the advances made in the physics of the magnetotail with reference to the problems he listed, and discuss the remaining issues. Answers to the problems he enumerated as (1) to (6) are given in the following. (1) The formation of the magnetotail is due to magnetic reconnection on the magnetopause. (2) Coherent, well-ordered tail exists at least to the distance of 200 Re and there is no indications of filamentation. (3) The merging across the neutral sheet is impulsive at the near-Earth neutral line. (4) Accelerations both in the magnetotail and in the solar flare are governed by magnetic reconnection. (5) Accelerations occur at the slow-mode shock and in the neutral sheet including the vicinity of the neutral sheet. (6) Electron islands events correspond to plasmoids and plasma-sheet boundary layer. Remaining important issues include (1) mixing of plasma-sheet and magnetosheath plasmas in the LLBL, (2) paucity of the slow-mode shock identification, and (3) trigger of the near-Earth reconnection.

GA3.08/W/16-B1 1430

AURORAL POLEWARD BOUNDARY INTENSIFICATIONS: A FUNDAMENTAL MAGNETOSPHERIC DISTURBANCE COUPLING BURSTY PLASMA SHEET FLOWS TO THE AURORAL IONOSPHERE

L. R. Lyons (Department of Atmospheric Sciences, UCLA, Los Angeles, CA 90095-1565, USA, email: larry@atmos.ucla.edu); G. T. Blanchard (Department of Chemistry & Physics University of

Southeastern Louisiana SLU 10878, Hammond, LA 70402-0878, USA); T. Nagai (Department of Earth and Planetary Sciences, Tokyo Institute of Technology, Tokyo 152, Japan); T. Yamamoto, T, Mukai, A. Nishida (All at: Institute of Space and Astronautical Science, Sagamihara 229, Japan); J. C. Samson (Department of Physics, University of Alberta, Edmonton, Alberta, T6G 2E9, Canada); S. Kokubun (Solar-Terrestrial Environment Laboratory, Nagoya University, Toyokawa 442, Japan)

Poleward boundary intensifications are nightside geomagnetic disturbances that have an auroral signature that moves equatorward from the poleward boundary of the auroral zone. They occur repetitively, and they appear to be the most intense auroral disturbance at times other than the expansion phase of substorms. They connect to the magnetotail via upward field-aligned currents that are sufficiently intense that a field-aligned potential drop is required. We have used data from nightside conjunctions of the GEOTAIL spacecraft in the magnetotail with the CANOPUS ground-based array in central Canada. During periods with identifiable poleward boundary intensifications, we find that the plasma sheet has considerable structure and bursty flow activity. During periods without such intensifications, the plasma sheet is far more stable with little flows. This is consistent with the intensifications being the result of the mapping to the ionosphere of the electric fields that give rise to bursty flows within the plasma sheet. Two different types of plasma sheet disturbance have been found to be associated with the poleward boundary intensifications. The first is fows that result from Speiser motion of particles in a localized region of thin current sheet. The second, seen preferentially in the near-Earth plasma sheet, consists of energy dispersed ion structures that culminate in bursts of low energy ions and isotropic low-energy electrons. Both are associated with localized regions of enhanced dawn-to-dusk electric fields.

GA3.08/W/23-B1 1450

CHARACTERISTICS OF AURORAL POLEWARD BOUNDARY INTENSIFICATIONS

Eftyhia Zesta (Department of Atmospheric Sciences, UCLA, Los Angeles, CA 90095-1565, USA, email: ezesta@atmos.ucla.edu); Larry R. Lyons (Department of Atmospheric Sciences, UCLA, Los Angeles, CA 90095-1565, USA); John C. Samson (Department of Physics, University of Alberta, Edmonton, Alberta, T6G 2E9, Canada), Erick Donovan (Department of Physics and Astronomy, University of Calgary, Calgary, Alberta, T2N 1N4,Canada)

Poleward Boundary Intensifications (PBIs) of the aurora are a frequently occurring auroral-zone disturbance. They consist of auroral enhancements that move equatorward from near the magnetic separatrix and are associated with ground magnetic disturbances of 20-100 nT and Pi2 pulsations. They are a phenomenon distinct from substorms, occurring both during substorm and non-substorm periods, and are often observed both during enhanced convection intervals and during quiet times. We used meridional scanning photometer data from the CANOPUS stations during the winter of 1996-1997 to identify a number of periods with PBI events. We investigate both the occurrence characteristics and the correlation of PBIs with the IMF direction and magnitude. We find that PBIs are statistically a dusk-to-midnight region phenomenon and are therefore associated with the upward region 1 field-aligned currents. We find that only half of our identified events are associated with substorms. The non-substorm associated PBIs are found to have a clear preference for a radial IMF. However, the radial IMF is a necessary but not sufficient condition for the occurrence of PBI events in the nightside aurora. We also examine all-sky-imager data from the CANOPUS station of Gillam at the time of our PBI events and determine the possible correlation of PBI events, identified in the meridional scanning photometer data, with short-lived, north-south aligned auroral arcs and with equatorward moving east-west aligned auroral arcs.

GA3.08/W/28-B1 1510

LOCAL INTENSIFICATION OF THE TAIL CURRENT AND ASSOCIATED OCCURRENCE OF MAGNETIC RECONNECTION IN THE MAGNETOTAIL

T. MUKAI, Y. Asano, I. Shinohara, and Y. Saito (Institute of Space and Astronautical Science, Yoshinodai, Sagamihara 229-8510, Japan, email: mukai@stp.isas.ac.jp); T. Nagai (Department of Earth and Planetary Sciences, Tokyo Institute of Technology, Tokyo 152-8551, Japan, email: nagai@geo.titech.ac.jp)

Recent GEOTAIL observations have clearly demonstrated a crucial role of magnetic reconnection in substorms. There are well-known growth phase signatures in the magnetotail, such as increasing pressure and configuration change to the tail-like magnetic field, representing enhancement of the tail current and thinning of the current sheet. However, these signatures are seen over a wide range of distances down the tail and are not enough to explain a certain location where the reconnection is first initiated. Fortunately we have found a substorm event in which the GEOTAIL spacecraft stayed in the current sheet at a distance of ~17 Re and could clearly observe temporal evolution of the tail current intensification and associated occurrence of magnetic reconnection there. Following the gradual increase in the growth phase, the tail current density increased sharply a few minutes before the onset. The tailward fast flows and increasing plasma temperatures were also observed to start in association with the intensification of the current density. These signatures can be interpreted as the initial occurrence of magnetic reconnection associated with local thinning of the current sheet (because the case is very rare). As time proceeds, the current sheet further thins and the current density is further intensified. This sequence evolves explosively through a few steps in several minutes, expanding the active region.

GA3.08/W/34-B1 Invited 1550

THE HALL TERM EFFECTS IN MAGNETIC RECONNECTION

Dr Masaki Fujimoto Dept. Earth Planet. Sci., Tokyo Inst. Tech

Geotail observations have shown that there are strong field-aligned currents (FACs) that are very likely to be the Hall current generated in magnetotail reconnection. 2D Hall MHD simulations do show that the FACs due to the Hall term are significant and should not be neglected in considering coupling to the ionosphere. These lead us to make 3D Hall MHD simulations of magnetic reconnection to study the three-dimensional structure of the generated FACs. Details of the results, especially in comparison with those obtained by MHD models, will be discussed.

GA3.08/W/11-B1 1620

SIMULATIONS SHOWING GENERATION OF FILAMENTARY FIELD-ALIGNED CURRENTS ABOVE THE AURORAL IONOSPHERE

Daniel W. Swift (Geophysical Institute, University of Alaska, Fairbanks, AK 99775-7320, USA, email: swift@gi.alaska.edu) Yu Lin (Physics Department, 206 Allison Laboratory, Auburn University, Auburn, AL 36849-5311, USA, email ylin@physics.auburn.edu)

A two-dimensional hybrid code is used to simulate the midnight meridian plane of the magnetosphere. The simulation domain extends from the Earth's ionosphere to 35 Earth radii in the antisunward direction and to 11 Earth radii along the polar axes. The simulation is driven by a dawn-to-dusk electric field imposed at the boundaries. The sequence of events follows those associated with the growth and expansive phases of the substorm. Momentum exchange between the plasma being accelerated Earthward in the neutral sheet and the magnetic field results in a stretching of the magnetic field lines and thinning of the plasma sheet. A pair of field-aligned currents develops connecting the inner edge of the plasma sheet to the auroral ionosphere, with the downward current equatorward of the upward current. The breaking of the inward plasma flow drives these currents. Next follows the apparent dipolarization. "Dipolarization" is carried outward by plasma rebounding off the dipole field. Ion-ion two streaming instabilities are excited behind the expanding dipolarization front. The effect of these instabilities is propagated Earthward along magnetic field lines by shear Alfvén waves. These are seen as field-aligned current filaments above the auroral ionosphere. We take the upward field-aligned current filaments as proxies for auroral arcs.

GA3.08/W/15-B1 1640

STUDY OF THREE-DIMENSIONAL HYBRID SIMULATION OF MAGNETOTAIL RECONNECTION

MASAO NAKAMURA(Solar-Terrestrial Environment Laboratory, Nagoya University, Honohara 3-13, Toyokawa, Aichi 442-8507, Japan, Email: nakamura@stelab.nagoya-u.ac.jp) and Masaki Fujimoto(Department of Earth and Planetary Sciences, Tokyo Institute of Technology, Oookayama 2-12-1, Meguro, Tokyo 152, Japan)

The three-dimensional structure of magnetic reconnection in a thin current sheet (thickness comparable to the relevant ion inertia length), which models the near-Earth tail current sheet just before substorm onsets, are studied by means of 3-D hybrid simulations (ion particle, charge neutralizing massless electron fluid). Magnetic reconnection is initiated by fixing a localized anomalous resistivity in the plasma sheet and generates fast plasma flows in the Earth-tail direction as a result of its explosive growth. On the other hand, the thin plasma sheet is unstable to the tail Kelvin-Helmholtz (K-H) instability, which kinks plasma sheet in the cross-tail plane. For the small resistivity cases, the tail K-H instability is well generated before the explosive growth of reconnection starts. While the kink structure of the plasma sheet modifies the plasma flow, the essential features, such as the dawn-dusk asymmetry of plasma flows and field configuration, still remains unchanged from the large resistivity case where the explosive growth starts before the influence of the tail K-H instability is visible.

GA3.08/E/04-B1 1700

SIGNATURES OF MAGNETOTAIL RECONNECTION DERIVED BY NUMERICAL SIMULATIONS AND VERIFIED IN SPACE

JOERG BUECHNER AND B. Nikutowski (Max-Planck- Institut fuer Aeronomie, Max-Planck-Str. 2, D-37191 Katlenburg-Lindau, Germany)

The true physics behind magnetic reconnection is still an open question. On the other hand large scale topological considerations have shown that reconnection must take place in the Earth's magnetotail. The magnetotail is, therefore, an appropriate site to test reconnection models. We have developed a kinetic model of three-dimensional reconnection and derived its signatures by kinetic plasma simulations. Here we present current results of numerical plasma simulations of specific signatures of collisionless reconnection through thin current sheets. We illustrate some of them in the context of ISTP spacecraft measurements of INTERBALL-1 and GEOTAIL.

GA3.08/W/20-B1 1720

A TAIL CROSSING AT 200 RE--GEOTAIL/HEP-LD OBSERVATION

B.Wilken, Q.G. Zong (both at Max-Planck-Institut fuer Aeronomie, D-37191 Katlenburg-Lindau,Germany, Email: wilken@linmpi.mpg.de) T. Doke (Advanced Research Center for Science and Engineering, Waseda university, Tokyo, Japan) S. Kokubun (Solar-Terrestial Environment laboratory, Nagoya University, Toyokawa, Japan)

In April 1994 Geotail was travelling on a deep tail trajectory. Sustained moderaten geoactivity was driven by the passage of a corotating interaction region (CIR) which started on 3 April and continued until 20 April. On 17 April a CME impinged on the magnetosphere and caused a major magnetic storm. Geotail observed the CME in the dusk magnetosheath/magnetosphere interface at a GSE position (-200,30,-5 Re). Shortly after the CME Geotail started the dusk-to-dawn tail passage. The general level of activity in the magnetotail was found to be very low which corresponded to rather quiet conditions in the geosynchronous orbit and on the ground. However, quasi-periodic low intensity energetic particle bursts embedded in plasmoid-like structures passed Geotail. In the absence of corresponding near-Earth disturbances it is suggested that the regular structures in the deep tail resulted from large amplitude Alfven wave in the solar wind.

GA3.08/E/07-B1 1740

NUMERICAL SIMULATION OF PLASMOID DYNAMICS

B P PANDEY, G.S.Lakhina and M.Roy (Indian Institute of Geomagnetism, Bombay 400 005, India, email: pandey@iig.iigm.res.in, lakhina@iig.iigm.res.in)

The plasmoid dynamics has been studied by a 2-D magnetohydrodynamic simulation code for a magnetotail configuration which takes into account the flaring of the tail. The plasmoid formation and its subsequent motion down the tail is followed for a few hundreds of Alfven time.
Simultaneously, the spatial and temporal evolution of density, pressure, temperature and magnetic field is studied. The results are compared with the Geotail observations.

THE RESPONSE OF THE MAGNETOSPHERE TO AN INTERPLANETARY SHOCK: GLOBAL SIMULATIONS OF THE SEPTEMBER 24, 1998 SUDDEN IMPULSE EVENT

J RAEDER, C T Russell (both at: Institute of Geophysics and Planetary Physics, University of California, 405 Hilgard Ave, Los Angeles, CA 90095, USA, email: jraeder@igpp.ucla.edu)

A very strong interplanetary shock was observed by the Wind spacecraft on September 24, 1998, 2221 UT. The resulting sudden impulse (SI) was observed by several magnetospheric spacecraft, as well as by ground magnetometers. This event gives us a unique opportunity to

study the response of the magnetosphere using our global magnetosphere - ionosphere model, and to compare our results in detail with the observations. Besides providing an assessment of the accuracy and robustness of our model for such an event, we will also present a more complete picture of the magnetospheric response as the observations alone could provide. In particular, we will discuss the propagation of the SI initiated waves through the magnetosphere, SI modifications to the current systems, and the causes of the ground magnetic perturbations.

GA3.08/W/04-B1 Poster **0900-02**

TAIL PLASMA FLOWS AND ELECTROJET ACTIVITY

Tsugunobu Nagai (Earth and Planetary Sciences, Tokyo Institute of Technology, Tokyo 152-8551, Japan, email: nagai@geo.titech.ac.jp) Tuija I. Pulkkinen (Finnish Meteorological Institute, P.O.Box 503 FIN-00101 Helsinki, Finland, email tuija.pulkkinen@fmi.fi) Peter Stauning, Danish Meteorological Institute, Lyngbyvej 100, DK-2100 Copenhagen, Denmark, email pst@dmi.dk) Toshifumi Mukai (Institute of Space and Astronautical Science, Sagamihara 229-8510, Japan, email: mukai@gtl.isas.ac.jp) Susumu Kokubun (Solar-Terrestrial Environment Laboratory, Nagoya University, Toyokawa 442-8507, Japan, email: kokubun@stelab.nagoya-u.ac.jp)

The spacecraft Geotail observes tailward/earthward convection plasma flows in the plasma sheet at radial distances of 10-30 Re in association with substorm activity. The ground magnetometer chains in Scandinavia and Greenland monitor electrojet activity, and the central latitude of the westward electrojet can be determined. In this paper, we examine the relationship between tail plasma flows and ground electrojet activity. Tailward plasma flows observed at 20-30 Re are usually associated with westward electrojets at magnetic latitudes of 64-68 degrees, whereas earthward plasma flows observed around 30 Re re often associated with the westward electrojet near 70 degrees. Unusual tailward plasma flows inside 20 Re are related with the westward electrojet near 60 degrees. We present several event studies and statistical results.

SUBSTORM ACTIVITY AS A SELF-ORGANIZED CRITICAL PHENOMENON

Vadim M.URITSKY, Mikhail I.Pudovkin (Department of Geophysics, St.Petersburg State University, Petrodvorets, St.Petersburg 198904, Russia, Emails: uritsky@snoopy.phys.spbu.ru, pudovkin@snoopy.phys.spbu.ru)

The effect of self-organized criticality (SOC) is proposed as an internal mechanism of generation of 1/f^b -like fluctuations in Earth's magnetosphere. It was suggested that localized in space current instabilities developing in the magnetospheric tail at the initial substorm phase can be considered as the SOC avalanches - dynamic clusters, superposition of which leads to the 1/f^b fluctuations of macroscopic characteristics of the system. Using sandpile model of SOC, numerical investigation of both spatially localized and global disturbances of magnetospheric current layer was carried out. The dependence of model's sensitivity on the accumulated internal energy was shown to be similar to that characterizing natural geomagnetic activity. The power spectrum of sandpile model fluctuations controlled by real solar wind parameters reproduces all distinctive features of the AE fluctuations spectrum, including presence of two frequency ranges with different spectral slopes, that provides an important evidence for our hypothesis. Furthermore, quantitative and qualitative conformity between disturbed dynamics of self-organized critical state of the model and the main phases of real magnetospheric substorm development is demonstrated.
The results obtained suggest that the application of the theory of SOC and cellular automaton technique creates a new promising approach for modelling substorm activity. This approach seems to be adequate for the describing of fractal stochastic features of geomagnetic variations which are difficult to interpret on the base of traditional methods.

ONE-DIMENSIONAL KINETIC MODEL OF THE PLASMA SHEET EVOLUTION DURING A SUBSTORM ACTIVATION

V.I.Domrin and A.P.Kropotkin, Skobeltsyn Institute of Nuclear Physics, Moscow State University, Moscow, 119899, Russia

A one-dimensional simulation model is constructed for analysis of the plasma sheet (current sheet, CS) evolution in the near-Earth tail region where an intense CS thinning is known to occur during a substorm activation. Dynamics of the hot plasma in the plasma sheet and of the ambient cold plasma is examined on the kinetic equation basis; a macroparticle code is used for ions to solve the equations while electrons are considered as a massless cold background. Self-consistent electromagnetic fields are calculated as numerical solutions of the Maxwell equations. The plasma sheet evolution takes place under action of an MHD disturbance that is applied on the boundary of the simulation box. That disturbance is assumed to be a consequence of fast tearing process occuring further in the magnetotail.
In the course of the simulated evolution, the electric field of the disturbance penetrates down to the central plane of the CS. That results in acceleration of ions in the CS; accelerated ions then escape CS along the field lines. Eventually the initial CS becomes replaced by an anisotropic one. The current is now carried by initially cold ions which are brought into CS by convection from the tail lobes. Magnetic field "annihilation" is a consequence: electromagnetic energy brought to CS from both sides, is transformed into energy of accelerated ions.

GENERAL ANALYTICAL THEORY OF SELF- CONSISTENT QUASIADIABATIC CURRENT SHEETS

Zelenyi Lev (Space Research Institute, Russian academy of sciences, 117810, Moscow, Russia, Email: lzelenyi@iki.rssi.ru); Sitnov Mikhail and MALOVA HELMI (Skobetsyn Institute of Niclear Physics, 117899, Moscow, Russia, email: stn@dec1.npi.msu.su, mlv@dec1.npi.msu.su)

The basics of unified analytical theory of the structure of self-consistent quasiadiabatic current sheets created by the impinging ion streams are presented. The problem is considered neglecting the jumps of the invariant Iz of nonmagnetized ions. Nonlocal analogue of the Grad-Shafranov equation for the sources of arbitrary anisotropy is obtained and solved numerically. The universal solutions corresponding to the regimes of strong and week anisotropies are investigated. Resulting self-consistent current is a sum of the drift cyclotron current and the magnetization currents flowing in the opposite directions. The maximum thickness of the current sheet is achieved in a case of weak anisotropy and equals to the thermal gyroradius of ions outside the sheet. In a case of strong anisotropy the sheet is compressed to minimal thickness. The effects of real nonadiabaticity are considered when the quasiadiabatic approximation is violated. Jumps of quasiadiabatic invariant Iz result in the gradual suppression of anisotropy and smearing of the current sheet. Influence of electron component creates an additional layer which also effectively broaden the current structure. We also discuss the relevant experimental data from ISEE and modern ISTP spacecraft (Geotail, INTERBALL) about the structure of the current sheets in the distant and near Earth parts of the tail.

EVIDENCES OF UNMAGNETIZED ELECTRON MOTION WITHIN THE PLASMA SHEET AND ITS POSSIBLE CAUSES

Marina STEPANOVA (Universidad de Santiago de Chile, Ecuador 3493, Casilla 307, Santiago, Chile, email: mstepano@lauca.usach.cl), Elizavieta Antonova, Ilya Ovchinnikov, Mickail Teltzov, Elena Vikhreva, (all at Skobeltsyn Institute of Nuclear Physics, Moscow State University, Moscow 119899, Russia, email: antonova@taspd.npi.msu.su)

We present the results of experimental and theoretical investigation of unmagnetized stochastic motion of elections and plasma mixing within the plasma sheet. Analysis of electron temperature distributions within the plasma sheet has been made using Intercosmos-Bulgaria-1300 polar orbiting satellite. It was shown, that the temperature, which has been obtained taking into consideration the acceleration of precipitating electrons by field-aligned potential drop, is nearly constant in the meridional direction within upward field-aligned current region and their values do not change for different orbits during a quiet geomagnetic time. Analysis of spatial fluctuations of recipitating electron fluxes at a fixed electron energy has shown, that fluctuation spectra of primary electrons have a power dependence and is close to the spectra of electric field fluctuations observed within the plasma sheet. The results of observations are interpreted as the consequence of stochastic plasma sheet particle motion and intensive plasma sheet plasma mixing. The role of different processes in such stochastization is analyzed. For the majority of plasma sheet ions, their Larmor radius can be comparable with the radius of curvature of magnetic field line which can be the source of stochastization. But, in case of electrons such mechanism can be effective only for particles with quite high energy or in the regions of extremely low Bz. Therefore, it is suggested that the main source of observed electron stochastization and one of the powerful source of ion stochastization is their motion in the inhomogeneous electric fields with characteristic scales comparable with particle Larmor radius. Chaotization of particle trajectories may be the part of stochastization process. Particle motion in the homogeneous magnetic field and regular inhomogeneous electric field having sinusoidal distribution in one direction and homogeneous distribution in perpendicular direction is analyzed as an example of a chaotic motion.

APPLICATION OF AN INVERSION METHOD BASED ON MID-LATITUDE MAGNETIC DATA TO ESTIMATIONS OF MEANINGS OF PARAMETERS OF THE GEOMAGNETIC TAIL AND THE IONOSPHERE

Vagina L.I.

On the basis of an inversion method based on mid-latitude magnetic data during the development of 71 substorms we have calculated characteristic temporary and spatial substorm current systems parameters: characteristic times of current increase and decrease, maximal current values, characteristic spatial sizes. The received characteristics were used to find the values of the constants for the homogeneous differential equation of the second order with constant factors. Using the received constants we have made estimations of meanings of parameters of the geomagnetic tail and the ionosphere. The meanings of estimated parameters have appeared within the limits of typical meanings of parameters of a geomagnetic tail and ionosphere, received other methods.

PECULARITY OF GEOMAGNETIC FIELD ON GEOSTATIONARY ORBIT, CONSEQUENCE FOR STATIONARY CONVENTION

KUZNETSOV S.N. (Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, 119899, Moscow, Russia, e-mail: kuznets@srdlan.npi.msu.su)

Analysis of GOES data on geomagnetic field during 1993-94 years shown that in time intervals near equinox we observe stationary increasing of the magnetic field near local midnight.This effect was not observed in solstice intervals. We proposed that this effect is projecting to midnight range of unreally position of field-aling currents. This effect may be connected with assimmetry in precipitation of cosmic ray electrons in magnetic lines of a plasma tail. The range of quasidipolar field near midnight may be foundation of tetha-strap in an aurora.

ON THE KELVIN-HELMHOLTZ HYDROMAGNETIC INSTABILITY

ANZOR GVELESIANI (Institute of Geophysics, Georgian Academy of Sciences, 1, M. Alexidze Str., Tbilisi 380093, Georgia, email: vazha@excite.com)

An analytical magnetohydrodynamic model of tangential discontinuity stability in the Earth's magnetosphere plasma sheath, magnetopause and plasma and neutral sheets is suggested. The general discussion relations for multilayer plasma flows of plane and cylindrical configuration are received. It is shown the role of the plasma compressibility and geometric parameters - thickness and curvature of layers boundaries - on the Kelvin-Helmholtz hydromagnetic instability. The compressibility of plasma results in destabilisation of plasma layers motion. It is found the parameter (product respectively the relations of plasma densities and magnetic fields squares of the neighbouring layers) from the value of each (more or less than 1) defines the effect of the geometry both of tangential discontinuity surface on the cylindrical and plane form of incompressible plasmatic jets.

SUN-ALIGNED AURORAL ARCS IN THE HIGH-LATITUDE MORNING SECTOR UNDER NORTHWARD IMF

Kazuo SHIOKAWA (Solar-Terrestrial Environment Laboratory, Nagoya University, 3-13, Honohara, Toyokawa, Aichi 442-8507, Japan, Email: shiokawa@stelab.nagoya-u.ac.jp)

Sun-aligned arcs are often observed in the high-latitude morning sector under the northward IMF conditions. On the basis of 6 year ground observation of the arcs at two Canadian stations (84MLAT and 78MLAT), we show characteristics of the arc appearance and motions. We found that most arcs for which we can define the direction of the motion move poleward with a typical velocity of 500 m/s. The arcs tend to move poleward repeatedly with a period of several minutes. Most of such events occur around the end of substorm-like magnetic activity, suggesting that the source of the moving arcs is related to the plasma sheet particles. Satellite observation shows that periodically-moving arcs occur during when both IMF Bz and By are positive or near zero. These arcs are caused by accelerated electron precipitation and are located around the boundary of the large-scale sunward flowing region at lower latitudes and the antisunward flowing region at higher latitudes. These results suggest that the arcs are connected to the boundary region between the plasma sheet and the low-latitude boundary layer in the morningside tail flank. From these observational facts, we discuss the source mechanism of the arcs, including pressure gradient force and flow shear in the tail flank.

THE POLAR CAP IONOSPHERE DURING PERIODS OF IMF BZ NORTHWARD ORIENTATIONS

C. E. VALLADARES (Institute for Scientific Research, Boston College, Chestnut Hill, MA 02167; email: cesar@dl5000.bc.edu)

When the IMF is directed northward, the ionospheric convection within the polar cap is more variable than during times of IMF southward. Measurements of the plasma convection during times of Bz north have shown the existence of sunward flows within the polar cap and the formation of three or four cells. These properties of the plasma convection are able to sustain the development of Sun-aligned and transpolar auroras practically at any location inside the polar cap. Another region of the polar cap, which seems to be strongly controlled by the IMF Bz, is the ionospheric cusp. When Bz points north, the footpoints of the merging region are displaced poleward and sometimes exist as two regions displaced in latitude by few degrees, each associated with field aligned currents. These facts point to the idea that reconnection may occur simultaneously on open and closed field lines. Particles impinging the cusp region show reversed ion dispersion and reversed convection. The IMF By component may also dictate the type of display seen at the ionospheric cusp. The ratio of By and Bz, under Bz positive conditions, may control the amount of closed/open field lines being reconnected. This paper reviews current measurements of the ionospheric cusp at darkness and the theoretical implications derived from joint optical and radio measurements.

MIDDAY AURORA AND DPY CONVECTION CURRENT FOR NORTHWARD IMF

Per Even Sandholt and Alv EGELAND (both at Deparment of Physics, University of Oslo, P. O.Box. 1048, Blindern 0316, Oslo, Norway, e-mail: p.e.sandholt@fys.uio.no)

We report a characteristic bifurcation of the aurora in the midday sector in association with northward turnings of the interplanetary magnetic field (IMF), leading to the coexistence of latitudinally separated forms, called types 1 and 2. The northernmost form (type 2), generally located north of the observation cite at 75 deg MLAT, is characterized by a brightening sequence during intervals of nonzero IMF By. The auroral observations are discussed in relation to the DPY convection current obtained from the IMAGE magnetometer chain. The type 2 auroral activity and its associated convection current are interpreted as ionospheric signatures of reconnection between the IMF and the terrestrial lobe field at the high-latitude magnetopause.

FLOWS AND CURRENTS NEAR THE CUSP UNDER NORTHWARD IMF CONDITIONS

D.L. MURR and W.J. Hughes (Center for Space Physics, Boston University, Boston MA 02215, USA; e-mail: murr@bu.edu)

Arrays of magnetometers provide a means of monitoring the high latitude ionospheric currents, and hence flows, over extended regions. We make use of magnetometer arrays in North America and Greenland to study flows during times of northward IMF and during transistions from southward to northward conditions. These combined magnetometer arrays provide a coverage of over 10 hours in MLT allowing us to monitor flows around noon continously for several hours. We find that flows change from predominently antisunward to predominently sunward when the northward component of the IMF becomes larger than about 2 nT. The transistion from one flow pattern to another is rapid, taking only a few minutes to completely change. From the portion of the ionosphere we are able to image, we see little evidence for convectin patterns with more than two cells, but patterns do evolve very quickly.

GA3.10/W/03-A6 **0950**

PARTICLE AND ELECTRIC FIELD MORPHOLOGIES FOR PERIODS OF BZ LARGE AND NORTHWARD

M.S. GUSSENHOVEN, D.H. Brautigam (Air Force Research Laboratory, Hanscom AFB, MA 01731) C.Y. Huang (Institute for Scientific Research, Boston College, Newton, MA 02159) F.J. Rich (Air Force Research Laboratory, Hanscom AFB, MA 01731)

A study is made of cases for which the Bz component of the interplanetary magnetic field (IMF) is large and positive for periods greater than 24 hours. The cases span Solar Cycle 23. Patterns of convection, of ion density and of precipitating auroral ions and electrons are determined for each case using data from the DMSP topside thermal plasma monitor and auroral particle detectors. Variations in the patterns are related to previous magnetospheric activity, solar wind kinetic energy, season, and solar cycle position. To this end, the patterns are also compared to statistical models for similar IMF and solar wind conditions for which persistence of conditions for 24 hours was not a requirement. They are also compared to magnetic cloud periods during which Bz slowly rotates from south to north (or vice versa), but typically stays in one configuration for less than 6 hours. Additional information on magnetospheric conditions is obtained from the CRRES data for several cases near solar maximum. WIND data provides information on low energy electrons and ions in the solar wind after before and during solar minimum.

MULTI-INSTRUMENT OBSERVATIONS OF THE DAYSIDE POLAR IONOSPHERE UNDER STEADY NORTHWARD IMF

S.E. PRYSE and A.M. Smith (Department of Physics, University of Wales Aberystwyth, Ceredigion, SY23 3BZ, U.K. Email: sep@aber.ac.uk, ams93@aber.ac.uk)

Results are presented from a multi-instrument case study of the polar dayside ionosphere under steady northward IMF. Optical emissions reveal Type 2 signatures, characteristic of lobe reconnection. The sunward plasma flow on lobe cells is identified by HF radar measurements. Downstream of the reconnection footprint, the reverse ion energy dispersion is seen in satellite particle data. Its effect is also evident in a tomographic image as a gradient in the altitude of the F-region ionisation peak, with altitude increasing with decreasing latitude. A steep latitudinal electron density gradient in the tomographic image, separating polar structure from the ionisation at lower latitudes, is interpreted as the adiaroic polar-cap boundary. Supporting evidence for the plasma structure is provided by electron density and temperature measured by the EISCAT Svalbard Radar.

IONOSPHERIC CONVECTION AND FIELD-ALIGNED CURRENTS DURING NORTHWARD IMF

L. G. Blomberg (Alfven Laboratory, Royal Institute of Technology, Stockholm, Sweden, email: blomberg@plasma.kth.se), J. A. Cumnock (Alfven Laboratory, Royal Institute of Technology, Stockholm, Sweden and William B. Hanson Center for Space Science, University of Texas at Dallas, Richardson, TX, USA)

The high-latitude ionosphere acts as a projection screen for electrodynamic processes in the magnetosphere. The interaction is particularly intriguing for northward IMF where the large-scale convection pattern may contain two, three, or four cells, and where polar current systems (NBZ currents) may occur in addition to the regular region 1 and region 2 currents. We review the current understanding of large-scale ionospheric convection and field-aligned currents during northward IMF. Results from applying the KTH convection model to northward IMF situations are shown, for events with a stable transpolar arc as well as for events where a transpolar arc is moving across the polar region. Recent data from the polar-orbiting Swedish microsatellite Astrid-2 are discussed.

GA3.10/E/04-A6 Invited **1115**

DAYSIDE FIELD-ALIGNED CURRENT SYSTEMS UNDER NORTHWARD IMF BZ

Shin-ichi OHTANI (The Johns Hopkins University Applied Physics Laboratory, Johns Hopkins Road, Laurel, MD20723-6099, USA, Email: ohtani@jhuapl.edu), Tomoyuki Higuchi (The Institute of Statistical Mathematics, 4-6-7 Minami-Azabu, Minato-ku, Tokyo 106, Japan,
Email: higuchi@ism.ac.jp)

The objective of the present paper is to report new attempts to study field-aligned currents (FACs) under northward IMF as well as to review recent studies. One of the major restrictions of investigating FACs with satellite magnetic field data has been that we have to count on visual examination of data plots. We recently developed an automatic procedure to identify FAC systems and applied it to the entire set of the DMSP-F7 magnetometer data, which consists of about 35,000 auroral zone crossings. In this paper we will focus on two interesting features of dayside FACs which we found to be related to the northward IMF orientation. One is the 4-sheet FAC structure. The associated polar distribution of FACs can be interpreted in terms of ionospheric convection, in which the existence of the lobe convection is essential. The preference of the event occurrence for northward IMF Bz also suggests that the field line merging between the IMF and the lobe magnetic field plays an important role. The other phenomenon to be reported is the disappearance of dayside FACs. Events are observed predominantly in the winter hemisphere, indicating that ionospheric conductance is important. By comparing FAC patterns in the summer hemisphere, we address the role of the ionosphere in the generation of FACs under northward IMF Bz.

GA3.10/W/25-A6 **1140**

PATTERNS OF ELECTRIC POTENTIALS AND FIELD ALIGNED CURRENTS FOR NORTHWARD IMF DERIVED FROM SATELLITE MEASUREMENTS

Daniel WEIMER (Mission Research Corporation, 1 Tara Blvd., Nashua, NH, 03033, USA, email: dweimermrcnh.com)

Results of empirical modelling of both the electric potentials and field aligned currents under conditions of northward IMF will be shown. Previous publications had shown that two-dimensional maps of the electric potential over the polar caps can be derived from measurements of the electric potential along multiple satellite passes, by using a least-error fit of spherical harmonic coefficients. By applying the same technique to satellite magnetic field measurements, new maps of field aligned currents have been obtained. The new method uses a "magnetic potential", which is obtained by rotating the measured magnetic field perturbations by 90 degrees and then integrating along the satellite path. Maps of this magnetic potential are then obtained from many combined passes by the spherical harmonic technique. The field-aligned current density is then calculated from the Laplacian of the magnetic potential, which will be shown to be equivalent to the curl of the two-dimensional perturbation vector field. Maps that are derived with this technique show unprecedented detail. How the electric potential and field aligned current patterns evolve as the IMF orientation changes from +Y to purely northward and then to -Y will be shown and discussed.

GA3.10/W/18-A6 1155

HIGH-LATITUDE IONOSPHERIC CONVECTION AND FIELD-ALIGNED CURRENTS DETECTED FROM GROUND MAGNETOMETERS AND FROM THE ØRSTED SATELLITE DURING NORTHWARD IMF CONDITIONS

Freddy CHRISTIANSEN, Vladimir Papitashvili*, Ole Rasmussen and Peter Stauning (all at Danish Meteorological Institute, Lyngbyvej 100, DK-2100, Copenhagen, Denmark, email: fch@dmi.dk, *also at SPRL, University of Michigan)

During southward interplanetary magnetic field (IMF) conditions the high-latitude ionospheric convection patterns usually display a large-scale, twin vortex system with the antisunward convection across the center of the polar cap and the sunward return flow at lower latitudes. However, during the northward IMF (NBZ) conditions, the antisunward convection almost ceases and is replaced by the sunward flow at the dayside portion of the near-pole region, while the two-cell system remains at lower latitudes forming a complicated convection pattern of three or more vortices. The NBZ convection pattern is generally associated with the Region 0 field-aligned current system in the central polar cap. These currents are possibly generated through high-latitude merging processes. We will focus on selected cases during NBZ conditions as defined by the IMF data obtained from IMP 8 and ACE spacecraft observations. The high-latitude ionospheric convection will be described from high-latitude ground magnetometer data, while the field-aligned current systems will be derived from high-precision geomagnetic measurements made by the Ørsted satellite.

GA3.10/W/06-A6 1210

INSTANTANEOUS GLOBAL PATTERNS OF HIGH-LATITUDE CONVECTION DURING NORTHWARD IMF

J. Michael RUOHONIEMI and Raymond A. Greenwald (both at Johns Hopkins University, Applied Physics Laboratory, Johns Hopkins Rd., Laurel, MD, 20723, USA,
email: mike_ruohoniemi@jhuapl.edu)

The nature of high-latitude convection for northward IMF conditions remains a somewhat unsettled problem. Although recent experimental results have tended to favor the multi-cell over the distorted two-cell model, these have been limited by the continuing difficulty of obtaining truly global-scale images of the instantaneous high-latitude convection pattern. The role of the azimuthal IMF component in ordering convection during northward IMF is also not clear. To date, the most complete portrayals of convection for northward IMF are due to large statistical studies.
With the SuperDARN network of HF radars in the northern hemisphere, it is possible, at times, to measure convection velocities over nearly _ of the entire pattern with a temporal resolution of 2 minutes. In earlier work involving common-volume measurements with one pair of SuperDARN radars an example of a single reverse dayside convection cell was shown (Greenwald et al. [1995]). Using a new technique to combine the line-of-sight velocity data from all six radars into a best-fit estimate of the global pattern, we have examined several periods of northward IMF. These demonstrate the prevailing morphology of the pattern for northward IMF (multi-cell) and its great variability. Comparison with statistical convection models indicate that, even when these express the appropriate multi-cell morphology, they usually significantly underestimate the magnitude of the flows. We attempt to characterize the emergence of multi-cell convection in terms of IMF and other factors and interpret the patterns within the context of solar wind-magnetosphere coupling processes.

GA3.10/W/26-A6 1225

SUNWARD CONVECTION AND GLOBAL MAGNETOSPHERIC OSCILLATIONS DRIVEN BY LOBE RECONNECTION DURING AN EXTENDED PERIOD OF NORTHWARDS IMF T.K.

Yeoman (Radio and Space Plasma Physics Group, Dept. of Physics and Astronomy, Leicester University, University Road, Leicester, LE1 7RH, U.K., email: yxo@ion.le.ac.uk) I.R. MANN (Dept. of Physics, University of York, Heslington, York, YO10 5DD, U.K., email: ian@aurora.york.ac.uk) G. Chisham and M.P. Freeman (British Antarctic Survey, High Cross, Madingley Road, Cambridge, CB3 0ET, U.K., email: gchi@pcmail.nerc-bas.ac.uk, mpf@pcmail.nerc-bas.ac.uk) J.A. Wanliss (Dept. of Physics, University of Alberta, Edmonton, Alberta, T6G 2J1, Canada,
email: wanliss@space.ualberta.ca)

We present observations from an interval of 11 hours of almost continuously northward IMF which suggest that lobe reconnection may have provided a powerful internal source for global magnetospheric oscillations. The interval is between around 2200 UT on the 19th, and 0900 UT on the 20th, March 1995. From 0400 UT, the SuperDARN Finland radar records good backscatter from high latitudes, and shows a well developed high latitude convection pattern consistent with clockwise flow driven by lobe reconnection under By positive conditions in the northern hemisphere. At around 0900 UT, the Finland radar again observes velocities consistent with continuing lobe stirring, however between the two radar observations the spectral widths suggest that the polar cap has contracted. The radar also detects intervals of convection consistent with four cell convection between these two times. Coincident observations from the IMAGE magnetometer array show the existence of two wave packets of discrete spectrum Pc5 waves, between 0300-0500 UT and 0600-0800 UT, having dominant period of around 512s and 430s respectively. Complex demodulation analysis reveals clear field line resonances (FLRs) in both cases, the first at 73 and the second at 75 degrees geomagnetic. The waves provide an excellent closed field line diagnostic which also show the polar cap to be strongly contracted at this time, the IMAGE estimates of the last closed field line being consistent with those inferred from the Finland radar spectral widths. Whether the northwards motion of the FLR is caused by contraction of the polar cap, or occurs due to local time changes in magnetic geometry is not clear. Unfortunately, the southern hemisphere radar at Halley has insufficient backscatter at polar cap latitudes to confirm whether or not the sunward convection which would be required to generate new closed flux and hence to contract the polar cap was occurring in the southern hemisphere during this interval. Interestingly, however, between 0300-0500 UT and at lower latitudes, the Halley radar does observe ULF wave activity coherent with and of the same period as the waves seen by IMAGE around 6 hours of local time away in the opposite hemisphere. The same wave packet was also seen near the equatorial plane on the dawn flank by Geotail. This shows the ULF waves to be truly global in nature. Since the solar wind speed is relatively slow, and the ram pressure relatively constant, we believe that the waves were not driven directly by the solar wind. Our observations suggest that lobe reconnection may have been responsible and that it may provide a powerful internal source for global magnetospheric oscillations.

TOPOLOGY OF MAGNETOSPHERE AND IONOSPHERE COUPLING

Patrick NEWELL (Johns Hopkins University Applied Physics Laboratory, 11100 Johns Hopkins Rd., Laurel, MD 20723)

The polar cap (and hence the magnetosphere) for northward IMF can be open and simply connected, open and not simply connected (theta aurora), or closed. Examples of all three states can be found, although by far the most common is open and simply connected (a region void of precipitation around the magnetic pole). This is because northward IMF intervals normally include brief southward IMF fluctuations, and dayside merging can open flux much more quickly (about 10**5 Wb/s) than it subsequently drains during quiet times (about 7 x 10**3 Wb/s in our estimate). Examples of these various states of the magnetosphere/ionosphere configuration will be given, along with the conditions under which they occur.

GA3.10/E/01-A6 Invited 1425

MAGNETOSPHERE-IONOSPHERE COUPLING AND THETA-AURORA FORMATION

Elizaveta E. ANTONOVA (Skobeltsyn Institute of Nuclear Physics, Moscow State University, Moscow, 119899, Russia; email: antonova@orearm.msk.ru, antonova@taspd.npi.msu.su)

The analysis of the experimental observations of the magnetosphere and the ionosphere under northward IMF conditions give the possibility to develop the theoretical approach to the magnetosphere-ionosphere coupling and theta-aurora formation. The theory consider the observed reconnection phenomena as the consequence of inner magnetosphere current dynamics.
Generation of electric field including large-scale dawn-dusk electric field is explained like the consequence of the existence of hot plasma pressure gradients in the magnetosphere producing large-scale field-aligned currents in the regions where magnetic field lines are closed and bulk plasma velocity is much lower then Alfven and sound velocity. The existence of plasma sheet developed turbulence is taken into account. The theory give the possibility to explain the plasma sheet bifurcation under northward IMF conditions, the formation of NBZ current system, the change of the electric field direction from dawn-dusk to dusk dawn in the center of polar cap (and corresponding change of plasma flow from antisunward to sunward).

GA3.10/W/04-A6 Invited 1450

ALMOST STATIC PLASMA SHEET IN GEOMAGNETICALLY QUIET TIMES

A. NISHIDA and T. Mukai (both at Institute of Space and Astronautical Science, Sagamihara, 229-8510, Japan, email: nishida@gtl.isas.ac.jp, mukai@gtl.isas.ac.jp); S. Kokubun (Solar Terrestrial Environment Laboratory, Toyokawa, 442-8507, Japan)

During geomagnetically quiet intervals, there are times when the flow velocity is very low (|Vx| < 100 km/s) in the distant plasma sheet. We shall call them as almost static plasma sheet. This paper studies characteristics of such cases in combination with those of PSBL and more normal (in terms of flow speeds) plasma sheet that were observed in close succession over a period of 12 hours at x = -112 Re. Bz was positive and |By| was much less than Bz in the almost static plasma sheet studied here. It is found that all the plasma sheet data points, including both very low speed and normal speed cases, satisfy the same temperature-velocity and density-velocity relations which are very well defined. In this sense the almost static plasma sheet is not an anomaly. Ion temperature that corresponds to zero flow velocity is about 300 eV. The temperature-velocity and density-velocity relations for the PSBL are clearly different from these and are almost orthogonal; that is, while in the lobe/PSBL density increases with |Vx| it decreases with |Vx| in the plasma sheet. In these correlation diagrams the points representing the almost static plasma sheet are located at the intersection between the lobe/PSBL and the plasma-sheet curves. This observation is discussed in the light of the statistical results on the structure and dynamics of the magnetotail in geomagnetically quiet times.

GA3.10/W/16-A6 Invited 1515

THE MAGNETOSPHERE UNDER NORTHWARD IMF: MODELS AND SIMULATIONS

Joachim RAEDER (Institute of Geophysics and Planetary Physics, University of California, 405 Hilgard Ave, Los Angeles, CA 90095, USA, email: jraeder@igpp.ucla.edu)

Substantial progress has been made over the past several years in modelling the magnetosphere under northward IMF conditions. Models have become capable of using measured solar wind and IMF data as input, thus enabling the direct comparison of model results with in-situ measurements of the magnetosphere, to the effect that model results are now much more reliable as in the past. We will review the modelling efforts of the past several years and discuss what the models can say about the reconnection geometry, tail structure, and magnetospheric and ionospheric convection under northward IMF. In particular we will address the still controversial issue of whether or not the magnetosphere can attain a closed topology during quiet times and/or northward IMF.

GA3.10/E/09-A6 1600

GLOBAL MHD SIMULATIONS OF THE SOLAR WIND-MAGNETOSPHERE COUPLING FOR NORTHWARD IMF

P. SONG, D. L. DeZeeuw, T. I. Gombosi, C. P. T. Groth, and K. G. Powell (The University of Michigan, Ann Arbor, MI, USA, e-mail: psong@umich.edu)

We present a series of global MHD simulations for northward IMF conditions. We investigate the effect of the solar wind velocity, density, and IMF strength on the length of the magnetotail. We will also investigate the global magnetic field configuration, ionospheric and magnetospheric plasma convection patterns and current systems for steady-state northward IMF conditions.

GA3.10/W/02-A6 1615

MAGNETOPAUSE CURRENT SYSTEMS AND TRANSPORT FOR ZERO IMF

B.U.Ö. SONNERUP (Thayer School of Engineering, Dartmouth College, Hanover NH 03755, USA, email: sonnerup@dartmouth.edu)W.W. White, K.D. Siebert, N.C. Maynard, and D.R. Weimer (Mission Research Corp., Nashua NH 03062, USA, email: bwhite@mrcnh.com, ksiebert@mrcnh.com, nmaynard@mrcnh.com, dweimer@mrcnh.com) G.L. Siscoe and G.M. Erickson (Center for Space Physics, Boston University, Boston MA 02543, USA, email: siscoe@buasta.bu.edu, erickson@buasta.bu.edu)

A numerical MHD-based simulation code is used to investigate the morphology and dynamical role of those global magnetospheric current systems that remain in the limit of vanishing interplanetary magnetic field (IMF). In this limit, reconnection does not occur on the magnetopause so that magnetospheric convection is driven exclusively by viscous/diffusive transport. The remaining current systems include the classical Chapman-Ferraro currents, the geotail currents and the Region 1 currents, all of which thread the magnetopause/low-latitude boundary layer (MP/LLBL) region. In particular, the Region 1 currents connect the LLBL to the high-latitude ionospheres, where they serve to maintain the standard two-cell polar-cap convection system. The associated polar-cap potentials, found in the simulations, agree well with values derived from observations when the IMF is weak. A simple analytical model of flows and fields in the equatorial MP/LLBL region has been developed. It describes density, velocity and magnetic-field variations across these layers and permits estimation of the effective, numerically produced, MP/LLBL transport coefficients associated with the code. Results indicate resistive and viscous diffusion coefficients that are in fortuitous agreement with estimates derived from in-situ observations of the LLBL.

GA3.10/W/01-A6 1630

LOW ENERGY IONS OBSERVED BY POLAR/TIDE FOR NORTHWARD IMF NEAR SOLAR MINIMUM

H. A. Elliott and R. H. COMFORT (both at The University of Alabama in Huntsville, CSPAR, TH S101, Huntsville, AL 35899, Email: comfortr@cspar.uah.edu) M. O. Chandler and P. D. Craven (both at NASA/Marshall Space Flight Center, Space Science Laboratory, ES83, Redstone Arsenal, Alabama, AL 35812) T. E. Moore (NASA/Goddard Space Flight Center, Laboratory for Extraterrestrial Physics, Greenbelt, MD 20771)

This study examines characteristics of low energy ions near the polar cap boundary and within the polar cap in relationship to convection velocities. Since convection has been shown to be related to IMF conditions, cases during northward IMF conditions will be contrasted with southward IMF cases. The primary source data for this study comes from the Thermal Ion Dynamics Experiment (TIDE) on the Polar satellite early in the Polar mission near solar minimum. TIDE can measure 3-D velocities and covers the low energy range 0-450 eV, with mass discrimination. The Polar orbit has apogee near 9 RE geocentric over the northern polar region and perigee near 2 RE over the southern polar cap. IMF conditions will be obtained from observations by Wind or IMP-8. Convection near the polar cap boundary is of particular interest since the convection there is often highly structured, and convection reversals may be associated with O+ outflow. Cleft ion fountain studies have shown that O+ flows out of the cleft and convects poleward as it falls into the polar cap. In addition to characterizing ion properties at both high and low altitudes for northward IMF for solar minimum, this study examines the density structures of O+ in relationship to the convection velocities and location within the polar cap. Initial analysis of TIDE data has shown that the O+ density can maximize poleward of a convection reversal that is found in the cleft region. The density then decreases across the polar cap. In the nightside auroral region, Transverse Ion Acceleration events have been shown to be co-located with convection reversals. Examining such relationships can provide insight into understanding the consequences of the 3-D flow on the density and temperature structures of O+ ions in the polar cap, and transport of O+ across the polar cap.

GA3.10/E/02-A6 1645

THE COUPLING MODE BETWEEN KELVIN-HELMHOLTZ AND RESISTIVE INSTABILITIES IN COMPRESSIBLE PLASMAS

Chen SHEN (Center for Space Science and Applied Research, Chinese Academy of Sciences, Beijing 100080, China, e-mail: sc@center.cssar.ac.cn); Zhenxing Liu (Center for Space Science and Applied Research, Chinese Academy of Sciences, Beijing 100080, China, e-mail: liu@center.cssar.ac.cn)

We have investigated the coupling mode between K-H and resistive instabilities using a compressible MHD simulation method. It is found that, in compressible plasmas, the coupling mode can take place in a limited range of ambient shear flow velocity, beyond which the coupling mode is stabilized. The flow shear can significantly enhance the growth of the coupling mode. Only in a limited range of plasma beta, could the coupling mode occur. Through comparing the observation characteristics of the magnetic reconnection at Earth's magnetopause with the results here, we deduce that the coupling mode between K-H and resistive instabilities can appear at Earth's magnetopause, especially at the high latitude boundary layer when the IMF is northward.

GA3.10/L/01-A6 Poster 1700-01

THE RELATION OF HIGH-LATITUDE AURORAL ARCS TO THE PARTICLE PRECIPITATION REGIONS IN THE MORNING SECTOR

V.L.ZVEREV and V.G.Vorobjev (Polar Geophysical Institute, Academy, Apatity, Murmansk region,184200 Russia, Email: zverev@pgi.kolasc.net.ru

Ground-based observations of high-latitude auroral arcs in the 05-09 MLT sector by the all-sky camera at Vostok station (-83,3MLAT, MLT=UT-1) and simultaneous DMSP F6-F9 particle precipitation measurements have been examined. DMSP F6-F9 satellites have been processed by a neural-network-based automated identification algorithm (Newell et al.,1991) designed to indicate the source of precipitation. A total of 17 simultaneous events in 1985-1990 were analysed. The IMF Bz component was northward during these events. It was found that during these events in the regions of high-latitude Sun-aligned arcs the plasma mantle particle signatures have been observed. In most cases the locations of polar arcs are consistent with the particle definition of the poleward edge of the plasma mantle. The regions with the high-latitude Sun-aligned arcs were not separated from the main auroral oval by the particle precipitation typical for the polar cap. Some dusk-dawn asymmetry of particle precipitation boundaries locations d uring satellites passes was observed. P.T.Newell, S.Wing,C-I.Meng and V.Sigillito. The auroral oval position, structure, and intensity of precipitation from 1984 onward: an automated on-line data base. J.Geophys.Res. VOL.96, NO A4, 5877-5882, 1991.

GA3.10/E/10-A6 Poster 1700-02

THE STRUCTURE OF PLASAMA CONVECTION IN THE HIGH-LATITUDE IONOSPHERE FOR NORTHWARD IMF

N.V.ISAEV. Institute of Terrestrial Magnetism Ionosphere and Radio Wave Propagation , 142092 Troitsk, Moscow Region, Russia.

The results of the DC- electric field examination depending on the IMF based on measurements onboard the "Intercosmos-Bulgaria-1300" satellite are presented. It is shown that for a strong values of Bz (IMF)>0 and different directions of By (IMF) the electric field in the polar ionosphere is abruptly inhomogeneous - local increases of the electric field values up to 120 mV/m in the dayside and nightside auroral region. Besides, at strong Bz > 0 in the polar cap occur 2-3 vortex convective systems of definitely non-stationary character with convection velocity direction determined by the sign of By IMF. Empirical high-latitude electric field models have been constructed. Distribution of the potential in the polar ionosphere (global convection of the ionospheric plasma) for small values of Bz IMF and Kp index was calculated and formed on the basis of statistical data from satellites. It is obtained that large-scale convective cell (Bz<0) or two cells (Bz>0) can appear in the polar cap region, the direction of plasma rotation is determined by sign By IMF. The effect of the convection electric field penetration into the region of main ionospheric trough (MIT) is determined for the different directions of IMF and geomagnetic activities. It is concluded that the IMF structure is in general determined by a direction and intensity of electric field. The density inhomogeneity in the region of MIT develops as a result of gradient-drift instability.

GA3.10/W/10-A6 Poster 1700-03

GLOBAL OBSERVATIONS OF TRANSPOLAR ARC EVENTS

J. A. CUMNOCK (Alfven Laboratory, Royal Institute of Technology, Stockholm, Sweden and William B. Hanson Center for Space Science, University of Texas at Dallas, Richardson, TX, USA; email: cumnock@plasma.kth.se), L. G. Blomberg (Alfven Laboratory, Royal Institute of Technology, Stockholm, Sweden), R. Coley (William B. Hanson Center for Space Science, University of Texas at Dallas, Richardson, TX, USA), J. F. Spann (NASA Marshall Space Flight Center, Huntsville, AL, USA), F. J. Rich (Phillips Laboratory, Hanscom AFB, MA, USA)

It has been observed that the most stable theta aurora configuration (i.e., a transpolar arc extending along the noon-midnight meridian and attached to the auroral oval on both the day and nightsides) evolves from an expanded dawn or dusk side of the auroral oval. The transpolar arc evolves from the dusk (dawn) side of the auroral oval when the IMF is northward and By changes from positive to negative (negative to positive). The expanded dawn and/or dusk sides of the auroral oval map to an expansion of the plasma sheet in the magnetosphere. How the transpolar arc maps to the magnetosphere once it has separated from the auroral oval is not yet clear. While these transpolar arcs are normally associated with northward IMF, they can persist for as long as 30 minutes after the IMF turns southward. Preliminary analysis of the ionospheric signatures of this evolution are shown. The global UV patterns of interest are identified utilizing POLAR UVI data. Precipitating particles and the resulting density enhancements measured by the DMSP satellite are examined. Field aligned currents and plasma drifts are generated with the KTH convection model.

GA3.10/W/15-A6 Poster 1700-04

CONVECTION FLOW IN THE NORTHERN HEMISPHERE DURING INTERVALS OF POSITIVE IMF BZ AS OBSERVED BY THE SUPERDARN RADARS.

G. PROVAN and T. K. Yeoman (Department of Physics and Astronomy, University of Leicester, Leicester LE1 7RH, UK.)

Super Dual Auroral Radar Network (SuperDARN) is a global network of HF radars which provide information on the high-latitude ionosphere in the Northern and Southern hemispheres, obtaining the E x B drift of ionospheric plasma by scattering radio waves off F region irregularities. By merging the line-of-sight velocities observed by several pairs of SuperDARN radars, it has been possible to study the ionospheric convection flow over a large area of the high-latitude ionosphere. A number of cases studies have been performed on the effect of a northward Bz component of the Interplanetary Magnetic Field (IMF), as measured by the WIND satellite, on the convective flow of plasma in the high-latitude Northern hemisphere ionosphere as observed by the SuperDARN radars. The dynamics of the convection patterns and their relationship to the location and motion of the polar cap boundary are investigated.

GA3.10/W/05-A6 Poster 1700-05

CONVECTION SYSTEMS FOR GROUND STATE OF MAGNETOSPHERE

R. LUKIANOVA (Arctic and Antarctic Research Institute, Bering st., St.Petersburg, Russia, email: renata@geophys.spb.su)

Convection systems generated by different patterns of the ground state field-aligned currents taking place in periods of geomagnetic quiescence are calculated by method of numerical simulation. Method of calculation implies solution of the boundary problem for elliptic system of partial differential equations on the spherical surface, the electrodimanic connection between the hemispheres and realistic assumptions about the current systems and the ionospheric conductivities. The convection systems have been examined in a way that is consistent with Region 0, 1, 2 currents. It is shown that the main feature of the ground state convection in the polar ionosphere are convection cells attached to day-time cusp region. The convection cells are reduced to form smaller-scale structures at local times extending from dayside to nightside Calculation have been carried out for equinox and soltice in both hemispheres to show seasonal effects.

GA3.10/W/08-A6 Poster 1700-06

HIGH LATITUDE IONOSPHERIC CONVECTION AND FIELD-ALIGNED CURRENTS DURING NORTHWARD IMF: GLOBAL PATTERNS AND THEIR DYNAMICS

AARON RIDLEY (Southwest Research Institute, San Antonio, TX 78228-0510, USA, email: ridley@zed.space.swri.edu) Vladimir Papitashvili (Space Physics Research Laboratory, University of Michigan, Ann Arbor, MI 48109, USA, email: papita@umich.edu)

The IZMIRAN Electrodynamic Model (IZMEM) was recently re-calibrated against experimental observations made by five DMSP satellites between 1993 and 1996. We utilized the combined IZMEM/DMSP ionospheric electrostatic potentials (e.g., http://www.sprl.umich.edu/MIST) for systematic study of the ionospheric convection and field-aligned current dynamics in the dark and sunlit ionospheres during changing northward IMF conditions. The cross-polar potential differences and changes in the convection pattern are studied as a function of the IMF Bz and

various By over the both northern and southern polar regions. We test the predictive capabilities of this model by comparing the modeled potential and field aligned current patterns to results derived from the AMIE (assimilative mapping of ionospheric electrodynamics) technique. In order to determine how the models compare, we have run both during periods of dynamic, northward, IMF. It is found that when the IMF is low-pass-filtered, both the IZMEM model and the AMIE technique show similar behavior as the convection evolves during IMF changes and that changes occur almost simultaneously over the entire polar cap. It is further found that while the behavior is similar, the base patterns can be significantly different. This is explained in terms of the viscous interaction pattern.

GA3.10/W/17-A6 Poster **1700-07**

HIGH-LATITUDE IONOSPHERIC CONVECTION FOR NORTHWARD IMF

L. A. DREMUKHINA, Ya. I. Feldstein, A. E. Levitin (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation, Troitsk, Moscow Region, 142092, Russia,
email: lgromova@izmiran.troitsk.ru)

The complexity of ionospheric convection patterns for northward IMF makes difficult to understand the behavior of plasma at high latitudes. Every empirical model of high latitude ionospheric convection (developed from satellites or radar observations, or utilizing the ground magnetograms inversion technique) is based on some definitions, "a priori" determining differences in convection over the polar region for particular IMF strength and direction as well as for various solar wind parameters. In this study we carry out comparisons of the basic convection patterns developed during northward IMF with the satellite and radar data. The presentation will focus on reasons how the multi-vortex convection patterns can be obtained for northward IMF from satellite passes. When only the satellite observations are taken into account in drawing the near-orbit pattern, the localized multi-vortex system can easily be produced. However, that kind of drawing can be disputed from the analysis of the global convection patterns modeled for particular situation in the IMF during the satellite pass.

GA3.10/E/07-A6 Poster **1700-08**

THE IMF DEPENDENCE OF HIGH-LATITUDE FIELD-ALIGNED CURRENTS AS ESTIMATED FROM MAGNETIC SATELLITE DATA

Nils OLSEN, Therese Moretto and Eigil Friis-Christensen (Danish Space Research Institute, Juliane Maries Vej 30, DK-2100 Copenhagen, e-mail: nio@dsri.dk)

We have estimated high-latitude field-aligned currents from data of high-precision low-altitude satellites like MAGSAT and Oersted. After subtraction of a main field model, the data were divided according to season and the direction of the y- and z-component of the IMF, and averaged on a grid (2 deg geomagn. lat. / 1 hour MLT). Then the radial component of the current density was estimated from the averaged horizontal magnetic field of the four neighboring grid-cells. We present average field-aligned current patterns for nine different directions of the IMF and for different seasons, and compare our results with those obtained from magnetic ground-based data.

GA3.10/W/12-A6 Poster **1700-09**

AIR FORCE STATISTICAL AURORAL MODELS (AFSAM)

D.H. BRAUTIGAM (Air Force Research Laboratory, Hanscom AFB, MA 01731, USA,
email: brautigam@plh.af.mil)

Since 1985, the Air Force Research Laboratory (AFRL) has created a series of statistical auroral models based on electrostatic analyzer data (electron and ion flux) from the Defense Meteorological Satellite Program (DMSP) satellites. A set of hemispheric auroral maps are constructed over a wide range of auroral activities, parameterized both by Kp and by interplanetary conditions. Of particular relevance to this session are the maps which are parameterized according to the z-component of the interplanetary magnetic field (Bz) and solar wind speed (Vsw) [Brautigam, et al., JGR, 96, 1991]. Individual maps are created by compiling the raw data into average spectra over a spatial grid defined by corrected geomagnetic latitude and local time coordinates. From these average spectra, a number of average quantities are derived, including integral number flux, integral energy flux, Hall and Pedersen conductivities, and average energy. Analytical fits to these average quantities have been recently completed, with the goal of making the models more accessible to ionospheric modelers. Sample maps constructed from the analytical fits will be presented to compare and contrast the Bz north with the Bz south cases.

SEASONAL EFFECTS IN MODELLED IONOSONDE DRIFTS AT CASEY, ANTARCTICA

P. R. Smith(1),(2), P. L. DYSON(2), and R. J. Morris(3): (1)Dept. of Electronic Engineering, LaTrobe University, Bundoora, VIC 3083, Australia (2)Dept. of Physics, LaTrobe University, Bundoora, VIC 3083, Australia (3)Australian Antarctic Division, Channel Hwy, Kingston, TAS 7050, Australia

A digital ionosonde located at Casey, Antarctica (at -81° CGL), in the southern polar cap, has collected four years of F-region plasma drift measurements. This large data-set was used to create linear regression models of the plasma flow, parameterized by the direction and strength of the Interplanetary Magnetic Field (IMF) in the By-Bz plane. The drift is primarily influenced by the IMF Y and Z components, but separate models created for summer and winter show there exists a definite seasonal effect. The summer hemisphere convection pattern is predicted to include a lobe cell circulating on open field lines, embedded within one of the merging cells. The drift vectors at Casey's latitude are consistent with convection patterns derived from DMSP satellite data, with a larger, rounder dusk cell for -By (for southern hemisphere), but more evenly sized cells for +By. The Casey model is also consistent with patterns from the Weimer 96 (W96) electric potential model generated for dipole tilts of ±15°. The W96 model is used to track the movement of convection cell centers with season and illustrates, for example, that in summer the dusk cell center passes poleward of Casey for a large -By component while in winter it does not. An effect analogous to the seasonal one should also be caused by the direction of the IMF X component, which is frequently overlooked. Using equinox data only to negate seasonal effects, drifts associated with negative Bx are very similar in appearance to summer, and likewise for positive Bx and winter.

GA3.10/E/08-A6 Poster **1700-11**

THE MAGNETOSPHERE AND IONOSPHERE UNDER NORTHWARD IMF ION ENERGY DISPERSION EVENTS IN THE CUSP/CLEFT AND MANTLE: GENERAL DISPERSION SIGNATURE

Marina GONCHAROVA, W.Lyatsky, and V.Kriviliov (Polar Geophysical Institute, Apatity, Russia); David G.Sibeck (APL/JHU, Laurel, Maryland, USA)

From the DMSP F7 satellite measurements for September, October and November 1984, the general dispersion signature of precipitating ions (the signature responcible for the average energy decline with changing latitude) are investigated in the 08 - 14 MLT sector under quiet IMF Bz/By conditions just above the boundary of the most sharp growth of the 100 eV tlectron flux with increasing latitude. Total of 112 polar cap crossings were considered. The meridian component of the dispersion-forming velocity and the probable injection source latitude inferred from the general dispersion pattern measurements are studied as functions of IMF Bz/By, immediate and 30 minute forestalling, solar wind velocity, solar wind electric field, 3-hr Kp index and magnetic local time (MLT). The poleward dispersion-forming velocities are found to drop with increasing IMF Bz southward and to rise with IMF Bz northward though the equatorward energy declines were also present by this polarity.The results obtained in the cusp/cleft would suggest the presence of the Axford-Hines mechanism activity footprint under IMF Bz<0 and would be in favor of 4-vortex convection system in the cusp/cleft and mantle under IMF Bz>0. The likelihood of the dispersion-forming velocity patterns at lower and higher atitudes with the expected convection patterns of Axford-Hines and Dungey type respectively imply the convection flow input is dominating when shaping the general dispersion signature. So far, the counterstreaming general dispersion signatures under Bz>0 included into analysis can be understood as a result of a joint activity of both convection types.

PLASMA ENTRY INTO THE MAGNETOSPHERE UNDER NORTHWARD IMF CONDITIONS DURING THE RECOVERY FROM STRONG CME-DRIVEN COMPRESSION

HANNU E. J. KOSKINEN*, Anssi M. Malkki, Tuija I. Pulkkinen, Esa J. Kallio (Finnish Meteorological Institute, Geophysical Research, P.O.Box 503, FIN-00101 Helsinki, Finland, e-mail: Hannu.Koskinen@fmi.fi; *also at University of Helsinki, Department of Physics) William K. Peterson (Lockheed Martin Space Physics Laboratory, Palo Alto, CA 94304, USA) Ingrid Sandahl (Swedish Institute of Space Physics, P.O. Box 812, S– 98128, Kiruna, Sweden) Kile B. Baker (The Johns Hopkins University, Applied Physics Laboratory, Laurel, MD 20723– 6099, USA)

The solar wind plasma entry into the magnetosphere under northward IMF conditions is a more difficult process to describe than the entry during southward IMF because subsolar reconnection process cannot be invoked. We investigate the entry process starting from observations of several impulsive dispersion ramps of magnetosheath protons observed by the Interball-2 satellite on January 11, 1997, when the magnetosphere was recovering from strong compression caused by the plasma cloud of a coronal mass ejection event. These dispersion ramps were observed in the evening sector at high magnetic latitudes over a wide local time sector. One of the ramps was detected also by the Polar satellite at higher altitude when its ground track crossed the track of Interball-2 in close temporal conjugacy. The ions were observed in a region of sunward convection. A remarkable feature of the observations was that the spacecraft data indicate substantially higher ion drift speed than a reasonable ionospheric convection speed during northward IMF, a discrepancy confirmed by simultaneous SuperDARN observations. In addition to data analysis we examine the process using a phenomenological model for the solar wind-magnetosphere interaction, which includes 3D models both for the magnetosheath and for the magnetosphere.

FAST EARTHWARD PLASMA FLOWS OBSERVED IN THE MID/DISTANT TAIL UNDER QUIET CONDITIONS: RELATION TO SUBSTORMS

Oleg TROSHICHEV (Arctic and Antarctic Research Institute, 199397, St.Petersburg, email: olegtro@aari.nw.ru) Susumu Kokubun, Yohsuke Kamide (Solar Terrestrial Environment Laboratory, Nagoya University, Toyokawa, Aichi, 442, Japan) Toshifumi Mukai and Tatsundo Yamamoto (Institute of Space and Astronautical Sciences, Sagamihara, Kanagawa 229, Japan)

Abstract. Measurements of the magnetic field and low energy plasma by the GEOTAIL spacecraft have been used to study fast earthward plasma flows in the distant (130-200 Re) and middle (40-80 Re) tail and their relation to substorms. Results of the analysis show that high-speed earthward ion flows are often observed in the mid/distant tail under conditions of low magnetic activity (AE<100 nT), when IMF BZ component is northward or oscillates about zero. The considerable part of the fast earthward flows (29% in the distant tail and 53% in the middle tail) seems to be precursor of the substorm onsets on the Earth. These flows occur at closed magnetic field lines. The cause and effect relations between fast earthward plasma flows in the distant tail and substorm activity suggest that neutral line can form at distances far beyond 100 Re in quiet conditions.

GEOMAGNETIC RESPONSE TO MULTIPLE SOLAR WIND PRESSURE VARIATIONS DURING NORTHWARD INTERPLANETARY MAGNETIC FIELD CONDITIONS

Patrizia FRANCIA, Umberto Villante (both at Dipartimento di Fisica,Universita' de L'Aquila, L'Aquila, Italy; Email: patrizia.francia@aquila.infn.it), Stefania Lepidi (Istituto Nazionale di Geofisica, Roma, Italy; Email: stefania.lepidi@aquila.infn.it) and Alan J. Lazarus (Center for Space Research, MIT, Cambridge, USA; Email: ajl@space.mit.edu)

A study of the geomagnetic field response to a series of consecutive solar wind pressure variations has been performed during interplanetary events characterized by stable northward magnetic field conditions. The geomagnetic field H component well responds to the solar wind pressure changes on a time scale of few minutes. The amplitude of the geomagnetic field response is found to be different at different local times, showing greater values around local noon and midnight.

TURBULENT PLASMA SHEET DURING NORTHWARD INTERPLANETARY MAGNETIC FIELD CONDITIONS

Elizaveta E. Antonova and Ilya L. Ovchinnikov (both at Skobeltsyn Institute of Nuclear Physics, Moscow State University, Moscow, 119899, Russia; email: antonova@taspd.npi.msu.su)

The theory of plasma sheet with medium scale developed turbulence predicted the existence in the plasma sheet of quasi-diffusion transport and the meaning of later obtained on the base

of ISEE data diffusion coefficient. Its application to the case of northward IMF orientation give the possibility to model the processes of plasma sheet bifurcation and theta-aurora formation. The input parameters in the quasi-3-dimensional plasma sheet model are electric field distribution at the ionospheric level and magnetic field model. Empirical electric field models and Tsyganenko magnetic field models were used for the obtaining of plasma sheet configuration under northward IMF conditions. The model plasma sheet has the bulge region in its center. The decrease of electric field in the bulge region due to particle drift and electric charge accumulation on the bulge borders lead to the bulge growth. The change of the electric field direction.

AN EFFECT OF NORTHWARD IMF ON PLASMA DYNAMICS IN GEOSYNCHRONOUS ORBIT

Nataliya A. VLASOVA, Elmar N. Sosnovets, Michail V. Teltsov, Nickolay N. Pavlov (Skobeltsyn Institute of Nuclear Physics, Moscow State University, Moscow, 119899, Russia, email: vlasova@taspd.npi.msu.su)

According to theoretical conceptions and available experimental data, a number of specific features arises under the northward IMF (Bz>0) in the magnetospheric electric field, field-aligned current, aurora and distributions of precipitating particles. What is about experimental results for the Bz>0 conditions, the most of these were obtained from the low-altitude polar spacecraft, geophysical rockets and high-latitude ground stations. In this paper we present our data from geosynchronous satellite for 1992-1994. The study concerns dynamics of plasmas of 0.1-12 keV energy.
During the northward IMF, the following features of the measured plasma were observed:
- in electrons: softening of the plasmasheet spectra, decreasing of intensity and disappearance of the diurnal variation;- in ions: formation of an intensive flux of ions of 5 keV through 12 keV energy in the night sector and disappearance of the diurnal variation;- recovery of all measured parameters after the IMF reorientation to Bz<0.
It is shown that at least qualitatively the reported effects can be explained in the frame of a model of "closed" magnetosphere under the northward IMF.The work has been supported by the RFBR grant 97-02-16870.

COLD, DENSE BOUNDARY OF MAGNETOSHEATH ORIGIN OBSERVED BY GEOTAIL IN THE FAR-TAIL PLASMA SHEET

R. T. MIST and C. J. Owen (Astronomy Unit, Queen Mary and Westfield College, London, UK), T. Mukai (Institute of Space and Astronautical Science, Sagamihara, Japan), S. Kokubun (Solar Terrestrial Environment Laboratory, Nagoya University, Toyokawa, Japan)

On September 25, 1994 the Geotail spacecraft was located close to the flank of the distant magnetotail (X=-170 RE, Y=24 RE and Z=-2 RE). During a 4 hour interval (13 - 17 UT) the spacecraft encountered both north and south lobes and the plasma sheet region before finally exiting into the magnetosheath. Within the plasma sheet, two different regimes were observed a fast flowing and slow flowing region. The slow flowing region is less dense and cooler than the fast flowing region. The properties of neither of these regions are consistent with simple reconnection models. Distributions taken from the LEP instrument show that the fast flowing region contains two populations. The first of these is similar in character to that observed in the slow flowing region. The second of these has similar characteristics to the magnetosheath. However, the peak flux of this population is about one half of the magnetosheath flux, and the bulk velocity is slightly lower than the sheath velocity. This suggests that a fraction of the magnetosheath population has crossed the magnetopause, losing energy in the process. We also note that the observed Bz in the plasma sheet/MSBL region is northward throughout, and is also very strongly northward at times. This suggests that the plasma sheet may well be on closed field lines. Hence we suggest that this may be evidence for magnetosheath plasma penetration into the plasma sheet across a closed magnetopause.

INTERPLANETARY CONDITIONS IN ASSOCIATION WITH PROLONGED GEOMAGNETIC CALM INTERVALS

G.K. RANGARAJAN Observatorio Nacional Rua General Bruce 586 Sao Cristovao Rio de Janeiro Brazil e-mail: ranga@dge1.on.br

From the 3-hourly index Kp of geomagnetic activity, we identify several intervals (at least four-day long sequences) when the magnetospheric conditions are considered very calm (as represented by Kp = 0 or 1). We examine 16 solar wind and IMF parameters in the vicinity of such intervals using the method of Principal Component Analysis to highlight the stability/variability of the solar wind and IMF. In addition, we also study the IMF/solar wind control of quiet / disturbed magnetospheric conditions using sequences when Kp =0-1 or Kp= 4-9 occurred at least for 8 consecutive intervals. The results are evaluated in terms of the variability of IMF and the contribution of the north-south component of the Interplanetary Magnetic Field.

EARLY LIFE OF CORONAL MASS EJECTIONS

N. GOPALSWAMY (NASA Goddard Space Flight Center, Bldg 26, Room G-1, Code 682.3, Greenbelt, MD 20771, USA, e-mail: gopals@fugee.gsfc.nasa.gov)

There are a number of dedicated solar instruments at present -- both ground based and spaceborne --that provide new information on coronal mass ejections (CMEs). Phenomena such as coronal dimming, coronal Moreton waves, shocks and coronal arcade formations have now become closely associated with CMEs and have provided several new insights into the CME process. Recent advances in our understanding of the near-surface manifestations of CMEs will be reviewed with particular emphasis on X-ray, EUV and radio observations from SOHO, Yohkoh, Wind/WAVES and Nobeyama Radioheliograph. Relationship between CMEs and other transient phenomena such as flares, prominence eruptions and shock waves will be discussed.

GA4.01/W/18-A2 **0930**

CMES AND GEOACTIVITY IN SOLAR CYCLE *23*

David F. WEBB, ISR, Boston College, 140 Commonwealth Ave., Chestnut Hill, MA02467-3862, USA, email: webb@plh.af.mil

CMEs are important for space weather because they cause the largest geomagnetic storms and often drive interplanetary hocks, a key source of energetic particle events. During the rise of the present solar cycle, oservations at the Sun using Yohkoh, SOHO, TRACE, radio and other data of CMEs and new knds of related phenomena such as halo-like CMEs and EUV surface waves have provided insight into the source regions and development of CMEs. Halo CMEs observed by LASCO since 1996 suggest the launch of geoeffective disturbances toward Earth. This has been confirmed by good correspondences found between halo CMEs with associated solar surface activity within about 30 degrees of sun center and shocks, magnetic clouds and geomagnetic storms at Earth 3-5 days later. I will discuss some common aspects of the recent Sun-Earth connection events and what they tell us about the structure of CMEs and their geoeffectiveness.

SOLAR ACTIVE FILAMENTS AS SOURCES OF THE NEAR EARTH DISTURBANCES

K.G.Ivanov and E.P.ROMASHETS Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation of Russian Academy of Sciences (IZMIRAN), Troitsk, Moscow Region, 142092 Russia, email: romash@izmiran.rssi.ru

The long-standing idea on the solar active filaments as sources of the near Earth geomagnetic disturbances (M.Valdmeier, 1946, Kkiepenheur, 1947) and its modern generalization (K.Ivanov, 1998) were applied to use the contemporary presentation of the active filament and prominence data in the Solar-Geophysical Data (Active Dark Filament (ADF), Arch Filament System (AFS), Disappearing Solar Filaments (DSF) and so on). The three examples of the near Earth interplanetary disturbances on Jan 1997, May 1997, and Jan 1998 generated by ADF and AFS will be considered.

RECENT OBSERVATIONS OF CORONAL MASS EJECTIONS

O. C. St. CYR (CPI/NRL, Code 682, NASA-Goddard, Greenbelt, MD 20771, USA, email: cst@sdac.nascom.nasa.gov)

We will review some new understandings and new questions concerning coronal mass ejections (CMEs) that have appeared with the onset of solar Cycle 23. White-light observations of CMEs have been obtained by groundbased and spacebased telescopes for almost 30 years. Literally thousands of CMEs have been identified and measured in data from Skylab, Solwind, SMM, MLSO, and SOHO observations. Many CMEs (both individually and in statistical studies) have been compared to other observations of solar, interplanetary, and planetary phenomena. From this, there is general agreement on the basic properties of CMEs: (1) their rate varies by a factor of ~10x in phase with other solar activity signatures; (2) the location of their appearance is somewhat variable during the solar cycle, with many (if not most) CMEs arising from pre-existing coronal structures; (3) the apparent size and speed distributions are asymmetric, with average width being ~50 degrees and average speed being ~400 km/s, both values as measured projected onto the plane-of-the-sky; (4) CMEs are commonly associated with the destabilization and eruption of other magnetic structures on the Sun (prominences and active regions); (5) CMEs are the primary cause of severe geomagnetic storms.
But there remain basic outstanding questions concerning CMEs: What is their true three-dimensional structure? What is the sequence of physical processes that leads to a CME, and can the launch of a CME be predicted? How are CMEs accomodated into the solar wind flow? Are there reliable signatures of Earthward-directed CMEs that are available by groundbased methods?

FLUX ROPE MODELLING OF ICMES OBSERVED AT MULTIPLE SPACECRAFT OVER VARIABLE SEPARATIONS

T. Mulligan and C. T. RUSSELL (both at Institute of Geophysics and Planetary Physics and the Department of Earth and Space Sciences, University of California Los Angeles, USA, e-mail: tamitha@igpp.ucla.edu) B.J. Anderson (Applied Physics Laboratory, John Hopkins University, Laurel MD, USA) M.H. Acuna and R.P. Lepping (both at Goddard Space Flight Center, National Aeronautics and Space Administration, Greenbelt MD, USA) J.T. Gosling (Los Alamos National Laboratory, Los Alamos, NM, USA) J.G. Luhmann (Space Science Laboratory, University of California Berkeley, USA)

Measurements of the interplanetary magnetic field with NEAR have been compared with those of the WIND spacecraft during the near simultaneous passage of ICMEs over a variety of separations.
Non-force-free magnetic rope models, fit to the observations using the downhill simplex inversion technique, show that when the azimuthal separation of the observations is of the order of 0.05 AU or less, the geometry and orientation of the ropes are similar at the two locations when allowance is made for expansion of the structure. This is not suprising as the typical radius of an ICME flux rope is on the order of 0.05 AU. Unexpectedly, near simultaneous ICME observations occur even when the separation is much greater than the size of an individual rope. Thus either the same rope has become very twisted and extends over a wide range of longitudes or multiple ropes are ejected from the sun simultaneously over a wide range of longitiudes. As the azimuthal separation increases the angular difference of the rope orientations increases, yet the overall appearance of the ropes and their helicity remain the same.

GA4.01/E/04-A2 1120

REMOTE RADIO TRACKING OF CORONAL AND INTERPLANETARY SHOCKS

M. J. REINER (Raytheon ITSS, Code 690.2, NASA/GSFC, Greenbelt, MD, 20771, USA, e-mail: reiner@urap.gsfc.nasa.gov)

Type II radio emissions observed by the WAVES experiment on the Wind spacecraft are generated by shocks that originate in the corona or interplanetary medium. These shocks may originate from blast waves associated with solar flares and/or from coronal mass ejections (CMEs) in the interplanetary medium. Type II radio emissions provide a means of remotely tracking shocks (and CMEs) from the solar corona out to 1 AU and beyond. When the observed radio intensity is displayed as a function of inverse frequency (1/f) versus time, the frequency-drifting kilometric type II radio emissions are organized along straight lines that converge to the CME liftoff time. The slopes of the lines vary as the ratio of the shock speed to the square root of the plasma density, normalized to 1 AU. Thus this method of analysis inherently reveals the dynamics of the CME in the interplanetary medium. When in-situ measurements of the shock are also made, we can determine unequivocally whether the type II emissions occurred at the fundamental or harmonic of the local plasma frequency in the upstream or downstream regions of the CME-driven shock. At high frequencies (1-14 MHz), corresponding to heliocentric distances within the field of view of the LASCO coronagraph, the frequency track of the type II radio emissions deviates from a straight line on the 1/f versus time dynamic spectra due to the complex behavior of the coronal density. Using coronal density models, derived from white light observations, we establish the relationship between the ground-based metric and space-based hectometric type II radio emissions and the LASCO CME. We find that in some cases, two temporally separated shocks are required to explain the coronal (high frequency) radio observations. One shock is generated by the CME and the other may be from the blast wave associated with the flare.

GA4.01/W/09-A2 1140

EISCAT MEASUREMENTS OF THE SOLAR WIND VELOCITY AND THE ASSOCIATED LEVEL OF INTERPLANETARY SCINTILLATIONR.

A.FALLOWS, A. R. Breen, P.J. Moran, C. A. Varley, and P. J. S. WilliamsUniversity of Wales, Aberystwyth, UK

Interplanetary Scintillation (IPS) in the radio signals from sources of small angular diameter is an indication of plasma irregularities in the solar wind. Previous measurements of the level of interplanetary scintillation have been of limited value without simultaneous measurements of solar wind velocity, and scattering per unit volume along the line of sight. Using the spaced antennas of EISCAT to measure IPS, and deriving the boundaries of fast- and slow-streams in the solar wind from optical measurements of the corona, comparison can be made between the level of scintillation and the presence of fast- and slow-streams along the line of sight. Especially interesting are those occasions when an interaction region occurs along the line of sight. Near such interaction regions it is expected there will be a deceleration of the fast stream, an acceleration of the slow stream, and an increase in the level of turbulence. EISCAT IPS measurements can provide evidence for each of these characteristics and follow their development with time as the interaction region moves outward from the Sun.

CORONAL SOURCES, 3D-STRUCTURE AND EVOLUTION OF CIRS DURING THE ONSET OF A NEW SOLAR CYCLE: SOHO, WIND AND ULYSSES OBSERVATIONS

Arik POSNER, Volker Bothmer, May-Britt Kallenrode, Horst Kunow, Reinhold Mueller-Mellin (all at Extraterrestrische Physik, IEAP, Univ. Kiel, Leibnizstr. 11, 24118 Kiel, Germany, email:posner@kernphysik.uni-kiel.de) Barbara J. Thompson and Adam Szabo (both at NASA Goddard Space Flight Center, Greenbelt, MD, USA, email: thompson@eitv3.nascom.nasa.gov) Robert J. Forsyth (Space & Atmospheric Physics, The Blackett Laboratory, Imperial College, Prince Consort Road, London SW7 2BZ, U.K., email: r.forsyth@ic.ac.uk) John T. Gosling (Los Alamos National Laboratory, NM, USA, email: jgosling@lanl.gov) Bernd Heber (MPAE, Max-Planck-Str. 2, 37191 Katlenburg-Lindau, Germany, email: bheber@linmpi.mpg.de) Alan J. Lazarus (Massachusetts Institute of Technology, Cambridge, MA, USA, email: ajl@space.mit.edu) R J. Marsden, T R. Sanderson (ESA/ESTEC, Noordwijk, Netherlands, email: rmarsden@so.estec.esa.nl)

During the solar minimum in late 1996 the tilt of the magnetic dipole axis was low. The near Earth spacecraft SOHO and Wind detected recurrent energetic particle enhancements and CIR-associated features in the solar wind. EUV observations revealed the presence of warps in the polar coronal hole boundaries. Ballistical backmapping from 1 AU indicated that two extensions from the north polar coronal hole towards the heliographic equator coincided in heliolongitude with the in situ CIRs. At that time the Ulysses spacecraft, in a polar orbit about the Sun, was in a favorable position for a correlative study, at mid-northern heliolatitudes heading southward. For the first time since the northern polar pass, in September 1996 and at 32 deg N Ulysses dipped into the band of slower wind. As a consequence Ulysses encountered a recurrent series of CIRs. Estimations of the corresponding coronal source longitude for the CIR at Ulysses outside 4 AU coincided with one of the in-ecliptic CIRs. This study focuses on the 3D-structure of the CIRs including their sources, as well as on temporal effects from restructuring of the corona during the onset of the new solar cycle.

LONG-TERM MAGNETIC EVOLUTION OF AN ACTIVE REGION AND ITS FLARE \& CME PRODUCTIVITY

Lidia VAN DRIEL-GESZTELYI (Observatoire de Paris, DASOP/LPSH, F-92195 Meudon Cedex, France, Email: lvandrie@mesioq.obspm.fr), Cristina H. Mandrini (IAFE-CONICET, CC.67, Suc.28, 1428 Buenos Aires, Argentina, Email: mandrini@iafe.uba.ar), Barbara Thompson (NASA/Goddard SFC, Greenbelt, MD 20771, USA, Email: thompson@eitv3.nascom.nasa.gov), Simon Plunkett (USRA, Naval Research Laboratory, Washington, DC 20375, USA, email: plunkett@kreutz.nascom.nasa.gov), Salvatore Orlando (ESA Solar System Division, Space Science Dept., ESTEC, Noordwijk, The Netherlands, Email: orlando@so.estec.esa.nl), Pascal Demoulin and Guillaume Aulanier (both at Observatoire de Paris, DASOP/LPSH, F-92195 Meudon Cedex, France, email: demoulin@obspm.fr and aulanier@obspm.fr)

Using SOHO/MDI full-disc magnetic maps, we follow the magnetic evolution of a solar active region for several months in the period of July-November 1996. We extrapolate the photospheric magnetic fields in the linear force-free approximation and match the modelled field lines with the soft X-ray loops observed with the Yohkoh/SXT in order to diagnose the coronal magnetic shear. We find that while the turbulent motions diffuse the flux, the differential rotation, and possibly twisted flux emergence, increase the magnetic shear. Flares are observed during the first three rotations, while CME events (observed by SOHO/EIT and LASCO) originate from this AR from its emergence throughout its decay. We analyse the flares and look for related CME events. We find that the early CMEs are related to flare events, while the late CMEs are not. The late CMEs occur when the magnetic shear, after accumulating for four rotations, reaches a high level and saturates. We propose that the AR gets rid of excess shear and helicity through CME activity.

CHANGES IN THE HELIOSPHERIC MAGNETIC FIELD IN THIS SOLAR CYCLE:ULYSSES OBSERVATIONS

SMITH

When solar cycle 23 began in May, 1996, the Ulysses spacecraft was at 38=83 heliolatitude and a heliocentric distance of 3.7 AU and headed toward the equator and 5.3 AU which were reached in Dec.1997. Ulysses is now at 30=83 S headed for the south pole so that the spacecraft has been at relatively low latitudes and large distances during this entire interval. Since the beginning of the new cycle, we have sought evidence of changes in the HMF indicating the onset of solar activity leading to the next maximum.Three indicators of the onset have been identified: an abrupt increase in field magnitude in mid-1997 followed by a second increase in early 1998, (2) evidence of an increase in the inclination of the Heliospheric Current Sheet and (3) the reappearance and gradual increase in the numbers of Coronal Mass Ejections and Magnetic Clouds. The relative abruptness of these changes can be taken advantage of to seek corresponding changes in the sun and solar magnetic field.We have continued to monitor changes in the field during the march to solar maximum. The Ulysses results will be presented and compared with simultaneous changes in other indicators of solar activity at the sun and throughout the heliosphere including the onset and evolution of cosmic ray modulation.

MAGNETIC FIELD STRUCTURE OF TRANSIENTS AT ULYSSES: THEIR RELATIONSHIP TO CORONAL STRUCTURE AND CMES

R. J. FORSYTH and A. Balogh (The Blackett Laboratory, Imperial College, London SW7 2BZ, UK, email: r.forsyth@ic.ac.uk), E. J. Smith (Jet Propulsion Laboratory, Pasadena, CA 91109, USA), J. T. Gosling (Los Alamos National Laboratory, Los Alamos, NM 87545, USA)

In the course of its polar orbit around the Sun, the Ulysses spacecraft has encountered a large number of transient events in the solar wind which are the interplanetary consequence of coronal mass ejections or CMEs. In particular, since mid-1997, the number of transient events detected at Ulysses has been increasing as would be expected with the rise in solar activity. In this paper we focus on the magnetic field signatures of these events, discussing in particular whether or not they exhibit magnetic cloud signatures such as smooth rotations of the field direction and enhanced magnetic field strength with low variability. We make particular mention of transient events at Ulysses where a possible solar counterpart event has been identified in images from the Yohkoh or SOHO spacecraft and discuss the relationship between the heliospheric and coronal signatures.

GA4.01/W/05-A2 Invited 1450

ELECTRON CHARACTERISTICS OF CORONAL MASS EJECTIONS IN THE SOLAR WIND

R. M. SKOUG, W. C. Feldman, J. T. Gosling, and D. J. McComas (all at Los Alamos National Laboratory, MS D466, Los Alamos, NM, 87544, USA, email: rskoug@lanl.gov)

The solar wind plasma instrument (SWEPAM) on the ACE spacecraft, which has been in a halo orbit about the L1 point since December, 1997, has detected counterstreaming halo electrons (~100- 1370 eV) during approximately 20% of observations when the spacecraft was not connected to the Earth's bow shock. Counterstreaming electrons indicate that the spacecraft is on closed magnetic field lines, and thus indicate the presence of coronal mass ejections (CMEs) in the solar wind. This large fraction of closed field lines represents a rate of 2-4 CME events per month, and may be due in part to the high sensitivity of SWEPAM in this energy range. In this paper, we present characteristics of the electron distributions observed by SWEPAM during CMEs in the solar wind, including the presence of open or disconnected field lines (unidirectional electron flow), the electron pitch angle distributions, and the relative contributions of the core and halo electron populations. We find an anti-correlation between the ratio of halo to core density and the total electron density, as has been reported by other studies. However, we find that this behavior is not unique to CME events. Rather, the halo density contributes more to the total density during low density periods, regardless of the magnetic topology. We also investigate electron temperatures within CME events, including core and halo temperature contributions, temperature anisotropies, and variations with electron density.

GA4.01/W/04-A2 1520

INTERPLANETARY DISTURBANCES DURING THE ASCENDING PHASE OF THE SOLAR CYCLE 23

Takashi WATANABE (Department of Environmental Sciences, Ibaraki University, Mito 310-8512, Japan, e-mail: watanabe@env.sci.ibaraaki.ac.jp); Masayoshi Kojima and Munetoshi Tokumaru (Solar-Terrestrial Environment Laboratory, Nagoya University, Toyokawa 442, Japan)

We examine three-dimensional propagation properties of CME- associated interplanetary disturbances observed in the ascending phase of the Solar Cycle 23 (1997-1998). Data sources are solar wind data obtained by spacecraft and IPS (interplanetary scintillation) observations. Interplanetary consequences of halo" CMEs are found to have similar configurations; broad interplanetary disturbances with the local minimum of the propagation speed along the heliospheric current sheet, which was running near the ecliptic plane. This makes a clear contrast with interplanetary disturbances observed in the maximum solar activity phase, which are tend to be confined within the hemisphere where the relevant solar events take place. A correlative study between edge-on CME and geomagnetic data suggests that CME-associated interplanetary disturbances have a broad azimuthal extent during the ascending phase of the solar activity.

GA4.01/E/08-A2 1600

SPACE ENVIRONMENTAL CONDITIONS DURING APRIL-MAY 1998: PROTOTYPICAL SOLAR MAXIMUM EVENTS?

D.N. BAKER (Laboratory for Atmospheric and Space Physics, University of Colorado, Cam-pus Box 590, Boulder, Colorado, 80309-0590, USA, e-mail: baker@lynx.colorado.edu); J.H. Allen (NOAA, PO

Box 3000, Boulder, CO 80303); J.B. Blake (The Aerospace Corporation, MS 259, Los Angeles, CA 90009); S.G. Kanekal (Goddard Space Flight Center, Greenbelt, MD 20771); G.D. Reeves (Los Alamos National Laboratory, MS D-436, Los Alamos, NM 87545)

The space environment in April and May of 1998 is examined in detail. Evidence is found of highly disturbed solar, solar wind, and geomagnetic conditions in late April and early May. The combination of coronal mass ejections, solar flares, and high speed solar wind streams led to a powerful sequence of solar wind drivers of terrestrial magnetospheric processes. The result of the compounding solar wind disturbances was to produce a deep, powerful, and long-lasting enhancement of the highly relativistic electron (HRE) population throughout the outer terrestrial radiation zone. A new radiation belt feature was produced at L=2.2(±0.2) on 4 May and the subsequent HREs persisted at high intensities for the subsequent 2-3 weeks. The high-energy electron fluence levels at geostationary orbit were the highest in May 1998 that had been seen for the preceding two years. The April-May 1998 period provided a fascinating set of Sun-Earth connection events and in many ways may be considered a prototype of what may be expected frequently during the upcoming solar maximum period (2000-2002).

GA4.01/W/07-A2 Invited 1620

GEOSPACE REACTION TO BOTH SOLAR MINIMUM AND SOLAR MAXIMUM-DRIVEN EVENTS

Nicola J. FOX (JHU/Applied Physics Laboratory, 1100 Johns Hopkins Road, Laurel, MD 20723; and NASA/Goddard Space Flight Center, Code 696, Greenbelt, MD 20771;
email: nicola.fox@gsfc.nasa.gov)

The major focus of the Sun-Earth Connection program, and the ISTP program itself, is to study the physical processes that link the Sun and the Earth, specifically, to understand the transfer of energy from the Sun to the Earth and the response of the Earth's coupled magnetosphere-ionosphere-atmosphere system to this energy transfer. The variability in the energy transfer is of special interest. Two of the predominant time scales for solar variability are the solar cycle and transient events, the most prevalent of the latter being coronal mass ejections (CMEs). Dominant terrestrial reactions include magnetic storms or the ring current energization, substorms with ionospheric current enhancements, high energy radiation belt enhancements, energy deposition into the atmosphere to produce the aurora, joule heating, enhanced plasma circulation in the ionosphere and plasmoid release down the tail.
During the first 10 months of 1997, the satellite and ground facilities of the ISTP "observatory" tracked a number of solar-minimum type eruptions from the Sun, through interplanetary space, to the Earth. From November 1997, however, the events became more characteristic of solar maximum, particularly early in May 1998, when a series of three CMEs impacted the Earth in a few days. In this paper, observations from a variety of ISTP spacecraft, ground facilities and theory programs will be presented, together with supporting data from collaborating missions. We will compare the early ISTP events with those which have happened more recently, driven by a more active Sun. Thus we will look at a number of quantitative relationships as a function of the portion of the solar cycle from solar minimum, when the events are well spaced apart, to the more active phase of the solar cycle, when multiple events may be affecting in much more complex ways the terrestrial response.

GA4.01/W/03-A2 1650

HALO CMES AND THEIR ASSOCIATED GEOMAGNETIC ACTIVITY

Hildner Ernest. St. Cyr, Herlihy, Balch, NRL folk. NOAA Space Environment Center, 325, Broadway, Boulder, Colorado 80303, USA. E-mail: ehildner@sec.noaa.gov.

Starting January 1997, the whitelight coronagraphs of the LASCO instrument aboard the SOHO spacecraft began to see occasional coronal brightenings over a large fraction of all position angles around the sun, as projected in the plane of the sky (as seen from Earth). Because coronal mass ejections (CMEs) seen at the limb of the Sun usually appear to sweep a constant solid angle as they propagate outward, these brightenings surrounding the coronagraph's occulting disk – so-called 'halo CMEs' - were interpreted as CMEs propagating radially from the Sun nearly toward or away from Earth, becoming visible when they grew to subtend angles at SOHO larger than the coronagraph's occulting disk. With their greater than ambient density, often greater than ambient speed, and embedded out-of- the ecliptic magnetic field, it is to be expected that CMEs hitting Earth are likely to cause geomagnetic activity. In this paper, we report the results of our search for associations between halo CMEs and subsequent geomagnetic activity. We find that approximately 90 percent of severe geomagnetic storms were preceded by halo CMEs thought to be traveling Earthward. But only two-thirds of Earthward-directed halo CMEs preceded severe geomagnetc storms. Because the geomagnetic field was so quiet during the minimum between solar cycles 22 and 23, the association between each, rare, halo CME and the rare, subsequent geomagnetic activity is usually clear. Our results tend to confirm both the interpretation that coronal brightenings surrounding the coronagraph's occulting disk arise from CMEs headed Earthward and the expectation that an ejectum from the Sun usually, if not always, increases geomagnetic activity when it hits Earth.

GA4.01/W/08-A2 1710

HELIOSPHERIC X-RAY EMISSION ASSOCIATED WITH CHARGE TRANSFER OF THE SOLAR WIND WITH INTERSTELLAR NEUTRALS

Thomas E. CRAVENS (Dept. of Physics and Astronomy, University of Kansas, Lawrence, KS, 66045, USA, email: cravens@kuplas.phsx.ukans.edu)

X-ray emission has been observed from many objects throughout the solar system including the Sun, the Moon, the Earth, Jupiter, and comets. The discovery of X-rays from comet Hyakutake (Lisse et al., 1996), and later from a number of other comets, was surprising. One proposed emission mechanism that can explain most features of the observed emission is the charge transfer of heavy solar wind ions with cometary neutrals (Cravens, 1997). Highly stripped heavy (Z > 2) solar wind ions charge transfer with neutrals leaving the product ions with one more electron but still highly stripped and usually in an excited state. The solar wind ions then emit x-ray or extreme ultraviolet photons. Many different heavy ion species are present in the solar wind, reflecting the composition and the charge state distribution of ions in the solar corona. Soft X-rays should be emitted throughout the heliosphere due to the charge transfer of solar wind ions with interstellar neutral H and He atoms which are able to flow past the heliopause. The estimated total soft X-ray luminosity is about 10000 TW. These X-rays are emitted from the entire sky and are responsible for just a part of the soft X-ray background emission observed by the Einstein Observatory or ROSAT. However, unlike the part of the x-ray background coming from hot interstellar gas, the heliospheric x-ray emission should exhibit spatial and temporal variations that are associated with variations in the solar flux and composition. Of course, these solar wind variations reflect the changing conditions in the solar corona. The x-rays emitted from comets due to the charge transfer mechanism should also exhibit temporal variations due to solar wind variations. The expected morphology of the heliospheric x-ray emission will be discussed.

GA4.01/E/01-A2 1730

GLOBAL MHD SIMULATION OF A SPACE WEATHER EVENT: CME FORMATION, INTERPLANETARY PROPAGATION AND INTERACTION WITH THE MAGNETOSPHERE

C. P. T. Groth, D. L. DeZeeuw, T. I. Gombosi, and K. G. Powell (The University of Michigan, Ann Arbor, MI, USA, e-mail: groth@umich.edu)

The numerical simulation of the complete time history of a space weather event, including the onset and initiation of a coronal mass ejection (CME) at the solar surface, the progation of the CME and magnetic cloud from the solar corona into interplanetary space, and subsequent iteraction of the disturbance with the terrestrial magnetosphere, is considered using a three-dimensional global magnetohydroynamic (MHD) model. In the model, the solar wind and magnetospheric plasma flow is prescribed by solving the equations of ideal MHD using a parallel adaptive mesh refinement (AMR) upwind finite-volume scheme. The initial state of the corona and solar wind is described by assuming that the inner solar corona is a large rotating reservoir of hot plasma with an embedded magnetic field field represented by a tilted dipole and octupole. A value of 5/3 is used for the plasma specific heat ratio and a parameterized volumetric heating function is used to produce a solar wind, having both fast and slow streams. The CME is initiated by a localized isothermal density enhancement at the solar surface and the interaction of the CME with the magnetosphere is included as part of the computation. Results of the simulation will be described. This will include a discussion of the structure and evolution of the CME and its geo-effectiveness as measured in terms of its ability to drive geomagnetic activity.

DETECTION OF SOLAR LARGE-SCALE SHINING CHAINS AND THEIR RELATION TO CMES

Ilia CHERTOK (IZMIRAN, Russian Academy of Sciences,Troitsk, Moscow Region, 142092, Russia, e-mail: ichertok@izmiran.troitsk.ru)

An analysis of modified heliograms in the microwave (Nobeyama Radioheliograph), soft X-ray (Yohkoh/SXT), EUV (SOHO/EIT, TRACE), and other ranges has revealed a novel phenomenon of the large-scale solar activity: relatively weak extended shining chains with characteristic sizes comparable with the solar disk diameter. It turns out that rather often bright elements and points are not scattered chaotically through the solar disk, but are aligned at definite structures forming large-scale chains (and threads) of various (sometimes very puzzled) configurations.
The long-living chains exist and keep their general form during many days, can coincide with sharp boundaries of coronal holes and outline footpoint lines of some large X-ray arcades. The transient chains with a characteristic time scales from several hours to one day appear to be closely associated with coronal mass ejections (CMEs) and to outline the large-scale structures involved in the processes of a CME and post-eruption energy release in the corona. The features of the chains mean that some large-scale structures shine as a result of energy release associated either with the long-term evolution of the large-scale magnetic fields or with disturbances identified with CME events. It is probable, that the detected chains and threads Light separatrixes separating different interacting large-scale magnetic flux systems in the complex solar magnetosphere.

GA4.01/W/12-A2 Poster 1400-02

ANALYSES OF CME ONSET STUDIES USING EUV SPECTROSCOPY

Richard HARRISON, Rutherford Appleton laboratory, Space Science Department, Chilton, Didcot, Oxfordshire, OX11 0QX, UK, email: r.harison@rl.ac.uk

We present selected results from the SOHO multi-instrument campaigns to study coronal mass ejection (CME) onsets which make use of SOHO-CDS extreme ultraviolet data to derive plasma diagnostics in the CME onset region. For some events, we consider the low and high coronal response as well as the passage of the CME in interplanetary space. The relevance of these observations to established CME models is discussed.

GA4.01/W/19-A2 Poster 1400-03

EVOLUTION OF THE MAGNETIC STRUCTURE OF SEVERAL ACTIVE GROUPS IN CYCLE 23 AND HELIOSPHERIC EVENTS

BORIS IOSHPA and Vladimir Obridko (both at IZMIRAN, Troitsk, Moscow Region, 142092, Russia, Email: ioshpa@izmiran.troitsk.ru)

Magnetic field observations in active groups during 1986-88, carried out with a magnetograph at IZMIRAN, and magnetic maps from some other observatories have been used to analyze evolution of the magnetic structure in the photosphere, corona, and interplanetary space. The results are compared with the X-ray and EUV spacecraft data on structural variations and with CME occurrences.

GA4.01/W/01-A2 Poster 1400-04

THE EARLY STAGES OF CORONAL MASS EJECTIONS AS OBSERVED BY SOHO/EIT

B.J. THOMPSON, NASA Goddard Space Flight Center, Greenbelt, MD, USAO.C. St. Cyr, Computational Physics, Inc., USA H.S. Hudson, SPRC/ISAS, Japan S.P. Plunkett, USRA, Naval Research Lab, USA J.B. Gurman, NASA Goddard Space Flight Center, USA

As with all data collected with new instrumentation, a great deal of information can be extracted. Usually, there is more information than is deemed tractable, and the number of events required to form a "statistical" sample remarkably increases. After more than two years of operation, the EUV Imaging Telescope (EIT) on SoHO has observed several hundred CME's. These are being assembled into a catalogue of CME's, and are categorized according to their manifestation in the inner corona. By distinguishing between the variety of eruptions spanning the range of EUV signatures, information can be derived from the comparison and contrast of compatible events.

GA4.01/E/06-A2 Poster 1400-05

MODELLING OF DYNAMICAL SPECTRA PRODUCED BY TYPE II RADIO BURST

ROMASHETS E.P. and IVANOV K.G., Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation of Russian Academy of Sciences (IZMIRAN), Troitsk, Moscow Region, 142092 Russia, email: romash@izmiran.rssi.ru

It was shown earlier that disturbed HCS can reflect, deflect radio waves. In this work the attempt to model such situations was made and typical pictures for two different cases - when HCS was near ecliptic plane and far below or above it. The method used for calculation - to add all radio waves came from shock on its way from the Sun, taking into account their phases, time lags, amplitudes etc. We assumed that shock had speed 900 km/s, angular size 30*30.The results can clarify why sometimes strong shocks seen from interplanetary observations were not accompanied by type II bursts and related questions.

CORONAL MASS EJECTIONS ASSOCIATED WITH INTERPLANETARY DISTURBANCES OBSERVED WITH IPS

S. BRAVO and A. Carrillo (Instituto de Geofisica, UNAM, Coyoacan DF, 04510, Mexico, email: sbravo@tonatiuh.igeofcu.unam.mx)

We compare the observations of large-scale interplanetary disturbances by means of interplanetary scintillation (IPS) and the coronal mass ejections (CMEs) recorded during a 6 month period. We obtain that coronal mass ejections are more frequent than large-scale interplanetary disturbances by a factor of about 6, that is, only 1/6 of the CMEs had an associated interplanetary disturbance. We analyse the CME characteristics in order to find out which of them determine the capability of a CME to importantly disturb the interplanetary medium.

GA4.01/W/06-A2 Poster **1400-07**

MULTI-SPACECRAFT OBSERVATIONS OF INTERPLANETARY TRANSIENT SHOCKS

Americo GONZALES-ESPARZA and Miguel Yunez (both at Instituto de Geofisica, UNAM, Ciudad Universitaria, Mexico D.F. 04510, MEXICO, Email: americo@fis-esp.igeofcu.unam.mx)

We study multi-point observations of transinet shock waves by different spacecraft: Helios 1 and 2, IMP, and Voyager 1 and 2, during 1976 and 1977 (ascending phase of solar sunspot cycle 21). We discuss some properties of the propagation of transient shocks in the interplanetary medium, in particular with respect to the magnetic sector structure.

ON THE PREDICTION OF THE MAXIMUM AMPLITUDE AND TIME OF RISE FOR THE 23D SOLAR CYCLE

GALAL, A.A. (National Research Institute Of Astronomy And Geophysics, Helwan, Almarsad Street, Cairo, Egypt, email: salahmm@frcu.eun.eg); Hamid,R.H.(National Research Institute Of Astronomy And Geophysics, Helwan,Almarsad Street, Cairo, Egypt, email: salahmm@frcu.eun.eg)

The maximum amplitude and the time of rise for the cycle 23 have been predicted using spotless-event technique as precursor. This technique have been successfully used for the prediction of the mentioned parameters for the cycle 22. It is based upon the count of lengths and durations of spotless events during an interval of one year before and after the preceding minimum of the coming cycle.
The results obtained indicate that the cycle 23 is expected to be of moderate strength and its maximum sunspot relative number will be 147 +/- 17.11. The predicted time of rise of the cycle under examination is found to be 3.55 +/- 1.26 years.
Comparison of the present results with those obtained by geomagnetic precursors illustrates the sensivitivity of spotless event technique to the geomagnetic activity of solar origin.

LASCO AND EIT OBSERVATIONS OF CORONAL MASS EJECTIONS

Kenneth DERE (Naval Research Laboratory, Washington DC 20375-5320, email: dere@halcyon.nrl.navy.mil)

Observations of the Sun with the LASCO and EIT experiments on LASCO have provided a new and unique basis for studying coronal mass ejection (CME) physics. The EIT and LASCO together allow imaging of CMES from their initiation at the base of the corona through a distance of 30 solar radii. CMEs are often associated with magnetic neutral lines in association with emerging or decaying flux regions, flares and eruptive prominences. Their original extent can often span nearly the entire solar disk. However, the characteristics of the region giving rise to CMEs are still not clear. The appearance of many CMES indicates that they consist of helical magnetic flux ropes such as the magnetic clouds observed near the Earth. Observations of halo CMEs directed toward the Earth have proven to be a good predictor of geomagnetic storms caused by CMEs.

GA4.02/W/14-A4 Invited **0925**

INITIATION OF CME EVENTS: THE ROLE OF MAGNETIC SHEAR AND HELICITY

Lidia VAN DRIEL-GESZTELYI, Brigitte Schmieder Pascal Demoulin and Guillaume Aulanier (all at Observatoire de Paris, DASOP/LPSH, F-92195 Meudon Cedex, France, Email: lvandrie@mesioq.obspm.fr, schmieder@obspm.fr, demoulin@obspm.fr and aulanier@obspm.fr), Cristina H. Mandrini and Marcelo Lopez (both at IAFE-CONICET, CC.67, Suc.28, 1428 Buenos Aires, Argentina, Email: mandrini@iafe.uba.ar and lopez@iafe.uba.ar)

Recent multiwavelength observations (using SOHO, Yohkoh and ground-based data) as well as theoretical developments indicate the importance of highly sheared and/or twisted magnetic configurations in solar active regions (ARs) in the initiation of coronal mass ejections (CMEs). Through multiwavelength analysis of three representative events we make an attempt provide constraints for CME models. The first two events to be presented (25 Oct. 1994 and 14 Oct. 1995) start with the expansion of a sigmoids, which are associated with highly twisted magnetic flux tubes. Such events can be linked to highly twisted interplanetary magnetic clouds. Then, we show the importance of magnetic shear in a CME source region. A filament disparition brusque (DB) associated with a multiple CME event was observed on 25/26 September 1996. We show that both the DB and the CME occurred when the non-potentiality (magnetic shear) of the magnetic fields in the AR reached a high (threshold) level. We propose that highly twisted and sheared magnetic configurations located in a complex (multipolar) magnetic environment are good candidates for being source regions of CMEs.

GA4.02/W/16-A4 Invited **0945**

THE RELATIONSHIP BETWEEN PROMINENCE ERUPTIONS AND CORONAL MASS EJECTIONS

George SIMNETT (School of Physics and Space Research, University of Birmingham, B15 2TT, UK, Email: gms@star.sr.bham.ac.uk)

The SOHO observations with LASCO and EIT present an ideal opportunity to study the relationship between prominence eruptions and coronal mass ejections (CME). High-cadence measurements of prominence eruptions are demonstrating that the prominence eruption is not generally the cause of the associated CME, but that it is more probable that the destabilisation of the CME in fact releases the constraints on the prominence, causing it to erupt. We report here observations of associated CMEs and prominence eruptions covering the period of SOHO operations from mid-January, 1996 to mid-December, 1998. In addition to the causality, we find that in general the projected speed of the prominence eruption matches fairly closely the projected speed of the associated CME. Furthermore, the prominence eruption is generally simply one facet of the coronal transient activity, of which there are often several other discrete parts. The prominence eruption is also generally offset in heliolatitude from the centre of the CME. The relationship of these finding with current theoretical models is discussed.

GA4.02/W/13-A4 **1005**

CHANGES OF PHOTOSPHERIC AND CORONAL MAGNETIC FIELDS ASSOCIATED WITH LDES

X P ZHAO and J T Hoeksema (Hansen Experimental Physics Laboratory HEPL B204, Stanford University, Stanford, CA 94305-4085, USA, email: xpzhao@solar.stanford.edu)

Large-scale, long-duration soft X-ray eruptive events (LDEs) often originate in large-scale multipolar photospheric magnetic field regions. They involve reconfigurations of large-scale coronal magnetic field, such as the change in pre-existing coronal hole boundary, the formation of coronal loop arcades, and the occasional occurrence of "transient coronal holes". This work examines changes of the large-scale photospheric magnetic field before and after the four LDEs analyzed by Webb et al. (JGR, 102, 24161, 1997) to see if the changes are associated with differential rotation or emerging flux. We use a methodology developed recently for constructing a proxy of the instantaneous global photospheric magnetic field and for modelling change of large-scale coronal structures observed on time scale of a day or less to compute the large-scale coronal field before and after the LDEs. Our goal is to see how the coronal field reconfiguration relates to the change of the photospheric magnetic field.

GA4.02/W/05-A4 Invited **1020**

FLARES, RECONNECTION AND MERGING OF HELICAL MAGNETIC STRUCTURES

G. S. CHIO and C. Z. CHENG (Princeton Plasma Physics Laboratory, Princeton University, Princeton, NJ 08543)

Based on the theoretical model that flaring events are associated with magnetic energy release which takes place via magnetic reconnection processes we have demonstrated in numerical 2-1/2D MHD simulations that flaring events can occur in a bipolar magnetic arcade due to energy supply (or drainage) through the photosphere. The energy supply (or drainage) processes are through the fieldline footpoint motion (shearing, convergerging and diverging) and/or flux emergence. We will demonstrate the Poynting flux distributions in the photosphere of these processes and discuss how these energy exchange processes can affact the flaring events. We will also demonstrate how homologous flares successively take place in a magnetic arcade at the same place with a short time interval on the order of one day. Accompanying the homologous flare events are successive generation and merging of magnetic islands. With continuing supply of energy through the photosphere new magnetic island can created below a previously existing upper island, and this new island can rise faster and merge with the upper island very quickly to form a bigger island because they have same helicity. The combined island will continue to rise with a faster speed than the original upper island. As this process is being repeated, several impulsive events of magnetic energy release take place and the growing magnetic island is eventually driven away from the sun. Different types of footpoint motion can produce different Poynting flux distributions in the photosphere and the time interval between flaring events is accordingly varied.

GA4.02/W/07-A4 Invited 1100

RECENT STUDIES OF YOHKOH/SXT CME-RELATED STRUCTURES, AT SXR AND EUV WAVELENGTHS

STERLING, Alphonse C, Institute of Space and Astronautical Science

Although Coronal Mass Ejections (CMEs) were originally identified as white-light phenomena, they have since been extensively studied at other wavelengths from space-borne telescopes. In recent years, observations with the Soft X-ray Telescope (SXT) on the Yohkoh satellite have furthered our knowledge of these features at soft X-ray (SXR) wavelengths. Images from SXT prior to and after CME eruption hint at the nature of the magnetic structures that undergo expulsion. Frequently, the preflare SXR structures take the form of S-shaped features, often referred to as "sigmoids," which may indicate sheared magnetic fields. A powerful tool used in these studies is analysis of SXR "dimming" regions, in which the intensity of the corona near the eruption site drops precipitously near the time of the CME ejection. Analysis of these regions can give information on the temperature and mass of the ejected SXR material associated with the CME. There are also extensive contemporaneous studies of CMEs at EUV wavelengths obtained from, e.g., the EIT instrument on SOHO. In this presentation we review recent work on CME observations from SXT, and comparisons between the SXT CMEs and corresponding (or closely related) features seen at EUV wavelengths.

GA4.02/W/09-A4 Invited 1125

WHAT CAN WE LEARN ABOUT RECONNECTION FROM CME OBSERVATIONS?

Terry FORBES and Jun Lin (both at EOS Institute, University of New Hampshire, Durham, NH 03824, USA, Email: terry.forbes@unh.edu)

Recent, and continuing, improvements in X-ray telescopes and coronagraphs should make it possible to use observations of CMEs to answer several outstanding questions concerning the nature of magnetic reconnection in the solar corona. The detection of cusp features at the top of "post"-CME/flare loops by the Solar X-Ray Telescope (SXT) on Yohkoh is thought to be associated with the lower tip of a reconnecting current sheet, while the occasional detection of Y-shaped structures by the SOHO coronagraph on LASCO is thought to be associated with the upper tip of the same current sheet. It should be possible, at least in principle, to combine such measurements to determine the evolution of the current sheet, which is thought to be created by a CME. Here we show how the variation in the length of the current sheet with time allows a direct determination of the rate of magnetic reconnection and can also provide information on the nature of the econnection dynamics.

GA4.02/W/15-A4 1145

STATISTICAL ANALYSIS OF CMES AND THEIR SOFT X-RAY SIGNITURES

Shinichi WATARI (Communications Research Laboratory, 4-2-1 Nukuikita, Koganei, Tokyo 184-8795, JAPAN, email: watari@crl.go.jp) Takashi Watanabe (Ibaraki University, 2-1-1 Bunkyo, Mito, Ibaraki 310-8512, JAPAN, email: watanabe@env.sci.ibaraki.ac.jp)

Mark III K-coronameter (MK3) at the High Altitude Observatory (HAO)/Mauna Loa observatory covers the solar corona from 1.1 Rs to 2.4 Rs. Its field of view overlaps with that of the soft X-ray telescope (SXT) on board Yohkoh. It is possible to compare CMEs observed by the MK3 with soft X-ray observations directly. We examined the CMEs observed by both the MK3 and the SXT statistically. Almost half of the CMEs did not show any drastic soft X-ray activities. The soft X-ray activities were equally observed under the CME span and near footpoint of CMEs. Soft X-ray arcades were usually formed associated with the CMEs.

GA4.02/W/01-A4 1200

X-RAY PLASMA EJECTIONS ASSOCIATED WITH SOLAR FLARES

Masamitsu OHYAMA and Kazunari Shibata (National Astronomical Observatory, Japan, E-mail: ohyama@solar.mtk.nao.ac.jp)

Yohkoh discovered X-ray plasma (plasmoid) ejections in many impulsive and LDE flares. We analysed 39 limb flares between October 1991 and December 1994 which were observed with soft and hard X-ray telescopes, and found that X-ray plasma were ejected in 27 flares (about 70 %). This result indicates that X-ray plasma ejection is a general phenomenon associated with a solar flare. Moreover, we found that X-ray plasma started to be ejected before a maximum peak of hard X-ray emission. Next, we analysed an X-ray plasma ejection just before the onset of the hard X-ray emission quantitatively in detail. The X-ray ejecta formed after its footpoint brightened long before the impulsive phase. Before the impulsive phase the X-ray ejecta was already heated to about 10 MK and its electron density was already an order of magnitude larger than the typical density of the active-region corona. From these observational results we propose that the ejected plasma was supplied by the chromospheric evaporation caused by the preflare heating.

GA4.02/W/08-A4 1215

DYNAMICS OF SEVERAL EVENTS OBSERVED BY SXT AND TRACE

R.D. BENTLEY Mullard Space Science Laboratory, Holmbury St. Mary, Dorking, Surrey RH5 6NT, UK

Significant changes in emission in the corona observed by SXT. Where available, supporting data from SoHO and ground-based observatories have been used Observations made by TRACE at several wavelengths have been compared with data taken by the Yohkoh SXT instrument for a number of events. The good time cadence afforded by both instruments allow the dynamics of the solar atmosphere to be studied over a wide range of temperatures and heights. Where possible, active regions have been followed over a period of hours or days in order to try to track the evolution of structures that subsequently disrupt. The changes in the morphology region that result from such disruptions are discussed, particularly where they result in a for some of the events.

UNDERSTANDING CMEs AND THEIR SOURCE REGIONS

DAVID F. WEBB (ISR, Boston College, Chestnut Hill, MA 02467-3862, USA, email: webb@plh.af.mil)

CMEs are an important aspect of coronal and interplanetary dynamics. They can eject large amounts of mass and magnetic fields into the heliosphere, which can drive large geomagnetic storms, and interplanetary shocks a key source of energetic particles. However, our knowledge of the origins and early development of CMEs at the Sun is limited. CMEs are most frequently associated with erupting prominences and long-enduring X-ray arcades, but sometimes with little or no observed surface activity. I will review some of the well-determined coronal properties of CMEs and what we know about their source regions, including recent studies using Yohkoh, SOHO and radio data. One exciting, new type of observation is of halo-like CMEs, which suggest the launch of a geoeffective disturbance toward Earth. Besides their utility for forecasting the arrival at Earth of magnetic clouds and geomagnetic storms, halo CMEs are important for understanding the source regions and internal structure of CMEs since we can view and measure their characteristics along their central axes. I discuss some common aspects of the source regions of CMEs and what the recent ISTP-era events can tell us about the structure of CMEs.

GA4.02/W/34-A4 Invited 1525

THE CME AND PROMINENCE ERUPTION OF JUNE 2, 1998

S.P. PLUNKETT (1), A. Vourlidas (2), S. Simberova (3) (1) Universities Space Research Association, Naval Research Laboratory, Washington, DC 20375, USA. (2) Naval Research Laboratory, Washington, DC 20375, USA. (3) Astronomical Institute, Czech Academy of Sciences, 251 65 Ondrejov, Czech Republic.

Coronal mass ejections (CMEs) are frequently associated with erupting prominences near the solar surface. A spectacular eruption of the southern polar crown prominence was observed on June 2, 1998, accompanied by a CME that was well-observed by the LASCO coronagraphs on SOHO. The prominence was observed in its quiescent state and was followed throughout its eruption by the SOHO EIT and later by LASCO. Ground-based H-alpha observations of the prominence were obtained at the Ondrejov Observatory in the Czech Republic. A great deal of fine structure was observed within the prominence as it erupted. The CME contained a helical structure that is consistent with the ejection of a magnetic flux rope from the Sun. Similar structures have been observed by LASCO in many other CMEs. The relationship of the flux rope to other structures in the CME is often not clear. In this event, the flux rope clearly lies above the prominence, and it can be observed from the onset of the CME in the low corona all the way out to the edge of the LASCO field of view. We will discuss the relationship of the structures observed within the CME with the structure of the streamer and prominence before the eruption, and the dynamical evolution of the CME and prominence as it propagates outward from the Sun.

GA4.02/W/29-A4 1545

CME ONSET OBSERVED IN FE XII AND HE II

Delann\'ee C., Delaboudini\`ere J.-P. (Institut d'Astrophysique Spatiale, Universit\'e Paris XI, bat 121, 91405 ORSAY, France, E-mail: delannee@medoc-ias.u-psud.fr) Lamy P. (Laboratoire d'Astronomie Spatiale, Traverse du Siphon, Les Trois Lucs, 13012 Marseille, France, E-mail: lamy@astrsp-mrs.fr)

The Extreme ultra-violet Imagering Telescope provide observations of the whole solar disc in the chromospheric He and in the low coronal Fe In the chromospheric line, the ejections of the prominences are well observed. In the coronal line, propagations of cavities above the limb or of dimmings of the solar surface are observed. We compared the events seen in He and in Fe to the coronal mass ejections observed with the Large Angle and Spectrometric Coronagraph C2 in white light emitted in a region and at a time which can be related to the underling events. We found that the He events are very difficult to compare to the CMEs. They evolve on only two image in average. So we can suspect that we miss the most chromospheric event using a 17 minutes cadence between two images. In Fe the cavities and dimmings are related in the most of the cases to CMEs. They are emitted above active regions or prominences. Active regions produced faster (300 km s^{-1}) CMEs than prominences did (100km s^{-1}).

MAGNETIC STRUCTURE AND DYNAMICS OF CME IN DEPENDENCE ON THE ONSET CONDITIONS DURINGTHEIR DETACHEMENT - PLASMA SIMULATION RESULTS

JOERG BUECHNER (Max-Planck- Institut fuer Aeronomie, Max-Planck-Str. 2, D-37191 Katlenburg-Lindau, Germany)

We present results of plasma simulations of formation and evolution of the CME configurations.The CME formation is discussed in terms of three-dimensional kinetic reconnection. In particular we have investigated the influence of the magnetic field shear at the onset on the further evolution of magnetic fields and plasma inside CME's.

Presiding Chair: G. Simnet (Univ of Birmingham, UK)

GA4.02/W/32-A4 1635

CME INITIATION: MODELS AND OBSERVATIONS

WU, Dr S.T (The University of Alabama in Huntsville)

We use three types of observed coronal mass ejection (CME) events together with numerical magnetohydrodynamic simulation to illustrate three distinct CME initiation processes; (1) emerging flux, (2) photospheric shear motion and (3) plasma flow. Category (1) can be interpreted as the erupted filament disrupting a streamer to produce a CME, (06/07 Jan 1997). Category (2) is the case in which the photospheric shear motion disrupts the streamer when the filament is lifted up. In this case, we observed the CME first, followed by filament eruption (25/26 Sept 1996). Category (3) is entirely different from the previous two, this event (04/05 Oct. 1995) does not show any relation with the filament/flux-rope. Overall, we suggest the first two categories are flux-rope driven because the energy source, which propels the CME, is stored in the flux-rope and the third category is driven by plasma flow. It exhibits wave type characteristics and is the fastest (~600 km s-1) among the three events. Both observations and numerical MHD simulation will be presented to sustain our claims.

A STUDY OF THE EFFECTS OF EMERGING ACTIVE REGIONS ON THE LARGE-SCALE CORONAL MAGNETIC FIELD: POSSIBLE IMPLICATIONS FOR CMES

J.G. Luhmann and Y. Li (Space Sciences Laboratory, University of California, Berkeley, CA 94720, USA, email: jgluhman@ssl.berkeley.edu) J.T. Hoeksema and X-P. Zhao (Stanford University, Stanford, CA 94305, USA, email: todd@quake.stanford.edu)

We use simple potential field source surface representations of the large-scale coronal magnetic field and emerging active regions to investigate the global consequences of localized flux emergence. In our "experiments", we approximate the before and after states of coronal magnetic fields in response to the appearance of bipolar active regions in different locations with respect to large scale features such as the helmet streamer belt and coronal holes. These tell us about the sensitivity of the global field to the localized fields, giving insight about those particular scenarios that are subject to drastic reconfigurations or large open flux increases (possible signatures of major CMEs). While this approach does not simulate the detailed physical behavior and properties of the evolving system like global MHD models, it provides possible guidance for space weather forecasts as well as for future, more rigorous CME modelling efforts.

INVESTIGATING THE RELATIONSHIP BETWEEN EIT WAVES AND THE ONSET OF SOLAR FLARES

D.A. Biesecker (SM&A Corporation), B.J. Thompson (NASA/GSFC), S.P. Plunkett (USRA - NRL)

The mechanism or mechanisms, which trigger the initiation of a solar flare, are unknown. Here we investigate the occurrence of solar flares as the result of a passing disturbance, such as an EIT wave observed with the EIT instrument onboard the SOHO spacecraft. While not all flares are triggered by such a mechanism, it is possible that some flares are. Many authors have attempted to look for evidence of flare initiation as a result of another, earlier event. There is no evidence that sympathetic events occur frequently. There is some evidence, though not conclusive, that sometimes flares occur as a result of some sympathetic event. If it can be shown that EIT waves can cause a solar flare to be triggered, the mechanism of flare initiation can be investigated. We consider EIT waves as a potential source of sympathetic events since it has been suggested that EIT waves are a coronal counterpart to Moreton waves. A common idea is that flare initiation begins in the corona, so EIT waves interact with potential flare initiation sites. We investigate the possibility that EIT waves trigger flares with a statistical comparison of the flare occurrence rate in the time that EIT waves traverse the solar disk to the flare occurrence rate in intervals preceding EIT wave events.

VARIATION OF IONIC CHARGE STATES BETWEEN DIFFERENT SOLAR ENERGETIC PARTICLE EVENTS AS OBSERVED WITH ACE SEPICA

E Möbius, M A Popecki, L M Kistler, A B Galvin, D. Heirtzler, D. Morris, C. Siren (Dept. of Physics and Inst. for the Study of Earth, Oceans and Space, University of New Hampshire, Durham, NH 03824, email: Eberhard.Moebius@unh.edu); B Klecker, A Bogdanov, D Hovestadt, (Max-Planck-Institut für extraterrestrische Physik, Postfach 1603, D-85740 Garching, Germany)

With the ULEZEQ instrument on ISEE-3 the ionic charge states of Fe and Si ions measured during Fe and 3He rich solar events had been found to be substantially higher than during strong gradual events, which have a composition that resembles more closely that of the solar corona. This seemed to indicate a split into two different groups of source populations for the energetic particles with highly different temperatures. However, the results for small impulsive events had to be averaged over the entire observation period of about one year.
With its much larger geometric factor the SEPICA instrument on ACE allows for the first time to obtain direct charge state measurements for individual small events. The charge states of C, O, Ne, Mg, Si and Fe have been determined for a variety of solar energetic particle events. Except for C, which is already close to fully ionized for all events, there is a trend towards higher charge states for the small events that carry signatures of impulsive events. For events that show Fe charge states of about 20 all elements up to Mg and sometimes Si appear almost fully ionized. However, solar events are also observed that produce intermediate charge states. All elements seem to be affected in a similar way for individual events. Different from earlier reports the observed charge states appear to be compatible with single temperature ranges for any individual event. Possible correla-tions of the observed charge state variations with the presence or absence of CMEs during the events and with variations in the elemental composition will discussed. It is puzzling that events with substantial deviations from coronal abundances accelerate almost fully stripped ions, which do not lend themselves easily to fractionation processes based on mass and charge.

GA4.02/W/18-A4 **1735**

CORONAL MASS EJECTION EXPANSION AND ITS IMPLICATIONS DERIVED FROM CHARGE STATE DATA

Simon Hefti, Thomas Zurbuchen, Len Fisk, Nathan Schwadron, and George Gloeckler (all at Univ. of Michigan, College of Engineering, Dep of Atmospheric, Oceanic and Space Sciences, 2455 Hayward Street, Ann Arbor, MI 48109-2143, USA, Email: hefti@umich.edu)

The Coronal Mass Ejection (CME) passing the Advanced Composition Explorer (ACE) in May 1998 shows a very interesting composition, particularly of minor ion charge states. Not only are unusual ions like O3+ observed during this CME, but high and low charged ions are measured simultaneously (Gloeckler et al, 1998). This challenges theories of solar-wind like expansion of CMEs. We use the charge composition of He, O, and Fe, measured with the SWICS instrument on ACE together with a simple model of a expanding and cooling cloud to reconstruct the temperature history of the CME. We will discuss the implications of this data for the origin, expansion and size of CMEs.

SOLAR LARGE-SCALE SHINING CHAINS: TWO CME-ASSOCIATED EVENTS

Ilia CHERTOK (IZMIRAN, Russian Academy of Sciences, Troitsk, Moscow Region, 142092, Russia, e-mail: ichertok@izmiran.troitsk.ru)

Transient large-scale shining chains and threads, associated with the near-the-limb coronal mass ejections (CMEs) of 22 August 1996 and 2 June 1998, are analyzed by the SOHO/EIT, Yohkoh/SXT, and some other imaging data. It is found that a pronounced evolution of the chains and threads in the EUV, soft X-ray and other ranges can occur during many hours both before and after a CME on a considerable part of the visible disk but especially near the place of a CME eruption. It is difficult to ascertain the relation between chains and CMEs unambiguously. However, such a relation seems to be plausible because both the phenomena ultimately are consequences of the evolution of large-scale magnetic fields and have often a global character. It is reasonable to assume that the chains preceding CMEs display energy release resulting from Evolving large-scale magnetic structures at the stage when development of these structures is approaching to a CME eruption. On the other hand, the chains following CMEs can result from the post-eruption energy release when magnetic fields in an extended region of the corona, strongly disturbed by a CME eruption, relaxes to its initial state via magnetic reconnection in large-scale coronal current sheets.

SOLAR FLARES IN MAGNETIC INTERACTING ACTIVE REGIONS

L. GABRIELA BAGALA' (Max PLanck Institut fuer Extraterrestrische Physik, Postfach 1603, D-85740 Garching, Germany, Email: gbagala@mpe.mpg.de), C.H. Mandrini, M.G. Rovira (both at Instituto de Astronomi'a y Fi'sica del Espacio, IAFE, CC.67, Suc.28, 1428 Buenos Aires, Argentina) and P. De'moulin (Observatoire de Paris, DASOP, URA2080 (CNRS), 92195 Meudon Cedex, France)

We present in this poster a study of the active region (AR) 7031, where several flares occurred between January 26 and February 2, 1992. We analyse in detail the three largest flares observed on January 39, 1992, using H alpha and soft X-ray data (SXT, on board Yohkoh). Two of these flares are homologous and occurred in the northern part of the AR; while the third one, the most extended and intense in H alpha, was located towards the South. During its transit across the disc this region interacted with another one (AR 7038) located at the South, as indicated by the recurrent brightening in soft X-rays of an interconnecting loop.
Using a linear force extrapolation of the photospheric magnetic field, we compute the locations of regions of rapid change in field-line linkage, called Quasi-Separatrix Layers (QSLs), as we have done in previous works (see e.g. Demoulin et al. 1997, A&A 325, 317). QSLs are the likely places where the magnetic field can reconnect. The comparison between the position of flare brightenings and QSLs, let us conclude that these flares occurred due to magnetic reconnection driven by the interaction of different structures in the same AR. Although these interactions could be traced in the topology computed from a magnetogram obtained at the time of the third flare, the energy release switched on or off in one site or the other of the AR following the photospheric field evolution.
We also find field lines connecting AR 7031 and AR 7038, having footpoints at the QSLs computed when magnetograms belonging to both ARs are combined. This indicates that the evolution of the photospheric field in one AR induces energy release at the QSL common to both regions.

MEASUREMENTS OF SOLAR WIND VELOCITY OVER A WIDE RANGE OF HELIOCENTRIC DISTANCES

A.R. BREEN, R.A. Fallows, P.J. Moran, P.J.S. Williams University of Wales, Aberystwyth, Wales, E.U. M. Gurhathakurta Goddard Space Flight Laboratory, Greenbelt, Maryland, U.S.A. M. Kojima STELab, Nagoya University, Japan A. Ananthakrishnan Tata Institute for Fundamental Research, India

Measurements of Interplanetary Scintillation provide information on solar wind velocity over a wide range of distances from the Sun. Observations made at high radio frequencies can probe the solar wind close to the Sun, while observations at lower frequencies provide information on the solar wind at greater helocentric distances. These observations are of particular value in extending the profile of coronal velocities measured by spacecraft instruments out into the interplanetary medium.
In this paper we discuss the results of a series of co-ordinated observations Interplanetary Scintillation observations made at 327 and 931 MHz in August 1998 and a second series of observations involving coronal observations from SPARTAN-201 and interplanetary scintillation measurements at 931 MHz, made in October-November 1998. We also hope to report initial results from co-ordinated interplanetary scintillation measurements at 931 and 1400 MHz, made in May 1999. Taken together, these measurements provide solar wind velocities from inside 2 solar radii to beyone 100 solar radii.

H-ALPHA SOLAR TELESCOPE FOR ARGENTINA

M.G. ROVIRA (Instituto de Astronomia y Fisica del Espacio, IAFE, CC 67 Suc. 28, 1428, Buenos Aires, Argentina), L.G. Bagala (Max Planck Institut fuer extraterrestrische Physik, Postfach 1603, D-85740 Garching, Germany), O.H. Bauer (Max Planck Institut fuer extraterrestrische Physik, Postfach 1603, D-85740 Garching, Germany), R. Fernandez (Instituto de Astronomia y Fisica del Espacio, IAFE, CC 67 Suc. 28, 1428, Buenos Aires, Argentina), C. Francile (Observatorio Astronomico Felix Aguilar (OAFA), Avda. Benavidez 8175 Oeste, 5413 Chimbas, San Juan, Argentina), G. Haerendel (Max Planck Institut fuer extraterrestrische Physik, Postfach 1603, D-85740 Garching, Germany) and E. Rieger (Max Planck Institut fuer extraterrestrische Physik, Postfach 1603, D-85740 Garching, Germany)

The release of a large amount of energy in sheared magnetic fields and the subsequent acceleration of charged particles is a common phenomenon in the universe. Since in the Sun flares, eruptive prominences and coronal mass ejection's are the direct results of impulsive releases and particle acceleration and can be resolved spatially, its observation is of crucial importance in the understanding of these phenomena. In order to study the evolution of solar flares with high spatial (1.5 arcsec) and temporal (up to 2sec) resolution from ground, a solar telescope in H-alpha (6563 A) has been set up at the OAFA mountain astronomical observatory in EL Leoncito, San Juan, Argentina. HASTA (H-alpha Solar Telescope for Argentina) is a 110 mm refractor with a focal length of 165 cm, a tunable (+- 1A) Lyot-Filter with a bandwidth of 0.3 A and a PC-controlled CCD-camera with a resolution of 1280x1024 pixels. In patrol mode the camera takes an image every 30-sec. It is analysed and if a flare is detected the camera switches into high-speed mode. In this mode it takes and stores full frame images every 2 sec or sub-frame images (in the region where the flare is developed) up to 0.3 sec. The Hard Disk capacity allows two hours of high-speed recording. HASTA started operations on May 1998 and in this work we are describing the first results. HASTA complements three other solar instruments which have been or will be installed in the near future in El Leoncito: MICA, a mirror coronograph to observe the solar corona above the limb from 1.1 to 2 solar radii, a submillimeter radio-telescope for measurements up to Far Infrared, and a high resolution spectrograph. Combining the observations of these four instruments new insights into the active Sun phenomena can be expected.

EFFECT OF MASS VELOCITY AND AMBIPOLAR DIFFUSION IN THE C AND SI LINE PROFILES OF SOLAR PROMINENCES

M. ROVIRA (Instituto de Astronomia y Fisica del Espacio, IAFE, CC.67, Suc. 28, 1428, Buenos Aires, Argentina), J.M. Fontenla (771 West Dahlia Street, Louisville, CO 80027, USA), A. Costa (Instituto de Astronomia y Fisica del Espacio, IAFE, CC.67, Suc. 28, 1428, Buenos Aires, Argentina) and S. Patsourakos (Institut d'Astrophysique Spatiale, Unite Mixte Paris XI-CNRS, Batiment 121, 91405 ORSAY CEDEX, France

We developed a numerical code to solve the ionisation equilibrium equation for a given atom and a given atmosphere. The population for the different stages of ionisation, the source function and the optical depth can be obtained for different intensities and configurations of the flux mass. The line profiles are deduced in order to obtain patterns that can be compared with observations. Although this method can be applied to any atom and any atmosphere, in this case, we restrict ourselves to the C and Si atoms and to the thread prominences model developed in a previous paper. In this work we show that solving the ionisation equilibrium equations for the C and Si atoms significant differences in the line profiles are observed while the intensity and configuration of the flux mass are varied.

FIRST COMBINED OBSERVATIONS IN THE GERMAN-ARGENTINIAN SOLAR OBSERVATORY

G. STENBORG (Max Planck Institut fuer Aeronomie, Max-Planck-Str. 2, D-37191, Katlenburg-Lindau, Germany), L.G. Bagala (Max Planck Institut fuer extraterrestrische Physik, Postfach 1603, D-85740 Garching, Germany), R. Fernandez (Instituto de Astronomia y Fisica del Espacio, IAFE, CC 67 Suc. 28, 1428, Buenos Aires, Argentina), O. Bauer (Max Planck Institut fuer extraterrestrische Physik, Postfach 1603, D-85740 Garching, Germany), M. Rovira (Instituto de Astronomia y Fisica del Espacio, IAFE, CC 67, Suc.28, 1428, Buenos Aires, Argentina) and R. Schwenn (Max Planck Institut fuer Aeronomie, Max-Planck-Str. 2, D-37191, Katlenburg-Lindau, Germany).

The SOHO era revealed that mass ejections from the sun include not only hot coronal plasma but also cold prominence material. The role of solar activity (flares or filament eruptions) is not yet well understood. Furthermore, if the cold material pushes the hot one or if the hot one drags the cold one is still an unresolved question. Thus, crucial information about the onset of a coronal mass ejection (both in space and time) can be obtained by combining coronagraphic observations of the emission line corona and H alpha images of the sun disk at a high cadence as well as insight about the relation between prominences and coronal mass ejections can be provided. In the recently inaugurated German-Argentinian Solar-Observatory at El Leoncito, San Juan, Argentina, an H alpha telescope (HASTA) and a mirror coronagraph (MICA) daily image the solar disk and the inner solar corona. MICA is essentially similar to LASCO-C1 on board SOHO. Since its installation in August 1997 it has been imaging the inner corona with high temporal and spatial resolution in two spectral ranges: the well known green (~1.8 MK) and red (~1.0 MK) coronal lines at 5303 A and 6374 A respectively. Its field-of-view ranges from 1.05 to 2.0 solar radii above the sun center. Thus, it is ideally suited to observe the hot material and reveal the fast processes that occur in the coronal plasma. HASTA started operations on May 1998. It is a 110-mm refractor with a focal length of 165 cm, a tunable (+-1A) Lyot-Filter with a bandwidth of 0.3 A and a 1280*1024 CCD array. In patrol mode the camera takes images every 30-sec. In high-speed mode full frames can be taken every 2-sec and partial frame images every 0.3 sec.. We present observations as taken by both telescopes. Emphasis is put on future applications.

MULTIINSTRUMENT OBSERVATIONS OF 3HE AND 4HE FLUX SPECTRA IN IMPULSIVE SOLAR ENERGETIC PARTICLE EVENTS WITH ACE/SEPICA AND SOHO/HSTOF

A.T. BOGDANOV(1), E. Moebius(2), B. Klecker(1), M. Hilchenbach(3), D.Hovestadt(1),L.M. Kistler(2), M.A. Popecki(2), E.J. Lund(2), D. Heirtzler(2), A.B. Galvin(2) (1) Max-Planck-Institut fuer extraterrestrische Physik, Garching, D-85740, Germany, Email: atb@mpe.mpg.de (2) Space Science Center, University of New Hampshire, Durham, NH, 03824, USA (3) Max-Planck-Institut fuer Aeronomie, Katlenburg-Lindau, D-37189, Germany

We investigate the energy dependence of the 3He/4He ratio during a number of impulsive solar energetic particle events observed between September 1997 and December 1998. The data of two instruments with complementary energy ranges, the Solar Energetic Particle Ionic Charge Analyzer (SEPICA) on ACE and the time-of-flight mass spectrometer HSTOF on SOHO are used to cover the energy range from ~ 0.1 to 3.5 MeV/nuc. The observed monotonous increase of the 3He/4He ratio with energy which for the events with extremely high 3He abundances ranges between ~ 0.1 at the lower energy end and ~ 1 at the upper end confirms the trend known from previous ISEE observations and extends their energy range to lower values. We discuss the observational data on the background of existing theoretical work on selection and acceleration mechanisms in impulsive flares.

GA4.02/E/05-A4 Poster **0900-07**

MODELLING OF SHOCK WAVE SURFACE EVOLUTION AHEAD OF TOROIDAL MAGNETIC CLOUD ON IYS WAY FROM THE SUN TO THE EARTH'S ORBIT

E.ROMASHETS Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation of Russian Academy of Sciences (IZMIRAN), Troitsk, Moscow Region, 142092 Russia, email: omash@izmiran.rssi.ru

Fast magnetic clouds may create bow shocks in front of them, which in turn produce type II radio bursts in interplanetary space. We consider here isolated toroidal magnetic cloud evolving (expanding) on its way from the Sun. The position and shape of the shock surface determines the frequency depth and duration of radio emission at given frequency, and intensity. Fluctuations and unhomogeneities of ambient solar wind will also lead to broadening of emission lines and will cause changes of the cloud's shape and velocity even slow MHD speed the bow shock will disappear and there is no emission. We will show preliminary results of modelling of the evolution of toroidal magnetic cloud and associated shock on the basis of approach developed in Romashets (1996) and will use them for interpretation of radio busts of January 1997 and May 1997, observed by WIND and ULYSSES wave instruments.

THE RECONNECTION POWER AND RATE IN THE COURSE OF EACH OF THE TWO ACTIVE PHASES OF TYPE-LDE LARGE SOLAR FLARES

V. MISHIN (Institute of Solar-Terrestrial Physics,P.O.Box 4026, Irkutsk, 664033, Russia, email: mishin@iszf.irk.ru) C.-G. Falthammar (The Royal Institute of Technology, The Alfven Laboratory, Stockholm, Sweden, email falthammar@plasma.kth.se) A. Altyntsev (Institute of Solar-Terrestrial Physics, P.O.Box 4026, Irkutsk, 664033, Russia, email: altyntsev@iszf.irk.ru)

The time dependent values of open magnetic flux Psi in the flare-producing region were determined by Mishin et al., a, for three large flares of LDE type, 3B class. Two active phases are noticed for each of the flares, one during Psi growth, and next when Psi was fast decreasing. In this paper, estimates are made of the Poynting flux to the flare region from the outside and of the reconnection power and rate for each of the two active phases of each flare. In the CSHKP model, these two phases are produced by the reconnection in the closed and open parts of the magnetosphere, respectively. It is concluded from the calculated results that the reconnection power and rate of the open magnetic flux exceed those for the first active phase, as it was found in the case of magnetospheric substorms,

GA4.02/E/06-A4 Poster **0900-09**

TWO ACTIVE PHASES OF LARGE SOLAR FLARES OF LDE TYPE

V. MISHIN and A. Altyntsev (both at Institute of Solar-Terrestrial Physics,P.O.Box 4026, Irkutsk, 664033, Russia, email: mishin@iszf.irk.ru) C.-G. Falthammar (The Alfven Laboratory, Stockholm, Sweden, email: falthammar@plasma.kth.se)

Before Yohkoh, solar flares were classified into two types, such as LDE vs impulsive or eruptive vs confined, or two ribbons vs compact, etc. Yohkoh, however, revealed that both these types could be considered as the events, which are usually accompanied by eruptions of plasmoids or plasma jets (the unified model of flares, Shibata, 1996). In the present paper, Shibata's model is supplemented by H-alpha data on three large, class 3B, flares of LDE type: flare 1, 12.10.81 (Kurokawa, 1989), flare 2, 5.10.70 (Banin, 1982), and flare 3. 27.06.81 (Yazev, 1985). The known phase of two ribbons separation was observed in each of above flares, which is interpreted as the eruptive phase in the CSHKP model. According to this model, the area St inside the outer boundaries of two ribbons, measured at the end of the flare, was taken by us to be approximately equal to the largest (total) area during the flare, crossed by the open magnetic flux Psi, whose reconnection creates the flare eruptive phase. Further, for an arbitrary time t, we calculated the values of Psi as a product B cross S3, where B=250 Gauss is the accepted characteristic value, and S3=St-S2, with S2 being the area inside the outer boundaries of two flare ribbons measured at time t. The plot of Psi, obtained by such a way for flare 1, clearly shows two phases of Psi variation: Psi was growing during impulsive phase, 0607-0626 UT, and only after it, the phase of a fast decrease of Psi, which corresponds to the separation of two ribbons, was observed. These two phases both are active: the brightness and areas of the ribbons are comparable in both phases, and the hard X-ray intensity starts to increase at 0614 UT and peaks around 0626 UT. Thus, two active phases are noticed for flare 1, the first of which has no signatures of eruption. Similar conclusions were drawn from the data for flares 2 and 3, although these data are less complete.

GEOMAGNETIC SUPERSTORMS AND THEIR SOLAR AND INTERPLANETARY SOURCES

Dmitri I. PONYAVIN (Institute of Physics, University of St.Petersburg, 198904, Russia, e-mail: ponyavin@snoopy.phys.spbu.ru)

Geomagnetic activity variations recorded in St.Petersburg from 1841 to 1999 have been analysed. Statistics of major geomagnetic storms (superstorms) show a significant semiannual and dual-peak variation during a course of solar activity cycle. Superstorms occur in close association with recurrent streams of the solar wind. The role of interplanetary conditions and magnetic fields on the Sun, its organisation and evolution in appearing such phenomena was discussed.

THE MECHANISM OF PLASMA JET EJECTION FROM THE SUN.

I.M Podgorny (1) and. A.I. Podgorny (2) (1) Institute for Astronomy RAN, Moscow, 109 017, Russia. (2) Lebedev Physical Institute RAN, Moscow, 117 924, Russia,

The dynamics of vertical current sheet creation and plasma jet ejection are numerically simulated in resistive MHD approximation. Plasma compression and anisotropy of the thermal conductivity are taken into account. A solar flare appears prior to the jet ejection which has been observed by Yohkoh. Fast electron precipitation and Pedersen currentsm produce local chromospheric evaporation. After that a powerful post flare loop appears. The strong plasma fluxes meet at the loop top, and induce an upward plasma jet. As a result of jet motion across the magnetic field a current sheet is created. The reconnection in the current sheet gives rise to electron heating and soft x-rays radiation. The results of computation are compared with observed data.

INVESTIGATION OF ENERGY ACCUMULATION IN CORONA FOR ACTIVE REGION OF FLARE ON MAY 30 1991

A.I. Podgorny Lebedev Physical Institute RAN, Moscow, 117 924, Russia,

The possibility of magnetic energy accumulation at current sheet creation in corona for the active region AR NOOA 6654 which produced the flare May 30 1991 was investigated. The field of 4 main spots which were situated almost on the same line in the photosphere was approximated by field of 4 magnetic dipoles placed vertical under the photosphere. MHD equations were solved in the corona for magnetic disturbances corresponded to changing dipole moments and/or dipole motion. The numerical code PERESVET was developed which permitted to solve compressible MHD equations with dissipative terms and anisotropy of thermoconductivity. Absolutely implicit difference scheme was used. Calculations were done for large scale numerical region which contains all active region but have rough step and small scale region with fine steps but uncertainty of field setting on non-photospheric boundary. Comparing this calculations helped to separate the physical effect. Calculations for small scale region showed the possibility of current sheet creation which inclined on rather large angle to the photosphere which give possibility for CME appearance. Calculations for large scale region showed that for moving up two central dipoles or increasing their moments the current sheet was very weak. Decrease of two external dipoles caused the current sheet creation. Current sheet may be inclined to photosphere or be practically parallel to it depending on disturbance

SOFT X-RAY JETS AND THEIR RELATIONSHIP TO QUASI-STEADY CORONAL MAGNETIC STRUCTURES

Yoshimichi Nkagawa and Takashi WATANABE (Department of Environmental Sciences, Ibaraki University, Mito 310-8512, Japan, e-mail: nakagawa@env.sci.ibaraki.ac.jp)

Among coronal disturbances observed by Yohko SXT, soft X-ray jets are interesting

phenomena both from the observational and theoretical aspects. We study well-observed examples of large- scale soft X-ray jets through the comparison between Yohkoh SXT images and coronal magnetic configurations, which are inferred from photospheric magnetic observations (Kitt Peak) by using a potential field model. It is found that, for several events, jets were formed along the field line of long-lived (for 2-3 solar rotations) coronal field. According to the present study, the following scenario of the jet phenomenon will be proposed. (1) The magnetic configurations of the coronal region including the jet are predominantly governed by quasi-steady magnetic structures, which are well approximated by the potential model. (2) The emerging flux makes reconnection with the steady pre-existing magnetic field structures. (3) The soft X-ray jet is formed along the pre-existing field line.

FLARES, RECONNECTION AND MERGING OF HELICAL MAGNETIC STRUCTURES

G. S. CHIO and C. Z. CHENG (Princeton Plasma Physics Laboratory, Princeton University, Princeton, NJ 08543)

Based on the theoretical model that flaring events are associated with magnetic energy release which takes place via magnetic reconnection processes we have demonstrated in numerical 2-1/2D MHD simulations that flaring events can occur in a bipolar magnetic arcade due to energy supply (or drainage) through the photosphere. The energy supply (or drainage) processes are through the fieldline footpoint motion (shearing, convergerging and diverging) and/or flux emergence. We will demonstrate the Poynting flux distributions in the photosphere of these processes and discuss how these energy exchange processes can affact the flaring events. We will also demonstrate how homologous flares successively take place in a magnetic arcade at the same place with a short time interval on the order of one day. Accompanying the homologous flare events are successive generation and merging of magnetic islands. With continuing supply of energy through the photosphere new magnetic island can created below a previously existing upper island, and this new island can rise faster and merge with the upper island very quickly to form a bigger island because they have same helicity. The combined island will continue to rise with a faster speed than the original upper island. As this process is being repeated, several impulsive events of magnetic energy release take place and the growing magnetic island is eventually driven away from the sun. Different types of footpoint motion can produce different Poynting flux distributions in the photosphere and the time interval between flaring events is accordingly varied.

DISSIPATIVE CME PROCESSES

I.S.VESELOVSKY (Institute of Nuclear Physics, Moscow State University, Moscow 119899, Russia, email: veselov@dec1.npi.msu.su)

An attempt is undertaken to estimate the relative importance of dissipative MHD and kinetic plasma processes during CME initiation and evolution processes. Dimensionless parameter analysis is performed of the mass, momentum and energy conservation laws together with material and Maxwell equations. The complexity and the large diversity of real situations are explained by the nonlocal and nonlinear multi-scale nature of the CME phenomena. In addition to the ideal MHD processes, the heat conduction, viscosity and finite electrical conductivity are essential in different proportions for different eruptive events. Strong anisotropy is introduced by the magnetic fields in the transport processes. Higher order kinetic deviations (accelerated particles, nonthermal radiation etc.) are playing a comparable role in a bulk sense from case to case. A crucial role in the conditions that lead to plasma ejection belongs not only to the evolution of the photospheric fields. Electric currents and a free magnetic energy of the corona are also important and rather independent reservoirs of the dynamic plasma self-organisation.

ENERGY EVOLUTION OF CMES

JUN Lin and Terry G. Forbes (both at EOS Institute, University of New Hampshire, Durham, NH 03824, USA, email: jun.lin@unh.edu)

To model the energy evolution of a CME we use a two-dimensional flux-rope model, which drives the ejection by means of a catastrophic loss of mechanical equilibrium. Reconnection plays an essential role because without it the CME cannot escape into interplanetary space. In the model the initial energy release is independent of the reconnection process, but after a few minutes reconnection becomes increasingly important. Assuming that the flows into the reconnection region are less than the local Alfven speed, we show that the model generates a power output which closely resembles the so-called "light-curves" of Long Duration Events (LDE) associated with CMEs.

PROTON ENERGY SPECTRUM AND SOURCE NATURE OF THE LARGE SOLAR EVENT OF SEPTEMBER 29, 1989

E.V.Vashenyuk1, L.I.MIROSHNICHENKO(2), and A.O.Vdovichev(1) 1) Polar Geophysical Institute, Apatity, Murmansk Region, 184200, RUSSIA; 2) Instituto de Geofisica, UNAM, 04510, Mexico, D.F., MEXICO; Permanent address: IZMIRAN, Troitsk, Moscow Region, 142092, RUSSIA

Ground Level Enhancement (GLE) of solar cosmic rays on September 29, 1989 is studied. The event was remarkable for a number of unusual features. Among them were the double-peak increases observed at some neutron monitor (NM) stations and complicated behaviour of the proton energy spectrum and anisotropy. Two component structures of the proton intensity-time profiles in the event has been demonstrated. The first (prompt) component had a short duration and very hard energy spectrum. The second (delayed) component, being ejected from the Sun ~1 h later, was dominated by a particle population with the soft energy spectrum and gradual profiles. An existence of two different sources of particle acceleration separated in time and possibly in space during the event has been suggested. The properties of the prompt component give some evidences for its source is linked with a magnetic reconnection process in the trailing part of the ascending coronal transient. Parameters of the magnetic field and plasma in the source have been estimated by fitting observed proton spectrum to the calculated one in a computational model with a fast acceleration mechanism at the first stage of the event. Optimization procedure gave the following set of parameters: B = 91 G; n = 1.2_107 cm-3; L = 109 cm (B, n and L are magnetic field intensity, plasma density at the acceleration site and linear dimension of the current sheet, respectively). Such values of B and n are characteristic for the trailing part of coronal transient (behind of an eruptive filament) at the coronal heights of several tenth of solar radius, and the value of L is of order of filament length.

A STUDY OF PLASMA WAVES IN CMES AND THE SEARCH OF THE SOURCES OF ION ACOUSTIC WAVES IN THE SOLAR WIND

NAIGUO lin, P. J. Kellogg (School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota, USA) R. J. MacDowall (NASA/Goddard Space Flight Center, Greenbelt, Maryland, USA) J. T. Gosling, D. J. McComas (Los Alamos National Laboratory, Los Alamos, New Mexico, USA) R. J. Forsyth, A. Balogh (Imperial College of Science and Technology, London, UK)

In order to study the occurrence and properties of plasma waves associated with coronal mass ejections (CMEs), a number of CMEs observed by the Ulysses spacecraft in a large range of heliographic latitudes are examined. Four wave modes are observed within the CMEs: (1) Electric waves at a few kHz, which are interpreted as Doppler shifted ion acoustic waves (IAW). They are observed within the CME structures, where the proton temperature becomes low and thus the electron to proton temperature ratio is larger than one. The ratio varies significantly. A comparison of the intensities of IAW to the Te/Ti ratios may provide information on the damping rate of the waves. A survey of IAW intensity in the solar wind in a several year period, which include CME intervals, will be presented to examine the occurrence and intensities of IAW from different solar wind sources. The relation between the IAW intensity and the electron heat flux will also be discussed. (2) Electromagnetic whistler waves. They are observed in regions where the solar wind plasma is turbulent (near interplanetary shocks or during periods of increasing solar wind velocity). (3) Electric waves near the electron plasma frequency, which are probably generated by streaming electrons within the CME structure. (4) Electric fluctuations below the local electron cyclotron frequency are observed during periods of decreasing solar wind velocity, which is also a characteristic of an expanding CME.

MULTIPLE PARTICLE ACCELERATION AT THE SUN DURING LARGE EXTENSION AND LONG DURATION GAMMA RAY EVENTS

R. Pèrez Enrìquez(1) and L.I. MIROSHNICHENKO (2) Instituto de Geofisica UNAM, Mèxico, D. F., 04510, MEXICO; (1) Campus UNAM, Juriquilla, Querétaro; (2) Permanent address: IZMIRAN, Troitsk, Moscow Region, 142092, RUSSIA

Gamma ray lines (GRL) from the event of September 29, 1989 originated at solar longitudes of 25-30 degrees from the flare site. Although a CME-driven shock has been proposed as the most plausible mechanism to account for the accelerated particles responsible for the gamma rays, no generally accepted explanation exists at present. On the other hand, in 1991, at least three long duration GRL events (June 4, 11, and 15) were observed at several satellites. Likewise, none of the models put forward to explain these events are convincing. For example, the prolonged particle acceleration during the late stage of the flare of June 15, 1991 can explain many of the peculiar features of this kind of events, especially the accompanying microwave emission; however, it cannot account for the fact that this emission, at least in this particular event, is oscillating in nature. In our opinion, this kind of event should be considered in the framework of a new concept of multiple particle acceleration in the extended coronal structures. In this paper, we make a comparison of the situations involving these peculiar events and find reasons to suspect that a possible mechanism might involve the collapse of a large loop filled with stochastically accelerated particles. As a result of the collapse, a CME and a shock might be produced in the corona, and a precipitation of a fraction of the accelerated particle population into the chromosphere might occur. The interaction of these particles with the chromospheric material outside an active region would produce an extended long lasting GRL event; escaping particle population forms a long duration SPE in space.

EUV OBSERVATIONS OF THE DECEMBER 17 1998 CME ONSET

Dr Richard A. HARRISON Rutherford Appleton Laboratory

Extreme ultraviolet observations of the solar eastern limb on December 17, 1998, revealed an extremely active Sun with a complex, active loop system occupying much of the limb, including a prominence in the south. The activity included a significant eruption, which was subsequently seen in coronagraph data. The onset of this event is considered in detail and the relevance of established mass ejection models discussed.

MHD FLOWS SUPPORTING THE STATIONARY STRUCTURE OF 3D MAGNETIC NULLS AND THRESHHOLD TO THE COLLAPSE

Vyacheslav.S. TITOV and Gunnar Hornig (both at Theoretische Physik IV, Fakultaet fuer Physik und Astronomie, Ruhr-Universitaet Bochum, D-44780 Bochum, Germany,
Emails:st@tp4.ruhr-uni-bochum.de, gh@tp4.ruhr-uni-bochum.de)

The exact solutions of resistive magnetohydrodynamic equations describing stationary incompressible flows near a three-dimensional null point of magnetic field are found. It is shown that the magnetic null-point configuration with locally non-potential structure may be supported generally by a stationary non-potential flow of stagnation type if the current density does not exceed some critical value. This critical value coincides with the threshold one, which separates the topologically different cases of skewed improper and spiral nulls (see Parnell et al., 1995).
The obtained results imply that stationary MHD flows may support generally only the skewed improper null configuration but not the spiral one, while the latter is probably realised only in collapse-like non-stationary flows as (for instance) found by Bulanov and Olshanetsky (1984). The topological structure of the obtained solutions is studied in terms of the relative location of the one-dimensional and two-dimensional invariant manifolds (so called spine line and fan plane, in notations of Priest and Titov, 1995) of magnetic and velocity fields. The implication of these solutions for three-dimensional magnetic reconnection problem in active phenomena like solar flares and magnetospheric substorms is also considered.

THE 24-25 DECEMBER 1996 MAGNETIC CLOUD AND ITS ASSOCIATED RECONNECTION LAYER

C J FARRUGIA (Space Science Center, University of New Hampshire, NH 03824, USA, Email: farrugia@monet.sr.unh.edu), V S Semenov, I Kubyshkin (both at Institute of Physics, State University of St Petersburg, St Petergof 198904, Russia), H K Biernat (Space Research Institute, Austrian Academy of Sciences, A-8042, Graz, Austria), R B Torbert, L Janoo (both at Space Science Center, University of New Hampshire, NH 03824, USA), J D Scudder (Department of Physics and Astronomy, University of Iowa, Iowa City IA 52240, IO, USA), K W Ogilvie, L F Burlaga and R P Lepping (all at NASA Goddard Space Flight Center, Greenbelt MD 20771, USA)

A two-hour-long pressure balanced structure preceded the magnetic cloud observed by WIND on December 24-25, 1996. Not only does the magnetic field decrease to very low values; there are also perturbations in all solar wind parameters. Stress balance analysis is satisfied across the structure. Studying the configuration further, we show that the data may consistently be interpreted in terms of disturbances from a reconnection site close to the Sun which have been transported, with varying delay times, to 1 AU. The distance to the reconnection site is estimated.

LASCO HA OBERSERVATIONS OF THE SOLAR CORONA 19-22 JUNE 1998

MICHAEL D. ANDREWS (Raytheon ITSS, 4500 Forbes Blvd., Lanham, MD 20706, USA, Email: andrews@louis14.nrl.navy.mil) Angelos Vourlidas (Center for Earth Observing and Space Research Institute for Computational Science and Information, George Mason Univ. Fairfax, VA 22030, USA) Russell A. Howard (E. O. Hulburt Center for Space Research, Naval Research Laboratory, Code 7660, Washington DC 20375, USA)

On 19-22 June 1998, the LASCO team performed a special observation sequence using all three coronagraphs to search for Ha emission. Several Coronal Mass Ejections were observed. A C1 line-scan recorded at 01:05UT on 22 June 1998 recorded Ha emission that saturated the detector at line-center. This emission corresponded to the eruption of a prominence observed by the Nobeyama Radioheliograph at 17 GHz. There is no significant Ha emission associated with the leading edge of any of the several CMEs. One of the events does show fine scale Ha structure in C2. Due to the significant CME motion, the analysis of this emission is difficult. We will present a quantitative estimate of the Ha emission observed in the C2 field of view. The only Ha emission observed by the C3coronagraph is from the interstellar source RNGC 2174. There is no evidence of coronal Ha emission in the C3 data. LASCO is the Large Angle Spectroscopic Coronagraph which is one of the instruments on the Solar and Heliospheric Observatory (SOHO) which is a mission of international cooperation between NASA and ESA. The LASCO experiment was developed by a consortium of institutions from four countries: E. O. Hulburt Center for Space Research, Naval Research Laboratory, Washington, DC; Laboratoire d'Astronomie Spatiale, Marseille, France; Max-Planck-Institut fur Aeronomie, Lindau, Germany; and Space Research Group, School of Physics and Space Research, University of Birmingham, Birmingham, UK

SOLAR SOURCES OF HIGH-VELOCITY STREAMS IN THE SOLAR WIND

Mikhail I. PUDOVKIN, Svetlana P. Bogdanova, Svetlana A. Zaitseva (Institute of Physics, St.Petersburg University, St. Petersburg 198904, Russia, e-mail: pudovkin@snoopy.phys.spbu.ru)

Orientation of the magnetic field frozen in the plasma of high-velocity streams to the solar wind correlate with the direction of the large-scale solar magnetic field at the regions of associated solar flares. This result convincingly confirms the supposition that sources of those streams are located within the flare regions. The time taken by the stream to propagate from the Sun to the Earth is shown to depend on the location and duration of the corresponding flares and on the mutual orientation of the magnetic fields within the stream body and within the background solar wind.

DOES THE CYCLIC VARIATION OF CME VELOCITIES EXIST?

E.V.IVANOV, V.N.Obridko, and E.V.Nepomnyaschaya (IZMIRAN, Troitsk, Moscow Region, 142092, Russia, Email: solter@izmiran.troitsk.ru)

The cyclic variation of the annual mean CME velocities has been studied for the time interval of 1979-1989. The annual mean CME velocity displays a growth at the maximum and decrease at the minimum of the cycle and a secondary peak at the minimum of the cycle. It is shown that CME velocities and widths are mainly determined by the large-scale magnetic field system with a characteristic size of cells of about 40 degrees. The secondary peak of the annual mean CME velocity is due to a significant contribution of high-speed CMEs with a width of ~100 degrees at the minimum of the cycle, which means another large-scale magnetic field system with the size of cells of ~90-100 degrees.

ARE CMES MAGNETICALLY DRIVEN?

P. SUBRAMANIAN (GMU/NRL), A. Vourlidas (GMU/NRL), K. P. Dere (NRL), R. A. Howard (NRL)

It is commonly assumed that Coronal Mass Ejections from the Sun are magnetically driven. We address this question with data from the LASCO coronagraphs aboard the SOHO spacecraft. These observations provide fairly direct measurements of the kinetic and gravitational energy of CMEs. We determine the kinetic and gravitational energies and their evolution for several helical CMEs. We estimate the evolution of the magnetic energy based on the conservation of magnetic flux and observations of magnetic clouds near the Earth. From the magnitude and variation of these three forms of energy, we examine the energetics of CMEs from the perspective that they are driven through their internal magnetic energy.

THE SOLITARY STRUCTURES IN OVERDENSE IONOSPHERIC PLASMA

A.V. KOCHETOV and B.A. Mironov (both at Institute of Applied Physics, N.Novgorod, Russia, e-mail: kochetov@appl.sci-nnov.ru) G.I.Terina and V.N.Bubukina (both at Radiophysical Research Institute, N.Novgorod, Russia, e-mail: ter@nirfi.sci-nnov.ru)

The results of the modelling of non-linear dynamic effects arising in the ionospheric plasma under the action of the powerful radio waves are presented. Numerical solutions of non-linear Schredinger equation in the linearly inhomogeneous plasma layer excited by the heating radio wave were obtained. The processes of the formation of the solitary structures of the electric field and disturbances of plasma density and processes of their relaxation for different values of density gradient and the amplitude of the heating wave were analysed. The spatial evolution of the electric field and disturbances of the plasma density and time dependencies of the reflected signal were obtained. With the heater turn-on the penetration of the solitary structure into the overdense plasma takes place which increases under the heating power increase and the decrease of the plasma density gradient. The decreasing of the scale of the spatial soliton structure, the periodic and chaotic solitons generation during the heater time is observed. When the heater is turned off, the solitons continue to travel into the overdense plasma for some time, increasing in the amplitude, until they reach the turning point. Then they reflect and propagate into the underdense plasma, decreasing in the amplitude, and disappear. The obtained results allow to interpret the appearance of the scattered signal after the heater turn-off - "aftereffect plasma signal" (AEPS). The Education Department of Russia (grant N 97-0-5.3-113) supported this work.

THE CHROMOSPHERE/TRANSITION-REGION/CORONA/SOLAR-WIND SYSTEM: AN OVERVIEW

Thomas E. HOLZER (High Altitude Observatory, National Center for Atmospheric Research, P.O. Box 3000, Boulder, CO 80307-3000, USA, Email: holzer@ucar.edu)

It has become clear in recent years that a satisfactory understanding of solar wind acceleration requires consideration of the coupled system comprising the upper chromosphere, transition region, corona, and wind. The need to consider the chromosphere and transition region arises to some extent from the energy lost through heat transport from the corona to the chromosphere, but more importantly from the effect this heat transport has on the location of the transition region and thereby on the coronal base pressure. In addition, the processes controlling the abundance of helium in the corona (which may play a significant role in solar wind acceleration) are operative primarily in the upper chromosphere and transition region. Finally, it is possible that a significant fraction of the energy flux required to heat the corona and drive the solar wind is generated in the chromosphere and transported through the transition into the corona.
A number of recent studies have elucidated the effects on wind acceleration of simply parameterized energy transport and dissipation (as well as helium diffusion) in the chromosphere- corona system, and there have also been useful hydromagnetic simulations of the propagation and dissipation of large amplitude waves in the corona and solar wind. The time has now come, however, to carry out realistic simulations in the chromosphere-corona-wind system of specific processes that may be important in the transport and dissipation of energy, as well as in the diffusion of helium. With the advent of significantly improved observational information now available from such sources as the SOHO and TRACE missions, the results of such simulations could be thoughtfully compared with observations to reveal which physical processes are important in coronal heating and solar wind acceleration.

CORONAL HEATING; WHAT HAVE WE LEARNED FROM SOHO?

John L. KOHL (Harvard Smithsonian Center for Astrophysics, 60 Garden Street, Cambridge, MA 02138, USA, email: jkohl@cfa.harvard.edu)

Observations and analyses of data from the Solar and Heliospheric Observatory (SOHO) have revealed significant new information about the physical processes that deposit energy and momentum into the solar corona. The Michelson Doppler Imager has made detailed measurements of magnetic flux emergence and cancellation in network sites which are potential source regions for energy release. The Coronal Diagnostics Spectrometer and the Solar Ultraviolet Measurements of Emitted Radiation (SUMER) instrument have produced evidence that the electron temperature in coronal holes is lower than previously believed, but this result must be reconciled with higher "freezing in" temperatures derived from "in situ" observations. SUMER measurements of spectral line profiles near the base of coronal holes indicate that ion temperatures increase with mass-per-charge. Measurements of coronal holes up to 3 solar radii with the Ultraviolet Coronagraph Spectrometer find anisotropic velocity distributions with hydrogen speeds, perpendicular to the magnetic field, corresponding to temperatures that are much higher than those of the electrons, OVI perpendicular speeds corresponding to temperatures about 100 times that of hudrogen, and outflow speeds for hydrogen and O VI becoming supersonic within 2 solar radii with higher outflow speeds for the OVI. This presentation will review the latest results related to coronal heating from SOHO.

THE ENERGY BALANCE ANALYSIS IN THE SOLAR WIND FORMATION REGION

S.I. MOLODYKH, V.A. Kovalenko

Solar corona observations in the white light and in separate coronal lines have been used in analyzing the energy balance of the solar wind formation region within heliocentric distances 1.02-1.5 solar radius. It is shown that losses through emission in different coronal lines have a significant influence on the energy balance of the solar wind formation region. An analysis of observed coronal line profiles suggests the conclusion that the energy flux input to the solar wind formation region is constant. It is shown that the flow divergence in the solar wind formation region determines the parts of energy going into solar wind acceleration and lost due to emission in different coronal lines. An increase in flow divergence is accompanied by an increase in energy flux going into solar wind acceleration, and by a decrease in energy emitted in coronal lines. On the base of solar wind model is shown that magnetic field configuration determines the flow divergence and consequently affects energy balance. It is concluded that the main part of the energy flux which input to the solar wind formation region is the Alfven wave energy flux.

ELECTRON PROPERTIES CLOSE TO THE SUN FROM IN SITU CHARGE STATE DATA AND ELECTRON DISTRIBUTION FUNCTIONS

T. H. ZURBUCHEN, S. Hefti, L. A. Fisk, G. Gloeckler*, and N. A. Schwadron, (Department of Atmospheric, Oceanic, and Space Sciences, University of Michigan, Ann Arbor, MI, USA, 48109-2143, email: thomasz@umich.edu); D. Larson, and R. P. Lin, (Space Research Laboratory, University of California, Berkeley, CA 94720, USA) *G. Gloeckler also at Department of Physics and ISTP, University of Maryland, College Park, Maryland, USA, 20742

The ionic charge state of minor ions is a reliable tracer for electrons close to the Sun. The charge state can be determined in its frozen-in state at 1 AU by the SWICS experiment on

ACE. The suprathermal portions of electron distribution functions are also expected to provide information on the low corona. These distribution functions are independently measured by the WIND 3DP instrument.
The combination of these data provides a powerful set of constraints on models describing the radial dependence and the character of electron distribution functions close to the Sun. We will focus on the non-thermal properties of electrons in the solar vicinity and their effect on the freeze-in process of the ionic charge state of minor ions.

GA4.05/E/02-A1 **1010**

CO-ORDINATED INTERPLANETARY SCINTILLATION AND OPTICAL MEASUREMENTS OF THE ACCELERATION PROFILE OF THE SLOW SOLAR WIND

A.R. BREEN, R.A. Fallows, P.J. Moran, P.J.S. Williams Prifysgol Cymru, Abersytwyth, Wales, E.U.;R. Schwenn, N. Srivastava Max-Planck Institut fuer Aeronomie, Katlenburg-Lindau, Germany, E.U.

The slow solar wind is subtantially denser and more variable than the fast wind. Interplanetary scintillation measurements suggest that the slow wind has reached its 'cruising' velocity by ~30 solar radii from the Sun, while optical measurements of the drift velocity of large-scale irregularities suggest acceleration out to 25-35 solar radii. In this paper we compare the results of near-simultaneous IPS and optical measurements of slow wind velocity from EISCAT and LASCO, at heliographic distances between 2 and 50 solar radii. The effective fields of view of the two instruments overlap, allowing direct comparisons of velocities derived from the two techniques. We also hope to present the initial results of co-ordinated dual-frequency IPS observations (931 and 1400 MHz, covering ~10-50 solar radii) and optical measurements made in May 1999 using EISCAT, the MERLIN system and LASCO

GA4.05/W/05-A1 Invited **1050**

PROPAGATION AND DAMPING OF WAVES IN THE CORONA

Joseph V HOLLWEG (University of New Hampshire, USA, email: joe.hollweg@unh.edu)

In 1968, Hartle and Sturrock showed that a model electron-driven solar wind resulted in flow speeds at 1AU which were too slow and proton temperatures at 1AU which were much too low, especially when compared to the high-speed solar wind streams which were essentially discovered during the Skylab era. Moreover, it was soon realized that heavy ions in the solar wind were flowing faster than the protons and hotter than the protons roughly in proportion to their masses; heavy ions like iron were recognized to have temperatures at 1AU which were well in excess of the typical coronal electron temperatures. Clearly the protons and heavy ions were being heated and accelerated by some "non-thermal" source. In 1969 the discovery of ubiquitous low-frequency Alfven waves in the solar wind by Belcher, Davis, and Smith began three decades of work on the roles of waves in the solar wind. The waves were recognized to exert a wave pressure on the wind, and dissipation could lead to heating. The heavy ions were soon realized to require higher-frequency cyclotron-resonant waves. Descriptions for these effects in a multi-ion solar wind were available by the early 1980's, but various models failed in detail, mainly because they emphasized the effects of the waves in interplanetary space, but not in the corona itself. In fact an early study of resonant proton heating in the corona predicted coronal proton temperatures which were at the time regarded as too high, but which have been verified more recently by the remarkable UVCS/SOHO observations. The UVCS data now strongly suggest that resonant heating of protons and ions by waves is the dominant process heating coronal holes, and providing the thermal energy which is converted into flow energy. We will discuss some of the basic physics of the resonant heating and acceleration of coronal protons and ions, emphasizing the kinetic physics, and showing how it can account in principle for the basic UVCS observations. However, we will point out that there are basic questions concerning the wave source, and thus the origin and evolution of the power spectrum, knowledge of which is essential for calculating the resonances.

CORONAL HEATING IN MAGNETICALLY OPEN AND CLOSED REGIONS: SIMILARITIES AND DIFFERENCES

Prof. E.R. PRIEST and Dr. R.W. WALSH

Energy release in Stellar Coronae remains one of the main unanswered astrophysical questions. In the case of the Sun, it appears beyond doubt that the solar magnetic field as well as the turbulent motions of the photosphere play the most vital roles in this heating problem.
In this review the authors outline possible coronal heating mechanisms applicable to both open and closed magnetic structures. The dissipation of wave motions, sites of magnetic reconnection and magnetohydrodynamic turbulence are all possible candidates for providing the necessary coronal energy deposition.
For example, wave heating theories for coronal hole regions along with the associated concepts for polar plume activity will discussed. On the other hand, the evidence for magnetic reconnection within the corona from theoretical modelling as well as from SOHO observations is compelling. The important contribution made by coronal bright points will be summarised with examples from coordinated TRACE/MDI studies. Scaling laws for discrete energy release from both statistical models and EIT/SXT observations will be reviewed as well as the plasma dynamics, time variability and possible observational signatures of random, localised heating episodes within active region and large scale X-ray loops.

GA4.05/E/01-A1 **1210**

SURFACE WAVE INDUCED MAGNETIC RECONNECTION IN THE SOLAR CORONA

B. P. PANDEY (Indian Institute of Geomagnetism, Bombay 400 005, India, email: pandey@iig.iigm.res.in); G.S.Lakhina (Indian Institute of Geomagnetism, Bombay 400 005, India, email: pandey@iig.iigm.res.in); C Uberoi (Indian Institute of Science, Bangalore 560 012, India, email: cuberoi@iisc.ernet.in)

The low-frequency surface wave induced magnetic reconnection may be a possible candidate for the coronal heating and emission of jets and surges on the Sun. We demonstrate that the lifetime and scale lengths of the coronal plasmoid ejection compares favourably with the analytical results of surface wave induced tearing of the current sheet.

GA4.05/W/01-A1 **1220**

SAND-PILE MODEL OF CORONAL HEATING BY MICRO FLARES: EFFECT OF THE FORCING

O.V. Podladchikova, B. LEFEBVRE, V. Krasnoselskikh (LPCE/CNRS, 3A av. de la Recherche Scientifique, 45071 Orleans, France)

We model coronal heating of the quiet corona by means of micro flares in the framework of a "sand-pile" model. There exist such models of self-organised criticality applied in this context [1,2]. Here, we are interested in examining the dependence of characteristics of energy dissipation upon the statistical characteristics of the magnetic fields sources (forcing). The dissipation process is assumed to take place when the characteristic current density exceeds some threshold. This corresponds to the formation of multiple reconnection sites with small-scale current layers. It is shown how does energy dissipation is influenced by probabilistic as well as deterministic forcing terms.

THE SOLAR WIND

W.I. AXFORD and J.F. Mckenzie (Max Planck Institut fur Aeronomie, 37191 Katlenburg-Lindau, Germany.

In order to model the solar wind it is first necessary to understand that only the fast wind can be regarded as being time-stationary and that the slow wind is mainly an assembly of filamentary structures each carrying a non-stationary wind with an individual history and varying connection to the Sun. The fast wind is heated and accelerated by relatively high frequency waves which are emitted from the chromospheric network with an unknown spectrum and which ultimately damp mainly by cyclotron absorption. The latter has a characteristic effect on the behaviour of the plasma, notably in the ion temperature anisotropy and the heating and acceleration of minor ions. Furthermore it is essential that the correct geometry be used. It is also necessary eventually to match the solar wind solution to the source of the wind in the network: this is not simple because the source of energy probably lies in microflare activity which is inherently time- dependent and inhomogeneous. We describe a model of the fast wind which satisfies these requirements and also appears to be in good agreement with observations. Our approach is iterative in that we must first assume a heating function associated with wave damping, then calculate the corresponding wave pressure gradient and finally to determine the wave spectrum from a suitable wave transport equation assuming that the waves are Alfvenic. We also assume that wave-particle interactions determine the effective particle mean free path rather than Coulomb interactions and hence that ion heat conduction and viscosity do not play an important role. It is inevitable on the basis of a model of this type that the corona is very hot, the plasma accelerates rapidly within the first few solar radii and the minor species have temperatures per atomic mass unit which exceed the proton temperature and accordingly are accelerated more rapidly. There appears to be little room for any FIP effect apart perhaps from helium. The ion charge distributions must be determined by a high energy tail in the electron energy distribution and do not reflect the coronal temperature of the core electron.

PRIMARY FLOWS, THE SOLAR WIND AND THE CORONA

Swadesh MAHAJAN (Institute for Fusion Studies, The Univ. of Texas, Austin, TX 78712; email: mahajan@peaches.ph.utexas.edu); Riczard Miklaszewski (Institute of Plasma Physics and Laser Microfusion, 00--908 Warsaw, Str. Henry 23, P.O. Box 49, Poland; email: rysiek@ifpilm.waw.pl); Kommunela Nikol'skaya (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation (IZMIRAN), Troitsk of Moscow Region, 142092 Russia; email: hellab@izmiran.troitsk.ru); Nana Shatashvili (Plasma Physics Department, Tbilisi State University, Tbilisi 380028, Georgia; email: lkh@cosmr.acnet.ge)

Based on the conjectured existence of primary solar emanations (flows from the solar surface), a model for the Origin of the Fast Solar Wind, and the creation and primary heating of the coronal structures is developed. In this model the directed velocity fields are fully treated. Preliminary results reproduce many of the salient observational features both for the SW and for the structures which comprise the solar corona (for the quiescent Sun). We also derive the flux constraints on the primary emanations if they are to be the primary source which provides, on a continuous basis, much of the required material and energy. It is co-primacy accorded to the flows which is the distinguishing component of our model. The strong interaction between the fluid and the magnetic aspects of the plasma results in opening new avenues to explore the solar atmosphere. For example, we find that it is possible to have a fastly varying (spatially) velocity field with a relatively smooth magnetic field. The viscous dissipation of this velocity field, then, provides the primary, uniform heating for the coronal structures.

AN MHD MODEL OF TWO REGIMES OF THE POLAR SOLAR WIND ACCELERATION

Dr. Yuri PISANKO, Institute of Applied Geophysics, Rostokinskaya st.9, Moscow 129128, Russia; tel.: 007095-1813312; fax: 007095-1877513; Email: geophys@ns.wmc.rssi.ru

Remote observations of the polar corona on board of the SOHO have detected two different regimes of the rapid polar solar wind acceleration on the first few solar radii above the solar surface (presentations at the 5th SOHO Workshop by Kohl et.al. and by Brueckner et.al.). An attempt is made to propose an MHD model to describe both regimes taking into account the rotation of the magnetized Sun as an expansion under the inverted Rossby number. The model (Habbal & Tsinganos,1983,JGR,88,1965) of the steady isothermal solar wind with momentum deposition allowing a continuous (Parker's) solution as well as solutions with shock discontinuities is used as zero-order approximation (absence of rotation). The rotation induced effects, i.e. the double electric layer in the polar corona and the system of field-aligned electric currents above the double layer creating the additional pressure gradient and hence the additional polar solar wind acceleration are taken into account in the first-order approximation (slow rotation). In the framework of this model 1) the empirical polar solar wind acceleration curve derived from H I Ly alpha emission line intensity measurements from the SOHO UVCS (Kohl et.al.) is successfully simulated when a continuous (Parker's) solution is used as zero-order approximation; 2) SOHO LASCO observations of high (terminal) polar solar wind velocities close to the solar surface (Brueckner et.al.) are successfully simulated when a discontinues solution with shock transition (and momentum deposition) is used as zero-order approximation.

THOUGHTS ON THE FUTURE OF THE SOLAR WIND THEORY

L. OFMAN (Raytheon ITSS/NASA GSFC, Mail Code 682, Greenbelt, MD 20771, USA)

Solar wind has been studied theoretically for more than forty years since Parker's first paper in 1958. The theory of the solar wind is driven mostly by space based in-situ and remote sensing observations. The theoretical study of the solar wind is important for the understanding of the conditions of the interplanetary environment (i.e., space weather). This computationally

challenging problem parallels somewhat the advances in computational technology.
I will review some of the current solar wind models. These models can produce the gross properties (velocity, density, and temperature) of the solar wind with reasonable accuracy. However, this is usually achieved by an ad-hoc heating function and momentum addition incorporated into the MHD equations. Some of the major unresolved issues in solar wind theory are: the exact mechanism that leads to the heating and the accelerations of the fast solar wind; the mechanism that leads to the uneven flow of the slow solar wind and the transition to the fast flow; the 3D structure of the solar wind; and the excess heating and acceleration of the minor ions. The wealth of recently obtained observations of the solar wind are placing stringent constrains on solar wind models. In addition to the solar wind velocity the models must match the energy input, the mass flux, the density the temperature the magnetic field at the Sun and near Earth, and the unresolved `turbulent' velocities. SOHO observations suggest that the source of the solar wind energy and momentum is in the form of waves, with low-frequency MHD waves and high-frequency ion-cyclotron waves as the major candidates. The development of a global 3D solar wind model that incorporates the self-consistent heating due to waves, and more realistic energy equation that includes collisional and collisionless transport is needed. The ability of such a model to reproduce the observed solar wind is the ultimate test that will allow to rule-out or support various wave-heating and acceleration models.

FUTURE WORK ON CORONAL HEATING AND SOLAR WIND ACCELERATION, OBSERVATIONS

Hardi PETER, High Altitude Observatory / NCAR, Email: hpeter@ucar.edu

The space-based observatories SOHO and TRACE have shown some very interesting results on the structure and dynamics of the Sun and its atmosphere, e.g. the extremely high ion temperatures or the enormous variability in the corona. But one question is still open to debate: how to use these data to distinguish between different types of physical heating processes, as e.g. absorption of high-frequency Alfven-waves or reconnection events? It is of importance to ask this question also of future space-missions, as the Solar Probe or the Solar Orbiter. What can they really contribute to this problem? To what extend will they yield the possibility to measure e.g. high-frequency waves or the change of the magnetic field during reconnection events? Will they enable us to decide if the heating of the closed and open corona and the acceleration of the wind is due to a single or a multiple process? And is it possible to address one of the most interesting questions, namely why the Sun converts just that amount of energy flux into solar wind acceleration that we observe? As the corona and most probably its heating is controlled by the magnetic field, the strength and the direction of the latter one has to be measured in the corona and also in the underlying photosphere in order to study the connection between these two regimes. The up-coming Solar-B mission will enable one to study the photospheric magnetic field with increased spatial and temporal resolution. The development of a large mirror coronagraph combined with IR-polarimetry for measuring the coronal magnetic field is on its way. Finally the interaction with the stellar community should be intensified to take advantage of the study of different types of stars.

ALFVENIC STRUCTURES IN THE MAGNETOSPHERE AND THEIR ROLE IN ION AND ELECTRON ENERGIZATION

K. STASIEWICZ and Y. Khotyaintsev (Swedish Institute of Space Physics, Uppsala Division, SE-75591 Uppsala, Sweden, email: ks@irfu.se)

Alfvenic structures or nonlinear waves associated with large density depletions at small perpendicular scales are commonly observed in the magnetosphere. At lower altitudes (<3000 km) they have characteristics of shear Alfven waves with transverse scale and dispersion related to the inertial electron length. At larger distances, in hot magnetospheric plasma, the Alfvenic structures exhibit kinetic and compressional properties. On the basis of measurements obtained on Freja satellite we show that the Alfvic structures play important role in the electron and ion acceleration and in the formation of magnetospheric plasma cavities. The ion energization is shown to be related to chaotization of orbits and breaking of adiabaticity caused by strong perpendicular electric field gradients within the Alfvenic structures. The electron acceleration is related to the parallel electric field, and ponderomotive effects of the electric field car cause cavitation of ionospheric plasma! ried by inertial Alfven waves.

SOLITARY STRUCTURES, TURBULENCE AND QUASISINUSOIDAL WAVEFORMS OBSERVED IN THE CUSP AT 7-9 RE

J. S. PICKETT, J. D. Menietti, R. M. Braunger, E. B. Bogusch, W. S. Kurth, D. A. Gurnett and J. D. Scudder (all at Department of Physics and Astronomy, The University of Iowa, Iowa City, IA 52242, USA, email: pickett@uiowa.edu) B. T. Tsurutani (Jet Propulsion Laboratory, 4800 Oak Grove Drive, Pasadena, CA 92209, email: btsurutani@jplsp.jpl.nasa.gov)

Two of the waveform receivers who are a part of the Plasma Wave Instrument (PWI) on the Polar spacecraft have captured various waveforms in the cusp at radial distances of 7-9 Re. Both waveform receivers simultaneously sample three orthogonal electric field and three orthogonal magnetic field components (two in the spin plane and one along the spin axis) in the time domain. The Low Frequency Waveform Receiver (LFWR) records the waveforms incident in the 0.1 to 25 Hz range. In normal mode the LFWR samples at 100 Hz for 2.56 s every 28 s. The High Frequency Waveform Receiver (HFWR) records waveforms in the 0.2 to 25 kHz range. In high telemetry rate mode (data formatted into a digital data stream and telemetered directly to the ground), the HFWR samples at 71.43 kHz for 0.45 s every 9.2 s. These PWI waveform receivers obtain typical sinusoidal waveforms, e.g. low frequency equatorial waves and high frequency chorus, hiss and whistlers, throughout each orbit, which can be analysed in a straightforward manner using FFTs. Many of the waveforms obtained in the cusp do not lend themselves to this type of analysis since they appear as pulses, wave packet bursts, quasi-sinusoidal wave trains and turbulence. We have analysed these data in the time domain by transforming them to a B-field-aligned coordinate system. Other methods, such as wavelet analysis, are being used to obtain further information about these waveforms. Examples of the various waveforms and the results of analyses of will be presented. The role that these waves could play in particle acceleration and heating, if any, will be discussed briefly.

GA4.09/W/11-A6 **0920**

NONLINEAR PLASMA WAVES IN THE POLAR CAP BOUNDARY LAYER

Bruce TSURUTANI, J.K. Arballo, L.D. Zhang, D. Croley, (all at Jet Propulsion Laboratory, California Institute of Technology, Pasadena, CA 91109, email: tsurutani@jplsp.jpl.nasa.gov) Jolene Pickett and Donald A. Gurnett, (University of Iowa, Dept of Physics & Astronomy, Iowa City, IA 52242)

We show examples of solitary/nonlinear electric and magnetic plasma wave structures in the POLAR plasma wave data in regions called the Polar Cap Boundary Layer (PCBL). The wave mixture is a form of plasma turbulence and is related to enhanced low energy ions. We discuss the detailed feature of these waves, their global distribution and their possible interplanetary (WIND) control.

GA4.09/W/07-A6 Invited **0940**

FAST SOLITARY STRUCTURES

R. E. ERGUN, C. W. Carlson, J. P. McFadden, L. Muschietti, (Space Sciences Laboratory, University of California, Berkeley, CA.)

Large-amplitude, spatially coherent, plasma structures known as "fast solitary structures" or "electron phase space holes" have been observed in several regions of the magnetosphere including the auroral zone, plasma sheet boundary layer, and bow shock. There has been rapid theoretical progress in understanding these structures. Solitary structures can develop from bidirectional electron beams. Once developed, the one-dimensional properties, parallel to the magnetic field, can be adequately described by analytical treatment as BGK structures. Finally, there is evidence that the structures dissipate by radiating whistler waves. There remains, however, much work to do.
The origin of the bidirectional electron beams, the development of two- or three-dimensional structures, and the observed periodicity at the ion cyclotron frequency are not well understood, nor is the relationship of the structures to parallel electric fields. We show detailed observations from the FAST satellite that suggest that the solitary waves arise from an non-linear process that starts with an ion-cyclotron drift instability. This model can explain many of the observed properties electron solitary structures in the auroral zone including the perpendicular scale size, the periodicity, and the developmentof the bidirectional electron beam.

GA4.09/W/02-A6 **1000**

FAST SATELLITE MEASUREMENTS OF ION HOLE SOLITARYWAVE VELOCITIES USING PARTICLE OBSERVATIONS

J. P. MCFADDEN, C. W. Carlson, R. E. Ergun (all at Space Sciences Laboratory, University of California, Berkeley, CA 94720, USA, Email: mcfadden@ssl.berkeley.edu, cwc@ssl.berkeley.edu, ree@ssl.berkeley.edu)

Ion hole solitary waves are bipolar parallel electric field structures that are associated with up-going auroral ion beams. Recent measurements by the FAST satellite show the largest amplitude solitary waves can produce a measurable energy shift in the electron spectral peak. From the inferred potentials, which can exceed 100 Volts, the solitary waves are determined to be moving at 100-1000 km/s, and have scale sizes of a few kilometers (~10 Debye lengths). Measurements using separated dipole antennas support the high velocity for these structures. These observations contrast sharply with Viking reports of low velocity (5-50 km/s), small size (~100 m), small potential (~1 volt) solitary waves, as inferred from signal delays in separated Langmuir current probes. FAST records similar signals in its Langmuir current probes, however these signals are not caused by a decrease in density within the solitary waves. The current signals appear to be caused by the solitary wave electric field reducing the spacecraft photoelectron current to the probes, which produces a delay given by the wave half-period rather than a delay related to the solitary wave velocity.

MODULATIONAL INTERACTION OF THE LOWER HYBRID WAVES WITH ELF DENSITY PERTURBATIONS IN THE AURORAL IONOSPHERE: ION ACOUSTIC AND KINETIC ALFVEN MODES

V. D. SHAPIRO Physics Department, University of California San Diego, La Jolla CA 92093/0319 USA

It is well known that the auroral ionosphere is a place of very strong lower hybrid wave activity, most probably excited by the fluxes of the precipitated energetic electrons. In the paper a system of equations describing the coupling and modulational interaction of the lower hybrid waves with the extremely low frequency (ELF) density perturbations is constructed and analysed. Two versions of density perturbations in the form of either ion acoustic or kinetic Alfven waves are considered. In the coupling mechanism density perturbations are sustained by Reynolds stresses of the lower hybrid waves, while trapping of these waves into density depletions results in the proper modulation of wave intensity. The modulational instability driven by the coupling has been investigated, and thresholds in the lower hybrid wave energy have been calculated for both types of coupling and compared with observations. The nonlinear evolution of the modulational instability leads to the formation of the magnetic field aligned cavitons of the lower hybrid waves. In the case of ion acoustic cavitons a quasi - stationary structure, similar to those observed in the auroral ionosphere, can be formed. This structure is supported by a balance between the pumping of energy into lower hybrid waves by energetic electrons and energy dissipation due to Landau damping and transverse ion acceleration. In the case of Alfven waves a stationary envelope soliton is formed with the transverse size comparable to the electron skin depth. Lower hybrid oscillations, much shorter in wavelength, are trapped inside the density profile associated with such a structure.

NONLINEAR PROPAGATION OF DISPERSIVE ALFVEN WAVES IN SPACE PLASMAS.

P. K. Shukla Fakultat fur Physik und Astronomie, Ruhr-Universitat Bochum, D-44780 Bochum, Germany

There is a growing interest in understanding the properties of linear and non-linear dispersive Alfven waves in magnetized plasmas. Attention has then been focused on inertial and kinetic Alfven waves, with applications in the Earth's ionosphere and magnetosphere as well as in solar and laboratory plasmas. Our objective here is to discuss some linear and nonlinear mechanisms for generating dispersive Alfven waves in a magnetoplasma. When the amplitudes of dispersive Alfven waves are sufficiently large, they interact nonlinearly with themselves and also with the background plasma, thereby producing many interesting non-linear effects, such as the ponderomotive force driven density cavitation/rarefaction, and charged particle acceleration, energy cascading within the Alfven wave spectra, formation of coherent non-linear structures (envelope Alfvenic shocks, dark and bright Alfven solitons, as well as solitary Alfven vortices), and routes to chaos. Here, we describe the physics of the various non-linear processes involving finite amplitude dispersive Alfven waves, and present details of important non-linear models that could account for the salient features of some coherent non-linear structures. Possible applications of our investigation to space and laboratory plasmas are pointed out.

NONLINEAR ALFVEN WAVES IN SPACE PLASMAS: THEORY AND OBSERVATIONS

Oleg POKHOTELOV (Institute of Physics of the Earth, 123810 Moscow, Russia, Email: pokh@uipe-ras.scgis.ru)

In recent years new experimental results have pointed out the importance of large amplitude small-scale phenomena in auroral ionosphere and magnetosphere. We present a review of the modern theories of large amplitude non-linear inertial and kinetic Alfven waves in space plasmas. A special attention is payed to the study of the Alfven solitary wave structures. High time resoluton measurements performed by recent satellite missions in ionospheric and magnetospheric plasma provide strong evidence that a large number of auroral forms are related to solitary electromagnetic structures of similar sizes. It is shown that some of the observed electromagnetic structures can be described in terms of non-linear theory of large amplitude inertial Alfven waves. The stationary solutions of these equations in the form of a solitary dipole vortex and vortex streets are discussed. The examples of numerical simulation are presented. Such structures can exist in the space as well as in the laboratory plasmas. The generalisation of this theory to the case of relativistic electron-positron plasma is also reviewed. It is shown that the solitary structures in this case can be described by the similar equations which have the stationary solutions in the form, analogous to those in electron-ion plasmas. The deep physical similarity of magnetospheric processes and those in astrophysical plasmas is pointed out.

GA4.09/W/05-A6 Invited **1140**

CAVITATION OF LOWER-HYBRID WAVES IN THE EARTHS IONOSPHERE

H. L. PECSELI (Physics Department, University of Oslo, Norway, Email: hanspe@fys.uio.no), S. H. Kjus (Swedish Institute of Space Physics, Box 812, S-981 28 Kiruna, Sweden, email: solveig.kjus@irf.se), B. Lybekk (Physics Department, University of Oslo, Norway, email: blybekk@fys.uio.no), J. Trulsen (Institute for Theoretical Astrophysics, University of Oslo, Norway, email: jtrulsen@astro.uio.no), A. Eriksson (Swedish Institute of Space Physics, Uppsala, Sweden, email: aie@irfu.se)

Lower hybrid wave cavities detected by the FREJA satellite are analysed. Based on simple statistical arguments by use of signals from two density probes, it is possible to obtain rather general results concerning the individual shapes of these cavities. In particular it is demonstrated that a cylindrically symmetric Gaussian density depletion seems to give a very good fit for a vast majority of cases. The validity of this model is shown to give a great simplification in the interpretation of the data. As a result, a number of well-defined characteristics are obtained which have to be accommodated within an ultimate theory describing the observed wave phenomena. Methods for obtaining the velocity distribution of the cavities are also outlined. The statistical distributions of regions of occurrence, peak density perturbations, and cavity widths are presented, together with distributions of the lower-hybrid wave amplitudes associated with the cavities. Scenarios for the formation of the lower-hybrid wave cavities are discussed.

PARTICLE SIMULATIONS OF SOLITARY WAVES IN THE AURORAL REGION

T. Miyake, Y. Omura, and H. Matsumoto (all at Radio Atmospheric Science Center, Kyoto University, Gokasho, Uji, Japan, e-mail: miyake@kurasc.kyoto-u.ac.jp, omura@kurasc.kyoto-u.ac.jp, matsumot@kurasc.kyoto-u.ac.jp)

We perform two-dimensional electrostatic particle simulations of electron beam instabilities using parameters characteristic of the auroral region. Counter-streaming electron beams interact strongly to form large electrostatic potentials trapping the beam electrons. The potentials coalesce with each other to form electrostatic solitary waves (ESW) which have been observed by recent spacecraft in various regions of the magnetosphere. The nonlinear trapping of the electron beams leads to formation of electron holes in the velocity phase space. We study two cases with different thermal velocity of the electron beams,i.e., cold and warm electron beams. In the case of cold beams, we find two-dimensional potentials are formed under a relatively strong magnetic field corresponding to the electron cyclotron frequency equal to the electron plasma frequency. These two-dimensional potentials, however, are diffused by ions, and disapper with the time scale of the plasma oscillation period of ions. On the other hand, in the case of warm beams, one-dimensinoal potentials elongated in the direction perpendicular to the magnetic field at the saturation phase of the beam instability. As time gose on, these one-dimensional potentials are modulated with the ion gyroradius in the perpendicular direction, leading to formation of two-dimsntional structures which are stable for more than 26 plasma oscillation periods of ions.

GA4.09/W/13-A6 **1220**

ON THE DEVELOPMENT OF ION ACOUSTIC AND ION CYCLOTRON INTERMITTENCY IN THE AURORAL ACCELERATION REGION

Dr Abdelhaq M. Hamza

We analyze a simple model of ion fluctuations (ion acoustic and ion cyclotron fluctuations) driven by an electron current which leads to intermittent fluctuations when the linear growth rate exceeds the wave packet dispersion rate. The fluctuation amplitude $e\phi/T$ can be much larger than the order m_{e}/m_{i} level predicted by quasilinear theory or Manheimer's theory. Although the ion motion is linear, intermittency is produced by the strong nonlinear electron response, which causes the electron momentum input to the ion fluctuations to be spatially localized. We treat the one-dimensional case because it is especially simple from an intuitive and analytical point of view, but it is readily apparent that the effect occurs in a three dimensional magnetised plasma.

SELF-ORGANIZED CRITICALITY-A RATIONAL APPROACH TO TURBULENCE AND COMPLEXITY IN SPACE PLASMA PROCESSES

Chang, Prof Tom

Observations indicate that space plasma processes are generally multiscale, sporadic and localized. Examples include the intermittent nature of the magnetotail, the distribution of double layers in the auroral acceleration region, the fast electron holes and associated wave-particle interactions, the strongly interacting lower hybrid turbulence, solar flares and related disturbances. We suggest that most of these processes can be viewed as driven dissipative systems near "self-organized criticality (SOC)". Self-consistent simulations, cellular automata calculations, scaling laws, and power-law distributions, as well as renormalization group invariant arguments will be provided to demonstrate the plausibility of such a suggestion.

GA4.09/W/08-A6 Invited **1420**

ON TURBULENT RELAXATION OF A COLLISIONLESS PLASMA

Tadas K. NAKAMURA (Fukui Prefectural University, Fukui 910-1195, Japan, email: tadas@fpu.ac.jp)

Relaxation process of a collisionless plasma by a turbulent field is examined based on statistical theory. Essential mechanism of the relaxation process is similar to the "violent relaxation" of stars in a galaxy, which has been proposed by Lynden-Bell [1]. In the present paper, a method using H-function developed by Tremaine et al. [2] is applied. Correcting the flaws of their method, it has been shown that the most probable distribution function is a Maxwellian distribution when the phase space volume is mixed well by the turbulent field. This result explains "Langmuire's paradox"; the reason why the Maxwellian distribution is so commonly found in collisionless plasmas. [1] Lynden-Bell, 1967, MNRAS, v136, p101. [2] Tremaine et al., 1986, MNRAS, v219, p285.

ADVANCED STATISTICAL METHODS FOR ANALYZING SPACE PLASMA MEASUREMENTS

W. WERNIK and M. Grzesiak (both at Space Research Center, Polish Academy of Sciences, ul. Bartycka 18a, 00-716 Warsaw, Poland, email: aww@cbk.waw.pl)

Space plasma is a highly dynamic and irregular medium. Large amplitude fluctuations in the velocity, magnetic field, and density occur over wide range of spatial and temporal scales, suggesting the importance of non-linear processes. Linear analysis techniques, such as auto- and cross-spectra, and correlations, are obviously of limited value when non-linear processes dominate. In recent years sophisticated methods have been developed for detecting and quantifying non-linear systems. Some of those methods are briefly described and illustrated with examples using both synthetic and real data. Methods for testing for nonlinearities in seemingly stochastic data are described. Deeper insight into the physics of non-linear processes provides the wavelet transform. The main advantage of using the wavelet transform is that it preserves the information about local features (e.g. singularities) of the signal and allows its reconstruction only over a given range of scales (frequencies). This property is of particular importance in studying turbulence, which often shows coherent structures apparently related to non-linear processes. The structure function approach commonly used in describing and modelling the intermittent behaviour of turbulence is compared with the wavelet-based modulus maxima method. There are convincing arguments that strong turbulence can be decomposed into coherent structures, and random, stochastic fluctuations. Methods and criteria of such decomposition are presented and discussed. Some concepts developed in the context of dynamic systems, such as the system dimension, Lyapunov exponents, are briefly described. Importance of testing for the significance of the results is emphasised and illustrated.

A WAVELET ANALYSIS OF FIELD-ALIGNED ANISOTROPY IN MHD TURBULENCE

Tim HORBURY (Astronomy Unit, Queen Mary and Westfield College, London, email: t.horbury@qmw.ac.uk) Andre Balogh (The Blackett Laboratory, Imperial College, London)

We present a novel wavelet method of measuring the field-aligned anisotropy of MHD turbulence using single spacecraft observations. Using this method it is possible to calculate the anisotropy of power levels, spectral indices and intermittency. We show how these results can be related to the terms of the two-point correlation tensor of MHD turbulence, and can place limits on the three dimensional structure (for example, "slab" or "2D") of the fluctuations.

GA4.09/E/12-A6 **1520**

VERY LOW AMPLITUDE FLUCTUATIONS WITHIN CO-ROTATING TRAILING EDGES

Elizabeth Lucek (The Blackett Laboratory, Imperial College, London, email: e.lucek@ic.ac.uk) TIM HORBURY (Astronomy Unit, Queen Mary and Westfield College, London, email: t.horbury@qmw.ac.uk) Andre Balogh (The Blackett Laboratory, Imperial College, London) David McComas (Los Alamos National Laboratory, Los Alamos)

Ulysses magnetic field and bulk plasma observations within the trailing edges of high speed streams at mid-latitudes revealed the presence of an unusual population of very low amplitude fluctuations with a broadband 1/f magnetic field power spectrum on scales of minutes to hours. These fluctuations are unlike those in high or low speed streams nearby and often have very low cross helicity levels on hourly scales. This population was present in only some rotations, but has been observed in both Northern and Southern hemispheres. We present these observations, along with the results of a search for similar populations in data from Pioneer 10

A

and 11 and Helios 1 and 2, between 0.3 and 5 AU at low latitudes. The possible origins of this population (solar or local dynamics) are discussed.

INTERMITTENCY OF TURBULENCE IN SPACE PLASMA

Vincenzo CARBONE, Pierluigi Veltri, Luca Sorriso-Valvo Dipartimento di Fisica Universita' della Calabria 87036 Rende (CS), Italy Roberto Bruno Istituto di Fisica dello Spazio, Area di Ricerca di Tor Vergata, Roma, Italy

We present a review of a decade of satellite observations of turbulence in the Solar Wind plasma. Particular emphasis is done on the properties of intermittency of the turbulence, say the departure from a gaussian of the probability distribution functions of both velocity and magnetic fluctuations. The possibility of modelling the non-linear energy cascade taking into account intermittency is also presented.

GA4.09/W/12-A6 Invited **1620**

DISSIPATIVE PROCESSES IN COLLISIONLESS PLASMAS AND COHERENT ELECTROSTATIC NONLINEAR WAVES

MANGENEY A.Despa, Observatoire de Paris-Meudon, 5 Place Jules-Janssen, 92195 Meudon Cedex.

A number of observations made in the collision less plasmas of the earth environment suggest that in many cases the dissipation of large scale "MHD" perturbations occurs through the deformation of the distribution functions (formation of beams, holes, etc.) and the corresponding excitation of plasma waves. One of the striking results obtained in the recent years is that these waves are basically electrostatic and coherent, in the form of solitary structures or modulated wave packets. The details of these waveforms appear to depend of the region of observation, (which determine the plasma regime and the properties of the large-scale fluctuations). In this paper we shall first review the available observational evidence; then we shall discuss the relevant theoretical interpretations and numerical simulations that have been put forward to explain these observations.

THE ALFVEN RATIO TEST RE-EXAMINED

Jack D. SCUDDER (Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa, 52240, USA, email: jack-scudder@uiowa.edu)

From their earliest detection Alfven wave trains and rotational discontinuities have failed the Walen test for the proportionality between the vectorial changes of the magnetic field. The Alfven ratio is defined to be the multiplicative factor times the Walen proportionality factor that relates observed field and plasma flow velocity changes. For interplanetary examples thiss ratio falls between 0.5-0.8 and is systematically low against the value of 1 predicted by Walen. A similar deficit is recorded at Alfven wave structures standing at the magnetopause. This paper will explain the essentials of this discrepancy with a realistic model Alfven, showing that the cause of this systematically smaller Alfven ratio is the mistaken presumption (even for wavetrains dominated by long wavelength power) that the center of mass of the plasma can follow the torsioning of the magnetic field exactly. A much better theoretical and observational test for these structures is the electron fluid velocity that can more agilely follow the torsioning magnetic field. A model and observational tests from the Polar spacecraft will be illustrated that recovers the systematically smaller Alfven ratio for ions, while obtaining the correct Walen ratio for the electrons. Simulations of interplanetary wavetrains recover the small Alfven ratio, demonstrating the cause. Explicit techniques for correcting ion measurements short of measuring the electron flow velocity will be illustrated with the model and data. Interesting insights into the observed frequency (wavenumber) dependence of the Alfven ratio are recovered by this approach by exhibiting the full relationship between the ion flow vector's spatial profile in the wave and that of the magnetic field, demonstrating that it is not of theWalen form.

GA4.09/E/01-A6 **1700**

FLOW TURBULENCE IN THE EARTH'S PLASMA SHEET: WHAT IS GOING ON?

Joseph E. BOROVSKY, Herbert O. Funsten, Elena Neagu, and Richard C. Elphic (all at Space and Atmospheric Sciences Group, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, email: jborovsky@lanl.gov)

The turbulent bulk flows observed by the ISEE-2 spacecraft in the Earth's plasma sheet are examined. It is argued that these bulk flows are owed to an MHD flow turbulence rather than to an Alfven-wave turbulence. The role of magnetosphere-ionosphere coupling on the magnetospheric flow turbulence is examined theoretically. This coupling acts to (1) lower the turbulent Reynolds number of the plasma sheet, (2) introduce a time-delayed viscosity to the plasma sheet flows, (3) preferentially damp out magnetospheric vortexes with angular velocities that are antiparallel to B, and (4) transfer vorticity to larger spatial scales. It is argued that a "viscoelastic-fluid turbulence" description has some validity for the Earth's plasma sheet coupled to the dissipative ionosphere.

MAGNETIC DEPRESSIONS IN THE SOLAR WIND

Markus FRAENZ and David Burgess, Astronomy Unit, Queen Mary & Westfield College, London, E1 4NS,UK. email: m.fraenz@qmw.ac.uk

Magnetic depressions in the solar wind occur on a wide range of temporal scales, starting with magnetic holes with a duration of several seconds extending to larger scale structures of more than 30 minutes duration. Usually these depressions are bound by tangential discontinuities and stabilised by anisotropic proton distributions. Using data of the Ulysses magnetometer instrument we investigate which instability mechanisms can cause the observed structures. On the other hand the high occurrence rate of depressions leads to an asymmetry in the field distribution towards low values of |B|. This asymmetry can be expressed in the skewness of the distribution as a time dependent parameter. We investigate how this parameter depends on solar wind type and how it relates to the observed skewness in the plasma beta distribution. Finally we discuss whether the field asymmetry is a specific signature of instabilities or other non-linear processes leading to field energy loss like e.g. energy cascading.

NONLINEAR SOLITARY ROSSBY VORTICES IN THE EARTH'S IONOSPHERE

Tamaz KALADZE (I.Vekua Institute of Applied Mathematics, Tbilisi State University, 2 University str., Tbilisi, 380043, Georgia, E-mail: kaladze@viam.hepi.edu.ge)

The influence of the interaction between inductive current and the spatially inhomogeneous terrestrial magnetic field on the possibility of the formation of non-linear solitary Rossby vortices in the different slightly ionized D, E and F layers of the Earth's ionosphere is considered. It is shown that such interaction manifests itself only in the E and F layers and leads to the new effects and properties of the Rossby waves. The magnetised Rossby waves and solitary vortices are found in the E layer. The real natural mechanism which can lead to the inversion of propagation direction of free, noncaptured by flows, Rossby waves is indicated. The spatial inhomogeneity of the geomagnetic field causes opposite to the Coriolis force vorticity and in consequence weakens the vortical structures in the E layer. As regards the F layer, acting like viscosity the so-called induction inhibition stipulates the final damping of Rossby waves and solitary vortices. The corresponding rate of damping is defined. Thus, the longlive structures mainly exist in the D layer of the ionosphere in the form of solitary dipole Rossby vortices. Along with two-dimensional structures the three-dimensional pancake and cylindrical Rossby vortices of finite heights are constructed as well in the approximation of incompressible ionosphere. The corresponding original non-linear equations describing the dynamics of vortical formations are obtained.

TURBULANCE AND SOLITARY STRUCTURES IN SPACE PLASMAS

GA4.09/P/01-A6 Poster **1600-01**

STRONG VORTICAL (SOLITARY) TURBULENCE OF THE MIDDLE ATMOSPHERE

George D.ABURJANIA, Vachtang Jandiere (Insitute of Applied Mathematics Tbilisi State University str,. 2 380043, Tdilisi-43, Georgia, Email: aburj@viam.hepi.edu.ge/dtapha.keta.ge)

On the basis of the available data from observations and experiments, we can assume that before natural extraordinary phenomenons and during influence, the processes in the atmosphere develop according to the following scenario. Source of extraordinary influnence exits atmosphereic-pressur disturbances (Acoustic-gravity (AG) waves), over region of it's location by vertical pulsed action on air. AG waves prpogate vertically almost without damping tto the height of E-layer and give rise to collective motion in the form of nonlinear strongly localized AG vortices (solitons) structures. It was found that the energy of AG vortices becomes negative I the E-layer of stratified atmosphere. For the energetic standpoint, this layer is the most appropiate for the formation of these structures; hence they are self-sustaining (like autosolitons) due to dissipative processes. Vortex structures contain traped particales and mixing in an atmosphere can cause strong fluctuations of medium densit and an increase heat and particle transfer. Accordingly, strong turbulence state in atmosphere is excited. We assume turbulence to be gas of ensemblr randomly distribnbuted weakly interacted similar vortices, composing the ground state. We determine density flucuation spectrum and estimate turbulent diffusion coeffcient.

ON THE NATURE OF THE STRONG TURBULENCE OVER CUSP/CLEFT

S. Savin, , S. Klimov, M. Nozrdachev, S. Romanov, Yu. Yermolaev, V. Romanov (all Space Research Inst,, Russian Academy of Sciences, Profsoyuznaya 84/32, GSP-7, Moscow, 117810, Russia, E-mail ssavin@iki.rssi.ru), J.BLECKI, J. Juchniewicz, R. Wronowski (all Space Research Center, Polish Academy of Sciences, Warsaw, Poland), J. Buechner, B. Nikutowski (Max-Planck Inst. Aeronomie, Lindau, Germany), A. Otto (Geophys. Inst., U. Alaska, Fairbanks, USA), C. T. Russell (IGPP, UCLA, USA), K. Stasiewicz (Inst. Space Physics, Uppsala, Sweden), P. Triska (Inst. Atmospheric Physics, Praha, Czechia)

Interball-1 high latitude data have shown that just outside magnetopause main current sheet (MP) and at its boundary the turbulent boundary layer (TBL) exists with the average RMS maximum about 25 nT and the occurrence rate 83%. The compressible and non-compressible magnetic spectra comparison, electric to magnetic field amplitude ratios and the wave polarization have shown that the dominant waves/structures in TBL are consistent with the Alfvenic non-linear vortices (ANV). The trapped particle existence displays the strong non-linearity of the ANV, their characteristic scales are in the range 100-10000 km. The Interball-1 data shows that TBL is registered not only at high latitudes but also at low latitudes in the disturbed conditions; Polar data confirms that in the cusp vicinity. The ANV produce 'magnetic bubbles' with highly reduced magnetic field and heated plasma inside, average ion heating reaches 200-400 eV (i.e. 1.5- 3 times). Part of these 'bubbles' are transported inside MP, they constitute a mechanism of plasma penetration into the cusp/cleft. The geometrically TBL above the outer cusp could be presented as the spot of 6 Re with characteristic amplitude maximum of 37 nT. In the geomagnetic tail the TBL is seen along the mantle/LLBL boundary down to X= - 20 RE that might provide the direct solar wind plasma penetration into the near Earth tail via its flanks. We briefly compare AVN with time dependent 2D MHD and 3D kinetic modeling.

THE SOLITARY STRUCTURES IN OVERDENSE IONOSPHERIC PLASMA

A.V. Kochetov and B.A. Mironov (both at Institute of Applied Physics, N.Novgorod, Russia, e-mail: kochetov@appl.sci-nnov.ru) G.I.TERINA and V.N.Bubukina (both at Radiophysical Research Institute, N.Novgorod, Russia, e-mail: ter@nirfi.sci-nnov.ru)

The results of the modelling of nonlinear dynamic effects arising in the ionospheric plasma under the action of the powerful radio waves are presented. Numerical solutions of nonlinear Schredinger equation in the linearly inhomogeneous plasma layer excited by the heating radio wave were obtained. The processes of the formation of the solitary structures of the electric field and disturbances of plasma density and processes of their relaxation for different values of density gradient and the amplitude of the heating wave were analyzed. The spatial evolution of the electric field and disturbances of the plasma density and time dependencies of the reflected signal were obtained. With the heater turn-on the penetration of the solitary structure into the overdense plasma takes place which increases under the heating power increase and the decrease of the plasma density gradient. The decreasing of the scale of the spatial soliton structure, the periodic and chaotic solitons generation during the heater time are observed. When the heater is turned off, the solitons continue to travel into the overdense plasma for some time, increasing in the amplitude, until they reach the turning point. Then they reflect and

propagate into the underdense plasma, decreasing in the amplitude, and disappear. The obtained results allow to interpret the appearance of the scattered signal after the heater turn-off - "aftereffect plasma signal" (AEPS). This work was supported by the Education Department of Russia (grant N 97-0-5.3-113).

THE PERIODIC GENERATION OF CAVITON FORMATIONS IN MODIFIED IONOSPHERIC PLASMA

G.I.TERINA (Radiophysical Research Institute, Nizhny Novgorod, Russia, e-mail: ter@nirfi.sci-nnov.ru)

Results of experimental study of periodic variations of a "caviton" signal amplitude scattered by caviton formations in sounding of the artificial ionospheric turbulence by probing radio pulses of both ordinary and extraordinary polarization are presented. The experimental data were obtained at "Zimenki" and "Sura" heating facilities. The probing transmitter radiated radio pulses with a duration of 50 mks in the frequency range 5.50-5.87 MHz. The heating transmitter operated in range 4.5 MHz - 4.8 MHz (under sounding by X mode pulses) and 5.5 MHz -5.8 MHz (for O mode pulses). "Caviton" signal (CS) appeared when the heating transmitter was turned on, decreasing then in amplitude. The time dependencies of CS in the main are series of maxima. CS period was changed from a few milliseconds up to several seconds and increased with the decrease of the heating power, the increase of difference of heating and probing reflection heights and during the anomaly attenuation time. The decrease of CS period was observed with the approach of CS scattering height to the reflection height of the probing wave. CS amplitude decreased with CS period increase. At times the periodic and chaotic travel of CS maximum to smaller heights was observed with the velocity of the order and greater the ion sound velocity. The obtained results allow to study the peculiarities of periodic generation of caviton formations, arising in the ionospheric plasma under the action of powerful radio waves. This work was supported by the Education Department of Russia (grant N 97-0-5.3-113).

GA4.09/E/11-A6 Poster **1600-05**

STRUCTURE AND SOURCES OF LONG-PERIOD OSCILLATIONS NEAR HIGH-SPEED FLOWS OF SOLAR WIND

Mikhail Pudovkin (Department of geophysics, The Institute of Physics, St.Petersburg State University, Petrodvorets 198904, Russia, email: pudovkin@snoopy.phys.spbu.ru); Olga KHABAROVA(Department of Solar-Terrestrial Physics, The Institute of Terrestrial Magnetism, Ionosphere and Radiowaves Propagation, Russia 142092, Moscow region, Troitsk; email: MARY.L@izmiran.troitsk.ru)

A little studied phenomenon of a rise of steady long-period magnetohydrodynamic space plasma oscillations near high-speed flows of solar wind is considered in details. These oscillations with period from minutestill hours can be observed nearby both flows from solar flares (having shock wave ahead of main body of the flow) and recurrent flows (distinguished by a smooth profile of parameters increase). The identical structure of such oscillations does not speak about the unified mechanism of generation. The mechanism of the oscillations swing is different in each particular case. The calculations show that the long-period oscillations before flows from solar flares can be explained by a) ion-cyclotron instability of protons reflected from the shock wave, having speed large, than speed of ambient plasma and resonance inducing with MHD-waves (such instability gives periods about minutes for waves running along the magnetic field and about hours for practically perpendicular propagating waves) b) instability produced by reflection of cosmic rays from the shock wave (the wave, swayed by this way have maximum amplitude at perpendicular propagation and periods of oscillations from minutes till hours).
The oscillations inside the body of flare's flow can be considered as a result of Alfven wave passage through front of strong shock wave. The oscillations near recurrent flows can explain by gradient instability. The various periods of oscillations are corresponded to various component of plasma gradients.
The recurrent flows are registered after interception of the sector boundary more often. It can result in wrong treatment of the cause of considered oscillations appearance. I.e. the oscillations can be attribute of the current layer which generate MHD-waves at magnetic reconnection. An experimental material that illustrates above-mentioned mechanisms is selected.

ELECTRON ACCELERATION BY ALFVEN WAVES: FREJA AND SOUNDING ROCKET OBSERVATIONS

Y. KHOTYAINTSEV, K. Stasiewicz, M. Berthomier Swedish Institute of Space Physics, Uppsala Division, S-75591 Sweden e-mail: yuri@irfu.se M. Ivchenko Alfven Lab, Royal Institute of Technology, Stockholm, S-10044 Sweden

Alfven waves with frequencies of several Hz are usually observed in the auroral zone. In the low-beta ionospheric plasma Alfven waves are in the inertial mode. Field aligned electron populations with egergies 50-5000 Ev streaming through cold background plasma are observed in spatially localized regions with perpendicular to the magnetic field size in order of electron inertial length. Using observations from Freja and sounding rockets we show that electron acceleration is most likely caused by parallel electric field of the inertial Alfven wave.

ON PLANETARY NONLINEAR SOLITARY VORTICES IN THE MESOSPHERE

Anzor Gvelesiani (Georgian Academy of Sciences, Institute of Geophysics, 1 Alexidze Str., Tbilisi 380093, Georgia), Tamaz KALADZE (I. Vekua Institute of Applied Mathematics, Tbilisi State University, 2 University str., Tbilisi 380043, Georgia, E-mail: kaladze@viam.hepi.edu.ge)

The theory of nonlinear solitary dipole Rossby vortices for explanation of vortical perturbations in fields of wind's velocity and atmosphere's temperature (Energy Budget Campaign, 1980) observed at different heights of atmosphere is supposed. The corresponding calculations of parameters of spatially localized perturbations moving during the 1 week along parallel towards the East with the velocity of 10 m/s and transverse size of 1000 km are carried out. The comparison of numerical calculations by means of supposed theoretical model for nonlinear solitary dipole vortices with characteristics of observed longlive wave perturbation in the mesosphere (at heights of 80 km) shows the satisfactory agreement.

ION-ACOUSTIC SOLITONS AND DOUBLE LAYERS IN A TWO-ELETRON TEMPERATURE PLASMA

S.G.TAGARE (Department of Mathematics and Statistics, University of Hyerabad, Hyderabad 500046, India,. email: sgtsm@uohyd.ernet.in)

It is found that two-electron temperature plasma with isothermal par electrons and cold ions admits both compressive and rarefactive solitons par as well as compressive and rarefactive double layers (depending on the par concentration of low-temperature electrons). We have derived K-Dv par equation and and K-dV type equations with cubic and fourth order par nonlinearity at the critical density of low-temperature isothermal par electrons to discuss the properties of ion-acoustic solitons intwo-electron temperature plasma. In the vicinity of the critical electron density of low-temperature isothermal electrons we have derived K-dV type equation with mixed nonlinearity and solution of this equatiuon will have both compressive and rarefactive double layers for those values of critical electron density of low-temperature

MARS PRESENT AND FUTURE. UPPER ATMOSPHERES AND THEIR INTERACTIONS WITH THE SOLAR WIND

GA4.10/W/14-A4 Invited **0900**

THE MARS THERMOSPHERE: GLOBAL MGS ACCELEROMETER MEASUREMENTS

G.M. KEATING, R.H. Tolson, S.N. Noll, T.J. Schellenberg, R.L. Stephens, M.S. Bradford, D.T. Baird (all at George Washington University/NASA Langley, Hampton, VA, USA), S.W. Bougher (University of Arizona, Tuscon, AZ, USA) and J.L. Hollingsworth (NASA Ames, Mountain View, CA, USA)

An accelerometer experiment aboard the Mars Global Surveyor has provided insitu measurements of nearly 1000 vertical structures of the Mars thermosphere, compared to only 3 previously (Viking 1, Viking 2, Pathfinder). These measurements of vertical and latitudinal variations in density, temperature and pressure have been obtained in the afternoon in both the Northern and Southern Hemispheres between 110 and 170 km. The accelerometer experiment along with lower atmosphere measurements, has allowed us to establish the linkage between processes in the upper and lower atmosphere as well as linkage with topography. Unexpected results include: (1) enormous thermospheric responses in the Northern Hemisphere to regional dust storms in the Southern Hemisphere, (2) stationary (apparently topographically forced) planetary waves in the thermosphere which rotate with the planet creating factor of 2 variations with longitude, and (3) thermospheric densities persistently much higher than indicated in GCM's. The physical processes possibly responsible for these phenomena are discussed.

GA4.10/W/13-A4 Invited **0930**

SOLAR WIND INTERACTION WITH MARTIAN CRUSTAL MAGNETIC ANOMALIES

D. L. MITCHELL, R. P. Lin, M. OIEROSET (Space Sciences Laboratory, Univ. of Calif., Berkeley), D. Crider, C. Law, P. Walker, P. Cloutier (Rice Univ., Houston, TX), and M. H. Acuna (NASA-GSFC, Greenbelt, MD)

While aerobraking beneath the ionosphere, the Magnetometer/Electron Reflectometer (MAG/ER) experiment onboard the Mars Global Surveyor spacecraft has detected numerous magnetic anomalies in the martian crust, many of which exceed 100 nT at spacecraft orbital altitudes of ~110-170 km. Despite these strong local anomalies, the global dipole moment is less than 2 x 10^21 G-cm^3 and cannot contribute significantly to the effective size of the

obstacle presented by Mars to the solar wind. Consequently, the solar wind interaction with Mars is similar to that at Venus and at an active comet, that is, primarily an ionospheric-atmospheric interaction. During a typical periapsis pass, a distinct boundary is observed at ~300-500 km altitude where the flux of 0.1-1.0 keV electrons drops abruptly by about an order of magnitude. This is accompanied by a dramatic change in the electron energy spectrum: above the boundary, the spectrum is characteristic of the solar wind, while below the boundary, the spectrum is dominated by ionospheric photoelectrons. The photoelectron spectrum extends to ~1 keV and exhibits an Auger peak at ~500 eV, which is produced by K-shell ionization of atmospheric oxygen. This electron boundary marks the location where the solar wind is deflected around the ionospheric obstacle, resulting in a horizontal magnetic field that inhibits vertical transport and mixing of the solar wind and ionospheric plasmas. Occasionally, the spacecraft passed over a strong crustal magnetic anomaly while inside the ionosphere, resulting in a significant vertical field component. During this time, both the solar wind and photoelectron energy distributions are observed simultaneously. Photoelectrons travel upward along the magnetic field lines and out into the solar wind, while solar wind electrons precipitate downward into the atmosphere. This observation indicates that the crustal magnetic field is connected into the solar wind, providing a conduit for the exchange of ionospheric and solar wind plasmas.

GA4.10/W/12-A4 0950

STRUCTURE OF THE IONOSPHERES OF VENUS AND MARS

Andrew F. NAGY (Dept. Atmospheric, Oceanic and Space Sci., U. of Michigan, Ann Arbor, Mi., 48109, U.S.A., Email: anagy@umich.edu)

The ionospheres of the two terrestrial planets Venus and Mars are believed to have significant similarities. The composition and structure of the neutral upper atmospheres of both planets are CO2 dominated and the their temperatures are in the 200 to 300 o K range. A great deal of direct information is available about the ionosphere of Venus, mainly from measurements obtained by instruments carried aboard the Pioneer Venus Orbiter. On the other hand, the only direct ionospheric data from Mars are the two vertical profiles obtained by the retarding potential analyzer carried aboard the Viking landers. A large number of one and multidimensional models have been developed to describe the ionospheric structure of both planets. The Venus models were reasonably well constrained by the measurements, while the Mars calculations were guided to a degree by analogies to Venus. In this talk the obervational data base and the relevant model results are summarized and critically reviewed.

GA4.10/E/05-A4 1005

STRUCTURE AND DYNAMICS OF THE MARTIAN IONOSPHERE

Hiroyuki SHINAGAWA (Solar-Terrestrial Environment Laboratory, Nagoya University, Toyokawa 442-8507, Japan, email: sinagawa@stelab.nagoya-u.ac.jp)

The Mars Global Surveyor found that the surface magnetic field is likely to be smaller than about 5 nT, indicating that the solar wind interaction with Mars is similar to the solar wind-Venus interaction. This fact also suggests that the Martian ionosphere is filled with the solar wind-induced magnetic field, and that the magnetic field lines are transported downward in most of the dayside ionosphere. On the other hand, relatively large O2+ density in the topside ionosphere observed by the Viking spacecraft suggests that the ionospheric plasma should be transported upward. The observed electron density profiles of Mars also appear to be significantly different from those of Venus. Similarities and differences between the Martian ionosphere and the Venus ionosphere will be discussed based on our ionospheric MHD model of Mars. A few possible scenarios of structure and dynamics of the Martian ionosphere will be presented.

GA4.10/L/05-A4 1040

VARIABILITY OF THE MARS THERMOSPHERE : MGS TRENDS AND MODEL INTERPRETATION

S. W. BOUGHER (Lunar and Planetary Laboratory, University of Arizona, Tucson, AZ 85721; email: sbougher@lpl.arizona.edu); G. M. KEATING (George Washington University, NASA Langley, Hampton, VA 23681); J. R. Murphy (New Mexico State University, Las Cruces, NM 88003); J. L. Hollingsworth (NASA Ames Research Center, Moffett Field, CA 94035)

Mars Global Surveyor (MGS) recently obtained coordinated lower-atmosphere (thermal and/or dust) measurements and simultaneous upper atmosphere accelerometer data (densities, scale heights, temperatures) yielding the first quantitative glimpse of the lower atmosphere processes driving Mars thermospheric variations during low to mildly dusty conditions and during a regional dust storm event [Keating et al. 1998]. In particular, measurements from the z-axis accelerometer (ACC) aboard MGS have provided to date more than ~1000 vertical structures of the Mars thermospheric density and derived temperature and pressure, as compared to only 3 previous in-situ profiles. These data have been obtained over two distinct Mars seasons spanning solar minimum to moderate conditions: (Phase I) 7-months approaching perihelion from southern Spring to early Summer (Ls = 180 to 300), and (Phase II) 4.5-months near aphelion from northern Spring to early Summer (Ls = 30 to 95). The sampling coverage (170 km to as low as 110 km over most latitudes, limited local times, and selected longitudes) has permitted solar and seasonally driven variations to be monitored in the Mars thermosphere as a function of latitude, longitude, local time and altitude. Also, ``deep atmosphere weather'' patterns are visible at thermospheric heights, and may be composed of both stationary (fixed to surface features) and traveling planetary waves. Finally, the Noachis regional dust storm of late-1997 illustrated a global atmospheric expansion (contraction) with the onset (decay) of the storm consistent with lower atmosphere heating (cooling) and dust. Initial model studies have been conducted to simulate the Mars thermosphere variations and the lower atmosphere coupling observed by MGS measurements [Bougher et al. 1998]. The Mars Thermospheric General Circulation Model (MTGCM) (70-300 km) and the NASA Ames Mars General Circulation Model (MGCM) (0-90 km) have been crudely coupled for this purpose. Early simulations suggest that the mean solar cycle, seasonal-orbital, latitude, and diurnal variations of the Mars lower thermosphere (aerobraking altitudes) are generally reproduced. However, observed day-to-day variations over 100 to 130 km (especially longitude fixed variations) are not well modeled, owing to missing dynamical processess. Also, simulations have thusfar not been able to reproduce the rapid thermal expansion or the global response of the Mars atmosphere to the Noachis event. An improved coupling scheme is needed linking the MGCM and MTGCM to address these ``deep atmosphere weather'' features.

GA4.10/L/02-A4 1055

NEW ORBIT PLAN OF PLANET-B(NOZOMI) AND EFFECTS ON MARTIAN UPPER ATMOSPERE STUDY

K. TSURUDA, H. Hayakawa, and I. Nakatani(The Institute of Space and Astronautical Science, 3-1-1, Yoshino-dai, Sagamihara, Kanagawa 229-8510, Japan)

Japanese Mars orbiter Nozomi(Planet-B) was launched on July 4th, 1998. The main scientific objective of Nozomi is to study the interaction of Martian ionosphere with the solar wind. For this purpose, the Nozomi spacecraft carries 14 scientific instruments and takes an elliptical orbit of low periapsis altitude(150 km) and relatively large apoapsis distance of 15 Mars radii. The low periapsis altitude is chosen to study the structure and dynamics of the ionosphere under the strong interaction with the solar wind and large apoapsis distance is employed to study the Martian tail region where the escaping ionospheric ions will be detected. Nozomi was supposed to arrive at Mars on October 11, 1999, but unfortunately one of the valve in the engine module did not open completely during its departure from the Earth orbit on December 20, 1999 and Nozomi had to use more propellant to compensate the shortage of the thrust. As this result, it becomes difficult for Nozomi to be captured in the planned Mars orbit in 1999. ISAS decided to take another orbit scenario for Nozomi. According to the new orbit plan, Nozomi takes three rotations around the sun, twice Earth swing bys and arrives at Mars in December 2003. The propellant budget is sufficient for this new orbit scenario and originally planned orbit at Mars can be accomplished. Effects of this delayed arrival at Mars on Martian upper atmosphere study and possible sciences during Nozomi's long cruising in the interplanetary space will be discussed.

GA4.10/L/03-A4 1110

SOLAR WIND VARIABILITY OF THE MARTIAN HOT OXYGEN CORONA: DETECTION CAPABILITY OF PLANET-B

Helmut LAMMER (Institute of Space Research, Austrian Academy of Sciences, Elisabethstrasse 20, A-8010 Graz, Austria, Email: helmut.lammer@oeaw.ac.at); Willibald Stumptner and Siegfried J. Bauer (both at Institute for Space Research, austrian Academy of Sciences and Institute of Meteorology and Geophysics, University of Graz, Halbaerthgasse 1, A-8010 Graz, Autria, Email: willibald.stumptner@oeaw.ac.at).

The Japanese Planet-B spacecraft will have the possibility to detect for the first time in-situ with the neutral mass spectrometer the suggested hot oxygen corona on Mars, if the corona number density is at least in the order of 10000 [cm-3]. Since the most important mechanism for the production of the hot oxygen atoms in the Martian exosphere is electron dissociative recombination of ionospheric molecular oxygen ions, we investigated the solar wind variability of this production mechanism. Results from the Viking and Mars Global Surveyor missions have been used for this study. The resulting influence of the corona number density distribution was calculated with a Monte Carlo technique.
The Monte Carlo technique is used to simulate the atomic diffusion process in the Martian atmosphere by simulating the collision probability, particle direction and energy loss after collisions with random numbers. Our results show that the detection capability of the hot oxygen corona by Planet-B requires periods of high solar activity, which should occur during the Planet-B measurement phase. however, insitu-measurements of the hot oxygen number density would be important for adjusting atmospheric escape models, which is significant for evolution studies of the Martian atmosphere.

GA4.10/W/24-A4 1125

STUDIES OF THE SOLAR WIND - MARTIAN ATMOSPHERE INTERACTION BY ESA'S MARS EXPRESS

R. LUNDIN, S. Barabash and O. Norberg (Swedish Institute of Space Physics, Kiruna, Sweden)

Lacking a strong intrinsic magnetic field the planet Mars is continuously subject to atmospheric scavenging by the direct impact of solar wind plasma on the topside atmosphere. This scavenging process is known to be significant, depleting the present atmosphere at a rate corresponding to a total depletion in about 108 years. A possible source of replenishment, maintaining the existing atmosphere, may be subsurface deposits of volatiles. This also raises the question about the higher abundancy of volatiles that existed in the past. Is the main reason for loss of the martian atmosphere and hydrosphere indeed due to the solar wind interaction? One important science objective of the ESA Mars-Express mission is to study the solar wind interaction with the martian atmosphere using a partly new measurement technique - energetic neutral atom (ENA) imaging. Combined with measurements of the ionospheric plasma outflow, the ENA technique will make it possible to study the outflow locally (plasma) as well as globally (ENA imaging). A determination of the net outflow of energetic neutrals from the martian upper atmosphere will also be provided by the ENA-technique. Altogether, the objective is to provide a much improved quantitative measure of the loss from the martian atmosphere.

GA4.10/L/01-A4 1145

NUMERICAL SIMULATION OF MASS LOADING EFFECTS ON THE SOLAR WIND INTERACTING WITH THE MARS ATMOSPHERE

Yu Yi (Department of Astronomy and Space Science, Chungnam National University, Daejon, South Korea, E-mail: euyiyu@hanbat.chungnam.ac.kr), Jhoon Kim (Korea Aerospace Research Institute, Daejon, South Korea, Email: jkim@viva.kari.re.kr), Eojin Kim and Yong Ha Kim (both at Department of Astronomy and Space Science, Chungnam National University, Daejon, South Korea, E-mails: ejkim@astro6.chungnam.ac.kr, yhkim@hanbat.chungnam.ac.kr),

A three-dimensional compressible magnetohydrodynamic simulation of solar wind interaction with the Martian atmosphere was carried out to investigate the influence of pick up ion mass loading on the global structure of Mars magnetosphere. The code used for a simulation of comet interacting with solar wind [Yi et al. 1996] was modified for this purpose. It was assumed that the neutral atmosphere consists of mainly oxygen atoms and carbon dioxide molecules, whose radial distribution profiles were modeled with a spherical symmetry. It was also assumed that the neutrals ionized by solar EUV contribute for mass loading on the solar wind. The simulation was able to produce the similar features of the interaction of solar wind with the Venus atmosphere such as the bow shock, the magnetopause and the magnetic tail boundary even though those values are weaker.. The results were compared with results from pure gas dynamic simulations with and without the mass loading. The plasma and field measurements of NOZOMI, which is expected to arrive at Mars on October 1999, were predicted based on this simulation.

GA4.10/P/03-A4 1200

EFFECTS OF MAGNETIC FIELD ON THE NIGHTSIDE IONOSPHERE OF MARS: SOLAR WIND - MARS INTERACTION

S. A. HAIDER (Physical Research Laboratory, Ahmedabad 380 009, India, email: haider@prl.ernet.in; S. P. Seth (Bhavan's R. A. College of Science, Ahmedabad 380 001, India); Anil Bhardwaj (Space Physics Laboratory, Vikram Sarabhai Space Centre, Trivandrum 650 022, India).

Among the planets of solar system, our knowledge of magnetic field on Mars are not enough.

From the available data of magnetic field measurements onboard Mariner 4, Mars 2, 3, 5 and Phobos 2, several workers have reported that Mars has weak intrinsic magnetic field. Others have indicated that the Martian magnetic field is associated with interplanetary magnetic field. Recently, the Mars Global surveyor spacecraft has obtained magnetic field and plasma observations above 100 km. This observation suggests that solar wind interaction with Mars is in many ways similar to that of Venus, that is, primarily ionospheric-atmospheric interaction. To understand the solar wind - Mars interaction and its dynamical effect on the night-time ionosphere, a theoretical model has been developed to study ion and electron densities. In this model the production rates of N2+, O2+, O+ and CO2+ in the nightside ionosphere of Mars are calculated using analytical yield spectrum approach due to ion transport from the dayside by analogy to Venus where horizontal plasma transport was found to be an important source of nightside ionosphere in absence of intrinsic magnetic field of the planet. Later these production rates were used in continuity and momentum equations for the calculation of ion and electron densities. In this model the magnetic field in the ionosphere is assumed purely induced and horizontal. It is found that the ion loss due to horizontal plasma motion in presence of induced magnetic field is an important process for all ions above 150 km. Below this altitude the ionosphere of Mars is controlled by chemical equilibrium condition.

GA4.10/W/10-A4 1215

MULTI-FLUID MHD STUDIES OF THE SOLAR WIND INTERACTION WITH MARS

Yifan LIU, A. F.Nagy, T. I. Gombosi, C. P. T. Groth, D. L. DeZeeuw and K. G. Powell (University of Michigan, Ann Arbor, MI., USA; e-mail: anagy@umich.edu)

The interaction of the solar wind with non magnetic planets, such as Mars and Venus, involves their ionospheres. Single fluid MHD models, which incorporate some of the important mass-loading processes, have been useful in reproducing a variety of the observed features at these planets, such as the location of the bow shock, for example, but they do have obvious limitations. In our continuing, step-by-step, effort to develop appropriate and comprehensive models to study all of the interaction processes, we are developing a multi-fluid MHD model, based on the so called BATS-R-US (Block Adaptive-Tree Solar-wind Roe-type Upwind Scheme) numerical code. Our present model is a two-fluid one, which considers hydrogen and atomic or molecular oxygen ions, separately. We have used this model to study the interaction processes at Mars. We present results for mass- loaded simulation studies; we have paid special attention to the fluxes of oxygen ions in the tail, in order to be able to make comparisons with observations.

HOW THE SOLAR WIND INTERACTION WITH WEAKLY MAGNETIZED PLANETS CAN AFFECT ATMOSPHERE EVOLUTION: WHAT WE KNOW AND DON'T KNOW

J.G. LUHMANN (Space Sciences Laboratory,University of California, Berkeley, CA 94720, USA, email: jgluhman@ssl.berkeley.edu); R.E. Johnson (Department of Engineering Physics, University of Virginia, Charlottesville, VA 22901, USA, email: rej@virginia.edu); S.H. Brecht (Bay Area Research, Orinda, CA 94563, USA, email: brecht@hooked.com)

We review current understanding of the processes by which planets like Mars and Venus may have lost substantial amounts of atmosphere because they had weak internal magnetic fields throughout much of their early history. These processes include atmospheric ion pickup, sputtering by the pickup ions, and charge exchange with solar wind ions, which have occurred in addition to photochemically mediated escape, impact erosion, and hydrodynamic escape.
A major challenge confronting atmosphere evolution modelling is the lack of unambiguous constraints on many of the assumed conditions and parameters involved. We suggest work that can be done, including measurements, that would help us to narrow the range of possible evolutionary scenarios for such planetary atmospheres, and lead to a better evaluation of the solar wind's role.

GA4.10/L/06-A4 Invited 1430

EFFECTS OF PLASMA MIXING PROCESSES ON THE SOLAR WIND INTERACTION WITH NON-MAGNETIZED PLANETS

T. TANAKA (Communications Research Laboratory, Koganei-shi, Tokyo 184-8795, Japan, email: tanaka@crl.go.jp)

The solar wind interaction with the ionosphere of non-magnetized planets is numerically simulated in the framework of 3-D magnetohydrodynamics (MHD) with a two-component plasma. In cases 1 and 2, solar extreme ultraviolet (EUV) flux values is set so the peak ionospheric plasma pressure is below and above the incident solar wind dynamic pressure. While the formation of the bow shock and the magnetic barrier in the upstream region is seen in both cases, a clear formation of the ionopause is seen only in case 2.
In case 1, the interplanetary magnetic field (IMF) penetrates from the magnetosheath to the dayside ionosphere so as to adjust the ionospheric total pressure. Penetrating IMF affects the vertical motion of the ionospheric plasma. However, formation process of the ionotail is little affected by the penetrating IMF. In both cases 1 and 2, partial penetration of the IMF occurs from the magnetic barrier to the terminator ionosphere. The penetrated magnetic field emerges in the ionohole on the nightside. This nonideal MHD process characterized by the penetration of flowing magnetized plasma into non-magnetized plasma plays a principal role in the mixing interaction between the solar wind and the planetary ionosphere.

GA4.10/W/30-A4 1450

WIND ENHANCED ESCAPE, ION PICKUP AND THE EVOLUTION OF WATER ON MARS

R. E. HARTLE and H. G. Mayr (NASA-Goddard Space Flight Center, Greenbelt, MD Email: hartle@carioca.gsfc.nasa.gov)

Preferential loss of hydrogen over deuterium from Mars has produced a deuterium rich atmosphere possessing a D/H ratio 5.2 times that of terrestrial water. Rayleigh fractionation is applied, constrained by the deuterium enrichment factor, to determine the magnitudes of ancient and present water reservoirs on the planet. The dominant loss mechanisms of H and D from the current atmosphere are thought to be thermal escape and solar wind ion pickup of the neutral and ion forms of these constituents, respectively. During an earlier Martian epoch, only thermal escape was significant because Mars had a terrestrial sized magnetosphere that protected the atmosphere from solar wind scavenging processes. The magnitudes of present and ancient water reservoirs are estimated when thermal escape is considered alone and subsequently when the effects of ion pickup are added. The escape fluxes of H and D are significantly increased above the respective Jeans fluxes when the effects of thermospheric winds and planetary rotation are accounted for at the exobase. Such wind enhanced escape also increases as the mass of an escaping constituent increases; thus, the increase in the escape flux of D is greater than that of H. When the fractionation process is also constrained by the D/H ratio observed in hydrous minerals of SNC meteorites, an ancient crustal reservoir of Martian water is derived, tens of meters in global-equivalent depth, considerably exceeding that obtained with no winds. The reservoir becomes even larger when ion pickup processes are added.

GA4.10/W/04-A4 1505

2D HYBRID SIMULATIONS OF THE SOLAR WIND INTERACTION WITH MERCURY

M.HOPCROFT, S.C.Chapman (University of Warwick, Coventry, UK)

The results of an investigation into the interaction of the super-magnetosonic solar wind flow around Mercury, and the planet as a field and plasma source are presented. We wish to identify the key processes of energy momentum transfer that results in the global magnetospheric structure observed. Mercury is of particular interest as the typicalgyroradius of its pick- up ions is slightly larger than the planet itself, and so of the order of the characteristic scale of the magnetosphere.
The investigation was conducted by means of 2D hybrid numerical simulations which represent spatial coordinates in two dimensions whilst resolving three dimensional fields, velocities and bulk plasma vector variables. The hybrid scheme represents ion velocity distributions with computational particles advanced via the Lorentz force law, and the electrons via fluid equations where the inertial term has been neglected, the plasma is quasineutral. The source region consists of an inner dense core and an outer halo, to represent thermal and particle sputtered populations respectively. We examine the relative importance of these regions and the effect of including the planets' intrinsic magnetic field.

GA4.10/W/29-A4 1520

MAGNETOHYDRODYNAMIC SIMULATIONS OF THE VARIABILITY OF THE MARS BOW SHOCK

Eojin KIM, Yu Yi, and Yong Ha Kim (all at Department of Astronomy and Space Science, Chungnam National University, Daejon, South Korea, e-mail: ejkim@astro6.chungnam.ac.kr, euyiyu@hanbat.chungnam.ac.kr, yhkim@hanbat.chungnam.ac.kr), Jhoon Kim (Korea Aerospace Research Institute, Daejon, South Korea, Email: jkim@viva.kari.re.kr)

To investigate the variability of the Mars bow shock, a three-dimensional numerical magnetohydrodynamic simulations of solar wind interaction with Martian atmosphere were performed. In this calculation, a neutral atmospheric model was assumed as a source of mass loading ions. Only photoionization due to solar radiation was provided as an ionization mechanism. The neutral atmosphere was modeled with the oxygen and carbon dioide cloud. The simulation produced the global features of the interaction of solar wind with the atmosphere of unmagnetized planet such as the weak bow shock and the magnetic barrier. The influences of different values of solar wind parameters such as density, velocity and the interplanetaty magnetic field were considered to study the changes of Martian global structure due to those variations. In addition, several Martian atmospheric neutral oxygen density distribution profile models were tested. The best-fit parameters of solar wind and the variables of the neutral density distribution model were found to match the bow shock positions distances observed by the previous Mars exploration spacecraft.

GA4.10/W/22-A4 1600

GENERATION AND TRANSPORT OF DUSTY PLASMAS IN THE ENVIRONMENT OF OUTER PLANETS

Mihaly HORANYI (Laboratory for Atmospheric and Space Physics, University of Colorado, Boulder, CO 80309-0392)

During the Voyager, Ulysses and Galileo missions we learned to appreciate the importance of electromagnetic effects on charged dust in the Solar System. Planetary rings are examples where the orbital evolution of small dust grains can be strongly coupled to the plasma environment.
There are many exciting phenomena associated with the interaction of magnetospheric fields and plasmas ith the embedded dust grains. Lorentz resonances, gyrophase-drifts due to compositional and/or plasma density and/or plasma temperature gradients, transport due to charge or magnetic field fluctuations, shadow resonance and the coupling between radiation pressure and electrodynamic forces, for example, might all contribute to shaping the fine dust distribution in planetary rings. The dust becomes an integral component of the magnetosphere since it acts as a source/sink of the plasma. The produced low energy photo and secondary electrons or the sputtered off ions might significantly alter the magnetospheric plasma distribution, for example. Though many of these processes are now recognized, dusty planetary magnetospheres still hold surprises.
In this talk I will summarize our understanding of dusty plasma generation and transport at Jupiter and show that similar effects are also expected to shape the fine dust distribution in the magnetosphere of Saturn.

GA4.10/W/21-A4 1620

LOW LATITUDE JOVIAN X-RAY EMISSION FROM SCATTERING AND FLUORESCENCE OF SOLAR X-RAYS

Ahilleas N. MAURELLIS (Atmospheric Photophysics Group, FOM-Institute, AMOLF, Amsterdam, The Netherlands, email: ahilleas@amolf.nl) Thomas E. CRAVENS (Dept. of Physics and Astronomy, University of Kansas, Lawrence, KS, 66045, USA, email: cravens@kuplas.phsx.ukans.edu); G. R. Gladstone and J. H. Waite, Jr. (Dept. of Space Science, SWRI, San Antonio, TX, USA)

X-ray emission from Jupiter's equatorial region has recently been observed (Waite et al., 1997). X-ray emission from Jupiter's auroral region was previously observed by the Einstein and ROSAT X-ray observatories (Metzger et al., 1983; Waite et al., 1994). Both the estimated total auroral X-ray power and the total low-latitude X-ray power are on the order of 1 GW. The X-rays emitted from Jupiter are primarily "soft" X-rays with energies of up to a few hundred eV. One mechanism proposed for the auroral emission is heavy (mainly sulfur and oxygen) ion precipitation followed by line emission from highly excited, high charge state ions (Waite et al., 1994; Cravens et al., 1995). Waite et al. (1997) further suggested that the X-ray emission at low latitudes may also be explained by heavy ion precipitation, although the ions would originate in this case in the inner magnetosphere of Jupiter rather than in the middle magnetosphere. In this paper we explore alternative mechanisms for the observed low-latitude

X-ray emission related to scattering of solar X-rays photons: (1) scattering by H2 molecules, (2) fluorescent carbon K-shell scattering. (The carbon atoms are contained in the methane molecules located below the homopause). Our preliminary intensity estimates are about a factor of 10 less than the observed low-latitude intensities but many uncertainties are present in the calculations and are now being re-examined. Observations have shown that jovian X-ray emission is: (1) at a maximum in the subsolar region; (2) correlated in time with total solar X-ray emission (Gladstone et al. 1998), both of which are expected in a situation where solar photon scattering and fluorescence mechanisms are complementary to that of heavy ion precipitation in the production of equatorial X-ray emission.

GA4.10/W/32-A4 1635

AURORAL AND SATELLITE FOOTPRINT EMISSIONS AT JUPITER AND SATURN

J.H. WAITE, Jr., T. Majeed, G.R. Gladstone (all at SwRI, San Antonio TX 78228, USA, e-mail: hunter@kronos.space.swri.edu); J.T. Clarke (University of Michigan, Ann Arbor MI 48109, USA); J. Connerney (GSFC, Greenbelt MD 20771, USA); D. Grodent, J.-C. Gerard (both at University de Liege, B-4000 Liege, Belgium); S. Bolton (JPL, 4800 Oak Grove Dr., Pasadena CA 91109, USA); B. Mauk (APL, Laurel MD 20723, USA); R. Walker (UCLA, Los Angeles CA 90095, USA)

Two events have dramatically increased our ability to observe auroral emissions from the outer planets. The first was the detection, in 1988, of strong near-IR emissions from H3+ in Jupiter's auroral zone, which provided a sensitive means of probing the auroral ionospheres of the outer planets with ground-based telescopes. The second event was the deployment in 1990 of the Hubble Space Telescope, whose instruments have acquired increasingly high-resolution data on the FUV auroras of Jupiter and Saturn. Observations of FUV emissions with HST and of H3+ emissions from the ground have, in particular, led to significant advances in our knowledge of the jovian aurora, which, because of its brightness, has been the primary target of outer planet auroral observations. Spectroscopic data on H3+ emissions in the near-IR regime and on H2 band emissions at FUV wavelengths have yielded important new inputs for models of the thermal structure of Jupiter's auroral atmosphere, while imaging of the H3+ and FUV auroras has provided a detailed picture of the morphology of the auroral emissions, revealing their probable local-time and System III dependencies and responsiveness to solar wind as well as corotational influences. Emissions associated with the footprints of Io and Ganymede have also been identified. We review recent observations of jovian H3+ and FUV emissions and discuss their implications for our understanding of jovian aeronomy and of magnetosphere-ionosphere coupling in the Jupiter system. We conclude with a comparative look at Saturn's FUV aurora.

GA4.10/W/28-A4 1655

INTERACTION OF FLUX TUBE ELECTRONS WITH IO'S ATMOSPHERE

Marykutty MICHAEL and Anil Bhardwaj (Space Physics Laboratory, Vikram Sarabhai Space Centre, Trivandrum 695022, India, email: spl_vssc@vssc.org)

During its flyby in December 1995 Galileo passed within 1000 km of Io through its wake region. The Galileo plasma analyzers revealed the presence of a dense ionosphere of density 40000 electrons per cc. The energetic particle detector observed an intense, bi-directional, magnetic field-aligned beam of electrons of energy greater than 15 keV. These electrons may mirror and return in the vicinity of Io and may impact its atmosphere. A Monte Carlo model has been constructed to study the interaction of these high energy electrons with the neutral species present in the Io's atmosphere. The intensities of neutral O and S ultraviolet emissions resulting from the energetic electron impact on the atmospheric gases of Io are calculated and will be compared with the observed intensities particularly from the Hubble Space Telescope. Implications of the model for the ionization of the Io's atmosphere will also be discussed.

GA4.10/W/19-A4 1710

THE INTERACTION OF IO AND EUROPA WITH JUPITER'S MAGNETOSPHERE

Arvydas J. KLIORE, Aseel Anabtawi (Jet Propulsion Laboratory, California Institute of Technology, Pasadena, CA 91109, USA, e-mail: akliore@jpl.nasa.gov); Tamas Gombosi (Space Physics Research Laboratory, University of Michigan, Ann Arbor, MI 48109, USA, e-mail: tamas@umich.edu)

The Galileo orbiter has provided radio occultation measurements of the electron density profiles of the plasma surrounding Io and Europa. There have been six occultations of Io, providing twelve electron density profiles at various locations relative to the ram direction of the impinging particles of the Jupiter magnetosphere on Io, and eight profiles on Europa. The two satellites were found to have very different plasma environments, with Io having a proper ionosphere produced on top of an endogenous SO2 atmosphere by magnetospheric particle precipitation and solar EUV, while Europa has a tenuous plasma environment produced by the same mechanisms from an oxygen atmosphere itself also produced by sputtering of water ice from its surface by impinging magnetospheric particles. In both cases the observed electron density profiles are highly asymmetrical, with a compressed profile on the ram side, and an extended one on the wake side. The presence of several measurements for each satellite at different ram-to-wake directions provided data for estimating an approximate distribution of ionization from the ram direction to the wake direction, which were compared with the results of MHD simulations.

GA4.10/W/27-A4 1725

CARBON EMISSIONS IN COMETS: PREDICTION FOR ROSETTA

Anil BHARDWAJ (Space Physics Laboratory, Vikram Sarabhai Space Centre, Trivandrum 695022, India, email: spl_vssc@vssc.org); S.A. Haider (Physical Research Laboratory, Ahmedabad 380009, India)

Several emissions of carbon atoms in neutral (CI 156.7 nm, 165.7 nm, 193.1 nm) and ionized (CII133.5 nm) forms have been observed in comets. These emissions can be produced by various mechanisms, like, resonant scattering of solar radiation by carbon atom/ion, solar photon and electron impact dissociative excitation of major carbon containing species (viz., CO and CO2), electron impact excitation of C. The knowledge about the relative contribution from each of these mechanisms provide unique information regarding the physical and chemical processes occurring in the cometary coma. The CI 193.1 nm emission is unique in the sense that it arises from a transition in carbon atom that leaves the C in the metastable 1D state: suggesting that a large fraction of carbon in cometary coma reside in the metastable form. A coupled chemistry-transport model in conjunction with an efficient emission production code is used to study the chemistry of C(1D) atoms and the production of CI 193.1 nm emission in the coma of comet P/Wirtanen: the target of the ROSETTA mission. The model calculations and predicted intensity of the CI 193.1 nm emission will be presented and its implications for the carbon budget will be discussed.

THE OUTER PLANETS MAGNETOSPHERE

GA4.10/E/02-A5 Invited 0900

THE DYNAMICS OF JUPITER'S MAGNETOSPHERE

Vytenis M. VASYLIUNAS (Max-Planck-Institut fuer Aeronomie, D-37191 Katlenburg-Lindau, Germany, e-mail: vasyliunas@linmpi.mpg.de)

Plasma in the magnetosphere of Jupiter is predominantly injected deep within the magnetosphere and lost by outward transport. This simple fact implies the existence of most of the important processes of Jovian magnetospheric dynamics without by itself specifying their properties: plasma transport by interchange motions within the closed magnetic field region, reconnection of the magnetic field in the magnetodisc, ultimate loss of plasma down the magnetotail must all occur, but their driving mechanisms as well as their spatial and temporal scales remain largely uncertain or even unknown. I review the evolution of our ideas on these processes, the impact of observations from Galileo, and recent developments particularly concerning internal or external drivers and possible analogies to the magnetosphere of Earth.

GA4.10/W/15-A5 0930

LOCAL TIME ASSYMETRIES IN THE MAGNETOSPHERE OF JUPITER

KRISHAN K. KHURANA (Institute of Geophysics and Planetary Physics, UCLA, Los Angeles, CA 90095. USA)

We have used magnetic field data from the Real Time Science (RTS) mode of Galileo (resolution of 24 sec. or better) and the very low-resolution data from the Memory Read Out (MRO) of the MAG instrument (resolution 32 minutes) to study the configuration of Jupiter's magnetosphere. We show that in the middle magnetosphere (radial distance between 40 and 90 RJ), the field line sweepback is larger in the dawn magnetosphere compared to its value in the midnight and dusk sectors. We will show that these differences correspond to much larger radial currents in the dawn sector compared to their value in the midnight sector of the magnetosphere. By using current continuity, we will calculate the field-aligned current strengths and identify their sources in the magnetosphere.
Observations of the current sheet structure show that the current sheet crossing times are less delayed in the midnight and dusk sectors compared to the delays observed in the dawn sector. We will show that the current sheet is warped mainly by the effect of the solar wind flow on the magnetotail and not by the action of centrifugal forces on the plasma. We will present a new model of the structure of the current sheet that can predict the current sheet crossings with an accuracy of ~ 15 degrees in longitude. Finally, we show that the current sheet is much more disordered in the mid-night and dusk sectors compared to a relatively organized current sheet encountered in the dawn sector. Sources responsible for this asymmetry will be explored.

GA4.10/E/06-A5 Invited 0945

MAGNETIC RECONNECTION IN THE JOVIAN MAGNETOSPHERE

Raymond J. WALKER (Institute of Geophysics and Planetary Physics, University of California at Los Angeles, Los Angeles CA, 90095-1567, USA, email: rwalker@igpp.ucla.edu)

Magnetic reconnection is widely thought to be responsible for driving flows within the Earth's magnetosphere. In this paper we will consider the effects of magnetic reconnection within Jupiter's magnetosphere. Plasmas rotate with the planet throughout much of Jupiter's magnetosphere. However, the oppositely directed magnetic field in the Jovian magnetic tail is expected eventually to reconnect across the current sheet, allowing plasma produced near Jupiter to escape tailward. We will use observations from the Galileo spacecraft and global magnetohydrodynamic simulations to investigate the conditions under which reconnection becomes important at Jupiter. Reconnection between the interplanetary magnetic field (IMF) and the Earth's magnetic field at the dayside magnetopause is followed by reconnection within the magnetotail. At Jupiter our simulations indicate that reconnection caused by inertial effects can occur in the magnetotail even when there is no dayside reconnection. We will investigate the effects of the IMF on the reconnection in Jupiter's magnetotail. Initial calculations indicate that for northward IMF the tail neutral line moves toward Jupiter and drives stronger flows than without an IMF.

GA4.10/W/02-A5 1005

COMPARISON OF THE AZIMUTHAL FIELD COMPONENTS MEASURED DURING FLY-BYS OF JUPITER: PIONEER, VOYAGER AND ULYSSES OBSERVATIONS

E.J.BUNCE and S.W.H.Cowley (Department of Physics and Astronomy, Leicester University, UK)

Distortions of the jovian magnetic field out of meridian planes result from magnetospheric interactions with both the solar wind and the planetary ionosphere, each giving different dependancies on distance and local time. Here we will compare fly-by data from the Pioneer, Voyager and Ulysses spacecraft, as well as data from the Galileo orbiter as it becomes available, to examine the spatial variability of the azimuthal field component produced by these distortions, and to consider the implications for large-scale jovian magnetospheric dynamics. In the case of the azimuthal field perturbation which is due to magnetosphere-ionosphere coupling, the data will also be used to make an estimate of the effective value of the Pederson conductivity of Jupiter's ionosphere. This estimate requires use of magnetic models to map field lines between the spacecraft and the ionosphere.

GA4.10/W/08-A5 1020

JOVIAN CURRENT SHEET STRESS BALANCE AND MASS DENSITY

C. T. RUSSELL, K. K. Khurana and M. G. Kivelson (All at Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA 90095-1567, USA, email: ctrussell@igpp.ucla.edu),D. E. Huddleston (Hughes Space and Communications Company, El Segundo, CA, USA),J. A. Ansher, D. A. Gurnett and W. S. Kurth (All at University of Iowa, Iowa City, IA, USA),D. J. Williams (Johns Hopkins University, Applied Physics Laboratory, Laurel, MD, USA)

In the middle magnetosphere the magnetic and plasma pressure forces dominate the forces associated with rotation and the magnetosphere remains quasi dipolar. Beyond about 24 RJ in the Galileo epoch, the magnetosphere becomes disk-like with a thin central current and stretched lobes above and below at all local times. Estimates of the balance of forces indicate that this is the region where the centrifugal force dominates over the particle forces. We can use the magnetic measurements to estimate these various forces under simplifying assumptions and from those estimates deduce a value for the 'cold' mass of the magnetodisk

plasma. Herein we compare those estimates with the density deduced from the electron plasma frequency found from the plasma wave measurements and compare plasma pressure estimates with those observed.

GA4.10/W/26-A5 1035

PLASMA SHEET DYNAMICS IN THE JOVIAN MAGNETOTAIL: EVIDENCE FOR SUBSTORM-LIKE PROCESSES

J. WOCH, N. Krupp, S. Livi and B. Wilken (all at: Max-Planck-Institut für Aeronomie, D-37191 Katlenburg-Lindau, Germany, email: woch@linmpi.mpg.de); K.K. Khurana and M.G. Kivelson (both at: Institute of Geophysics and Planetary Physics, University of California Los Angeles, CA, USA) A. Roux and S. Perraut (both at: Centre d'Etude des Environnements Terrestre et Planetaires, Vélizy, France) P. Loaurn (CESR, Université Paul Sabatier, Toulouse, France) A. Lagg and D.J. Williams (both at: The Johns Hopkins University Applied Physics Laboratory, Laurel, MD, USA)

During Galileo's orbit G2 in 1996 the Energetic Particles Detector (EPD) onboard the spacecraft detected a number of particle bursts with large radial/antisunward anisotropies in the distant Jovian magnetotail [Krupp et al., 1998]. The bursts were embedded in predominantly corotating plasma. They showed a tendency to reoccur every 2 to 3 days. In this letter we focus on a detailed analysis of one of the bursts. Prior to the onset of the burst particle fluxes at low energies increase over several hours. The end of this plasma loading phase coincides with the detection of a flux rope like signature in the magnetic field evidenced by a bipolar excursion of the north-south component together with a strong core field. After the passage of the flux rope the plasma sheet has thinned considerably. At the boundary of the thin plasma sheet and in the lobe regimes strong wave emissions in the 100 Hz range are detected. Accelerated/heated ion beams first from the Jovian direction later from the tail direction are seen at the plasma sheet and lobe interfaces. The event is tentatively interpreted as a substorm-like process, where the magnetotail is internally driven unstable by mass-loading of magnetic flux tubes.

GA4.10/W/03-A5 Invited 1110

TRANSPORT OF ENERGETIC CHARGED PARTICLES IN JUPITER'S MAGNETOSPHERE

B. H. MAUK (The Johns Hopkins University Applied Physics Laboratory, 11100 Johns Hopkins Road, Laurel, Maryland 20723-6099; 240-228-6023; Fax: 240-228-6670; email: Barry.Mauk@jhuapl.edu)

The magnetospheres of Jupiter and Earth are representative of two extremes in the behaviors of the space plasma environments surrounding magnetized planets. Earth's magnetosphere is extremely dynamic because it is powered by its strong interactions with the highly variable interplanetary/solar wind environment. It is no surprise, then, that the transport of energetic particles within the Earth's magnetosphere is associated largely with dynamic "storm" and "substorm" processes that are caused by the solar wind interactions. Jupiter's magnetosphere, in contrast, is powered predominantly by the "rock-steady" planetary rotations. The processes that give rise to dynamics within Jupiter's magnetosphere are largely unknown, and the predominant mechanisms that cause the transport of energetic particles and other plasmas with Jupiter's magnetosphere are not established. During the Voyager era, researchers focused much attention on the so-called interchange instability as a cause of transport within the inner magnetosphere. Signatures of transport within the more distant magnetospheric regions included the so-called magnetospheric wind. More recently, new transport signatures have been identified that appear to have some similarities to Earth-magnetospheric dynamic events. There are speculations about possible roles for the interplanetary environment in either powering or stimulating some of the transport. Here we review the history and the status of our understanding the transport of energetic particles within the Jovian magnetosphere. Recent findings from the Galileo spacecraft are emphasized.

GA4.10/W/01-A5 1130

PROPERTIES OF GANYMEDE'S MAGNETOSPHERE AS REVEALED BY ENERGETIC PARTICLE OBSERVATIONS

D. J. WILLIAMS, B. Mauk, and R. W. McEntire (Johns Hopkins Applied Physics Laboratory, Laurel, MD 20723, USA)

Abstract energetic particle observations made during the Galileo satellite's close encounters with Jupiter's moon Ganymede provide a measure of many characteristics of Ganymede's magnetosphere, a magnetosphere larger than that of Mercury. Changes in energetic ion anisotropy signatures, caused by Jupiter's corotating magnetic field, show that Ganymede's magnetosphere significantly slows down the ambient nearly-corotating Jovian plasma. The data further indicate that this convection slow-down apparently extends at least several Jupiter radii away from Ganymede along Jovian field lines connected to the moon. The locations of these anisotropy signature changes occur at the locations of magnetometer and plasma wave magnetopause identifications that match surprisingly well the predictions of a simple model comprised of an intrinsic dipole field superimposed on Jupiter's ambient field. Loss cones measured throughout Ganymede's magnetosphere provide a quantitative estimate of the moon's surface magnetic field along the sub-satellite track that agrees well with model field predictions and provides verification of Ganymede's intrinsic magnetic field. On Jovian field lines connected to Ganymede, electrons are trapped between the moon and a near-Jupiter mirror point for several bounces as they convect across Ganymede's magnetosphere. This unique geometry allows a measurement of the amount of electron pitch angle scattering occurring in a single bounce between the Ganymede and near-Jupiter mirror points. The energy-dependent pitch angle diffusion coefficient and scattering lifetimes have been extracted from these observations. The consistency of these results from encounter to encounter demonstrates the stability of these processes, at least over the several month interval between encounters. Evidence for loss cone signatures established one Jovian rotation (~10 hours) earlier indicates that the entire Jovian L-shell region traversed by Ganymede provides an electron scattering environment similar to that measured on Jupiter-Ganymede field lines. Measurements from Galileo's last close encounter with Ganymede show electron pitch angle distributions characteristic of particles trapped on closed magnetic field lines in a distorted magnetospheric configuration. Thus with its distorted magnetic field and apparent radiation belt, Ganymede takes its place as a unique member of the solar system family of magnetospheres.

GA4.10/W/16-A5 1145

ENERGETIC HEAVY IONS IN JUPITER'S MAGNETOSPHERE

N. MURPHY (Jet Propulsion Laboratory, 4800 Oak Grove Dr., Pasadena, CA 91109, USA) C.M.S. Cohen and E.C. Stone (California Institute of Technology, 1201 E. California Blvd., Pasadena CA 91125)

The Galileo spacecraft penetrates deeply into the Jovian magnetosphere on each of its orbits, thus allowing a far more extensive survey of inner and middle magnetospheric processes than previously available. The spacecraft carries a suite of magnetospheric instruments, with the Heavy Ion Counter (HIC) providing information about the fluxes of energetic heavy ions in the energy range of 6 to 200 MeV/amu, and species from carbon through iron.
Ions in the HIC energy range provide useful diagnostics of many magnetospheric processes, including particle transport and absorption by moons. We will examine the variability of ion fluxes and pitch angle distributions over the HIC energy range between 9 and 20 Rj, in an attempt the shed light on the complex nature of Jupiter's magnetosphere. In particular we will examine the effects of Europa on the local particle distributions and estimate the rate of inward radial diffusion.

GA4.10/W/25-A5 1200

AURORAS ON THE OUTER PLANETS

Anil BHARDWAJ (Space Physics Laboratory, Vikram Sarabhai Space Centre, Trivandrum 695022, India, e-mail: spl_vssc@vssc.org); G. Randall Gladstone (Southwest Research Institute, San Antonio, TX 78238, USA, email: randy@whistler.space.swri.edu)

Auroras are emissions occurring at high latitudes of a planet resulting from the precipitation of energetic charged particles from the planets magnetosphere. Auroral emissions from the outer planets have been observed from ground, Earth-orbiting satellites, flyby spacecraft, and orbiter-based instruments at X-ray, UV, visible, IR, and radio wavelengths. The UV, visible, and IR auroras are atmospheric emissions, produced or initiated when ambient atmospheric species are excited by the precipitating particles, whileradio and X-ray auroras are beam emissions, produced by the precipitating species themselves. The emissions at different wavelengths provide unique and complimentary information, accessible to remote sensing, about the key physical processes operating in the atmospheric and magnetospheric regions where they originate. This paper will discuss our current understanding of the auroral emissions on Jupiter, Saturn, Uranus, and Neptune as revealed by through multi-spectral observations and supplemented by plasma measurements. A qualitative picture of the energetics and morphology of the aurora on the outer planets will be presented.

GA4.10/W/35-A5 1215

THE ENERGY BALANCE IN SATURN'S MAGNETOSPHERE

J. D. RICHARDSON (M.I.T., Center for Space Research, 37-655, Cambridge, MA, USA, 02139)

Recent observational and modelling work shows that Saturn's inner magnetosphere is dominated by neutrals. We review recent HST observations and the implications of these observations. Then we extend this work by looking at the energy balance for the plasma. Energy is lost via radiation and gained via ionization of neutrals, with coulomb collisions also important. Observations show that both electron and ion temperatures decrease towards Saturn, suggesting that the ion temperatures are driven by the pickup process. This study discusses how well "neutral theory" predicts observed temperatures and where additional energy source and losses are needed and speculates on what these might be.

GA4.10/W/18-A5 1230

ION DISTRIBUTIONS IN SATURN'S MAGNETOSPHERE NEAR TITAN

S. A. LEDVINA, T. E. CRAVENS (University of Kansas, Department of Physics and Astronomy, Lawrence, KS 66045, USA, email: cravens@kuplas.phsx.ukans.edu); K. Kecskemety (KFKI Research Institute for Particle and Nuclear Physics, H-1525 Budapest, Hungary)

Titan possesses an extensive atmosphere consisting of mainly molecular nitrogen and methane. These neutrals are ionized by photoionization and electron impact ionization forming an extensive ionosphere. At the time of the Voyager encounter Titan was found to be within Saturn's magnetosphere. Saturn's magnetospheric plasma impinges on Titan with a flow speed of about 120 km / s. The plasma analyzer on the Voyager 1 spacecraft detected H+ and N+ ions in the near-Titan wake with temperatures of about 200 eV and 2.9 keV, respectively [Hartle et al., 1982]. These ions will have gyroradii comparable to Titan's size [Luhmann et al., 1996], which has interesting consequences for the plasma interaction with that body. We numerically determine the trajectories of several thousand ions in the vicinity of Titan using for the required electric and magnetic fields the output from a three-dimensional MHD model of Titan. The MHD model is an improved version of the earlier model [Ledvina and Cravens, 1998], and includes ionospheric processes such as ion production, ion-neutral friction and dissociative recombination. We have calculated velocity space distributions of both pick-up and ambient ions using the numerically determined ion trajectories. These results are statistically analyzed to provide insight into the external plasma interaction with that satellite as well as to make predictions for the Cassini Orbiter particle experiments.

MAGNETOSPHERE MOON INTERACTIONS. WAVES AND INSTABILITIES

GA4.10/W/17-A5 Invited 1400

PLASMAS NEAR THE GALILEAN MOONS

W. R. PATERSON and L. A. Frank (Both at: Department of Physics and Astronomy, The University of Iowa, Iowa City, IA, USA, email: paterson@iowasp.physics.uiowa.edu)

The Galilean moons offer unique and exciting environments for studies of plasma processes. Measurements from the Galileo plasma instrumentation (PLS) reveal features of the interactions that occur as magnetospheric plasmas encounter each of the major satellites. Io's wake is found to have a dense ionosphere threaded with beams of electrons, and the flanks of the interaction region exhibit pickup hydrogen and other ions. Europa's contribution to the plasmas of the torus can now be quantified because pickup from its atmosphere and the entrainment of ions from the ionosphere are directly measured. The interaction at Ganymede is seen to be complex with a significant energy flux of electrons into the polar regions, an outflow of protons, and a system of currents carried by electron beams. Observations near Callisto show the presence of ions sputtered from the surface. In this presentation we review the observations and discuss recent results.

GA4.10/E/04-A5 1420

POPULATING JUPITER'S MIDDLE AND OUTER MAGNETOSPHERE FROM THE IO TORUS

R.L. RICHARD (Institute of Geophysics and Planetary Physics, University of California at Los

Angeles, Los Angeles, CA 90095 USA); R.J. WALKER (Institute of Geophysics and Planetary Physics, University of California at Los Angeles, Los Angeles, CA 90095 USA); M. Ashour-Abdalla (Institute of Geophysics and Planetary Physics and Department of Physics and Astronomy, University of California at Los Angeles, Los Angeles, CA 90095 USA); T. Ogino (Solar Terrestrial Environment Laboratory, Nagoya University, Toyokawa, Japan)

Jupiter's magnetosphere is thought to be populated by plasma whose ultimate source is the volcanically active moon Io. We have calculated the trajectories of ions from this inner magnetospheric source in electric and magnetic fields from global magnetohydrodynamic (MHD) simulations of the magnetosphere and its interaction with the solar wind. The MHD simulations show how the properties of Jupiter's magnetosphere depend on interplanetary magnetic field (IMF) conditions and the Io source. The ion trajectories allow us to evaluate the importance of physics not included in the MHD model such as non-adiabatic particle motion. We investigate how these ions populate the system by launching heavy ions from the inner magnetosphere and following them until they leave the simulation system, strike the inner boundary of the simulation or become trapped.

GA4.10/W/06-A5 1435

ENERGETIC ELECTRON BEAMS AND TRAPPED ELECTRONS AT IO

D J WILLIAMS1, R. M. Thorne2 and B. Mauk1 (1Johns Hopkins University Applied Physics Laboratory Laurel, MD 20723-6099, USA), (2University of California, Los Angeles Department of Atmospheric Sciences Los Angeles, CA 90095-1565, USA)

We present results from a continuing study of the magnetic field-aligned energetic electron beams and accompanying trapped electron distributions discovered during the Galileo satellite's passage through Io's cold, dense, low-speed wake on 7 December 1995 (Williams et al., 1996). A companion paper by Thorne et al. (1998) presents an analysis and explanation of the evolution of the electron pitch angle distributions measured on approach to Io and describes the resulting energetic electron flow paths and adiabatically "forbidden" regions expected to exist around Io. In Io's wake only bi-directional, field-aligned electron beams are seen--no ion beams are observed. At energies >~15 keV, the measured beams represent an energy flow of ~0.03 ergs cm-2 s-1 and if they penetrate Jupiter's atmosphere, can provide an energy deposition of ~15 ergs cm-2 s-1 at the foot of the Io flux tube. This is sufficient to stimulate observable aurora in Jupiter's atmosphere. Extrapolating the measured spectra to lower energies yields much higher values (eg. ~10^4 ergs cm-2 s-1 at 0.25 keV). The angular width of the measured trapped-like electron distributions is independent of energy and varies across Io's wake in a manner consistent with the measured magnetic field variation. We conclude that these electrons are trapped in Io's magnetic field configuration. The narrowness of the beams and the simultaneous existence of an apparently unaccelerated trapped electron population provide evidence that the source region for the beams is close to Jupiter. A deconvolution of the detector response to the beams gives a beam angular half-width of ~ 6*, placing the formation of the beams at an altitude of ~0.6 - 0.7 RJ. The slight energy dependence of the beam width provides a rough upper limit estimate of <~1.8 (10)8 cm-3 for Io's neutral SO2 atmosphere in the flyby region. No proposed acceleration mechanism operating close to Io (neither double layers nor Fermi acceleration via propagating Alfven waves) is able to reproduce measured beam characteristics.

GA4.10/W/11-A5 Invited 1450

SOURCES AND TRANSPORT OF PLASMA IN THE IO TORUS

Frand CRARY (Laboratory for Atmospheric and Space Physics, University of Colorado, Boulder, USA)

The Io torus is generated by the escape of neutral gases from Io, and their subsequent ionization; the structure of the torus is determined by (among other things) this source and the processes which transport away from the source. This presentation will review the existing theories and observations of the Iogenic plasma source and of the transport processes, and then describe results of recent analysis of observations made by the Galileo spacecraft. Measurements made during the Dec. 1995 encounter with Io allow estimates of Io's neutral exosphere and place limits on the near-Io plasma production rates. Plasma observations made in the Io torus indicate that the abundance of oxygen ions increases with distance from Io. This had previously been suggested to explain Voyager ultraviolet spectra, and may indicate a source of oxygen from Europa. Finally, the Galileo spacecraft observed a number of events associated with plasma transport. Some of these events are in good agreement with theoretical descriptions of flux tube interchange. Other events have a more complex structure, and measurements of inward flow velocities show that they are associated with transport.

GA4.10/W/31-A5 1510

PLASMA INTERACTIONS WITH THE GALILEAN MOONS OF JUPITER

Margaret KIVELSON (Department of Earth and Space Sciences and Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA 90095-1567, USA,
email: mkivelson@igpp.ucla.edu)

Half way into its fourth year in orbit around Jupiter, Galileo has acquired data on several passes by Jupiter's three outer Galilean moons and on one pass by Io. The diversity of observed signatures is astonishing. At Europa and Callisto, the data support the concept of conducting layers not far below the surface, a conclusion that has led to reconsideration of the ways in which the outer icy layers of these moons have cooled. There is evidence that the structure of the Alfvén wings at Ganymede and Europa is consistent with theoretical proposals of Neubauer (1998). Our proposal that the field-aligned currents carried in the Alfvén wings are intense enough to produce signatures in Jupiter's ionosphere are supported by Hubble images recently acquired by Clarke and co-workers. In the wakes of both of these bodies, ion pickup dominates part of the ULF power spectra and can be used to estimate the pickup rate of heavy ions.
Ganymede's mini-magnetosphere has revealed a remarkable complexity of structure both in particle distributions and in field fluctuations. The opportunity to investigate an approximately steady state magnetosphere allows us to test our ideas of convection and reconnection. Io remains perplexing, and we will review the issues that remain unresolved but may be

GA4.10/E/07-A5 Invited 1525

THE MAGNETOSPHERE OF SATURN AND ITS INTERACTION WITH TITAN

T. I. GOMBOSI, D. L. DeZeeuw, C. P. T. Groth, K. C. Hansen, K. Kabin, and K. G. Powell (The University of Michigan, Ann Arbor, MI, USA e-mail: tamas@umich.edu)

This talk will briefly review our pre-Cassini understanding of the Saturnian magnetosphere and its interaction with Titan. We will also present the results of a new multiscale MHD simulation of the Saturnian plasma environment. The simulation explores the magnetohydrodynamic coupling between Saturn and Titan, as well as the influence of the IMF and planetary rotation on the large-scale features of the Kronian magnetosphere.

GA4.10/W/20-A5 1545

ION PICKUP AND ASYMMETRIES IN EUROPA'S WAKE

M. VOLWERK, M.G. Kivelson and K.K. Khurana

The plasma pick up near Europa [Kivelson et al., 1998, submitted to JGR] gives rise to strong wave activity at frequencies f < 0.4 Hz in the geometrical wake region, which is defined as the region behind Europa of width 2 Re (Europa radii) perpendicular to the plasma flow. In the E11 and E15 flybys we can identify a region of left-handed polarized waves, with strong coherence between the two components perpendicular to the background magnetic field, at a frequency near 0.2 Hz. This is consistent with ion cyclotron waves generated by the ring current distribution of the freshly picked up ions near Europa. The frequency matches the gyrofrequency of a singly charged, 32 AMU mass ion (S or O2). The wave activity gets transformed into local ion density cf. Huddleston et al. [JGR 103, 19887, 1998]. The activity during the E4 flyby seems more difficult to explain by pick-up processes.
There is an asymmetry in the wave activity and the crossing of the Alfven wing created by Europa. This asymmetry could be caused by the magnetic induction effect of the moon embedded in Jupiter's time varying magnetic field. It seems to agree with the model by Neubauer [preprint, 1998], describing the offset of the Alfven wings due to induction effects.

GA4.10/W/34-A5 Invited 1620

PLASMA WAVES IN THE OUTER PLANET MAGNETOSPHERES

W. S. Kurth, D. A. Gurnett (Dept. of Physics and Astronomy, University of Iowa, Iowa City, IA, 52242, Email: william-kurth@uiowa.edu), A. Roux (CETP/UVSQ, Velizy, France), S. J. Bolton (Jet Propulsion Laboratory, Pasadena, CA 91109).

Based on Voyager observations at Jupiter, Saturn, Uranus, and Neptune, one finds a number of similarities in the plasma wave spectra in the outer planet magnetospheres and these are shared in many respects with those in the terrestrial magnetosphere, as well. This result is profound, given the dramatic differences in size, heliospheric distance, dipole and rotation axes orientations, and internal sources of plasma across these five planetary magnetospheres. In this short review we address such similarities and use recently obtained Galileo observations to update the situation at Jupiter and suggest the types of advances that are possible with the arrival of Cassini at Saturn in 2004.

GA4.10/E/03-A5 1640

PARTICLE ACCELERATION BY MAGNETIC RECONNECTION IN THE JOVIAN MAGNETODISC

Joerg BUECHNER (Max-Planck- Institut fuer Aeronomie, Max-Planck-Str. 2, D-37191 Katlenburg-Lindau, Germany)

Current Galileo investigations have shown that in the course of substorm-like dynamic events plasmoid-like structures are formed in the Jovian magnetotail (cf. Woch, Krupp, et al., this meeting). We present results of calculations of particle acceleration by magnetic reconnection processes, demonstrating similarities and differences of reconnection related particle acceleration in the magnetotails of the Earth and Jupiter. For example, in contrast to the Earth tail the specifics of the Jovian magnetodisc field structure and strength allows also the immediate acceleration of electrons to high energies.

GA4.10/W/05-A5 1655

MIRROR MODE STRUCTURES AT THE GALILEO FLYBY

C. T. RUSSELL, R. J. Strangeway, M. G. Kivelson and K. K. Khurana (All at Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA 90095-1567, USA, email: ctrussell@igpp.ucla.edu); D. E. Huddleston (Hughes Space and Communications Company, El Segundo, CA, USA); X. Blanco-Cano (University of Mexico, D.F., Mexico)L. A. Frank, W. Paterson, D. A. Gurnett and W. S. Kurth (All at University of Iowa, Iowa City, IA, USA)

As Galileo passed through the wake of Io it encountered a number of magnetic depressions that have been interpreted to be the result of the mirror mode instability. Herein we examine the magnetic signatures of these structures and simultaneous measurements of the electron density and temperature. These structures have phase fronts that propagate at large angles to the magnetic field and scale sizes of several ion gyro radii. The density enhancements that accompany the magnetic field depressions range up to 200% of the background density. The spread in normal directions suggests that the depressions are cylindrical and not sheet-like.

GA4.10/W/09 A5 1710

ASPECTS OF THE OUTER JOVIAN CURRENT SHEET ASDETERMINED FROM PARTICLE SIMULATIONS

L YIN, P L PRITCHETT, and F V Coroniti (all at Department of Physics and Astronomy, University of California, Los Angeles, CA 90095-1547, USA, email: ylin@physics.ucla.edu, pritchet@physics.ucla.edu),L A Frank and W R Paterson (both at Department of Physics and Astronomy, The University of Iowa, Iowa City, IA 52242, USA)

The Galileo spacecraft has made extended observations of the middle and outer Jovian magnetosphere, including the outer current sheet region in the Jovian tail. We examine the electromagnetic behavior of the current sheet by means of self-consistent, 2-D particle-in-cell simulations. A cold plasma source, representing plasma transported outward from Io, is injected into a rapidly rotating dipole-like field configuration. We investigate the temporal variability of the plasma sheet near and outside of the Alfven point with the aim of determining how a centrifugally slung plasma may break the magnetic field topology and escape into some sort of steady or turbulent outflow. We observe substantial ion heating and formation of non-Maxwellian velocity distributions inregions where super-Alfvenic outflow andfast-shock-like layers form.

GA4.10/W/23-A5 1725

MAGNETIC SOUNDING OF THE CONDUCTIVITY STRUCTURE OF GALILEAN MOONS USING MULTIPLE FREQUENCIES OF JUPITER'S FIELD

C. ZIMMER, K. K. Khurana, M. G. Kivelson (Institute of Geophysics and Planetary Physics, University of California Los Angeles, USA)

Evidence from Galileo measurements for a secondary magnetic field produced by Europa and Callisto as a response to the primary time-varying field of Jupiter implies the presence of conducting media close to the moon's surfaces. To first order, the magnetic signatures at both

moons are consistent with the inductive response of a perfectly conducting spherical shell. For finite conductivities, the secondary field is both reduced in amplitude and delayed. An analytical expression can be obtained for a layered spherically symmetric model of the moon's interior (Srivastava [1966]). Assuming from the Galileo data that the amplitude of the secondary field at the synodic period is 80% or more of the perfect conductor response, we find that the required conductivities must be at least of the order of 0.1 S/m. This is most probably an indication for salty oceans lying beneath the visible rigid ice crust. If the conductivities are comparable to that of oceans on Earth, they must be at least a few km thick. Due to the concentration of currents close to the "meridian" plane perpendicular to the main direction of the time-varying primary field, the oceans need not be global to produce the observed induction effect. Further constraints on the characteristics of the conducting regions can be obtained by taking into account the other frequencies contained in the primary field, particularly at the orbital periods of the moons. The amplitudes at different frequencies are a function of the tilt and offset of the Jovian dipole, the eccentricity and inclination of the moon's orbit, and

GA4.10/W/07-A5 1740

OBLIQUE ION CYCLOTRON WAVES IN THE NEAR-IO TORUS

X. BLANCO-CANO (Universidad Nacional Autonoma de Mexico, D.F., Mexico, email: xbc@fis-esp.igeofcu.unam.mx), C. T. Russell, D. E. Huddleston, R. J. Strangeway, M. G. Kivelson, K. K. Khurana (University of California, Los Angeles, CA, USA)

Ion cyclotron waves were identified in the Galileo magnetic field data in the near-Io torus. These waves are generated by pickup ion instabilities. To zeroth order they grow at the sulfur dioxide gyrofrequency, are left-hand polarized and propagate along the magnetic field. A more detailed study reveals that the waves grow over a finite bandwidth, propagate at an angle to the field and are elliptically polarized. In this work we perform a kinetic dispersion analysis and show that the growth rate of oblique cyclotron modes can be significant in the multicomponent plasma near Io. We find that variations in the sulfur dioxide pickup ion density may lead to the observed bandwidth of frequencies.

GEOMAGNETIC OBSERVATORIES AND REPEATED STATIONS IN JAPAN

Satoru TSUNOMURA and Takaji Kurihara (both at Kakioka Magnetic observatory, Japan Meteorological Agency, Kakioka 595, Yasato machi, Niihari-gun, Ibaraki-ken 315-0116, Japan, email: stsunomu@mri-jma.go.jp), Arata Sengoku and Yoshiharu Nagaya (both at Maritime Safety Agency, Hydrographic Department, 5-3-1 Tukiji, Chuo-ku, Tokyo 104-0045, Japan, email: asengoku@cue.jhd.go.jp), Shouichi Matsumura (Geographical Survey Institute, 1 Kitasato, Tsukuba, Ibaraki-ken, 305-0811, Japan, email: matsumura@gsi-mc.go.jp),Masahisa Sugiura (Research Institute of Science and Technology, Tokai University, 2-28 Tomigaya, Shibuya-ku, Tokyo 151-0063, Japan, email: sugiura@jspan.kugi.kyoto-u.ac.jp),Toyohisa Kamei (WDC-C2 for Geomagnetism, Graduate School of Science, Kyoto University, Sakyo-ku, Kyoto 606-8502, Japan, email: toyo@kugi.kyoto-u.ac.jp)

For historical reasons, three government institutions, the Japan Meteorological Agency (JMA), the Geographical Survey Institute (GSI), and the Maritime Safety Agency, share the responsibilities of routine geomagnetic observations in Japan. The Kakioka Observatory, which is under JMA, is responsible for the long-term precision observations at Kakioka, Memambetsu and Kanoya, and for the tests of magnetic instruments. The GSI, an agency responsible for the production of magnetic charts on land, conducts repeat magnetic surveys at over 100 stations in Japan and operates magnetic observatories at Kanozan and Mizusawa as reference points for the repeat stations. Since 1996, the GSI has been operating continuous magnetic observation system at 11 field stations. The responsibilities of the Maritime Safety Agency include the production of marine magnetic charts, the conduct of shipboard magnetic observations over the oceans near Japan, and the operation of the magnetic observatory at Hatijyo as the reference point for their magnetic surveys. The magnetic observatories mentioned above are equipped with a fluxgate magnetometer and a proton precession magnetometer for variation measurements and with a magnetic theodolite and a proton precession magnetometer for absolute measurements. In addition, the Kakioka Observatory conducts variation measurements with a high sensitivity, high time resolution fluxgate magnetometer and additional Overhauser type proton precession magnetometers. In this paper, characteristics of the instruments used by the three agencies are described. Discussions also refer to the increasing difficulties faced by these agencies concerning the operation and maintenance of the magnetic observatories and repeat stations.

GEOMAGNETIC D, H AND Z RECORDINGS AT EQUATORIAL OBSERVATORIES

R.G.RASTOGI, (Department of Physics, Gujarat University and Physical Research Laboratory, Ahmedabad 380 009 India, email: parvs@prl.ernet.in)

Classically the most important component of geomagnetic field at equatorial stations is considered to be the horizontal field H. The other components D and Z are comparatively ignored and some ambiguities have occurred in the publication of these data. Some new results related to the quiet and disturbed time observations are discussed and a need to improve the sensitivity of D and Z records are discussed. Importance of the operation of regular observatories in Sri Lanka, Central Africa, Brazil and Vietnam are stressed.

GA5.01/W/03-A1 0920

EXPERIENCE OF ABSOLUTE BASELINE CONTROL OF MAGNETIC RECORDING INSTRUMENTS AT TERRA NOVA BAY OBSERVATORY, ANTARCTICA

Lili CAFARELLA, Antonio Meloni, Paolo Palangio and Achille Zirizzotti (Istituto Nazionale di Geofisica, via di Vigna Murata 605, 00143, Rome, Italy, email: cafarella@ing750.ingrm.it)

The magnetic observatory at the Italian Base Terra Nova Bay in Antarctica (Lat. 74.695º S, Long. 164.124º E, Mag. Lat. 77.32º S (IGRF 1990)) started its operations in 1986/87. During the years, the obtained data were used for studies on secular variation, seasonal effects on geomagnetic daily variation, solar cycle influence on magnetic activity, pulsation studies and data reduction during magnetic surveys. Geomagnetic observatory instruments are installed on solid rock and include two proton precession magnetometers for digital recording of total intensity F and two recording systems, using fluxgate magnetometers for monitoring time variations of H, D and Z. Absolute measurements are made independently using a DI fluxgate theodolite magnetometer; they are input to a mathematical procedure in order to determine baseline values for the relative fluxgate measurements. Absolute magnetic measurements are also made continuously by means of an independent fluxgate vectorial magnetometer that was operating automatically since summer 1997/98 and was checked against the other two magnetometers. Baselines computation results for all magnetic elements show the very high stability of this new instrument.

GA5.01/E/03-A1 0935

A PARTLY MANNED GEOMAGNETIC OBSERVATORY DEPLOYED IN ANTARCTICA PROVIDES A RELIABLE, STABLE TIMELY DATA SET

J. Miquel TORTA (Observatori de l'Ebre, CSIC, 43520 Roquetes, Tarragona, Spain, email: ebre.jmtorta@readysoft.es) John C. Riddick, Chris Turbitt (both at British Geological Survey, email: jcr@wpo.nerc.ac.uk) Alberto Castejon and Alicia Garcia (both at Programa Nacional de Investigacion en la Antartida, email: castejon@pna.es)

During the 1996-1997 Austral summer survey a new geomagnetic observatory was deployed at the Spanish Antarctic Station, Juan Carlos I (Livingston Island, South Shetland islands). The main instrument is an Overhauser magnetometer deployed at the centre of a pair of dual axis Helmholtz coils, in a deltaD/deltaI configuration. For the absolute measurements of D and I a D/I-fluxgate theodolite is used. The site is only manned during the summer, but the variometer is left recording throughout the rest of the year. It is designed for low power consumption, with an embedded PC as the main processor unit, including three RS232 ports allowing automatic measurements from the proton precession magnetometer, regular time synchronisations from a GPS and serial transmission of data. An internal flash memory disk offers a secure medium for storing up to one year of vector data. Power supply is guaranteed by a combination of solar cells and wind generators which charge a battery rack.
This system has revealed itself to be very reliable, providing uninterrupted 24V DC for two years now. For the real time access to the data, there exist three possibilities which have been checked during the last survey: using either METEOSAT or GOES Data Collection Systems, or by retrieving them by modem through INMARSAT. Stability is another of the abilities of the system since, apart of a slight drift in I observed during the first survey, H and Z baselines are kept within 5 nT since then, and D baseline within 1'.

QUALITY ASSURANCE OF CHAMBON LA FORET GEOMAGNETIC DATA BY INTER-COMPARISON OF MAGNETOMETERS

MIOARA MANDEA ALEXANDRESCU and Jean-Louis Le Mouël (Institut de Physique du Globe de Paris, 4 Place Jussieu, 75252 Paris Cedex 05, France, email: mioara@ipgp.jussieu.fr, lemouel@ipgp.jussieu.fr)

In Chambon la Forêt observatory three magnetometer systems are running: VFO, TSA and 390. Each one includes a triaxial variometer in the variometer building and an Overhauser magnetometer measuring the absolute total field intensity: two of the three Overhauser are in the variometer building, the third in the absolute house (from summer 1996 onwards). This installation gives us the ability to check continuously the differences of the total field intensity between the variometer building and the absolute house. Any change in these differences could mean either a problem with one of the magnetometers or the presence of a localised interfering magnetic field. In this paper we present results from this inter-comparison of data for the 1996 - 1998 period. Two kinds of perturbations can appear. These disturbances, very different in form and amplitude, are presented and their causes are discussed. We stress the importance of such inter-comparisons in assuring the highest quality of magnetic observatory data.

THE MAGNETIC OBSERVATORY OF FÚQUENE, COLOMBIA:NEW INSTRUMENTATION

ARIAS WILLIAM and Quintero Wilson. (Instituto Geográfico "Agustín Codazzi". Carrera 30 No. 40-51, Santa Fe de Bogotá, Colombia. Phone 57 1 368 7441. fax 57 1 368 0991; 57 1 368 1040. email: jwarias@igac.gov.co

Fuquene Observatory is situated on a small island about 100 km from Santa Fe de Bogotá, and was purpose built for magnetic work. Now is also installed a meteorological station, a seismological station and strong motion station. The Observatory is operated by the Geophysical Section of the Instituto Geográfico "Agustín Codazzi". Continuos geomagnetic measurements began in 1954.
As a result of a project of updating the geomagnetic network, the Instituto Geográfico "Agustín Codazzi" installed a Digital Magnetic Observatory in September 1995, close to the analogue three components Ruska Variometer, installed in 1954.
The digital system of three components fluxgate magnetometer (GEOMAG) measure the D, H, and Z components of the geomagnetic field.
Absolute observation has been carried out using a classical Askania magnetometer for H and D. For total intensity (F) it is used a Geometric PPM. I values are calculated from the H and F measurements. Two QHM are also used for the precise determination of horizontal intensity.
In December 1998, the Askania Magnetometer was replaced by a Diflux – Theodolite (FLM1/B fluxgate magnetometer electronics) with a resolution of 0.1 nT, manufactured by the Royal Meteorological Institute of Belgium. In 1999 with the co-operation of this Institute, it will replace the analogue variometer for a digital variometer and also the old Ruska magnetometer used in field work for a Diflux.
The result of comparisons of magnetic data recorded in both, the analogue and digital Observatory of Fúquene will be presented in this paper.

ON THE ACCURACY OF MAGNETIC SCALAR MEASUREMENTS WITH MODERN OPTICALLY PUMPED MAGNETOMETRES.

E. B. ALEXANDROV, S.I.Vavilov (State Optical Institute, St.Petersburg 199034, Russia.)F

The problems of accuracy of the magnetic-field scalar measurements (mainly in observatory environment) are reviewed. Nowadays, three types of optically pumped atomic resonance magnetometers are considered to be most accurate: the potassium narrow-line Mx-magnetometer and two combined systems – the alkali-helium Mz-magnetometer and tandem combinations of different Mx-Mz-type magnetometers. A common feature of all these instruments is their good baseline stability - not worse than 0.05 nT. This was directly confirmed by long-term comparison of a Cs-He combined magnetometer with a Cs-K tandem magnetometer. The expected long-term stability of the tandem-type magnetometers with one of its constituent being a narrow line potassium Mz-magnetometer is better than 0.01 nT. Other characteristics of the instruments (short-term resolution, response time, expected absolute accuracy and others) are analysed and compared.

GA5.01/E/29-A1 1100

BI-COMPONENT MAGNETOMETER-VARIOMETER BASED ON SCALAR CAESIUM SENSORS

An. P. NAUMOV, (D.I.Mendeleyev Institute for Metrology / VNIIM, St Petersburg, 198005, Russia, email: slovo@mail.line.ru) Yu. V. Tarbeyev and I.S. Chasiev (both at VNIIM, St Petersburg, 198005, Russia, email: hal@onti.vniim.spb.su)

The magnetometer-variometer (MV) consisting of a scalar fast-acting optical pumped caesium sensor inside of quartz astatic coil-system has been developed. This device was developed for decision of problem of the exact measurements of ULF Earth's magnetic field variations in active tectonic regions. (The vector of source magnetic moment of ULF signals has direction along of geomagnetic field vector). All construction of device contains two parts: MVa and MVb. The MVa measures of the Z component of Earth's field and consists of a quick response Cs sensor (of Sx type) and quartz coil-system (along of magnetic meridian). The MVb measures of the total intensity of Earth's field, he consists of a quick response optical pumped Cs sensor too (of Szx type) and disposed side by side. High sensitivity of the MV (resolution - 0.01 nT) assures precision measurements and magnetic location of geovariation sources. Measurement cycles 0.2-1.0 seconds, the accuracy of the field measurement is not worse than 0.5 nT.

GA5.01/E/13-A1 1115

A NEW TANDEM SCALAR MAGNETOMETER BASED ON POTASSIUM-39 4-QUANTUM TRANSITION

E.B.Alexandrov, M .V. Balabas, A. K .VERSHOVSKII. (S.I.Vavilov State Optical Institute, St.Petersburg 199034, Russia.)

A new tandem-type quantum magnetometer is described. As any tandem magnetometer it consists of a fast-response self-oscillating unit and a high precision low-speed Mz unit. Unlike the Bender's prototype our tandem comprises a single atomic cell with a mixture of potassium and cesium at certain proportion. Cesium vapor is used in the self-oscillating unit. Its output signal after frequency doubling is slightly shifted to match the narrow potassium resonance, which provides the high accuracy of the instrument. The special frequency shifting scheme using 32-bit synthesizer was designed. As a reference potassium resonance line the four-quantum resonance m=-2<==>m= +2 is chosen. The four-quantum resonance has an advantage of perfect frequency linearity with magnetic field strength and the highest resolving power. The output resolution of the magnetometer is about 1 pT/(Hz)^1/2 while its absolute accuracy is expected to be of the order of 10 pT.

GA5.01/E/14-A1 1130

THE LONG TERM STABILITY OF THE USGS DELTA I - DELTA D (DIDD) SYSTEMS

LEROY W. PANKRATZ(US Geological Survey, PO Box 25046, MS968, Denver Federal Center, Denver, Colorado, USA,80225-0046, email: pankratz@ghtmail.cr.usgs.gov) Edward A. Sauter(U S Geological Survey, PO Box 25046, MS968, Denver Federal Center, Denver, Colorado, USA,80225-0046, email: esauter@ghtmail.cr.usgs.gov)

The US Geological Survey presently operates thirteen geomagnetic observatories throughout the continental United States, alaska, Guam, Hawaii and Puerto Rico. In addition we have international co-operative agreements with Brazil, Hungary, India and South Korea operating geomagnetic observatories. All of these observatories are equipped with Fluxgate Magnetometers, Geometrics or GEM Systems Proton Magnetometers and Synergetics Data Collection Platforms. In addition most of these observatories provide weekly absolute calibrations provided by Diflux Magnetometers and supplemented with DIDD's. This paper will attempt to address and analyse the long-term stability of the DIDD's employed at many of the United States observatories.
The method of analysis will include comparison of the baseline differences derived from the Diflux observations and those generated from the DIDD. In order to proceed we have made the reasonable assumption that the fluxgate magnetometer can be considered stable over a minimum two-hour period. Thus the Diflux derived baselines can be compared to the two DIDD observations which most surely flank those of the Diflux. Therefore the DIDD baseline can be extrapolated between these two points and a difference derived. It has been determined that in all three elements H, D and Z the differences vary by no more than +/- 1.25 nt during any thirty day period. Long term data comparisons including temperatures will be presented.

GA5.01/W/16-A1 1145

STABILITY OF DELTA "I" - DELTA "D" (DIDD) QUASI-ABSOLUTE SYSTEM

Laszlo HEGYMEGI, Alpar Kormendi, Andras Csontos, Balazs Heilig (Eotvos Lorand Geophysical Institute, Budapest, Columbus utca 17-23, H-1145, Hungary, email: hegymegi@elgi.hu)

Geomagnetic recording systems are generally relative instruments, their baseline is changing with time. The baseline has to be determined regularly with an absolute instrument. It would be an ideal solution if we could use absolute instrument for recording the field variation. There were several attempts in the past to realise this idea but because of several disadvantages of the constructed instruments these efforts did not proved to be very successful.
Some years ago in co-operation of Eotvos Lorand Geophysical Institute (ELGI), U.S. Geological Survey (USGS) and GEM Systems a new quasi-absolute system (DIDD) was developed which consists of a small size spherical coil system and an overhauser proton magnetometer. The system performs a complete set of measurements in every two seconds and provides the absolute value of the field vector F, the declination D and Inclination I. The stability of the data measured depends mostly on the mechanical stability of the coil system.
To verify the stability of the new DIDD system working in Tihany Observatory of ELGI, declination and inclination absolute measurements were carried out by two declination-inclination theodolite (DIM) twice every week. The result of this investigation is presented in this paper.

GA5.01/W/08-A1 1200

NEW DESIGN IN LINEAR FLUXGATE SENSORS

Otto NIELSEN(Institute for Automation, Technical University of Denmark, DK-2800 Lyngby, Denmark, email: ovn@iau.dtu.dk); Ole RASMUSSEN(Danish Meteorological Institute, Lyngbyvej 100, DK-2100 Copenhagen, Denmark, email: or@dmi.dk)

Based on the experiences from the ORSTED satellite magnetometer a new linear fluxgate sensor has been developed. The sensor core is made from an amorphous metal alloy with has been given a special heat treatment to minimise the magnetostriction and the noise. The mechanical parts of the sensor are made from glas and quartz to minimise thermal drift.Preliminary results will be presented showing noise figures lower than 20 pT RMS and offset drifts as low as 5 nT over a temperature range of 80°C.

GA5.01/E/06-A1 1215

MORE ABOUT THE MAGNETOMETERS NOISE

Rikhard Berkman and Valery KOREPANOV (Lviv Centre of Institute of Space Research, 5-A Naukova str., 290601, Lviv, Ukraine, email: vakor@isr.lviv.ua)

The modern requirements of magnetic surveys data quality need to lower as much as possible the magnetometers noise level (NL). By this, all zero line instabilities are kept in mind as NL: from very long time fluctuations (1 year and more) to some Hertz and more.
Two types of magnetometers are examined as the most widespread ones: search-coils and flux-gates. For each type the semi-empirical expression allowing to estimate the theoretically lowest possible NL is derived. The most important parameter determining NL - sensor length - is singled out. Then using the NL criterion the recommendations as to the proper choice of flux-gate or search-coil magnetometers are given if it is necessary to study the magnetic fluctuations in the intermediate frequency band where both types seem to be equally efficient. For search-coils magnetometers a new calculating method using so called generalised parameters is proposed. It is shown that using this method an optimal combination of search-coil magnetometer is achieved for given limitations. Some practical examples confirm good matching of calculated and obtained NL parameters. The physical nature of the flux-gate sensor noise is investigated more in details and main factors contributing to its NL are discussed. For extremely low frequency, the deviation of magnetic noise distribution from the normal low is shown, and lower than 1/f slope of the NL dependence from the frequency is confirmed. The optimal parameters of the core material for flux-gate sensor are discussed and the special influence of Curie temperature of such alloys is illustrated. Some other peculiarities of flux-gate sensor construction are discussed which can essentially improve the magnetometer parameters.
Their practical level for recently developed magnetometers is reported.

GA5.01/P/02-A1 1230

MAGNETIC MODEL FOR A NOT STEEL-FREE THEODOLITE

V. AUSTER MAGSON GmbH, Rudower Chaussee 6, 12489 Berlin

In the geodetic practice, for example in the forestry, also at present theodolites in connection with a sensitive compass are used. Therefore we carried out experiments with a "DI-Flux" equipment, consisting of a theodolite ELTA 50 (ZEISS) and a full scale flux - gate magnetomter (MAGSON). Using POISSON's equations for the magnetic deviation we calculated a model for the magnetic disturbance on the sensors place. Basing on this we developed a methode, which gives an automatic adjustment to magnetic north as zero point for the measurement of the horizontal angle.

SOLAR ECLIPSES MAGNETIC EFFECTS, A REVIEW

A. Orozco and E. HERNANDEZ (Instituto de Geofisica, Ciudad Universitaria, 04510, Mexico, D.F., Mexico; Adolfo (tonatiuh.igeofcu.unam.mx; Estebanh (tonatiuh.igeofcu.unam.mx).

The magnetic effects of solar eclipses have been measured since the beginning of this century. In the first time it was concluded that the source of this effects was at an atmospheric layer above 100 km and the model in general only took into account the total shadow area. The confirmation of the existence of the ionosphere gave a new push to this study, using ionosondes to monitor the changes in electrical conductivity and free electron content during the totality of the eclipse phenomena. Anyway, there was a lack of cualitative and cuantitative explanation of some of the main aspects of this effect. Particularly an asymmetry of the peak effect respect to the optical totality and the apparent existence of magnetic effects outside the general path of the eclipse.
In this paper we present an overview of these stages of the problem and a cualitative model that explains the principal characteristics of the phenomena.

GA5.01/W/21-A1 1415

FIELD AND OSERVATORIES MAGNETO-TELLURIC WIDE AREA NETWORK

Eugene KOPYTENKO, Yury Kopytenko, Andrej Radilov (SPbF IZMIRAN, Muchnoj per.2, Box 188, St.Petersburg, Russia, email: ek@eak.izmi.ras.spb.ru)

SPbF IZMIRAN is continued its developing in the field of high sensitive magnetometric system. On the base of MVC-2DS, multipurpose magnetotelluric station, it was build Wide Area Network for monitoring quick running processes both in magnetic and telluric fiedls, and in a third (three component) geophysical channel in quasi real time. System consist of Remote Station equipped with high sensitive torsion type magnetometer, 24-bit resolution Analogue to Digital Converter driven by GPS controlled clock, remote PC runnig under LINUX (UNIX clone OS) and Laborotory's Server. Data are buffered at remote PC. Server collects it and transmitts it to the computers wich are included into the list of receipients.

GA5.01/E/16-A1 1430

MAGNETOMETER FOR FIELD SURVEYS: TESTS AND FIRST RESULTS

Hans-Joachim LINTHE (GFZ Potsdam, Adolf-Schmidt-Observatory, Lindenstr. 7, D-14823 Niemegk, Germany, email: linthe@gfz-potsdam.de) Valery Korepanov and Leonid Rakhlin (Lviv Centre of Institute of Space Research, 5-A Naukova str., 290601 Lviv, Ukraine, email: vakor@isr.lviv.ua)

The repeat surveys are one of the most difficult tasks if high quality results of magnetic investigation have to be obtained. First of all it is because the field magnetometer for this work has to combine high quality of the observatory instrument with good temperature stability and convenience of rapid installation in operative position.
To facilitate these works a fully autonomous magnetic station LEMI-008 was developed. Its main advantages are:
- wide measurement range (up to 100 000 nT);
- wide operating temperature range (-5 (+40 (C);
- GPS synchronization and coordinates determination;
- flush-type internal memory;
- low weight and power consumption.

The latest modernization was made with the sensor suspension: all system is fixed in fully hermetized housing with gimbals using the needle balance. It is firmly blocked during transportation and quickly released after installation. The developed tests of the magnetometer were executed: temporal and thermal drifts determination, tilt compensation ratio study, multiple switching on and off influence etc. and their results are reported. First results of field measurements are presented and the estimation of their quality is made.

GA5.01/E/07-A1 1445

GEOMAGNETIC SUPER-REPEAT STATIONS

Charles BARTON and Andrew Lewis (Australian Geological Survey Organisation, GPO Box 378, Canberra ACT 2601, Australia, email: cbarton@agso.gov.au)

Experience in Australia has demonstrated that frequent (annual) occupations of a relatively small number of well-placed magnetic repeat stations is more cost-effective than five-yearly occupations of many stations. The main advantage of this "Super-Repeat Station" strategy is improved ability to track and predict the secular variation. Other advantages are better and quicker identification of bad data, more flexibility in avoiding magnetically disturbed observing conditions, easier schedules for field parties, steady-state annual funding demands, and reduced costs.

GA5.01/E/26-A1 1500

COMPARATIVE ANALYSIS OF DIFERENT PROCEDURES FOR THE EXTRACTION OF THE DIURNAL VARIATION

MANUEL CATALÁN,Antonio Pazos (Geophysic Department, Royal Naval Observatory, San Fernando 11100, Cádiz, Spain)

During one month (August)in the summertime of 1995, 1996 and 1997 ,an amrine geophysical campaign has been carrying out at the Spanish Exclusive Economic Zone (ZEE) at the Balear Sea (West Mediterranean), as a collaboration between the Spanish Defence Ministry, and the Spanish Oceanographic Institute (IEO).
For different reasons, at 1995 we were not able to have a reference magnetic station at a close area, so o correct the diurnal variation data we were obliged to use a reference station (San Pablo-Toledo observatory) that, on average, is 600 km. away from the working zone.
This fact, usually, is corrected affecting the reference station data by a scale factor, once have been corrected by time difference. This correction does not take into account possible scattered effects.
We have developed a procedure based on the Transfer Function concept result from the analysis, at frequency domain, of one-month magnetic registers obtained from 1996 campaign using two reference stations:
- The same one we used at 1995, that is San Pablo-Toledo
- Another nearby site of the surveyed zone, situated on a hill of Mahon Naval Station (Minorca, Balearic Island).

In this job we compare classical methods with this procedure, using magnetic registers of 1997 campaign.
Result shows that errors are in the same order for this procedure and classical methods. Nevertheless, a better behaviour could be obtained using our method during quiet days.

GA5.01/E/24-A1 1515

IMPROVEMENTS IN REPEAT STATION NETWORKS FOR DEVELOPING COUNTRIES

Luiz Muniz BARRETO (Observatorio Nacional. Rua General Bruce,586.-20921-400 Rio de Janeiro,RJ. Brasil, email: barreto@on.br)

To understand the geomagnetic field behaviour we need to know its changes in space and time. To achieve a global coverage of space variations it would be necessary a dense network of observing stations. Besides this, a complete knowledge of time changes requires that, in each of these stations would be installed instruments to cover the whole time geomagnetic spectrum. These requirements are impossible to be achieved. A feasible solution was adopted : a possible network of magnetic observatories where all time changes are recorded, and a supplementary network of repeat stations where punctual values are obtained.
We must understand that the results and objectives of both kinds of stations are different. About 40 years ago, geomagnetic data from specific satellites have improved our data collection but, in spite of this modern method, we cannot neglect good ground level data, for many reasons (anomalies, observing continuity, for instance). In general, we could say that a desired complete coverage of the geomagnetic field could be obtained from a global network of geomagnetic observatories, economical and logist reasons inhibit the existence of an adequately dense network. The actual geographic distribution of permanent geomagnetic stations shows that, besides the great gaps of the oceans, seas and remote regions, the area covered by Developing Countries (DC) has a poor density of such stations. Notwithstanding the limited output from repeat station networks, they are useful to prepare magnetic charts and to study secular variation, mainly in large area countries. It is essential that they could produce good data with adequate periodicity and continuity. A scrutiny of the actual conditions of DC repeat stations shows technical and economical problems, as well as a bad use of the results. In order to improve the situation some procedures must be made. They include a priority to place the observing points, taking into account local peculiarities such as special geomagnetic patterns (EEJ, SAGA, regions with high values of the secular variation, for instance), besides a reduction of the time in field work by using modern instruments and procedures. Some trials were made in Latin-America with reasonable results.

GA5.01/E/25-A1 1530

SECULAR VARIATION CHARTS OBTAINED FROM MAGNETIC REPEAT STATION NETWORK IN VIETNAM

H D CHAU, T Q Hao, V T Son (Hanoi Institute of Geophysics, Box 411 Buudien Boho Hanoi Vietnam, email: chau@igp.ncst.ac.vn)

Geomagnetic secular variation charts were constructed from the absolute measurements of the geomagnetic field carrying out at the repeat stations network in Vietnam for epochs 1991.5 and 1997.5. The calculation of charts was based on the absolute data from 56 magnetic repeat stations, sparsely distributed all over the territory of Vietnam.
The results are given in the form of several tables (magnetic secular variation of the field elements in the various stations for period from 1991 - 1997). The magnetic secular variation charts for 7 elements X, Y, Z, T, H, D, I were calculated using the analytical method of approximation of magnetic secular variation field following a second degree polynomial. The characteristics of magnetic secular variation field of every element were shown. Secular variation of total magnetic field and its components in Vietnam are varied in the following intervals:
18 nT/year < dT < 31 nT/year;
-8 nT/year < dH < 20 nT/year;
56 nT/year < dZ < 78 nT/year;
-0.5 '/year < dD < 3.0 '/year;
3.8 '/year < dI < 6.7 '/year;
-6 nT/year < dX < 18 nT/year;
-6 nT/year < dY < 35 nT/year.
These results were compared with the IGRF Secular Variation Model.

GA5.01/W/19-A1 1600

COMPARISON BETWEEN TWO PERIODS OF DETAILED GEOMAGNETIC SURVEYS CARRIED OUT IN ISRAEL

Boris SHIRMAN (Survey of Israel, Lincoln str. 1, 65220 Tel-Aviv, Israel, email: rd_soi@hotmail.com)

Geomagnetic anomaly component maps of Israel made in two surveys in 1983-1985 and 1993-1995 are presented. Maps of total field, horizontal and vertical components and declination were constructed based on absolute measurements at 140 and at 130 points during the first and second surveys respectively. Site locations and geographic azimuth were determined using GPS and GIRO instruments. Geomagnetic measurements were performed by a total field proton magnetometer (ELSEC-770) and declination-inclination magnetometer (ELSEC-810) with an accuracy of 1 nT and 10'', respectively. All measurements were brought to base lines of the Amatsia and Bar-Giora observatories in 1984 and 1991. The anomaly field was calculated as residual between the averaged measurements and IGRF-1995 (7th generation). All components of the residual field were gridded using the Kriging method.
The main features of the maps may be described briefly as follows. The central area of the country is dominated by the large Hebron anomaly which peaks about 200 nT in the H-component against a background of about -100 nT. Several intense anomalies of 150-200 nT are observed in the southern part of the Negev desert. In the northern part of the country, the positive Carmel anomaly, which peaks at about 200 nT in the total field, stands out. A special feature of the D-component anomaly map is a positive anomaly extending along the Mediterranean coast that is not observed in the total field maps.
These features are typical for both surveys. The distribution of the differences between the surveys are presented as residual maps. These differences are defined as random distribution of the field with ± 20 nT amplitude. This quantity increases at anomaly locations. The main reason for such differences is an inconsistency between the measured points at two periods. The residual maps give an accuracy estimate of the map construction.

GA5.01/P/04-A1 1615

MAGNETIC SURVEY FOR EL - QUSEIR - EGYPT.

FATHY MOHAMED AHMED , National Research Institute of Astronomy and Geophysics , Helwan Cairo , Egypt. Fax : 002 - 02 -5548020)

Observations were made for the area northwest of El Quseir Egypt by two proton magnetometers , one for the base station and the other one for the Survey. Total magnetic Intensity anomalymap was made for the area. It shows that the basement Complex of the area has 12 step faulting systems, 4 horsts, 6 grabens took place from 13 normal faults.

GA5.01/E/10-A1 1630

COMBINATION OF EUROPEAN REPEAT STATION SURVEYS

Monika KORTE and Volker Haak (GeoForschungsZentrum Potsdam, Telegrafenberg, D-14473 Potsdam, Germany, email: monika@gfz-potsdam.de)

Geomagnetic repeat station surveys should provide a good basis for a detailed investigation of the spatial distribution of secular variation and detection of its possible anomalies.
Our aim was to carry out such an investigation on a continental scale by combining repeat station data of several European countries. Such a combination shows good results when calculating a smoothed model of large-scale secular variation but fails when trying to model anomalies. There are two main reasons for this. In some countries there have only been magnetic ground vector surveys, which are neither repeated in short enough time spans nor do they offer the desired accuracy. Even repeat station surveys sometimes seem to lack accuracy. If the data are not carefully corrected for external influences, the errors in the measured absolute values can reach the values of annual secular variation.

GA5.01/E/05-A1 1645

AN OVERVIEW OF COMPASS ROSE SURVEYS IN THE UNITED STATES

BERARDUCCI A.M., (U.S. GEOLOGICAL SURVEY, GOLDEN, COLORADO, USA)

The U.S. Geological Survey, Geomagnetism Group has considerable experience performing magnetic surveys of compass calibration pads (compass roses). The Group also provides consultation on compass rose construction and calibration training to companies who do their own surveys. Few private survey firms are capable of doing these surveys. The FAA (Federal Avaiation Administration) provides specific guidelines for compass roses. In this paper, the variety of instruments and techniques used in performing compass rose surveys and techniques used in data reduction are described. In doing these surveys, geomagnetism programs can provide a valuable service to commercial and military aviation communities. Income generated from compass rose surveys can be a significant source of income for a geomagnetism program.

A VECTOR MAGNETOMETER FOR QUASI-ABSOLUTE MEASUREMENT OF THE GEOMAGNETIC FIELD AT SEA

Toby D G CLARK and Chris W Turbitt (British Geological Survey, West Mains Rd., Edinburgh, EH9 3LA, Scotland, UK; e-mail: t.clark@bgs.ac.uk)

A vector magnetometer is being developed to measure the strength and direction of the geomagnetic field at sea from a sailing vessel. Its purpose is to make geomagnetic measurements during a voyage to circumnavigate the Atlantic to mark the 300th anniversary of Edmond Halley's voyages in the "Paramore" and his chart of the Earth's magnetic field. The instrument consists of a tri-axial full-field fluxgate magnetometer, supplied by the Danish Meteorological Institute, mounted on a rigid frame together with the four antennas of an Ashtech 3DF GPS Attitude Determination Unit (ADU). The ADU is capable of measuring the attitude of the frame (and hence magnetometer) in pitch, roll and true heading with an accuracy of 0.2 degrees at a rate of 2Hz. A proton magnetometer will also be incorporated to provide absolute measurements of the magnetic field intensity. The calibration of the instrument will be described, and we will also discuss its application in making repeat station measurements at sea.

GA5.01/E/02-A1 **1715**

TIME SERIES ANALYSIS BY NI SIGNAL PROCESSING SUITE

Alpar KORMENDI (Geofizikai Obszervatorium, H-8237 Tihany, Kossuth L. u. 91, Hungary, email: alpar2@mail.matav.hu)

The high computing power of contemporary PCs and advanced data processing software made possible to analyse large data sets in a laboratory or at home. National Instruments (US) offers several toolkits for sophisticated data analysis. Paper demonstrates the use of Joint Time Frequency Analysis (JTFA) to reveal periodical components in long time series and how to remove (or select) the detected components by digital filters designed (DFD) on the "a priori" knowledge of the frequency spectra. Daily and hourly means of the geomagnetic variations recorded from the beginning of the century have been analysed for selected observatories of the northern and southern hemisphere. Some results were surprising at least for the author.

VIDEO OF MAGNETIC REPEAT STATION SURVEY WORK IN AUSTRALIA, 1937

Dudley Parkinson (68 Risdon Road, Newtown, TAS 7008, Australia) and CHARLES BARTON (Australian Geological Survey Organisation, GPO Box 378, Canberra, ACT 2601, Australia, Email: cbarton@agso.gov.au)

This video is a 20 minute extract from a film made by photojournalist Jim Fitzpatrick in 1937 showing a magnetic repeat station occupation carried out by Wilfred C. Parkinson. Parkinson was employed by the Department of Terrestrial Magnetism, Carnegie Institution of Washington. The survey work, which extended to Papua New Guinea and many Pacific islands, was undertaken during three years away from his duties as officer-in-charge of the Watheroo Magnetic Observatory in Western Australia. A modern commentary has been added by Parkinson's son (the first author) to explain the methods and instruments being used.

THE ALGERIAN REPEAT STATION NETWORK

A. ABTOUT, F. Anad and N. Akacem (C.R.A.A.G., Algerian Research Center of Astronomy, Astrophysics and geophysics, B.P. 63 Bouzareah, Algeriers, Algeria, e mail: geoph@ist.cerist.dz)

Several maps of the element of the geomagnetic field in Algeria are presented. They were carried out from the magnetic repeat station network of 1989- 1993 and 1997. The maps include inclination, declination, vertical, horizontal and total intensities and their corresponding secular variations.
The algerian geomagnetic repeat station network consists of 35 stations chosen to give a fairly uniform distribution throughout the country. All magnetic data were reduced to the Tamanrasset Observatory.
Maps obtained display a regular evolution of the terrestrial magnetic field. In addition, magnetic anomalies at the Hoggar shield and the Sud atlasique flexure are observed.
Finally, we present a comparison between these maps and those obtained from the IGRF values.

MAGNETIC SURVEY FOR ARAB REPUBLIC OF EGYPT

FATHY MOHAMED AHMED (Nationa!Research Institute of Astronomy and Geophysics Helwan, Cairo, Egypt, Fax 002 - 02 - 5548020)

Observations were made for Arab republic of Egypt for the Geomagnetic field elements Vertical, Horizontal , Declination , and total force. 10000points of observations were observed along all accessible roads of Egypt. The magnetic Daily recordi Tfgs of Misallat observatory were used to eliminate. the daily variations to reduce the field observationsto the datum. Contour maps were made for the Geomagnetic field of Egypt.

REPEAT SURVEYS AND ITS RESULTS IN CUBAN ARCHIPELAGO

Rosa ALVAREZ (Institute of Geophysics and Astronomy, Science, Technology and Environmental Minister, 212 N. 2906 e/ 29 y 31, La Lisa, Havana, Cuba)

This is a recount of the magnetic survey repetition and others vectorial surveys in the territory of the Cuban Archipelago where the first repeat station net was established since 1965 and the last in 1999. Part of the work was the evaluation and selection of the repeat net station of first and second order according to geographical localization, effect of the regional and local Sq variation and results.
The elaboration of the data permitted to establish the behavior of the secular variation in the period under analysis. It is very important the adequate knowledge of the minimum and maximum values of the variation's period for the region with a purpose to determinate the frequency of the repetition survey.
The obtained data were used in the determination of the secular variation and evaluation of the regional magnetic models for 1965-1999.

INVESTIGATION OF THE GEOMAGNETIC FIELD ON THE TERRITORY OF THE CZECH REPUBLIC FOR 1995.5 AND ITS SECULAR VARIATION

Pavel Hejda and Josef Horacek (both at Geophysical Institut AS CR, Bocni II/1401, 141 31 Prague, Czech Republic, email: ph@ig.cas.cz)

The measurements of geomagnetic field on the territory of the Czech Republic cover continuous observations at the Geomagnetic observatory Budkov, measurements at 7 repeat stations (carried out about every two years) and magnetic survey. A recent stage of magnetic surveying activity was started in the fifties by setting up a fundamental network of the first order consisting of 199 points. The network was re-occupied in 1976-78 and 1994-1996. The last magnetic survey was carried out by a flux gate theodolite for measurements ofdeclination and inclination and by a proton precession magneto meterfor the total intensity. The azimuth was determined by the Sun observations.
All values were reduced to the epoch 1995.5. With regard to ratherlong period of the measurements (more than 2 years) the temporal and spatial changes of the secular variation had to be taken into consideration when reducing data. The main problem was how to estimate the unknown secular variation at the individual points. As the Central Europe is covered by a quite dense net of geomagnetic observatories, we have used their annual means together with the repeat stations data for creating a regional model of secular variation. Nevertheless, this process was not free of complications, because our study revealed large discrepancies in some observatory data. A plausible solution was found after more detailed analysis and with help of IGRF secular variation model.

A MODEL OF GRID MAGNETIC ANGLE FOR GREAT BRITAIN

SUSAN MACMILLAN and Jim Carrigan (British Geological Survey, Murchison House, West Mains Road, Edinburgh EH9 3LA, UK. email: S.Macmillan@bgs.ac.uk, J.Carrigan@bgs.ac.uk)

Using declination data from observatories and repeat stations, a model of grid magnetic angle (the angle between grid north and magnetic north in the horizontal plane) for the period 1999 to 2002 is derived for Great Britain. We describe the reduction to magnetic quiet level of the raw data, the derivation of a regional secular- variation model and reduction of data to epoch, and the final computation of grid magnetic angle. The resulting model is used in a service to provide magnetic information to the Ordnance Survey, the national mapping agency.

THIN STRUCTURE OF SECULAR VARIATION OF GEOMAGNETIC FIELD IN EUROPE

Valentyn MAKSYMCHUK (Carpathian Branch of Subbotin Institute of Geophysics NASU, 3b,Naukova Str, Lviv, 290601, UA, email: valentyn@carp.lviv.ua)

To analyze secular variation on the territory of Europe, average annual values of X, Y, Z - components of geomagnetic field on the European network of magnetic observatories in 1950-1993 have been used. During the time interval in question there existed in Europe two focuses of SV: European, with the epicenter in Southern Europe, and Arctic, with the epicenter in the north of Europe. Dynamics and kinematics of these focuses had the crucial influence on the structure of the field SV. Both focuses had low intensity (20-40 nT/year). It looks like the European focus appeared in Southern Europe (in the region of the Balkans) in the fifties in the result of transfer of the Caspian focus. Velocity of its drift during this period made up approximately 2 grade/year. The Arctic focus of SV emerges in the region of Scandinavia in the seventies. It drifted south, its speed of transfer in separate attained 15 grade/year. In 1980-1990 SV focus remained steady in Central Europe, approximately in the vicinity of European SV focus in the sixties. Analysis of annual maps of SV convincingly demonstrates that there were 2 SV focuses in Europe at that time. By the end of the eighties Arctic focus finally disappeared, and European SV focus still existed on the territory of Central Europe. Calculations of SV centers depth were performed. Despite of the differences in SV field morphology and intensity, drift velocities, the depth of their sources turned to be rather close and were within 3500-4500 km, corresponding to the liquid part of the Earth's core.

GEOMAGNETIC SURVEY OF ESTONIA

H. NEVANLINNA (Finnish Meteorological Institute, P.O.Box 503, FI-00101 Helsinki, Finland, email: heikki.nevanlinna@fmi.fi) K. Pajunpää (Finnish Meteorological Institute, Nurmijärvi Geophysical Observatory, FI-05100 Röykkä, Finland, email: kari.pajunpaa@fmi.fi) L. Kreen (Estonian Air Navigation Services, Lennujaam 2, EE-0011 Tallinn, Estonia, email: lauri@eans.ee)

During summer 1998 geomagnetic field components were measured at 11 sites in Estonia. One of the aim of the project was to re-measure declination at airport reference point (ARP) that have not been done since the Soviet era in Estonia. By collecting all the declination data available in the Soviet geomagnetic maps in the 70's, a reconstruction of the distribution of declination in Estonia was carried out and a preliminary declination chart (1: 500 000) of Estonia for 1998.0 was published [1]. The plan is to make in the near future a more detailed geomagnetic survey (say in 30 km x 30 km grid) of Estonia by using a movable DI-flux together with the proton magnetometer.

CERTIFICATION OF AIRCRAFT COMPASS CALIBRATION BASES: A JOB FOR GEOMAGNETIC OBSERVATORY PEOPLE

JEAN L. RASSON, (Institut Royal Meteorologique, Centre de Physique du Globe, B-5670 Dourbes Belgique)

An airport should have a special area where the magnetic compasses of aircraft can be checked and calibrated. This area (the Compass Base) should be surveyed for establishing it's magnetic cleanliness and for measuring the Magnetic Declination on it. This very specialised task is easily accomplished by geomagnetic observatory staff using the standard absolute instrumentation. We review the procedures and requirements for Compass Base surveying. An example at the Brussels International Airport is presented.

GA5.01/E/32-A1 Poster **0900-09**

THE MAGNETIC REPEAT STATION SURVEYS IN SWEDEN

Kjell Borg and Gerhard SCHWARZ (Geological Survey of Sweden, Box 670, S-75128 Uppsala, Sweden, email: gerhard@sgu.se)

In recognising the need for more systematic magnetic observations a net of sites was established in Sweden in the 1920s that were almost evenly distributed over the country and intended to serve as repeat stations for future re-occupations. In 1930 the net consisted of 86 stations. A number of them were installed in remote areas and the effort in surveying these sites periodically was very large. Therefore, this extended net of observational points was reduced to only 10 sites in the early 1950s. The remaining sites were then revisited every other year until today.
We will present here the procedures for measuring secular magnetic variations and their development in time. The derived normal magnetic field will be compared in space and time with other available magnetic reference fields. We will outline future perspectives and strategies for secular magnetic variation measurements in Sweden and compare them with ordinary magnetic observatory recordings.

GLOBAL DP2 CURRENT SYSTEM OBSERVED IN CIRCUM-PAN PACIFIC MAGNETMETER NETWORK

Hiroshi TACHIHARA, Manabu Shinohara, Hideaki Kawano, Kiyohumi Yumoto (all at Dept. of Earth and Planetary Sciences, Kyushu University, Fukuoka, 812-8581 Japan,
Email: tachi@geo.kyushu-u.ac.jp), Yasuo Kitamura (Tohoku Institute of Technology, Sendai, 982-8577 Japan) and CPMN Group

We have started geomagnetic observations at seven stations in the magnetic equator (|MLAT|= 0-1.55) as the Circum-pan Pacific Magnetometer Network (CPMN). These stations are located along the magnetic equator and scattered at the places in local time of midday to midnight. We can expect the detailed analysis of local time variation of the equatorial electrojet from this global observation arrangement. Moreover, these observations can reveal the details and local time dependence of disturbance energy transfer in the earth ionosphere, from the auroral to the equatorial region in company with other global observations in mid- to high-latitudes. We present the analysis of DP2 current system observed in the magnetic storm time on August 26, 1998 by using the magnetic data from these CPMN network.
Our newly established equatorial observations are at Ancon (Peru ; MLAT=1.55 ; MLT midnight in UT = 4.80), Guadalupe (Peru ; MLAT=-0.02 ; MLT= 4.74), Canete (Peru ; MLAT=0.78 ; MLT= 4.77), Yap (Micronesia ; MLAT=0.45 ; MLT= 15.13), Davao (Philippines ; MLAT=-1.35 ; MLT= 15.88), Cebu (Philippines ; MLAT=0.73 ; MLT= 15.96) and Bac Lieu (Vietnam ; MLAT=0.85 ; MLT= 17.02). These stations are located quite near to the magnetic equator. We examined the global DP2 current system in the magnetic storm time on August 26, 1998 by using these equatorial data as well as other CPMN data. It is well known that global DP2 current system consists of twin-vortex currents in dawn and dusk sides and the global eastward current in the dayside and nightside equatrial regions. Our analysis revealed the strong eastward current in the dayside equatorial region and, however, variation of currents in the nightside equatorial region. We will present several analysis of global DP2 current system focused to the equatorial currents.

USE OF GEOMAGNETIC INDUCTION VECTORS TO CONTROL MAGNETOMETER DATA QUALITY

Ari VILJANEN (Finnish Meteorological Institute, Geophysical Research Division, P.O.B. 503, FIN-00101 Helsinki, Finland, email: ari.viljanen@fmi.fi)

Geomagnetic induction vectors are used in scientific investigations to locate highly-conducting anomalies in the earth. Another application is found in a long-term control of magnetometer data quality. This is based on the time-independence of the induction vectors, because the earth's structure does not vary. Consequently, changes in vectors indicate instrumental problems, man-made noise or, mostly at high latitudes, the source effect due to non-uniform ionospheric currents. The latter is a natural phenomenon to be distinguihed from the first ones. This presentation illustrates the use of induction vectors to control the IMAGE magnetometer data recorded in Fennoscandia and Svalbard, where the source effect also plays a significant role.

AUTOMATED COMPUTATION OF ABSOLUTE OBSERVATIONS FOR OBSERVATORIES AND REPEAT SURVEYS

BERARDUCCI, A.M., (U.S. Geological Survey, Golden, Colorado,USA) Worthington, E.W., (Geophysical Institute, University of Alaska, Fairbanks, Alaska,USA)

The USGS is using a spreadsheet program for computing DI-Flux absolute measurements. The program is primarily used at Observatories and Repeat Stations, though it has applications wherever DI-Flux observations are made. The program computes absolute values, baseline values, baseline averages and standard deviations. Macros are used to output each set of observations, a summary of baselines and historical graphs of baselines. Use of the program allows for electronic transfer of results to the main office immediately after the data has been entered. It has also helped reduce computation errors and has automated compilation of absolute and calibration files.

CONTROL METHODS FOR GEOMAGNETIC FIELD MEASUREMENTS BASED ON PROTON PRECESSION SIGNAL PROCESSING

Olga DEKUSAR, Alex Denisov, Vladimir Sapunov, Dmitriy Savelyev, Serg Kiselev (Ural State Technical University, Quantum Magnetometry Laboratory, Mira St., 19, Ekaterinburg, 620002, RUSSIA, email: sva@dpt.ustu.ru)

This report proposes technical methods, which can be useful for measurement of the geomagnetic field in the observatory and fieldwork. The use of proton precession signal processing allows to improve not only sensitivity of proton magnetometers but also analysis of the magnetic variations.
To control of proton magnetometer accuracy, the QMLab offers to use a quality measurement criterion (QMC) based on time analysis of proton precession signal periods. The QMC can be determined in units of magnetic fields (nT) in single reading. This criterion is equal to a standard deviation of continuous measurements at stable geomagnetic fields. The QMC is not susceptible to geomagnetic variation and takes into account real conditions (proton signal value, noise, magnetic gradient, etc). A self-adapting cut of proton signals by signal statistic analysis is useful to suppress harmful pulses (lightning, microphone effect, malfunction, etc). In this case, the QMC outputs a real measurement accuracy also. The methods are field-tested and are introduced in the QMLab Overhauser magnetometer POS-1. In this report, the algorithm and background of signals processing are submitted.
It is discussed a background of algorithm and signal precession treatment to measure of geomagnetic field rate in single reading. Thus, a proton magnetometer can operate us a new devise namely a speed magnetometer. Sensitivity was evaluated about 0.01 nT/sec for Overhauser's speed magnetometer at 3 sec sampling rate. This method may are useful at rather slow measurements.

A NEW GENERATION OF U.S. MAGNETIC OBSERVATORY DATA ACQUISITION SYSTEMS

D.C. HERZOG (USGS, Box 25046 MS 966, Denver Federal Center, Denver, Colorado, 80225-00466 USA, email: herzog@ghtmail.cr.usgs.gov)

The U.S. Geological Survey's (USGS) Geomagnetism program is undergoing a major modification in the data acquisition systems (DAS) used at its network of 13 magnetic observatories. The correct data collection platforms (DCP) are nearly two decades old and lack sufficient capabilities to perform the functions required for today's observatory operations, including: the collection and storage of 1-second data; orderly shutdown & start up in the event of power failures; and dedicated access to the Internet. The new generation of DAS will use commercial, off-the-shelf personal computers (PC's) with multi-user, multi-tasking operating systems (OS) for observatory operations including: 1-second data recording and storage; numerical filtering; GPS time synchronization; satellite data transmissions; on-site data access, display, and diagnostics; ftp and e-mail operations; and remote system administration from the data collection & processing center located in Golden Colorado.

ABOUT THE METHOD OF SPIKES FILTERING IN DIGITAL RECORDS

Gianibelli Julio C., CABASSI, Iris R., and KHON,Jaqueline (Dep. of Geomagnetism and Aeronomny, Faculty of Astronomical and Geophysical Sciences, La Plata University, Paseo del Bosque s/n, 1900 La Plata, Argentina, email: jcg@fcaglp.fcaglp.unlp.edu.ar, rosy@fcaglp.fcaglp.unlp.edu.ar, jkhon@fcaglp.fcaglp.unlp.edu.ar)

Normally, the geomagnetic variations are masked by a noise mixing forming random spikes in the digital records. Three types of filters are analised: the observations comparison method, the window-filter based on the median determination, and the FFT filter by means of a low-pass window. The application of these methods allow us to establish important characteristics using the median filter method for the Q-days or minimum magnetic activity. Thus, insulated spikes or, sometimes, consecutive apikes are present on the temporal sampling of the system. When the density of spikes is high in the digital records, the FFT and low-pass filters help us for the variation determination. Examples with Trelew magnetic observatory data are showed.

RESULTS OF THE INTERCOMPARISON OF THE DI-FLUX THEODOLITES AT GEOPHYSICAL OBSERVATORY "KLYUCHI", NOVOSIBIRSK, RUSSIA

S.Y. KHOMUTOV, O.I. Fedotova, V.V. Kuznetsov, A.F. Pavlov, N.N. Semakov (Institute of Geophysics SB RAS, Koptyug av., 3, Novosibirsk 630090, Russia; email: hom@uiggm.nsc.ru)

DI-flux system for absolute magnetic measurements is developed at Geophysical observatory "Klyuchi" (Novosibirsk, Russia). It includes a standard theodolite 3T2KP with resolution of 2" (precision system) or theodolite 4T30P with resolution of 30" (field system), manufactured on PO "UOMZ" (Ekaterinburg, Russia), fluxgate sensor mounted on the telescope and electronic null indicator. All magnetic units of the theodolites were replaced on non-magnetic ones. The results of the intercomparison of the absolute D and I measurements using two precision systems, one field system and theodolite Theo 020 are presented. Theo 020 is used at the observatory for the magnetic field monitoring and it is considered as a reference for comparison.

THE DIGITAL VARIATION STATION FOR MAGNETIC OBSERVATIONS

S.Y. KHOMUTOV, A.N. Fedorov, V.V. Kuznetsov, (Institute of Geophysics SB RAS, Koptyug av., 3, Novosibirsk 630090, Russia; email: hom@uiggm.nsc.ru), V.K. Palamarchuk (Okeangeologia, St.-Petersburg, Russia), A.I. Zhelevsky (Institute of Automation and Electrometry SB RAS, Novosibirsk 630090, Russia)

The operating sample of vector digital magnetometer with the synchronous registration, was devised by us. The Earth's magnetic field components are registered simultaneously by two identical measuring systems separated by up to 800 m and controlled by common PC. Zeeman effect is used to registrate the magnetic field in sensors. The sensors are fixed in the Helmholtz coils. The PC programs appended, ensure automatic data registration and process. Dynamic range of field absolute measurements: from 20 000 to 100 000 nT. Resolution is equal to 0.01 nT for the accumulating time 0.2 sec. Stability of the field absolute values averaged per one day is equal to 0.1 nT. This magnetometer was field tested as the part of the station for the magneto-telluric sounding and also as registrator of the magnetic field components on the airplane.

SODANKYLÄ POLAR YEAR OBSERVATORY 1882-1883

H. NEVANLINNA (Finnish Meteorological Institute, P.O.Box 503, FI-00101 Helsinki, Finland, email: heikki.nevanlinna@fmi.fi), J. Kultima (University of Oulu, Sodankylä Geophysical Observatory, FI-99600, Finland, email: johannes.kultima@sgo.fi)

Sodankylä was one of the 11 stations that were in operation during the First International Polar Year 1882-1883. In this poster we demonstrate results of magnetic observations carried out in Sodankylä (September 1, 1882 - August 31, 1883) in a similar manner that is the usual practice for modern geomagnetic observatory data. The magnetic field during the Polar Year period 1882-1883 was very disturbed. One of the greatest (eighth strongest according to the aa-statistics 1844-1998) magnetic storm occurred on November 20th, 1882. The motivation to publish and analyse more than 100-year old geomagnetic data arises from the fact that the quality of the data collected at Sodankylä is good for e.g. analysis of the time behaviour of the geomagnetic activity. The data, about 28 500 hourly readings of the declination (D), horizontal (H)-, and vertical component (Z) of the geomagnetic field is now in electronic form and will be distributed to the World Data Centers. The quality and homogeneity of magnetic observations of D and H is good but Z is less reliable. Similar data analysis of geomagnetic data from other geomagnetic observatories (like Helsinki 1844-1910) has been successful in reconstructing geomagnetic activity index series for the 19th century (the data is available through internet: ftp://www.geo.fmi.fi /pub/data/Helsinki/). Such analyses, as well the utilisation of Sodankylä Polar Year data presented here, promote the construction of long time series of geomagnetic activity that are important in studies of e.g. space climate.

HIGH-SENSITIVE MAGNETIC CLEANLINESS STUDY - PROCEDURE DEVELOPMENT AND TEST RESULTS

Kari PAJUNPAA (Finnish Meteorological Institute, Nurmijdrvi Geophysical Observatory, FI-05100 Rvykkd, Finland , email: kari.pajunpaa@fmi.fi) Viktor Tarassov and Valery Korepanov (Lviv Centre of Institute of Space Research, 5-A Naukova str., 290601 Lviv, Ukraine, email: vakor@isr.lviv.ua)

Nurmijarvi magnetic obsrvatory has well-known calibrating facilities allowing to verify practically all parameters of Earth's field magnetometers. Last year taking into account very favourable surroundings it was completed by a new magnetic cleanliness measuring system which was built in order to solve very important tasks: magnetic cleanliness study and discovered magnetic moments compensation. One of the first system applications is to serve to European and especially local satellite instruments manufacturers.
An existing reference coil system and electronics for magnetometer calibrations were utilised as basic components for the new equipment. A non-magnetic rotating table and a sensing three-components flux-gate magnetometer were installed additionally in the coil system center and corresponding interactive software was written for fast and accurate measurements. A low-frequency (1-10 Hz) demagnetising facilities are available and their higher frequency (50 Hz) development is under construction. Tested bodies with dimensions of about half a meter and weight till 30 kg can be brought inside the coil system. The software is based on LINUX operating system and allows to choose operation modes of rotating table and reference coil system in dependence of the test procedure progress and to compensate automatically Earth's magnetic field variations. Parameters and operational features of the system as well as first measurement results will be presented.

THE DELTA I - DELTA D (DIDD) QUASI-ABSOLUTE COIL SYSTEM. IT'S HISTORY, EVOLUTION AND FUTURE

LEROY W. PANKRATZ, (US Geological Survey, PO Box 25046 , Mail Stop 968, Denver Federal Center, Denver, Colorado, USA, 80225-0046, email: pankratz@ghtnail.cr.usgs.gov),Alpar Kormendi, (Eotvos Lorand Geophysical Institute, Budapest, Hungary, email: alpar2@mail.matav.hu)

Standard geomagnetic recording systems in use today are relative instruments; the absolute baseline of which changes with time. The absolute baseline of the variation instrument requires regular calibration with an independent, true absolute instrument. Several attempts in the past 35 years have been made to develop a quasi-absolute instrument. However, due to cumbersome control and recording systems these concepts were soon abandoned. In order to achieve near absolute stability an absolute instrument has been adapted to measure field variations. The proton precession magnetometer, which is a scalar instrument, is used to measure the components of the Earth's Geomagnetic Field by applying momentary, sequential deflection fields in mutually orthogonal coils. In the case of the classical proton precession magnetometer, the sampling rate is relatively low, resulting in a time difference between the measurement of individual components which can produce measurement errors especially during rapid variations in the field. Another problem which was the difficulty of producing homogeneous fields in a large volume occupied by the sensor of proton precession magnetometer. An inhomogeneous field yields a rapid signal decay, providing an inaccurate measurement. In order to accommodate the rather large sensors available years ago, in a homogeneous volume required large Helmholtz coils. These early coils were in excess of 70 cm in diameter. The resulting coil system was expensive, less stable and required a large pier and shelter.
Recent attempts have concentrated on much smaller spherical coils and the overhauser proton magnetometer. In addition, advances in electronic and computer circuitry have allowed rapid switching of coil bias currents and acquisition and preprocessing of the data.

NETWORKED AUTOMATIC DATA PROCESSING AT IRKUTSK GEOMAGNETIC OBSERVATORY

Victor Egorov, Stanislav Nechaev, and Alexander POTAPOV (all at Institute of Solar-Terrestrial Physics, P.O.B. 4026, Irkutsk, 664033 Russia, e-mail: potapov@iszf.irk.ru)

Irkutsk magnetic observatory has a 113-year history. First measurements were taken here in 1886. Irkutsk observatory changed from an analog to digital form of recording, starting in January 1996. At present a three axis quartz variometer with digital output (one minute values of three components) is used as a sensor. It is connected to the observatory local network consisting of four computers. The net provides data acquisition and preliminary processing including on a routine basis, as well as data transmission through a telephone line under remote control to the Institute of Solar-Terrestrial Physics (ISTP) 30 km from the observatory. The information collector at ISTP has access to the local Institute's network and the global Internet. From the observatory to ISTP, the data are transferred automatically once every three hours (an one-hour regime is available). Once a day the data are sent to the INTERMAGNET geomagnetic information node in Edinburgh via e-mail (automatic transmission is under development). The three-hour preliminary K index and one-hour local magnetic variation amplitude are estimated in the automatic mode and disseminated through the local net to users. Data quality control is provided by weekly absolute measurements using the scalar magnetometer and declinometer/inclinometer system. Error analysis and hardware control help to ensure data quality.

RESULTS OF DIFLUX INTERCOMPARISONS AT THE 8TH WORKSHOP ON GEOMAGNETIC OBSERVATORY INSTRUMENTS, DATA ACQUISITION AND PROCESSING IN VASSOURAS, BRASIL, SEPTEMBER 1998

JEAN L. RASSON, (Institut Royal Meteorologique, Centre de Physique du Globe, B-5670 Dourbes Belgique Ronaldo Marins Carvalho, Observatorio Nacional, Rua General Bruce 586, 20921-400 Rio de Janeiro, RJ Brasil)

An extensive inter-comparison of geomagnetic observatory instrumentation took place during the "8th Workshop on Geomagnetic Observatory Instruments, Data Acquisition and Processing" in Vassouras, Brasil, during September 1998. In total 15 DIfluxes of various makes from 3 continents (Zeiss 020, Zeiss 010, Bartington, Ruska, Sokkisha) were inter-compared using the observatory INTERMAGNET digital fluxgate variometer baseline and proton precession magnetometer. The results for the DIfluxes are presented. This inter-comparison allows us to make a global appreciation on the observation accuracy currently achieved.

NEW PROCESSOR OVERHAUSER SENSORS INTENDED FOR OBSERVATORIES AND FIELDWORK

Vladimir SAPUNOV, Dmitriy Saveliev, Alex Denisov, Sergey Kiselev, Olga Dekusar (Ural State Technical University, Quantum Magnetometry Laboratory, Mira St., 19, Ekaterinburg, 620002, RUSSIA, email: sva@dpt.ustu.ru)

The QMLab develops Overhauser cycling magnetometers of total and components geomagnetic field that are based on unique stable working substances, computer methods of calculation and sensors optimisation, digital processing methods of proton free precession signal. Examples of these techniques are presented, paying particular attention to the new processor Overhauser sensor POS-1 in which novelties are applied in most extent.
The sensor small-size head (working volume is only Dia30x70 mm) offers smaller Braunbeck's coil size up to 20 cm at measurement of the geomagnetic field components by proton precession methods. Highest signal to noise ratio of our sensor OS-2 (it is used the DNP-ampoule A-54/30) allows to measure geomagnetic components up to 0.03 nT sensitivity and up to 1 nT absolute accuracy (G. Dgirov, Kazakhstan; V. Pak, St-Peterburg).
The field-cycling Overhauser and proton standard sensors are analogous with each other but FC-Overhauser mode ensures the best property (rms up to 0.01 nT, accuracy 0.1-1 nT, drift less 0.05 nT/year). In particular, there is simple opportunity to improve of proton existing magnetometers by Overhauser's sensors.

PRODUCTION AND USE OF GEOMAGNETIC INDICES (IAGA)
Location: Muirhead Tower, 112 LR2

Wednesday 21 July AM

Presiding Chair: H.-J. Linthe (GFZ Potsdam, Niemegk, Germany)

GA5.06/E/01-A3 **0900**

ON LINE DATA AVAILABILITY: THE EXPERIENCE OF THE ISGI PUBLICATION OFFICE

J. PARIS (CETP, 4 Avenue de Neptune, F-94107 Saint Maur des Fosses Cedex, FRANCE) and M. MENVIELLE (CETP and Universite Paris Sud, FRANCE)

A software for routine derivation and dissemination of quick-look values of K derived planetary geomagnetic indices am and aa is run by the ISGI Publication Office since the end of 1996. The minute values are automatically got from 15 observatories on a daily basis through data transfer facilities like ftp procedure or e-mail. Our experience shows that:
1. a delay on the order of two weeks is necessary to get the data allowing the derivation of longitude sector indices, such as those provided in the frame of the Oersted program;
2. the on line data availability allows a routine derivation of quick-look planetary indices at day D+2;
3. shortening the delay of dissemination of quick-look planetary indices requires to reduce the number of observatories and to get directly the data from the observatory.

GA5.06/E/02-A3 **0920**

PRODUCTION AND DISTRIBUTION OF THE KP AND DERIVED INDICES - CONTINUATION OF A TRADITION

Hans-Joachim LINTHE (GFZ Potsdam, Adolf-Schmidt-Observatory, Lindenstr. 7, D-14823 Niemegk, Germany, email: linthe@gfz-potsdam.de)

Scientific applications require continuous series of geomagnetic activity indices. Besides of long-term series more and more the near real-time derivation becomes important. The global geomagnetic indices Kp, ap, Cp extend back to January 1932 and are now provided twice a month on a routine basis. At the beginning of the year 1997 the tradition of these indices was

taken over from the Institute of Geophysics of the University Goettingen to the Adolf-Schmidt-Observatory Niemegk. The indices are calculated under full concideration of the method approved by the IAGA. The current stage of the production will be presented. The indices are calcutated halfmonthly and distributed per e-mail, FTP and presented on WWW. It should be discussed the question of increasing the frequency of the production and distribution.

GA5.06/W/01-A3 0940

DERIVATION OF NEAR REALTIME DST INDEX

Toyohisa KAMEI (WDC-C2 for Geomagnetism, Graduate School of Science, Kyoto University, Sakyo-ku, Kyoto 606-8502, Japan, email: toyo@kugi.kyoto-u.ac.jp); Masahisa Sugiura (Research Institute of Science and Technology, Tokai University, 2-28 Tomigaya, Shibuya-ku, Tokyo 151-0063, Japan, email: sugiura@jspan.kugi.kyoto-u.ac.jp)

Responding to the growing demands for quicker availability of the Dst index, we have started derivation of Near Real-time (Quick-look, QL-) Dst index. In the past the Dst indices were made available in two steps. In the first step, a Provisional Index is derived as soon as the necessary (provisional) data are received from the contributing observatories, and is disseminated by post or by other means. The Provisional Index is meant for uses for diagnostic purposes only. The second is a final index of high quality suitable for scientific analyses, which is derived and distributed annually. Now we have added one more version for quick-look monitoring purposes. This version is derived by data transfer through the INTERMAGNET system and having cooperation from the contributing stations. It is derived using estimated baselines and simplified Sq models. It is updated with a time delay of 3 hours to 3 days and is made available through WWW of WDC-C2 for Geomagnetism, Kyoto (http://swdcdb.kugi.kyoto-u.ac.jp). However, the user is strongly advised to use the QL-Dst index only for monitoring purposes. The unchecked, uncalibrated data directly sent from the stations are used, and these data contain spikes, errors and missing values. For scientific analyses we advise to use the final Dst index or at least the provisional Dst index. The user for forecasting should be aware that the QL-Dst index is updated from time to time, and should use the latest version. Update information is provided separately from the WWW services.

GA5.06/W/09-A3 1000

CHARACTERISTICS OF THE INDIVIDUAL AE STATIONS WITH RESPECT TO THEIR CONTRIBUTION TO THE AE INDICES

Toyohisa KAMEI and Tohru Araki (both at WDC-C2 for Geomagnetism, Graduate School of Science, Kyoto University, Sakyo-ku, Kyoto 606-8502, Japan, email: toyo@kugi.kyoto-u.ac.jp); Masahisa Sugiura (Research Institute of Science and Technology, Tokai University, 2-28 Tomigaya, Shibuya-ku, Tokyo 151-0063, Japan, email: sugiura@jspan.kugi.kyoto-u.ac.jp)

The AE indices are derived using data from 12 stations along the auroral zone. Since 1996 one of these stations, i.e. Cape Wellen (CWE), has stopped operation due to power failure. We have analyzed the contributions of individual stations to the AE indices in order to delineate the effect of the loss of CWE. This station is situated at a latitude (invariant latitude 62 degrees) somewhat lower than the other AE stations; for this reason the station has been thought to be of less importance than the other stations. By our analysis we conclude that CWE indeed does not contribute to AE Under quiet and moderately disturbed conditions (AL > -500nT or AE < 1000nT), but it can significantly contribute to both AL and AU under disturbed conditions (-500nT < AL or AE > 1000nT). As the CWE record saturates at -2000nT, this station has failed in the past to demonstrate its potential importance during disturbed periods. Since it appears very difficult to re-open the CWE station, an effort is being made to open a replacement station near Pebek in Siberia to fill in the large gap between Tixie and Barrow. For this replacement station, we plan on installing a magnetometer with a wider dynamic range than with the CWE instrument. However, our attempt to create this new AE station is encountering great difficulties because of local political and economical situations. Through this analysis we conclude that we should increase AE stations at invariant latitude 62-63 degrees to obtain improved AE indices for disturbed periods.

THE ISGI WWW HOMEPAGE

J. Paris, C. Vernin (CETP, 4 Avenue de Neptune, F-94107 SAINT MAUR DES FOSSES CEDEX, FRANCE) and M. MENVIELLE (CETP and Universite Paris Sud, FRANCE)

The ISGI Publication Office has recently established a WWW homepage at the following address: http://www.cetp.ipsl.fr/~isgi/homepag1.htm
The ISGI WWW site aims at providing simple and efficient access to geomagnetic indices, either directly or through mirror links to the WWW sites of the ISGI Collaborating Institutes (GFZ Potsdam, Germany; WDC-C2 for Geomagnetism, Kyoto, Japan; Observatori de l'Ebre, Roquetes, Spain). The information and data series available at the ISGI WWW site are:

- information on ISGI;
- information on indices derivation and availability;
- provisional and definitive values of AU, AE, AL, aa (Kpa), am (Kpm), Kp, and Dst indices as monthly tables or ASCII files (hourly values for AU, AE, AL, and Dst; 3-hour values for the K-derived indices);
- definitive list of ssc;
- quick-look, provisional, and definitive values of K-derived longitude sector activity indices
- quick-look values of aa (Kpa) and am (Kpm) indices, for the current month and the two previous ones;
- musical diagrams (as postscript files) for aa and am indices;
- ISGI Monthly Bulletins for the current year and the two previous ones;
- selected papers about new advances in indices derivation

GA5.06/W/07-A3 1100

WHEN DO THE GEOMAGNETIC AA AND AP INDICES DISAGREE?

Helen E. COFFEY and Edward H. Erwin (both at Solar-Terrestrial Physics Division, NOAA National Geophysical Data Center, World Data Center A for Solar-Terrestrial Physics, 325 Broadway, Boulder, CO 80303 USA, email: hcoffey@ngdc.noaa.gov)

The next geomagnetic cycle has been predicted using the long term aa index database. Current real timepredictions use the Ap index. Unfortunately, the aa and Ap index do not always agree. The correlation is at the 0.8 level, even though the two aa stations are included in the Ap index. We investigate the differences between these indices, looking for trends at different levels of activity, different solar cycle periods, different times of the day, different Bz orientations, etc. Plots are presented to display these results.

GA5.06/W/03-A3 1120

SOLAR CYLE CHANGES IN THE STATISTICAL PROPERTIES OF MAGNETIC INDICES

Robert L. MCPHERRON (Inst. of Geophys. and Planet. Phys. and Dept. of Earth and Space Sci., University of California, Los Angeles, CA 90095-1567, e-mail: rmcpherron@igpp.ucla.edu)

The most frequently used indices include Kp, AE, PC and Dst. These indices were originally defined as simple measures of the strength of different current systems that produce the disturbances collectively known as geomagnetic activity. Kp is a measure of bay disturbances by subauroral and midlatitude stations. AE, or more precisely, AU and AL, respectively measure the strength of the eastward and westward auroral electrojets with auroral zone stations. PC utilizes a single polar cap station to measure the strength of the sheet current that returns current from the electrojets across the polar cap. Finally, Dst measures the strength of the ring current with equatorial stations. Since geomagnetic activity is driven by the solar wind these indices are highly correlated with each other and with a variety of solar wind coupling functions. Furthermore, because the properties of the solar wind depend on the Sun the indices all exhibit correlations with indices of solar activity such as the sunspot number. In this paper we investigate the properties of these indices and their interrelations as a function of the solar cycle. We expect that the indices will exhibit semi-annual variations, 27-day recurrence and diurnal variations, and that these change systematically with the solar cycle. Our initial results are surprising. For example, AL weakens towards solar max while AU strengthens such that AE shows almost no variation. Also, Kp displays a clear semi-annual variation while the AE index does not. These results suggest that there are systematic effects in the indices that cause them to behave in unexpected ways. We will illustrate other properties of the indices and attempt to explain their behavior in terms of physical processes and the methods of derivation. We conclude with recommendations for improvements in the indices.

GA5.06/W/08-A4 1140

SEARCH FOR QUIET, REGULAR, AND DISTURBED DAYS DEFINITION

Severino L. G. DUTRA and Nalin B. Trivedi (Instituto Nacional de Pesquisas Espaciais-INPE, C.P. 515, São José dos Campos, SP, 12201-970, Brazil, e-mail: dutra@dge.inpe.br, trivedi@inpe.dge.br); Jose M. DA COSTA (Universidade de Taubaté-UNITAU, Taubaté, SP, 12020-270, Brazil, e-mail: dacosta@dge.inpe.br)

The studies of the Sq geomagnetic field day-to-day variability are based on the concept of "quiet" geomagnetic time. Presently, the most accepted method for Sq determination uses the average of field values from a selection of five geomagnetic quietest days for each month. These five quiet days are selected within few days after a month is over by the International Service of Geomagnetic Indices and announced to the geophysical community. However chosen quiet days are not necessarily very quiet and its selection is difficult during the period of high solar activity. This work presents a method that enables the best determination for geomagnetic quiet, regular neither quiet nor disturbed) and disturbed days. It uses geomagnetic indices directly related with the solar activity.

GA5.06/E/05-A3 Invited 1400

POLAR CAP (PC) MAGNETIC ACTIVITY INDEX: REVIEW AND NEW DIRECTIONS

O. A. TROSHICHEV and R.Yu.Lukianova (both at Arctic and Antarctic Research Institute, 38 Bering St.,St. Petersburg, 199397, Russia, email: olegtro@aari.nw.ru); V. O Papitashvili* and P. Stauning (both at Danish Meteorological Institute, Lyngbyvej 100, DK-2100, Copenhagen, Denmark, email: vp@dmi.dk; *also at SPRL, University of Michigan)

The PC index has been proposed as index characterizing magnetic activity in the polar cap related to the interplanetary magnetic field penetrating into the magnetosphere.The PC index is derived on the base of two near-pole stations,Thule in the Northern Hemisphere and Vostok in the Southern Hemisphere, because of ionospheric conductivities are quite different in the winter and summer polar caps. In this presentation, we focus on a study of the PC indices derived from a number of near-pole stations, such as Vostok, Thule, Savissivik and Nord, all stations being located above 80 degrees of invariant latitude. These independent indices are compared with the cross-polar electric field derived from the convection patterns obtained from a network of the polar cap stations. Ground magnetic variations are also compared with high-precision magnetic measurements on board the Danish Oersted satellite. These results can be utilized for investigations of dynamics of the high-latitude plasma convection, as well as for validation of the new 1-minute PC index. The major motivation of this study is to provide such an index that could be regarded as a measure of the convection electric field generated in the polar ionosphere by the solar wind- magnetosphere coupling and value of the corresponding transpolar current.

GA5.06/W/04-A3 1440

REAL-TIME MONITOR OF GEOMAGNETIC FIELD IN THE NEAR-POLE REGIONS FOR THE SPACE WEATHER FORECAST

Tsutomu NAGATSUMA (Hiraiso Solar Terrestrial Research Center, CRL, 3601 Isozaki, Hitachinaka 311-1202, JAPAN, Email: tnagatsu@crl.go.jp), K. Hayashi (Department of Earth and Planetary Science, University of Tokyo, 3-1 Hongo 3chome, Bunkyo-ku, Tokyo 113, Japan), H. Ishibashi, T. Obara, and M. Kunitake (both at Hiraiso Solar Terrestrial Research Center, CRL, 3601 Isozaki, Hitachinaka 311-1202, JAPAN)

Solar wind electric field that penetrates into the magnetosphere is a driving force of magnetospheric disturbances. The magnetic activity in the near-pole regions is controlled by this electric field. The PC index proposed by Troshichev et al. (1988) is based on this idea. Therefore, it is expected that the magnetic activity in the near-pole regions and PC index is a useful for the nowcast and forecast of magnetospheric disturbances. Now the data from Vostok, southern near-pole region are being collected in real time based on the INTERMAGNET project. We plan to collect the data from Eureka (Canada), northern near-pole region in real time and produce an index for the space weather forecast using the same method of PC index. In this paper, the possibility of PC index as nowcast and forecast of magnetospheric disturbances and the similarity and difference between the index produced from Eureka data and PC index produced from Thule data.

GA5.06/E/03-A3 1500

DYNAMICS OF THE AURORAL ELECTROJETS IN TERMS OF DP-1 AND DP-2 VARIATIONS

Vladimir SHELOMENTSEV (Institute of Solar-Terrestrial Physics, 664033, P.O.Box 4026, Irkutsk, Russia, email: vshel@iszf.irk.ru)

A study of the geomagnetic disturbances is defined in many respects by the diagnostics of the substorm phases and amplitude. Along this line, a relationship of the auroral indices AE with the geomagnetic variations DP-1 and DP-2 is investigated based on a determination of the appropriate polar cap indices PC1 and PC2 (with a high temporal resolution in 1.5 min). A good correlation between AE and PC1, PC2 testifies about an opportunity to diagnose AE on the polar cap data, and to valuate the contributions of the variations DP-1 and DP-2 into an instant value of the AE-index. Such contributions were estimated using the multiple regression analysis. A notion about the two-component westward auroral electrojet (controlled by both of the dawn-dusk electric field and the conductivity) is a point at issue. Results are discussed also in terms of driven and loading/unloading processes in the magnetosphere. This study is supported by the RFBR grants 95-05-14385, 98-05-65120.

GA5.06/W/05-A3 1520

FEASIBILITY AND VARIABILITY OF HIGHER-TIME RESOLUTION "KP-LIKE" GEOMAGNETIC INDICES

D. DELLA ROSE, J. J. Sojka, R. W. Schunk, and L. Zhu (Center for Atmospheric and Space Sciences, Utah State University, Logan, Utah 84322-4405, e-mail: sls0r@cc.usu.edu)

Historically, the 3-hour Kp index has widely been used as a measure of geomagnetic activity for ionospheric studies. Specifically, it is the index used to determine the geomagnetic dependence of statistical auroral patterns as well as convection electric field patterns. Its pseudo anti-logarithm, the ap index, is similarly used in statistical models of the neutral atmosphere and neutral wind. Geomagnetic activity is, however, known to act on time scales significantly shorter than three hours, e.g., the auroral electrojet index (AE) shows rapid changes on time scales of minutes. The question then arises as to whether it is reasonable to consider higher-time resolution "Kp-like" indices? If so, is it then true that such higher-time resolution indices are good proxies for the temporal behavior of ionospheric drivers?
We have already partially addressed these issues by driving the Utah State Time-Dependent Ionospheric Model (TDIM) with higher-time resolution "Kp like" indices. We now continue the work by examining the contribution of geomagnetic indices in ionospheric modelling versus other factors such as the IMF dynamics. We will also use ionospheric observations, such as auroral imagery, to compare against the results of our higher-time resolution TDIM simulations. These same high-latitude observations will also be contrasted with results derived from other existing geomagnetic indices, such as the PC index. In so doing, we attempt to identify the effectiveness of short-term geomagnetic variability on the ionosphere, and thus better understand the temporal variability spectrum relevant to the ionosphere.

GA5.06/E/06-A3 1600

USE OF KP INDEX IN THE FORECAST OF SOLAR ACTIVITY

G.K. RANGARAJAN and L.M. Barreto (Observatorio Nacional Dept. of Geophysics Rua General Bruce 586 Sao Cristovao Rio de Janeiro Brasil e-mail: ranga@dge1.on.br)

It is now well established that geomagnetic activity in the declining phase of a solar cycle is a useful precursor of the amplitude of the solar activity in the next cycle. In the present analysis, we show that the FREQUENCY of OCCURRENCE of Kp index with values (0 - 1) representing geomagnetic calm and with values (4 - 7) representing moderate magnetic disturbances, typically associated with high speed solar wind streams responsible for recurrent geomagnetic storms in the declining phase is linearly related with the sunspot maximum of the next cycle. Highest correlations are obtained when the frequencies are averaged over three years preceding the solar minimum epoch.
In addition, we show that the frequency of occurrence of consecutive 4 or 6 intervals of Kp index with the same magnitude (0 - 1) or (4 - 5) are also equally reliable as predictors of the ensuing solar maximum. We find that the rate of increase of sunspot number to the solar maximum and its subsequent rate of decline can also be predicted reliably using the occurrence frequencies of Kp index with magnitude (0-1) or (4-5). Based on the observations for the past six solar cycles we expect the coming solar maximum to be associated with an annual mean sunspot number of about 140 with a rate of increase of 34 per year to the maximum epoch followed by a decline at the rate of 25 per year.

GA5.06/W/02-A3 1620

PREDICTION OF THE AMPLITUDE OF SUNSPOT CYCLE 23

Rajmal JAIN

A few prediction methods to forcast the solar activity have been developed using the "precursor" techniques and are found to be successful. On the basis of geomagnetic activity aa indices during the descending phase of the preceding cycle, we have established an expression which predicts the maximum annual mean sunspot number in cycle 23 to be 166.2. This indicates that cycle 23 would be a highly active and historic cycle. The average geomagnetic activity aa index during the ascending phase of cycle 23 would be about 24.9, comparable to 22.2 and 24.8 in cycles 21 and 22 respectively. This further indicates that during the ascending phase of cycle 23 energetic two-ribbon flares will be produced so as to give rise to strong proton events.

GA5.06/W/06-A3 1640

THE UTILITY OF THE AP INDICES TO DETERMINE THE NOCTURNAL REFERENCE LEVEL FOR THE SURVEYS DATA CORRECTIONS

GIANIBELLI Julio C., and CABASSI, Iris R. (Dep. of Geomagnetism and Aeronomny, Faculty of Astronomical and Geophysical Sciences, La Plata University, Paseo del Bosque s/n, 1900 La Plata, Argentina, email: jcg@fcaglp.fcaglp.unlp.edu.ar, rosy@fcaglp.fcaglp.unlp.edu.ar)

The minimum magnetic activity level to correct the surveys by diurnal variation, using low and middle latitude observatories, is analysed through ap index. The relationships between the minor magnetic activity over the monthly Q-days five and the solar cycle in the period 1932-1998 is studied. An example with digital data of the total intensity on pre-selected intervals over the period 1993-1998 of Trelew magnetic observatory is presented. An evolution model and analytic prediction of the Nocturnal Reference Level are showed.

GA5.09/W/10-A2 0930

AN ESTIMATE OF THE ERROR OF THE IGRF/DGRF FIELDS 1900-1995

Frank LOWES (Physics Department, University of Newcastle, NEWCASTLE UPON TYNE NE1 7RU, UK, email: f.j.lowes@ncl.ac.uk)

The IGRF coefficients inevitably differ from the correct values. Estimating the uncertainty of numerical models is difficult, but, mainly by comparing some IGRF and DGRF models with ones produced later, I have tried to produce realistic estimates of the coefficient accuracies.
For simplicity the errors are summarized in terms of the root-mean-square vector error in the corresponding field at the Earth's surface. (What is averaged is the square of the length of the expected vector difference between the model and true vector fields, and the average is taken over the Earth's surface.) The rms errors suggested vary from a few hundred to a few nanotesla. Here it is assumed that the IGRF is trying to model the (low-pass filtered) field due to all (long-period) internal sources - it is meant for users interested in the field outside the Earth, not for core-field theoreticians.
So far we have rounded the main-field coefficients to 1 nT; this in itself contributes a root-mean-square error of about 9 nT. If we do in fact get a succession of global magnetic field satellites in the future, we should be able to achieve consistently higher accuracy, and perhaps should reconsider the rounding level.
Similarly, so far we have truncated the spherical harmonic series at n=10. gain, with consistently better data, some extension could be justified.

GA5.09/W/02-A2 0950

A MODEL OF GEOMAGNETIC FIELD AT EPOCH 2000.5

Miora Mandea ALEXANDRESCU and Benoit Langlais (Institut de Physique du Globe de Paris 4 Place Jussieu 75252 Paris Cedex 05, France, email: mioara, email: langlais@ipgp.jussieu.fr)

Earth's deep interior studies are heavily dependent on the Earth's main field and its secular variation models. An important aspect in modelling is the goof distribution of available data over the globe and acquired over long periods of time. Satellite data provide the best geographic coverage, but - for the moment - are unlikely to be available except after possibly long intervals of time (about 20 years between MAGSAT and OERSTED). Then, at the present date, to build a main field model at epoch 2000.5 we only have access to surface data (when OERSTED data will be available the situation will be compleatly different). Indeed, a dataset as large as possible adjusted to 1997.5 is used to model the geomagnetic field for this epoch (80 Gauss coefficients for the main field and 3 for the external field). In order to extrapolate this model to the epoch 2000.5 a secular variation model is applied. In doing so we pay attention to the distribution of geomagnetic observatories and continuity of time-series. The data are extrapolated from 1997.5 to 2000.5 and in this way it is possible to get annual means from the same observatories over a 35-year period. This dataset is then used to compute secular variation models for each year, which permit us to extrapolate the main field model from 1997.5 to 2000.5. The paper presents the data (with comments on distribution and quality), the inversion and extrapolation methods, and the obtained models.

GA5.09/W/06-A2 1010

A MODEL OF RECENT AND FUTURE SECULAR VARIATION

Susan MACMILLAN (British Geological Survey, Murchison House, West Mains Road, Edinburgh EH9 3LA, UK. email: S.Macmillan@bgs.ac.uk)

In connection with the current IGRF revision, a series of models of the secular variation for the period 1990 to 2005 was needed. I describe how secular-variation records at magnetic observatories and repeat stations are extended to 2005 using linear prediction filters and linear regression respectively, and how the models are produced.

GA5.09/W/09-A2 1030

ADJUSTING SHC COEFFICIENTS TO N = 15 FOR EPOCH 2000.

Joseph CAIN and David Mozzoni (both at Geophysical Fluid Dynamics Institute/FSU, Tallahassee FL 32306-4360,USA, e-mail: cain@geomag.gfdi.fsu.edu and cyric@leyla.gfdi.fsu.edu)

Most reference models of the internal geomagnetic potential function have attempted to define the "main" internal field by limiting the analyses to spherical harmonic degrees up to n = 13 of the potential function without the use of higher terms. Such models contain intrinsic "aliasing" errors in practice in spite of theory that properly orthogonalized analyses should be error free. Though small due to the relatively low power of higher degree contributions at satellite altitude, there is no need to add yet another error source to those already extant from electrical currents below, within, and above the volume of measurement considering modern computer resources. Models presented herein utilize high degree terms previously derived from LEO Magsat data (to n = 60), updating those that can be improved with the higher altitude data provided by Ørsted and Astrid-2, and holding higher terms fixed. Major anomalies are automatically incorporated in the analyses and little harm is done by including small noise contributions in the "bland" areas. This technique allows adjustments of the main field contributions to terms in the transition region, $14 < n < 17$ where though diminishingly less important, the changing main field nevertheless can be determined. The satellite data themselves are utilized in conjunction with secular change estimates obtained from surface observatory hourly values.
The external field contributions are handled by techniques developed for POGO and Magsat and employ surface variational data as well as ad hoc techniques to incorporate variations that are due to broad scale magnetospheric effects (Dst) as well as those that are more dependent on magnetic local time and magnetic latitude (e.g. Sq). The resultant models can be used as a "reference" with the user making the decision as to truncation level, or identification of degrees believed to be "crustal" compared to "core." They also have the advantage of providing those interested in ionospheric and magnetospheric studies the confidence that most significant internal crustal noise has already been removed.

GA5.09/W/03-A2 1110

AN IGRF 2000 CANDIDATE MODEL BASED UPON OERSTED SATELLITE DATA

T.J. SABAKA (Raytheon ITSS Corp., Lanham, MD 20706, USA, email: sabaka@linus.gsfc.nasa.gov; Oersted Main Field Working Group)

The Danish satellite Oersted, launched in January 1999, is to provide the best sampling of the geomagnetic field for main field modelling purposes since the Magsat mission of 1980. An IGRF 2000 candidate model, derived from this high-precision vector data set and supplemental observatory measurements, will be presented.

GA5.09/W/08-A2 1130

CANDIDATE MODELS FOR IGRF 2000-2005

BONDAR Tatiana N and Golovkov Vadim P (both at IZMIRAN, 142092 Troitsk, Moscow region, Russia, email: golovkov@izmiran.rssi.ru)

Candidate model for the IGRF2000.0 and the corresponding model for the secular variation 2000.0-2005.0 are presented. Forecast of the field changes for a few years is uncertain due to stochastic nature of both external and internal variations. We tryed to decrease as much the forecast uncertainty using a few independent algorithms and comparing the forecast results. These algorithms are as follows:
1 IZMST (Golovkov et al., 1997) was taken as a basic ones. The time functions of this model were extrapolated with parametric method till epochs 2000.0 and 2005.0.
2 A new generation of IZMST was developed with a new set of natural orthogonal components. These new NOC's were derived from a few observatories which annual means series were extrapolated by hand.
3 By hand extrapolations of annual means series from whole observatories on the globe were used as the data set for independent SH analysis for both epochs.
Comparison of modeled field shows a rather good agreement over whole globe except two regions. Largest declinations of the models take place over East Pacific and Indian Oceans. Arguments in favour of the second algorithm are presented, but definite conclusion can be done after analysis of data from coming Oersted mission.

GA5.09/E/01-A2 1150

POTENTIAL EFFECTS OF INDUCED MAGNETISATION IN A SPHEROIDAL SHELL

Andrew Jackson (School of Earth Sciences, Leeds University, Leeds LS2 9JT, UK, Email: jackson@earth.leeds.ac.uk), Vincent LESUR (School of Earth Sciences, Leeds University, Leeds LS2 9JT, UK, Email: lesur@earth.leeds.ac.uk) and Denis Winch (Department of Applied Maths, University of Sydney, Sydney NSW 2006, Australia).

Runcorn in 1975 established that, in a linear approximation, a spherical shell of constant susceptibility which is magnetised by an internal magnetic field does not generate any external field. He applied this result with great success in explaining the very small external field of the moon. The situation on the earth may be different because of its larger flattening.
We analyse the external field generated by a shell of constant susceptibility and defined by two oblate spheroids when it is magnetised by an internal magnetic field of arbitrary complexity. An exact calculation takes into account the magnetic field of the crust itself, generating fields which depend on the square of the susceptibility; we call these the non-linear terms. We find an analytical expression for such a crustal field, expressed in an oblate spheroidal coordinate system, that take into account both the effects due to the flattening of the earth and the non-linear effects.
In the limit case of the spherical shell, the basis becomes the usual spherical system of coordinates and by Runcorn's theorem, only the non-linear terms can produce an external field. For each spherical harmonic degree, the crustal field coefficient is a small portion of the internal magnetic field coefficient. Therefore the crustal field is weak and dominated by the long wave-lengths. In the case of an oblate spheroidal shell, the flattening of the earth introduces a linear term. However, the external field which is generated is still dominated by the non-linear effects.

HIGH LATITUDE GEOMAGNETIC VARIATION REFERENCE FIELD MODELS FOR 20-22 SOLAR ACTIVITY CYCLES

Vladimir PAPITASHVILI (Space Physics Research Laboratory, University of Michigan, Ann Arbor, MI 48109, USA, email: papita@umich.edu); Boris BELOV (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation, IZMIRAN, Troitsk, Moscow Region, 142092, Russia, email: bbelov@adonis.iasnet.ru); Natalia Papitashvili (Raytheon STX and NSSDC, NASA/Goddard Space Flight Center, Greenbelt, MD 20771, USA, email: natasha@nssdca.gsfc.nasa.gov)

We present a newly obtained set of linear regression models of the ground magnetic response on 1-nT changes in the corresponding interplanetary magnetic field (IMF) components for the 20-22 solar activity cycles (from 1965 to 1997). These models are obtained over both the northern and southern polar regions and for different seasons of a year (summer, winter, and equinox). Data from 116 magnetic observatories were collected and quality controlled. The hourly means of the IMF and ground geomagnetic field components are analyzed utilizing the linear "black box" approach. The spherical harmonic analysis is applied to obtain a set of harmonic coefficients capable of modelling the ground geomagnetic responses on changing IMF conditions for any time instance between 1965 and 1997. The new set of models is compared with similar models obtained during the development of IZMIRAN Electrodynamic Model for two solar activity maximums (1968-1969 and 1979-1983). It shown that generally there are little differences in the models harmonic coefficients through the solar activity cycles. This allows us to apply the obtained results beyond of the studied interval.
Validation of the new linear regression models against magnetic observatory data is also presented and discussed.

GA5.09/P/01-A2 1230

A REMARK ON THE VERTICAL MAGNETIC FIELD NEAR THE GEOMAGNETIC POLES IN SUMMER

Naoshi FUKUSHIMA (Dept. of Earth and Planetary Physics, University of Tokyo, Tokyo 113-0033 Japan. email: fukusima@nipr.ac.jp)

For improving the Near-Earth Reference Field Model it will be necessary to pay special attention to a remarkable decrease in the magnitude of vertical geomagnetic field z in the summer polar regions centring the northern or southern magnetic poles, which amounts even to several tens of nT. This peculiar phenomenon was known since the Second International Polar Year 1932-1933, through an extensive analysis of world data by Vestine et al. compiled in the Carnegie Institution of Washington Publication No. 580 (1947). With the aid of the data during IGY and succeeding years, Mansurov and Mansurova (1971) demonstrated that the same kind of z-decrease was observed also at Vostok, magnetic south pole station in the Antarctica. It is worth noting here that the geomagnetic anomaly maps by Langel and Estes (Figs. lb and 2b on pages 2497-8 in JGR 90 [1985] for the calculated difference of z-values at 500 km level from their model based on the Magsat data) show the greatest negative anomaly over Vostok, because they used the Magsat data during the austral summer.
Since the peculiar decrease in the geomagnetic z-field near the magnetic poles is observed only in local summer seasons, it will be practical to prepare in advance a correction for this summer phenomenon, in order to discuss real magnetic anomalies of inner origin in the polar regions.

THE EARTH'S MAGNETIC FIELD IN THE 18TH AND 19TH CENTURIES FROM FRENCH ARCHIVAL DATA

Mioara Mandea ALEXANDRESCU (Institut de Physique du Globe de Paris, 4 Place Jussieu, 75252 Paris Cedex 05, France, email: mioara@ipgp.jussieu.fr), Andrew Jackson (Leeds University, Leeds LS2 9JT, UK email: A.Jackson@earth.leeds.ac.uk), Anne Murray (London, UK)

We aim to show how our database (on which models of the historical magnetic field are based) has been improved by exploiting archive records available in the Paris libraries (Archives Nationale and Bibliotheque Nationale). One of the most accurate sources for studying the past behaviour of the Earth's magnetic field is the series of declination measurements taken over the last few hundred years by land observers or by mariners on voyages of trade, plundering and exploration. These data exist in the original ships' logs or as compilations held by hydrographic institutions in order to make charts of declination for the use of shipping. The data in the Paris archives exist in both forms, but we report on the use of some very large compilations which we have discovered. After correcting for differences in the reference longitude used when the measurements were recorded, the measurements were checked by comparing them with estimates calculated from Bloxham and Jackson's model ufm2. The number of useful measurements recovered in this way is of the order of 60000, covering the late 18th and early 19th centuries, although there is likely to be some duplication. Some studies on the statistics of the compiled data are presented, and we discuss how they can be integrated with the existing dataset.

GA5.09/W/05-A2 Poster 1400-02

SPHERICAL CAP HARMONIC ANALYSIS OF GEOMAGNETIC VARIATIONS OVER JAPAN

Golovkov Vadim P., FILIPPOV Sergey V., Burdelnaya Irina A. (all at IZMIRAN, 142092, Troitsk, Moscow region, Russia, e-mail: golovkov@izmiran.rssi.ru), Fujiwara Satoshi (Mizusawa Geodetic Observatory Geographical Survey Institute, Kitasato-1, Tsukuba, Ibaraki 305, Japan, e-mail: fujiwara@gsi-mc.go.jp), Tanabe Tadashi (Geography and Crustal Dinamics Research Center Geographical Survey Institute, itasato-1, Tsukuba, Ibaraki 305-0811, Japan, e-mail: tanabe@gsi-mc.go.jp).

The space-time model ROM - FAR EAST70/95 has been described by Golovkov et al. (1997). In this model Natural Orthogonal Components (NOC) are used for modelling temporary functions and rectangular Legendre polynomials are used as spatial functions describing geomagnetic field variations. The model covers the area of the Japanese Islands and, partially, surrounding seas. Data from Japanese magnetic observatories and the first class repeat station network were used. For filling empty (no data) areas (the seas) the global models were used. Now new model of this region - CAP-NOC-JAPAN70/95 - is presented. This model also use the NOC analysis for separating temporal variations, but the spherical cap harmonic analysis (Haines, 1985) is used to describe the spatial distribution of geomagnetic variations. Both two models cover almost the same area (the Japanese Islands and surrounding seas) and use the same data set for analysis (Japanese repeat station and observatory data). Results of modelling and the comparison of these regional models over the small region as well as comparisons with global model IZMST are presented. The methodical questions of regional modelling as well as accuracy of obtained models are discussed.

GA5.09/W/04-A2 Poster 1400-03

A NEW RESULT OF THE WESTWARD DRIFT IN THE GEOMAGNETIC FIELD

Wen-Yao XU AND Zi-Gang Wei (Institute of Geophysics, Chinese Academy of Sciences, Beijing 100101, China, email: wyxu@mail.c-geos.ac.cn)

A technique of correlation analysis of moving random patterns is used to the non-dipole part of the Earth's magnetic field in order to study its westward drift. The technique considers the overall features of the pattern insted of some special contous lines or the focus. The results show that the Asia Anomaly drifts westward at an average speed of 0.07 degree per year during 1900-2000. The time variation of the drift speedindicats three periods of the westward drift. During 1900-1930 the Asia anomaly steadyly drifted westward at a speed of 0.1 degree per year, then the drift turned to northwest, and finally the drift almost stopped after 1980. The other large-scale magnetic anomalies also show their owncharacteristics in westward drifts.

GA5.09/W/01-A2 Poster 1400-04

REGIONAL MODELS OF GEOMAGNETIC FIELD CHANGES OVER CANADA

BURDELNAYA Irina A., Golovkov Vadim P. (both at IZMIRAN, 142092, Troitsk, Moscow region, Russia, email: golovkov@izmiran.rssi.ru), Newitt Larri R. (Gelogical Survey of Canada, 1 Observatory Cres, Ottawa,Canada,K1A OY3).

Regional space-time models of the geomagnetic field have been produced by a variety of techniques for describing temporal and spatial variations. The Canadian Geomagnetic Reference Field for 1995 (CGRF95) has been described by Haines and Newitt (1997). Cosine functions were used to express the time variations and spherical CAP harmonics to describe the spatial distribution. The ROM-Canada has been described by Golovkov et al.(1997). A new high precision regional space-time of the geomagnetic field model over Canada, CAP+NOC(71/95), has been created. The model uses the methods of both the NOC analysis,which separates temporal variations, and the CAP analysis (Haines,1985),which models the spatial distribution over the Canadian region. The three models use ordinary observatory annual means and Canadian repeat station data. Results are presented which

show comparisons of these regional models over the same region as well as comparisons with global models IGRF, IZMST. The comparisons are of interest for modelling the magnetic field over a portion of the globe.

REDUCTION OF GEOMAGNETIC DAILY VARIATION EFFECTS IN SATELLITE DATA USED FOR MAGNETIC FIELD MODELLING

Peter R SUTCLIFFE and Pieter B Kotzé (Hermanus Magnetic Observatory, P O Box 32, Hermanus 7200, South Africa; E-mail: psutclif@csir.co.za and pkotze@csir.co.za)

A regional geomagnetic daily variation model is developed using magnetic observatory data and artificial neural network (ANN) techniques. Input variables considered in the daily variation model are geomagnetic latitude, season, sunspot number, and degree of geomagnetic activity. Spherical harmonic analysis techniques are then used to extend the validity of this ground-based model to satellite altitudes. This extended model is then used to correct for the effects of the geomagnetic daily variation in satellite data used for geomagnetic main field and anomaly modelling. Results demonstrating the effects of correcting for the daily variation in satellite data over southern Africa are shown.

ORIGIN OF MAGNETIC ANOMALIES OF LOWER CRUSTAL ROCKS

Gunther KLETETSCHKA, Patrick Taylor, Mike Purucker, and Peter Wasilewski (all at codes 921/690, GSFC/NASA, Greenbelt, USA, email: gunther@denali.gsfc.nasa.gov); Dhananjay Ravat (Department of Geology 4324, SIUC, Carbondale, 62901, USA)

Remanent and induced magnetization must both be considered when attempting to explain the source of crustal magnetic anomalies. Magnetite, hematite, or pyrrhotite are the responsible minerals. For magnetite, remanent and induced magnetizations are of the same order of magnitude. Hematite and pyrrhotite have negligible induced magnetization. The remanent magnetization of hematite is of the same order as both the remanent and the induced magnetization of magnetite. The remanent magnetization of pyrrhotite is in the same range or larger than the remanent magnetization of magnetite. Samples of hematite and magnetite bearing rocks were collected along a traverse from background into the supposed source of the significant crustal magnetic anomaly which occupied a 50-100 kilometer region in central Labrador. Induced magnetization of the rocks did not change in any significant way along the traverse including the boundary from background to the apparent source of the magnetic anomaly. However, the remanent magnetization changes significantly and can account for the crustal magnetization signature in this region. These field data together with the magnetic property studies of the collected samples and the known properties of the important magnetic minerals indicate that magnetic anomaly modelling cannot be realistic without the consideration of the remanent and the induced magnetization.Considering this conclusion we are using the Kursk iron ore region as a test case. The Kursk region has voluminous amounts of geologic and geophysical data, rock magnetic data and multilevel magnetometer data, including satellite data. Consequently we will attempt to model magnetization source(s) using remanent and induced magnetic signatures constrained by geologic and geophysical data.

TITANOHEMATITE AS THE CARRIER IN REMANENCE-DOMINATED MAGNETIC ANOMALIES: ROCK MAGNETIC AND PETROGRAPHIC STUDIES OF THE RUSSELL BELT MICROCLINE SILLIMANITE GNEISS, ADIRONDACKS, NEW YORK, USA

Laurie L. BROWN (Department of Geosciences, University of Massachusetts, Amherst, MA 01003, USA, email: lbrown@geo.umass.edu); Suzanne A. McEnroe (Norges Geologiske Undersokelse, Trondheim, Norway, email: Suzanne.McEnroe@ngu.no)

A large (2240 nT) negative aeromagnetic anomaly over microcline-sillimanite-quartz gneisses in the Russell belt, northwest Adirondack Mountains, New York was first investigated by Balsley and Buddington some 40 years ago. Anomaly lows are closely related to surface outcrops known to contain metamorphic hematite. The granulite-facies metamorphism here dates from the Ottawan phase (1100-1000 Ma) of the Grenville Orogeny. It is obvious from the anomaly that there is a strong remanence contribution to the aeromagnetic signal. Samples from six sites in the Russell belt have been collected, providing 36 oriented cores for rock magnetic and petrographic studies. The gneisses contain up to 3% iron oxides, predominantly titanohematite, occurring as both ilmenohematite and hemoilmenite, as well as nearly pure hematite. Microprobe data indicates the range of compositions of titanohematite to be from 78 to 99% Fe2O3 end member. Rare grains of pseudo-single domain end member magnetite have been observed. Bulk susceptibility measurements yield a bimodal distribution with over 70% of the samples having values less than 9x10-4 SI, and a median value for all samples of 4.2 x 10-4 SI. NRM intensities are strong, with a mean of 3.6 A/m, and average directions of declination 290 and inclination -65. Not surprisingly, the Koenigsberger ratios (Q values) are high, ranging from 0.4 to 562, with a mean Q for all samples of 170. Progressive thermal demagnetizations show very little loss of magnetization until 600 C; generally 90 to 95% of the original remanence remains at this temperature. Low temperature measurements of remanence reveal both Verway and Morin transitions in some samples, as well as only Morin transitions in other samples. Hysteresis properties show considerable variation, with the ratio of coercivity of remanence to saturation coercivity varying from 1 to 18, although 75% of the samples have ratios of 3.2 or less. The ratio of saturation magnetization to remanent magnetization varies from 0.131 to 0.739 with a mean of 0.407. Hysteresis curves are typically wasp-waisted or "hummingbird" in shape. Wasp-waisted loops retain their distinctive shape up to 575C and by 600C have reverted to lozen-shapes. Original hummingbird loops retain their shapes above 600C.
All rock magnetic and petrologic data indicate that titanohematite is the predominant oxide present in any grain size, from MD to SD. Although the high NRM intensities are not easily explained with small amount of titanohematite present, it is the primary carrier of remanence. Titanohematite may be an important phase in aeromagnetic studies and could be contributing to deep crustal anomalies.

PETROPHYSICAL DATA FOR MAGNETIC AND GRAVITY ANOMALY INTERPRETATION

Juha V. KORHONEN (Geological Survey of Finland, P.O. Box 96, FIN-02151 ESPOO, Finland, Email: juha.geofys@gsf.fi) and Michael Purucker (Geodynamics Branch and Raytheon ITSS, Goddard Space Flt Ct Greenbelt, MD 20771, Email: urucker@geomag.gsfc.nasa.gov)

The usefulnes of regional, continental, and global scale magnetic and gravity data will be considerably increased when combined with petrophysical information. Using petrophysics the anomalies can be associated with definite geological fformations and lithologies an separated into shallow and deep seated sources. Correlation between density and magnetic properties establishes to what extent the magnetic and gravity anomalies are caused by the same sources. Defining the magnetization and density from petrophysical information leaves more freedom to interprete other source parameters . An attempt was made to collect metainformation on petrophysical data sets. A questionary was sent to 110 organizations or persons. 14 responses were received, totalling 468 000, 513 000, 279 000 and 12 600 measurements of bulk density, magnetic susceptibility, intensity of remanence and direction of remanence respectively in 8 countries. The received metadata information is available at the address http://www.gsf.fi/ where references to data owners are given. Most of the current data is clustered on the Fennoscandian shield which has an average data density of 30 measurements of susceptibility and bulk density values per 100 sq km. Combined with geological data this information allows estimation of average upper crustal magnetization for interpretation of Kiruna, Gulf of Finland and Baltic MAGSAT magnetic anomalies and corresponding magnetic provinces in more near surface studies. For the most part, there is little petrophysical control on the 60 magnetic anomalies observed at satellite altitude. Based on the published literature, we feel that more petrophysical data must exist at geological institutions around the world. To accumulate this information, the questionnaire will remain open and the WWW metadatabase will be updated upon receipt of new information.

GA5.11/W/04-A3 Invited **1010**

THE CALCULATION OF MAGNETIC COMPONENTS AND MOMENTS FROM TMI: A CASE STUDY FROM THE TUCKERS IGNEOUS COMPLEX, QLD

Phillip W. SCHMIDT (CSIRO Exploration and Mining, North Ryde NSW, Australia 1670, email: p.schmidt@syd.dem.csiro.au); David A. Clark (CSIRO Exploration and Mining, North Ryde NSW, Australia 1670, email: d.clark@syd.dem.csiro.au)

This paper re-examines some largely forgotten methods that are eminently adaptable to modern computing environments. The methods were originally formulated before the advent of electronic computers and do not appear to have been fully developed, or given the attention they deserve. Components of anomalies can be derived from total magnetic intensity (TMI) observations, or indeed, any other component irrespective of its direction. For large anomalies which distort the local field so it can no longer be treated as a potential field an iterative method enables estimates to converge on accurate solutions. Furthermore, for an isolated anomaly integrals of first order moments of the components yield information such as the direction and magnitude of the total anomalous magnetic moment of the source.
Examples of the application of the methods are derived from a survey over the Tuckers Range area of north Queensland. This survey was chosen because the magnetic properties of the lithologies giving rise to the magnetic anomalies have been thoroughly studied. The selected areas contain many anomalies showing effects of magnetic remanence of reverse polarity. The results of the methods used herein agree well with those expected from the measured magnetic properties and magnetic modelling.

GA5.11/W/07-A3 Invited **1100**

MAGNETIC PROPERTIES AND MAGNETIC SIGNATURES OF PORPHYRY-RELATED GOLD AND COPPER-GOLD DEPOSITS IN EASTERN AUSTRALIA

David A. CLARK (CSIRO Exploration and Mining, PO Box 136, North Ryde, NSW 1670, Australia, email: d.clark@syd.dem.csiro.au)

Intrusive igneous rocks that are genetically associated with Au and Cu-Au deposits have certain features in common: they are derived from high temperature melts that have undergone substantial fractional crystallisation, and they are almost invariably oxidised. Substantial metasomatised aureoles, often with remanence-dominated magnetisations, are commonly developed around the mineralising intrusions. Fractional crystallisation within oxidised suites produces strong magnetisation contrasts. Zoned magnetic signatures are associated with larger plutons and complex signatures, indicative of multiple nested intrusions of varying composition, are also commonly associated with deposits. Hydrothermal alteration substantially modifies the magnetic properties of the various intrusive phases and the host rocks. Magnetic signatures of alteration can provide a guide to mineralised centres within the system.Magnetic signatures of intrusive-related (Cu)-Au deposits depend strongly on the geological setting, but in a relatively predictable way. This allows magnetic exploration models to be developed from geological models of the magmatic and hydrothermal evolution of gold-bearing porphyry systems.Case studies of the magnetic petrophysics, magnetic petrology and magnetic signatures of several porphyry-related (Cu)-Au deposits from eastern Australia illustrate these generalisations.

GA5.11/W/05-A3 **1120**

INTERPRETING THE AEROMAGNETIC SIGNATURE OF ILMENITE DEPOSITS IN ROGALAND, NORWAY: THE IMPORTANCE OF PETROPHYSICAL MEASUREMENTS AND ROCK-MAGNETIC PROPERTIES

Suzanne A. MCENROE (Norges Geologiske Undersokelse, Trondheim, Norway, email: suzanne.mcenroe@ngu.no)

Petrophysics, rock-magnetic properties and magnetic petrology are required for accurate geological interpretation of magnetic surveys. Exploration for the titanium minerals ilmenite and rutile, which is a strategic mineral, will continue well into the next century. With the possibility that synthetic rutile can to be produced from ilmenite, accurate methods for ilmenite exploration are become increasingly important. Igneous and metamorphic ilmenite deposits and hemo-ilmenite rich rocks commonly have remanence-influenced or -dominated aeromagnetic anomalies. Allard Lake, Canada; Adirondacks Mtns, USA and Rogaland,

Norway are such examples. Understanding the parameters which control the magnetic signatures of ilmenite deposits greatly enhances exploration. To further this aim, a large petrophysical data set and detailed rock-magnetic measurements have been made by Norwegian Geological Survey for ilmenite deposits and associated rocks in the Rogaland region of Norway. In addition, the magnetic characteristics of the surrounding anorthosite body and the coeval mafic intrusions were examined.
Bulk magnetic measurements of the NRM and susceptibility show a wide range of values, and yield Koenigsberger ratios (Q values) from >1 to >> 100. Samples with low Q values are generally from mafic intrusions which have near end-member ilmenite with minor or no hematite lamellae and abundant coexisting magnetite. These magnetites have a wide range of microtextures produced by exsolution and oxidation-exsolution. Samples with high Q values are harder to interpret, but very important because they come from intrusions rich in ilmenite or hosting ilmenite ores. The hosting anorthosite body has Q values up to 150. Actively mined and historic ilmenite deposits in the Rogaland region all contain ilmenite with abundant {0001} hematite exsolution lamellae. Historic, ilmenite deposits have Q values up to 30. Samples taken from the Tellnes deposit, one of the world's largest active ilmenite mines, have Q values up to 12. "Pure ilmenite" dikes have Q values up to 58. To identify the magnetic phases responsible for the high Q values, detailed rock-magnetic measurements, optical identification and microprobe analyses were used. Verwey and Morin transitions, hysteresis properties were measured and combined with thermal and AF demagnetization spectra. The sources for the high Q values were: 1) ilmenite-hematite, 2) ilmenite-hematite and/or magnetite-ilmenite exsolution in pyroxenes, 3) fine inclusions in plagioclase. These measurements further enabled us to interpret the airborne magnetic data and to explore for further ilmenite reserves.

GA5.11/L/01-A3 Invited **1140**

MAGNETIC SIGNATURES OF IMPACT STRUCTURES - THE ROLE OF PETROPHYSICS

Lauri J. Pesonen and Juha V. KORHONEN (both at Geological Survey of Finland, P.O. Box 96, FIN-02151 Espoo, Finland, Email: lauri.pesonen@gsf.fi, juha.korhonen@gsf.fi)

The magnetic methods provide four types of data of terrestrial meteorite impact structures. First, they have lead to new discoveries of impact craters (e.g., Suvasvesi, Finland). Second, they provide additional (to gravity, seismics, etc.) estimates of morphometric parameters of impact structures. Third, magnetic modellings, coupled with paleomagnetic data of the impact rocks, have lead to estimates of the age of impact events (e.g., Siljan, Sweden). Fourth, the polarity reversals in the impact rocks have provided further constraints for the age of impact events (e.g., Chixculub, Mexico). However, the applications of magnetic data of impact structures is often hampered by the lack of petrophysical data of the rocks from the structures. Here we outline the known magnetic signatures of terrestrial impact structures with emphasis on the role of petrophysical data of impactites and target rocks in constraining the magnetic modellings and the datings.
The magnetic anomalies of impact structures are generally subdued due to impact induced decrease in susceptibility and NRM of host rocks. Peak anomalies can occur in places where impact melt is present (e.g., Lappajärvi, Finland). Impact breccias and suevites often have relatively strong remanent magnetisation (high Q-values) due to impact induced TRM (e.g., Ries, Germany). In some cases the NRM of the breccias is randomized causing the weak magnetic anomaly relief. In a few instances a SRM (shock remanent magnetization) has been isolated in impact rocks (e.g., Slate Islands, Canada). The magnetic signatures of the complex structures are broader and relatively less pronounced than for simple structures due to smaller depth to diameter ratio. The complex structures may also show a broad central anomaly (positive or negative) due to central uplift of the target basement.

GA5.11/W/06-A3 **1200**

GEOPHYSICAL INDICATIONS OF MAGMATIC AND TECTONIC ACTIVITY IN THE NORTHERN PART OF BARENTS SEA

Andrew ZAYONCHEK, Vladimir Glebovsky, Evgeniy Korago, Sergei Maschenkov, Evgeiny Mysatov, Mihail Zykov (all Russian Research Institute for Geology and Mineral Resourses of the World Ocean,1, Angliysky Pr., St. Petersburg, 190121, Russia, E-mail: andrew@vniio.nw.ru)

In accordance with existing geological information the major magmatic activity in the northern part of Barents Sea occurred during Jurassic-Cretaceous times. Joint analysis of geophysical data and geological observations on Franz Josef Land revealed the evident relationship between potential fields anomalies and known magmatic occurrences. It was found that main igneous sources correspond to the high intensity magnetic anomalies. This allowed to develop the geophysical criterion's for contouring igneous structures and apply them to the adjacent sea areas were direct geological is poor. In our study we have used the regional gravity, magnetic anomaly and seismic reflection data. Structural interpretation was based on the various geophysical maps: gravity Free-air, Bouguer anomalies and their transformations (vertical and horizontal gradients, local and regional anomalies), bathymetry and magnetic anomalies. Additional information was obtained from the calculations of depths to magnetic sources performed by Werner deconvolution technique. To study the magmatic occurrences we used detailed magnetic anomaly maps, based on the 1x1 km grids. The presented study allowed to clarify the position of general tectonically and magmaticelly active zones in the region. In some areas the main directions of the faults related to the magmatic activity (which previously were seen in the seismic data) were revealed.

ORIGIN OF MAGNETIC ANOMALIES OF LOWER CRUSTAL ROCKS

Gunther KLETETSCHKA, Patrick Taylor, Mike Purucker, and Peter Wasilewski (all at codes 921/690, GSFC/NASA, Greenbelt, USA, email: gunther@denali.gsfc.nasa.gov); Dhananjay Ravat (Department of Geology 4324, SIUC, Carbondale, 62901, USA)

Remanent and induced magnetization must both be considered when attempting to explain the source of crustal magnetic anomalies. Magnetite, hematite, or pyrrhotite are the responsible minerals. For magnetite, remanent and induced magnetizations are of the same order of magnitude. Hematite and pyrrhotite have negligible induced magnetization. The remanent magnetization of hematite is of the same order as both the remanent and the induced magnetization of magnetite. The remanent magnetization of pyrrhotite is in the same range or larger than the remanent magnetization of magnetite. Samples of hematite and magnetite bearing rocks were collected along a traverse from background into the supposed source of the significant crustal magnetic anomaly which occupied a 50-100 kilometer region in central Labrador. Induced magnetization of the rocks did not change in any significant way along the traverse including the boundary from background to the apparent source of the magnetic anomaly. However, the remanent magnetization changes significantly and can account for the crustal magnetization signature in this region. These field data together with the magnetic property studies of the collected samples and the known properties of the important magnetic minerals indicate that magnetic anomaly modelling cannot be realistic without the consideration of the remanent and the induced magnetization.Considering this conclusion we are using the Kursk iron ore region as a test case. The Kursk region has voluminous amounts of geologic and geophysical data, rock magnetic data and multilevel magnetometer data, including satellite data. Consequently we will attempt to model magnetization source(s) using remanent and induced magnetic signatures constrained by geologic and geophysical data.

MAGNETIC PETROPHYSICAL STUDY IN THE HAMERSLEY PROVINCE, WESTERN AUSTRALIA AND ITS APPLICATION IN AEROMAGNETIC INTERPRETATION - I: MAGNETIC PETROPHYSICS

Wanwu GUO, Zhengxiang Li, Michael C. Dentith and Christopher McA. Powell (Tectonics Special Research Centre, Department of Geology and Geophysics, The University of Western Australia, Nedlands, Perth, WA 6907, Australia, Email: wguo@geol.uwa.edu.au)

The Hamersley Province is situated in the northwest of Western Australia. It contains extensive banded-iron formations (BIFs) and large iron deposits. Such a type of BIF-derived iron deposit, which mainly consists of hematite/martite and goethite, dominates the world's iron-ore reserves and outputs. A few magnetic petrophysical and palaeomagnetic studies have been conducted in the Hamersley Province, but sampling in these previous studies was not systematic. Therefore, to properly interpret aeromagnetic data in the Province, it was necessary for us to undertake a systematic magnetic petrophysical investigation. This paper presents the main magnetic petrophysical results. Applications of these results in aeromagnetic interpretation in the Province will be presented in the next paper.
Five hundred and seventy-three oriented samples from natural exposures and eleven industrial drill cores were collected from the Province. Bulk susceptibility, anisotropy of magnetic susceptibility (AMS) and natural remanent magnetisation (NRM) of all the samples were measured. More than 1000 data sets of each of the three parameters were obtained.
Five out of the six BIF units (Marra Mamba, Bruno's Band, Dales Gorge, Weeli Wolli, and Boolgeeda) all show a similar logarithmic bimodal distribution in mean bulk susceptibility (MBS), which means that there are two major susceptibility groups for each unit. However, the MBS of Joffre BIFs exhibits a logarithmic normal distribution. The Weeli Wolli, Joffre, Dales Gorge and Bruno's Band BIFs have the highest MBS. The Boolgeeda BIF has intermediate MBS, but it is still higher than that of iron ores and other non-BIF units. The Marra Mamba BIF has the lowest MBS, which is even lower than the iron ores. Iron ores have intermediate MBS. Brockman martite-hematite ores have slightly higher MBS than Marra Mamba martite-goethite ores. Other non-BIF units generally have low MBS. The Dales Gorge, Joffre and Weeli Wolli BIFs have high AMS with well-developed bedding-parallel or sub-bedding-parallel magnetic foliation. Some hematite ores, the Boolgeeda BIF and the Mt. McGrath hematite conglomerate have low AMS with recognisable sub-bedding-parallel magnetic foliation. The intensively weathered Marra Mamba BIF and other non-BIF units are generally isotropic. The in-situ NRM directions of all the BIF units are random in terms of magnetic interpretation. This is likely…

MAGNETIC PETROPHYSICAL STUDY IN THE HAMERSLEY PROVINCE, WESTERN AUSTRALIA AND ITS APPLICATION IN AEROMAGNETIC INTERPRETATION - II: AEROMAGNETIC INTERPRETATION

Wanwu GUO, Michael C. Dentith, Zhengxiang Li and Christopher McA. Powell (Tectonics Special Research Centre, Department of Geology and Geophysics, The University of Western Australia, Nedlands, Perth, WA 6907, Australia, Email: wguo@geol.uwa.edu.au)

Banded-iron formations (BIFs) are very special in magnetic interpretations. BIFs usually produce strong magnetic anomalies, from which geophysicists can easily approach the objective area. On the other hand, it remains problematic how to accurately determine which portion of an anomaly may be produced by high-grade ores, often having lower magnetism than BIFs, from the huge magnetic 'sea' dominated by the BIF's contribution. In the Hamersley Province, only a few magnetic petrophysical studies directly target magnetic anomalies of BIFs, ores and other units, but sampling in these previous studies was not systematic and modelling was relatively simplified and not linked to the iron ore deposits. Therefore, a systematic magnetic petrophysical investigation especially designed for magnetic anomaly interpretations was needed in the Province and recently completed. The previous paper reported the main magnetic petrophysical results of this investigation. This paper presents the applications of these magnetic petrophysical results to aeromagnetic interpretations in the Province.
Different from any other rocks, BIFs are characterised magnetically by high susceptibility, significant anisotropy of magnetic susceptibility (AMS), intensive natural remanent magnetism (NRM) and strong self-demagnetisation effects. These factors make the features of a BIF-related magnetic anomaly very complicated. In this paper, these effects are systematically analysed and illustrated by our theoretical models. One synthetic example and two practical examples considering these effects are also given.

The first example shows a synthetic ground magnetic profile over the West Angelas deposit. The result indicates that the total magnetic response is dominated by …

GEOLOGICAL INTERPRETATION OF SYSTEMATIC AEROMAGNETIC AND PETROPHYSICAL DATA FROM FINNISH LAPLAND, THE NORTHERN FENNOSCANDIAN SHIELD

Meri-Liisa AIRO, Geological Survey of Finland, PO BOX 96, FIN-02151 Espoo, Finland, fax: +358-205 50 12, Email: meri-liisa.airo@gsf.fi

A synthesis for the tectonic history of the Precambrian high-grade gneiss and granitoid area in southeastern Finnish Lapland was derived from integrated studies of regional geophysical data sets. The tectonic imprints in the aeromagnetic, gravity and digital elevation data were evaluated by incorporating systematic petrophysical data into the interpretation. The investigations aimed to explain the relationship between magnetic signatures and geology, particularly in terms of magnetic petrology. The results show that the present aeromagnetic character of southeastern Finnish Lapland was mainly produced during two major deformational events. The same weakness zones that were created due to the fragmentation of the Archaean crust during the continental rifting period at 2.5-2.1 Ga ago, were kinematically reactivated during the Svecokarelian deformation at 1.9-1.8 Ga ago. These weakness zones emerge as crustal scale fracture and shear zones in the regional aeromagnetic and gravity data. They separate the more coherent crustal blocks, which are characterized by typical magnetic anomaly patterns and trends and Bouguer-anomaly levels. The high-resolution aeromagnetic data reveal variation in composition and petrofabrics of the anomaly sources. There are signs that crustal stress is still released along the same weakness zones during the postglacial time, but part of the large scale bedrock structures in southeastern Lapland may originate from the late Archaean. The Archaean structures are hard to recognize since they were later obscured by the Palaeoproterozoic tectonics.

ANALYSIS AND INTERPRETATION OF GEOLOGICAL, ETROPHYSICAL AND GEOPHYSICAL DATA FOR THE KRAKA PHIOLITE ON THE SOUTH URALS

Natalia FEDOROVA, Kirill Ivanov (Institute of Geophysics, 100 Amundsenstr., Yekaterinburg, 620016, Russia, email: eva@maglab.mplik.ru)

Kraka massives and surrounding continent-slope and volcanic complexes are not typical for the western paleocontinental sector of the Urals. It was main argument for idea that Kraka hyperbasite complex with environments are allochton package overthrusted to the West from a zone of a Main Uralian Fault on a distance no less than 20 km. Petrological and geochemical researches of hyperbasites are conducted, and stratigraphy and tectonic of surrounding complexes are also studied. The interpretation of gravity and magnetic fields are carried out and alternative variants of cross-sections are constructed. The results of study showed that massives have the flat position. The greatest depth of hyperbasite complex under the Middle Kraka is 3.5 km while the depth for sources of the South and the North massives are 2.0 km. In the Kraka region the autochton, paraautochton and four allochtones are allocated and the plates initially occupying probably more eastern and/or deeper positions were disposed in higher structural level at the final package of tectonic plates. Our data allows to assume that the whole package was folded just after overthrusting, i.e. at Early Carboniferous. In Triassic the region undergone post-collision extension, during which system of large normal faults was generated and metamorphic complexes of the Uraltau anticlinorium were uplifted to the surface. Investigations are being done in framework of "Europrobe".

FAULT GOUGE AS A SOURCE OF THE GEOMAGNETIC FIELD ANOMALY

Dr. Norihiro NAKAMURA (The Tohoku University Museum)

Regional static anomaly for geomagnetic field are often observed along active faults. Previous studies interpreted the anomaly as placing the high susceptible dyke-like body along faults. Here we propose the alternative physical source for this anomaly. In brittle fault zones, the circulating fluid can chemically alter the magnetic properties of rocks. But, few theoretical relation between magnetic properties and chemical reactions in magnetic bodies has not been considered yet. In the light of irreversible thermodynamics, a new model for susceptibility change of rocks associated with chemical potential change induced by chemical reaction of magnetic bodies is proposed. The model indicates that the change in magnetic susceptibility is attributed by the negative change in chemical potential of rocks. In the hydration process with fluid-rock boundary, the chemical potential of rocks decreases as that process proceeds. Thus, it is expected that fault gouge zones show the high value in magnetic susceptibility rather than the surrounding wall rocks, because gouge zone with a high specific surface area can react with fluid easily. The comparison of our model with the natural data along the Nojima earthquake fault gives a good correlation that fault gouge has a two-order-of-magnitude higher value in bulk magnetic susceptibility (magnetic source was a ferrimagnetic goethite) than the wall rock. Because of this unusual magnetic properties of fault gouge, the rock-magnetic study affords us an interesting key to analyze the ferrimagnetic mineral localization in fault zones and the physical candidate of the geomagnetic field anomaly along faults. This study may lead to more realistic physical model needed in our understanding of the electromagnetic properties of faulted zones.

USING TEXTURAL MEASURES OF AEROMAGNETIC DATA TO INFER LITHOLOGY

Mark GETTINGS (U.S. Geological Survey, Geologic Division, Suite 355, 520 N. Park Ave., Tucson, AZ 85719, USA, email: mgetting@swfo.arizona.edu)

Aeromagnetic data of high spatial resolution contains information related to the distribution of magnetic sources at many scales. This information can be quantified by textural measures (such as number of peaks and troughs or roughness and relative amplitudes) and can be used to help identify the lithology of the source rocks both where exposed and beneath cover. Data processing proceeds by calculating the desired textural measures in a moving window on the original flight-line data (not low-pass filtered, gridded data). Using flight-line data utilizes the full information content but introduces a directional bias in the result because of wide flight-line spacing. Two robust measures that have been used are Euclidean length per km and number of peaks and troughs per km within the window. Window width is selected to be about the same length as the minimum characteristic length of geological features of interest; the textural measures will detect all features of larger characteristic lengths. Each textural measure value then forms a data point at the center of its window. A grid of each textural measure is then computed. The textural measure grids are then combined using fuzzy logic to produce a new grid of categories (e.g. many peaks and troughs and large amplitude versus few peaks and troughs and large amplitude) which can then be correlated with the geology in areas of exposed rocks. This procedure has been applied to an aeromagnetic dataset flown at 250-m line spacing, 250-m terrain clearance, and an along-line spacing of approximately 9m between data points in the Santa Cruz Valley and Santa Rita Mountains area of southeastern Arizona. The results show that the textural measures can be followed beneath cover for shallow and intermediate depths of both alluvial and magnetic volcanic cover.

DENSITY AND MAGNETIC PROPERTIES OF CRYSTALLINE ROCKS OF THE RUSSIAN PART OF THE FENNOSCANDIAN SHIELD

Anatoli Tchepik (North-West Regional Geological Centre, 24/1 Odoevsky street, St.Petersburg, 199155, Russia, Email: root@geol.spb.su); Lioudmila JDANOVA (State company "Mineral", 6 Veselnaya street, St.Petersburg,196106 Russia, Email: frank@DF3136.spb.edu); Larisa Galitchanina (Geological Institute of the Kola Sci. Centre of Russian Academy of Sciences, Apatity, 184200, Russia); Nikolai Philippov, Gennady Muradymov, Anton Radchenko (State company "Mineral", 6 Veselnaya street, St.Petersburg, 196106 Russia, Email: frank@DF3136.spb.edu)

Published earlier petrophysical material, as: "The Petromagnetic and Petrodensity maps of geological formations of the eastern Baltic Shield at a scale of 1:1 000 000 (editor N.Dortman, 1977) and other compilations (L.Galitchanina, et al. 1988, V.Tyuremnov et al.1982, I.Azbel et.al. 1993) do not enable to use petrophysical properties for detailed geological interpretation on PC. The project "The Geological and Geophysical Maps of the Russian part of Fennoscandian Shield 1:1 mill." started in Russia in 1997. It includes collecting information of density and magnetic properties of crystalline rocks and construction of petrophysical Database (Paradox on PC). The responsible organizations are North-West Regional Geological Centre, Petersburg Geophysical Expedition (before November 1998) and State Company "Mineral" (since November 1998). Petrophysical properties will be compared with digital geological data and used for interpretation of the gravity and magnetic anomalies of the Shield. This project will fill a gap in the petrophysical information available for modern, computer-based methods using magnetic and gravity maps. Authors present the Petrophysical maps for different areas of the Russian part of Fennoscandian Shield: published earlier and based on digital petrophysical Database.

DIFFERENT VIEWS OF BEDROCK IN PETROPHYSICAL DATA SETS

Heikki Saavuori and Juha V. KORHONEN (both at Geological Survey of Finland, P.O. Box 96, FIN-02151 ESPOO, FINLAND, Email: heikki.saavuori@gsf.fi, juha.korhonen@gsf.fi); Rein Vaher (Geological Institute of Tallinn, 7 Estonia Ave., EE-0001, Tallinn, Estonia, Email: rein@pzgeol.gi.ee)

The Geological Survey of Finland started petrophysical measurements for magnetic and gravity anomaly interpretation in 1954. The first petrophysical data base was established in 1971. The current PARADOX application PETROBASE 2.0 represents the fifth generation. The data consists of magnetic properties and bulk density measured from 250 700 samples, corresponding to an average data density of 74 samples per 100 sqkm in the level of whole country. The set is spatially inhomogenous, however, because of varying exposure of bedrock in different parts of the country and differing sampling techniques. Hand specimens (131,000 samples) taken from exposures, represent 3 per cent of bedrock at high local topographic level. A subset of this, the dyke samples (8000 specimens), represents more middle and lower crustal properties than the upper crust. Resampled cores (111,600 specimens) were originally drilled for mineral prospecting and stratigraphical studies and are partly of local nature, partly well representative in formational level. Boulders of local glacial till (8100 samples) represent approximately 50 per sent of the bedrock of the source area. These boulders are typically transported less than 500 m from its source in Northern Finland. The Estonian data set (3000 samples) was drilled from Precambrian basement through Phanerozoic sediments and the sites were selected by geophysical maps. The anomaly distribution partly affected this sampling. The different sources give us a different view of petrophysical characteristics. Overall regional properties can be obtained by properly weighting the data. A study is going on how to do this using regional geophysical information. The poster displays the new petrophysical maps of Finland and results from comparison of petrophysical properties in different types of sample sets.

MAGNETIC SURVEYING AT THE EASTERN SPANISH COAST. THE EXCLUSIVE ECONOMIC ZONE PROJECT (ZEEE)

M.CATALAN (J.Martin,J.A.Marin,and R.Alvarez (Geophysics Department, Royal Naval Observatory, San Fernando, Spain); M.Pardo,J.Rico (Hydrographic Institute Spanish Navy, S/N, 11007 Cadiz, Spain); P.Herranz, J.L.Sanz, C.Palomo and J.Acosta (Spanish Oceanographic Institute, Avda. Del Brasil 31, 28020 Madrid, Spain)

The Exclusive Economic Zone project is an ambitious multi-disciplinary study, that started in 1995, as a collaboration of the Spanish Defence Ministry with the Spanish Oceanography Institute (IEO), acting as co-ordinators, the Hydrographic Institute of the Navy (IHM) and the IEO.
Several Spanish Institutions are involved in it. Its aim is to obtain additional information related with classical geophysical disciplines like gravimetry, geomagnetism, or bathymetry, etc, that could allow a deeper knowledge of the Spanish Exclusive Economic Zone. As marine acquisition platform it is being used the Spanish Research Vessel HESPERIDES. Along 1995,1996 and 1997 summertime (August), activities were concentrated at the Spanish Gulf of Valencia and Balearic Sea area. The geomagnetic side of the project is a responsibility of the Geophysic Department of the Spanish Royal Naval Observatory at San Fernando. In this marine survey, several magnetic instruments were involved: One classical marine proton magnetometer and an Overhauser effect marine magnetometer. As fixed reference station we installed a magnetometer at Minorca Island (Balearic Island). The aim of this project, in the geomagnetism aspects, is to conform not only a spatial database but also a series of Total Field and Magnetic anomalies series of charts to be edited as a collaboration between the IHM

and the IEO. We will present in this Communication, the details of this project, in the geomagnetic aspect, some results obtained in the 1995-97 period at the Valencia gulf and Balearic Sea, and the present and next future activities at the Canaries Islands Zone.

GA5.12/W/01-A2 0950

MAGNETIC ANOMALIES IN THE NORTH PACIFIC

Nobuhiro ISEZAKI (Department of Earth Sciences,Chiba University, 1-33, Inageku, Chiba, 263-8522, JAPAN, Email: nisezaki@earth.s.chiba-u.ac.jp) Takemi Ishihara (Marine Geology Department, Geological Survey of Japan, 1-1-3, Higashi, Tsukuba, 305-8567, JAPAN, Email: tishi@gsj.go.jp

The geological and geophysical atlas for the Pacific (GAPA) has been under the press for long time. This atlas will contain the magnetic anomaly map of the Pacific using the magnetic data provided by the NGDC (National Geophysical Data Center) of NOAA (WDC-1) in 1985 We will show survey tracks, the magnetic anomaly contour and profile maps in the Pacific. We will present a new map using additional recent NGDC data as well. Through the program for compiling and publication of the geological /geophysical data of world oceans under the auspices of the International Oceanographic Commission (IOC) of UNESCO, mainly entrusted by the Soviet Union, firstly the Atlas for the Indian Ocean was published in 1975 and for the Atlantic Ocean later in 1990. The atlas for the Pacific Ocean was scheduled to publish in 1994, however, the great change was occurred in Soviet Union in 1991 and this program was suspended hereafter. One of the authors (Isezaki) presented the magnetic anomaly map in the Pacific Ocean based on the data obtained before 1985 provided by the NGDC. Recently we got data from NGDC from 1958 till 1993 and made a new magnetic anomaly map in the north Pacific because there are not enough data to make a contour map in the south Pacific. In the NGDC data, there are about 15,278,670 data in the North Pacific Ocean in which the oldest was measured in 1958. The characteristics of magnetic anomaly pattern in the North Pacific Ocean are the lineation distribution. There are two magnetic bights in the NW and NE corners of the North Pacific Ocean, which are clearly presented in the coloured map. We will present the track line map and the result of statistics of data used as well.

GA5.12/L/01-A2 1010

RESULTS OF RUSSIAN MAGNETIC SURVEYS IN THE ARCTIC AND ATLANTIC OCEANS

GLEBOVSKY V.YU, Maschenkov S.P. (both at VNIIOkeangeologia, 1, Angliysky pr., 190121, St.-Petersburg, Russia, Email: gleb@vniio.nw.ru), Merkuriev S.A., Sochevanova N.A. (both at Institute of Terrestrial Magnetism, Ionosphere and Radiowave Propagation, St.-Petersburg Filial, 2, Muchnoy per., 191023, St.-Petersburg, Russia, Email: sam@NF1480.spb.edu).

The Arctic and North Atlantic oceans are the main regions for regular magnetic investigations were carried out by various Russian agencies. The Deep Arctic ocean and Russian Arctic shelf are covered byaeromagnetic surveys. The total length of aeromagnetic profiles in theArctic region is about 2,000,000 line km. All magnetic anomaly profile data were digitized combined, totally reprocessed and loaded into the coherent magnetic data base. The new magnetic compilation in the Arcticocean is much more detailed than those developed by GSC-Atlantic (Verhoefet al., 1996).
The most part of Greenland-Norwegian and Reykjanes (betweenIceland and Charlie-Gibbs FZ) Regions are covered by marine magnetic surveys. Two additional marine magnetic datasets collected within 200 km wide swaths of the Canary-Bahamas and Angola-Brazil Geotransects (CBG and ABG). Marine magnetic data are mostly in a digital, partly in an analogous form. The most part of magnetic anomaly data in the North Atlantic and within ABG are not available yet for the geoscience community.
Existing computer generated colour shaded relief maps, examples of not published initial anomaly magnetic profile data, and schemes of marine and airborne tracklines for all mentioned above regions of the Arctic and Atlantic oceans are presented.
Being reprocessed and compiled with magnetic data have been collected by western countries the Russian data would provide significant additional information for geological and tectonic interpretation.

GA5.12/W/02-A2 1100

ADMAP - A DIGITAL MAGNETIC ANOMALY MAP AND DATABASE FOR ANTARCTICA

P.MORRIS (British Antarctic Survey, High Cross,Madingley Road, Cambridge CB3 0ET,UK, email: pmor@bas.ac.uk) R.B von Frese (Dept. of Geological Sciences & Byrd Polar Research Center, The Ohio State University, Columbus, OH 43210,USA, email: vonfrese@osu.edu)

With encouragement from IAGA and SCAR a working group of scientists from eight countries, including representatives of nearly all with major magnetic activities in the Antarctic, met in Cambridge in September 1995 to consider the establishment of a digital database of magnetic data and the production of a magnetic anomaly map of the continent. It was agreed to create a database and digital grid for the region south of 60degS. This would involve the integration of all available ground, airborne and marine surveys with satellite data being used, where appropriate, to link separated surveys and infill blank regions. Given the distribution of the existing datasets and the regional interests of the various research groups involved, the study area was divided into three equal sectors in which the data could be compiled separately. The three datasets could then be brought together to form a complete set for the whole continent. Since that date the members of the working group have been active with two further meetings being held, in Italy and the United States, to discuss the progress of the work and present related research findings. The compilation is now reasonably well advanced with two of the sectors being essentially complete. It is hoped that the complete grid and database will be available in the year 2000. We shall describe some of the practical problems, which have had to be overcome during this work and report on the latest situation.

GA5.12/E/10-A2 1120

AEROMAGNETIC ANOMALY MAPPING AND THE GEOLOGIC ARCHITECTURE OF CENTRAL GONDWANA

Colin REEVES and B.K. Sahu (International Institute for Aerospace Survey and Earth Sciences (ITC), Kanaalweg 3, 2628 EB Delft, The Netherlands. E-mail: reeves@itc.nl)

Most of the world's Precambrian geology is hidden by younger cover formations. Mapping the magnetic anomalies arising from the hidden igneous and metamorphic terrane provides a unique window on the unseen crystalline geology. In the Precambrian terranes of central Gondwana (Africa, Antarctica, Madagascar, India, Sri Lanka) many hundreds of individual aeromagnetic surveys have already been compiled to give continental-scale syntheses of magnetic anomaly patterns that are now continuous over many large areas. While problems still surround the free publication of many of these data sets, many outline interpretations have been published and may be augmented where the magnetic data can be accessed. We have digitally assembled and elaborated these interpretations for the fragments of central Gondwana using the Cambridge 'Atlas' PC software. This has made possible the refining and defining in terms of absolute Euler rotation poles a defensible, tight re-assembly for central Gondwana. The result is presented as a map that shows a number of circular or highly rounded Archean nuclei around which the terranes created or reworked during the Proterozoic show structures that are largely concentric. Outcrop data and radiometric dating can be used by those having access to these and other data to verify and refine our geometric model that is available digitally. During the Phanerozoic, the extensive Karoo-Gondwana rifting (late Carboniferous to earliest Jurassic), supercontinent fragmentation (mid-to-late Jurassic) and renewed rifting in the Tertiary all appear to have, for the most part, avoided the Archean nuclei but followed instead the grain of the Proterozoic terranes.

GA5.12/E/08-A2 1140

A DECADE OF MAGNETIC COMPILATIONS: FROM MICRO TO MACRO

FAIRHEAD, J. D., Green, C. M. and Mushayandebvu, M. F. (GETECH, School of Earth Sciences, University of Leeds, Leeds, LS2 9JT, UK, email: jdf@getech.leeds.ac.uk)

Magnetic data compilations over the last decade have ranged in size from countrywide to continental scale and are now rapidly becoming global. Academics and explorationists to provide important insights into earth structure and geological processes at varying scales and resolutions are using them. These compilation projects, initiated by GETECH in 1989, have preserved historic data that otherwise might have been irretrievably lost and would not have been possible without the generous financial support of both the oil and mineral industries and the foresight and encouragement of national organisations. Innovative techniques have been developed to recover data and reprocess them into consistent, merged grid and profile databases. The presentation reviews a decade of magnetic compilations carried out by GETECH, often in association with other groups, for Africa, South America, Eastern Europe, FSU, China, Middle East and South East Asia, and illustrates the variable data types, problems and solutions. The importance of quality control, recognising resolution limitations as well as accurately recording survey technical specifications helps to preserve the long-term usability of these data sets. Availability of such data for academic research is encouraged, albeit within a legal framework proprietary data owners, governments and sponsors externally impose that on GETECH. The volume and spatial distribution of the compiled magnetic (and gravity) datasets that now exist allows their use in studies directed at earth evolution in new interactive ways, within a plate tectonic environment, using specially designed computer visualisation software. Such software besides identifying the inadequacies of current global plate tectonic model parameters does allow the investigation of the pre-drift structure and configuration of continents and their subsequent evolution and deformation.

GA5.12/W/07-A2 1200

GRADIENT GEOMAGNETIC SURVEYS AT STRATOSPHERIC ALTITUDES: THEIR STRENGTHS, PECULIARITIES AND INTERPRETATION

Yu Tsvetkov (IZMIRAN, Troitsk, Moscow Region, 142092, Russia) M PURUCKER (Geodynamics Branch, Goddard Space Flight Ct, Greenbelt, MD20771 USA, email: purucker@geomag.gsfc.nasa.gov) N Rotanova (IZMIRAN, Troitsk, Moscow Region, 142092, Russia)

The measurement of gradients of the geomagnetic field by stratospheric balloons along continental-scale transects offers a new perspective on the geomagnetic field complex. The proper interpretation of these surveys requires an understanding of the peculiarities of both the survey technique and the ability to separate the multiple sources of the geomagnetic field. The measurement devices are three scalar proton-precession magnetometers separated along a 4-km vertical line at equal distances. We will show that this measurement configuration is optimised for the extraction of remanent and induced magnetic signals from the entire thickness of the crust. The peculiarities of the technique that should be understood by an interpreter are 1) deviations of the measurement axes from a vertical line because of stratospheric winds, 2) rotations about the vertical axes, 3) vertical pendulum oscillations, and 4) day-night altitude differences. We will discuss these peculiarities, the errors they introduce into the measurements, and their alleviation. These gradiometer measurements provide a view of a range of wavelengths intermediate between those sensed by aeromagnetic surveys on the one hand and satellite magnetic surveys on the other hand.

GA5.12/W/08-A2 1220

ACCESS TO AIRBORNE AND MARINE DATA THROUGH THE IAGA WG-V9 WEB SITE

S. J. MCLEAN and C. A. Williams, National Geophysical Data Center, 325 Broadway, Boulder, CO USA 80303

At the 8th Scientific Assembly of IAGA in Uppsala, Sweden, the World Data Center-A in Boulder, Colorado agreed to develop and host the web site for Division V Working Group 9 Magnetic Anomalies (Land And Sea). The purpose of the web site is to provide access to data and information pertaining to the development of the world magnetic anomaly map. The status of the web site (at URL http://www.ngdc.noaa.gov/IAGA/wg9/) will be explained and possible directions for the future explored. The goal of the Working Group is to provide access to publicly available grids and metadata with information on related restricted higher resolution. We will demonstrate a pilot system to access magnetic grids via the WWW. The ESRI Spatial Data Engine (SDE) and Oracle database are the heart of the data access. If large file size presents a data transfer problem, we offer an alternate off-line data distribution method using CD-R or DVD-R.

ON USING DOWNWARD FIELD CONTINUATION TO DETERMINE WORLD MAGNETIC ANOMALY MAPS

Wigor A. WEBERS, GeoForschungsZentrum Potsdam, Telegrafenberg, D- 14473 Potsdam, Germany

The spatial wavelengths of the internal magnetic field sources are differently represented in the SHA terms when SHA field models of different concentric reference spheres as the Earth=92s surface and the satellite altitude are compared. This reflects the different physical content of both field data sets and can be evaluated by downward field continuation.
The mathematical reason is that both the SHA field models are infinite power series expansions of different convergence quality. In practically treating them they were truncated at a definite index N and used as finite partial sums. This does not remove the mathematical background, which explains that upward and downward field continuations are inverse ill-posed problems.
Referring SHA field models of concentric reference surfaces to each other only by the ratio of the radii is therefore an approximation that can be restrictedly used only because of increasing errors. As a consequence this shows that global ground-based and satellite anomaly fields significantly differ. Applying the downward field continuation procedure WIGCONT

demonstrates the problem and enables to combine both anomaly maps.

APPLICATION OF THE 3D FILTERING FOR THE DERIVATION OF MAGNETIC ANOMALY MAPS FROM THE MEASUREMENTS OF SATELLITES

Károly KIS (Geophysics Department, Loránt Eötvös University, Ludovika tér 2, 1083 Budapest, Hungary, email: kisk@ludens.elte.hu Géza Wittmann (MOL Rt, Hungarian Oil & Gas Co., Exploration, Field Development and Reservoir Engineering, Batthyány u. 45, 1039 Budapest, Hungary, email: gwittman@mol.hu)

Derivation of magnetic anomaly maps from the measurements of satellites is regarded as a problem of interpolation. The presented procedures were applied for the scalar and vector data of the Magsat. The processed anomaly maps are derived for the European region. The first phase of the data processing includes the correction of effect of the external and induced magnetic fields; separation of the data into dawn and dusk parts; and selection of the data according to the planetary Kp index. In the second phase of the data processing Gaussian low-pass and band-pass; and Laplacian low-pass and band-pass filterings are applied for the solution of the interpolation problem. The data are interpolated for the surface of a sphere of radius 6771-km. The interpolation procedures are designed in spatial frequency domain and implemented in space domain. The derived anomaly maps are compared to the regional geological structure of the European region.

HOW CAN GLOBAL SPHERICAL HARMONICS ASSIST IN MAP CONSTRUCTIONS?

Joseph CAIN and David Mozzoni (both at Geophysical Fluid Dynamics Institute/FSU, Tallahassee FL 32306-4360,USA, Email: cain@geomag.gfdi.fsu.edu and cyric@leyla.gfdi.fsu.edu)

We here compare maps constructed from band-passed global geomagnetic anomaly models with those computed from other authors who processed data residuals beyond a scale size represented by SHC to n =13. The more recently constructed maps appear to be smoother than those previously. It is shown that while most features seen at satellite altitude are amply described using up to n = 40, the few strong anomalies require terms of the order of n = 60 even though surface projections show noise patterns in the "bland" regions. This technique, or any other, does not resolve the problem of separating the contributions from the main field in the size range corresponding to 3 < n < 15.
Obtaining near surface observations that are consistent in accuracy and especially in level that can be incorporated in global modelling at high degree is yet a problem. We recommend that international agreements to draw a "standard" global geomagnetic map be approached cautiously so "users" of such standard maps are clearly aware of the limitations. Further, because regional maps will continue to be made by near surface data, that any such to be considered part of a "standard" either be adjusted to the levels that can be determined from global satellite results, or that level differences are part of the data for each map. Producers of future near-surface surveys should be advised that maps produced from such surveys would be much more valuable if there were adequate information to determine the absolute level at some specific universal time so as to aid in integrating with global models. It would also be valuable to perform sample resurveys of some areas where small-scale maps are available to provide such data, or the map levels readjusted.

GA5.12/W/03-A2 1500

USE OF MAGNETIC SATELLITE DATA IN LARGE SCALE AEROMAGNETIC AND MARINE COMPILATIONS

K A WHALER (Department of Geology and Geophysics, University of Edinburgh, West Mains Road, Edinburgh EH9 3JW, Scotland, e-mail: kathy.whaler@ed.ac.uk); D Ravat, Department of Geology, Southern Illinois University at Carbondale, Carbondale, IL 62901-4324, USA

Satellite data are most useful in large-scale compilations of near surface magnetic anomaly data when they are downward continued to the same level as the survey data. Most previous methods have either only been able to downward continue over continental scale areas, or have not preserved the resolution of the satellite data. We present the results of applying the conjugate gradient algorithm to downward-continue global three-component satellite anomaly datasets. The shortest wavelengths present in the satellite data agree well with the longer wavelengths present in surveys with high altitude, long tie lines. Examples will be shown using data from the former Earth Physics Branch of the Geological Survey of Canada, where the anomalies agree both in pattern and amplitude. Individual small-scale surveys can then be 'draped' onto such models, providing the intermediate wavelength control not present in the surveys, which otherwise causes levelling problems in large-scale compilations. The advantages and some of the problems in this type of an approach will be discussed.

TOWARD THE WORLD MAGNETIC ANOMALY MAP: METHODS AND EXAMPLES OF MERGING REGIONAL-SCALE NEAR SURFACE AND SATELLITE-ALTITUDE MAGNETIC DATA

D. RAVAT (Dept. of Geology, Southern Illinois University at Carbondale, Carbondale, IL 62901-4324, U.S.A., email: ravat@geo.siu.edu) M. Purucker (Raytheon-STX/Geodynamics Branch Code 921, NASA-GSFC, Greenbelt, MD 20771, U.S.A., email: purucker@geomag.gsfc.nasa.gov) K. Whaler (Dept. of Geology & Geophysics, Grant Institute, West Mains Road, Edinburgh, EH9 3JW, Scotland, U.K., email: whaler@mail.glg.ed.ac.uk) M. Pilkington (Geological Survey of Canada, 615 Booth Street, Ottawa,Ontario, CANADA K1A 0E9, email: pilkington@gsc.NRCan.gc.ca)

Many previous regional-scale comparisons of near-surface and satellite-altitude magnetic anomaly data used methods and procedures that assumed that either the field at one of the altitudes was accurate or analytical rectangular co-ordinate continuation methods were adequate. These assumptions were partly incorrect and led to imprecise results that showed that the two sources of data were not compatible. We have developed a methodology in which we invert both the sources of the data to a common set of spherical-co-ordinate equivalent sources. Our results show that the near-surface and satellite-altitude fields are highly compatible over all regions we have analysed so far (Canada, the U.S., and parts of Antarctica). For these regions, the spatial correlation coefficients between the observed and the inverted fields are around or above 0.90. Rigorous wavenumber-domain comparisons indicate also the high correspondence between the fields at the relevant wavenumbers (~500-3000 km). Our results show that, in general, long wavelengths (>1000 km) in near-surface compilations are less accurate than those in satellite data and vice versa for short wavelengths (<500 km), as might be expected intuitively. Thus, the approaches that utilise and benefit from the individual strengths of these data, such as our approach, should be more suitable for the preparation of the world magnetic anomaly data.

GA5.12/W/05-A2 Poster 1600-01

A NEW MAGNETIC ANOMALY MAP OF THE CENTRAL SECTOR OF EAST ANTARCTICA

ALEXANDER V. GOLYNSKY1 & V. N. Masolov2 1VNIIOkeangeologia, 1 Angliysky Ave., 190121, St. Petersburg, Russia. (email: sasha@gus1.vniio.nw.ru) 2 PMGRE, 24, Pobeda St., 189510, Lomonosov, Russia.

Aeromagnetic and marine observations in the central sector of East Antarctica and adjacent seas of Indian ocean have been compiled in a new database as a part of the initiative to produce a new magnetic anomaly map of Antarctica (ADMAP). Extensive regional magnetic flights by Russians expeditions commenced in 1955 has resulted in over 260 000 line kilometres of data collected with line-spacings of about 5 km, 20 km and 50 km. The aeromagnetic and marine data used in the compilation consists of a combination of digitally recorded data and data digitised from published and unpublished profile maps. These were edited to remove high-frequency errors before network adjustment was carried out. Data for each individual survey were projected and gridded by using either a 1.5-km or 5 km grid interval. Surveys using line spacings of 50 km or more were initially gridded at a coarser interval, then regridded. In the final compilation step the surveys were merged together using Geological Survey of Canada grid stitching program and gridded at intervals of 5 km. The most advantageous result of this compilation is the shaded-relief map, which show one of the most complete and coherent perspectives to date of the region's magnetic character. In combination with other types of data, this information promises to shed new light on the structure, processes and tectonic evolution of the ice-covered Antarctic continent and surrounding ocean. It will be a valuable tool for structural and tectonic correlations between fragments of Gondwana, and as such will be a key element of the proposed World Magnetic Anomaly Map. The magnetic anomalies correlate with many of the study area's structural features. On continent interpretation of magnetic data allowed to better define the boundaries between the Archean stable blocks and the Proterozoic mobile belts, and to trace these boundaries beneath the ice sheet. In sedimentary basins these data provided an important source of information about the depth and tectonic nature of the basement and thickness of sedimentary cover.

AEROMAGNETIC MAP OF THE RUSSIAN PART OF THE FENNOSCANDIAN SHIELD 1:2.5 MILL

Anatoli Tchepik (North-West Regional Geological Centre, 24/1 Odoevsky street, St.Petersburg, 199155, Russia, Email: root@geol.spb.su Lioudmila JDANOVA (State company "Mineral", 6 Veselnaya street, St.Petersburg, 196106 Russia, Email: frank@DF3136.spb.edu

The project "The Geological and Geophysical Maps of the Russian part of Fennoscandian Shield 1:1 mill." started in Russia in 1997. It includes the construction the digital model of Aeromagnetic Map in a scale 1:1mill. On the base the authors of this abstract are making the matrix (1x1 km. grid). The responsible organisations are northwest Regional Geological Centre, Petersburg Geophysical Expedition (before November 1998) and State Company "Mineral" (since November 1998). At the same time, in 1997 the Geological Surveys of Finland, Norway and Sweden together with the Northwest Regional Geological Centre, Russia have started the compiling of digital geological and geophysical maps in a scale of 1 : 1 mill. The Geological Survey of Finland (GTK) co-ordinates the work, that is planned to be completed by the end of 2000. A preliminary map of the Russian part has been included into the preliminary versions of common Aeromagnetic Map of the whole Fennoscandian Shield: a preliminary version (0.3) of the Magnetic map in a scale of 1:2 mill has been compiled in August 1997 and presented at the 8th Scientific meeting of IAGA in Uppsala and at the Crustal Model Workshop in Espoo (Korhonen et al. 1997); a preliminary version (0.5) of the Magnetic map in a scale 1: 4 mill. has been compiled in November 1998 and presented at the 3th workshop Svekalapko in Repino (Russia). The authors present a new version of the Aeromagnetic Map of the Russian part of the Fennoscandian Shield with additional aeromagnetic data for Northern and Western parts. The checking of magnetic map level has been done by a measuring tie line.

MAGNETIC DGRF-65 ANOMALY MAP OF THE FENNOSCANDIAN SHIELD 1:4 MILL

Juha V. KORHONEN (Geological Survey of Finland, P.O. Box 96, FIN-02151 ESPOO, Finland, Email: juha.geofys@gsf.fi), Sven Aaro (Geological Survey of Sweden, P.O.Box 670, 75128 Uppsala, Sweden, Email: sven.aaro@sgu.se), Jan Reidar Skilbrei (Norges geologiske undersF8kelse, Postboks 3006 Lade, 7002 Trondheim, Email: jan.skilbrei@ngu.no), Anatoli Tchepik (Northwest Regional Geophysical Centre, 24/1 Odoevsky Street, 199155 St Petersburg, Russia, Email: root@geol.spb.su, Lioudmila Jdanova (State Company "Mineral", Veselnaya Street 6, 196106 StPetersburg, Russia, Email: frank@DF3136.spb.edu)

In 1997 the Geological Surveys of Finland, Norway and Sweden and the Petersburg Geophysical Expedition started to compile a magnetic DGRF-65 anomaly map in a scale of 1:1 mill on a 1 km x 1 km grid. The purpose was to support studies of crustal structure and evolution in the Fennoscandian Shield and to contribute on the world aeromagnetic map. The participating countries will provide the data of their territory as 1 km x 1-km subgrids after making reductions to DGRF-65 anomaly level. Most of the data originates from airborne surveys; ground and seaborne information will patch gaps. Consistent anomaly levels will be ensured by long tie lines. Available petrophysical data (270 000 measurements of induced and remnant magnetisation) will be used to compile magnetic characteristics of major geological formations and to further calculate a 5 km x 5 km geologically weighted magnetisation grid. The aim is to interpret the depth extent of major surficial geological formations, and to identify previously unknown magnetic anomaly sources at depth. A preliminary magnetic anomaly map on a scale of 1:4 mill on a 2 km x 2 km grid and examples of petrophysical correlation of anomalies are at display.

GA5.12/L/03-A2 Poster 1600-04

AEROMAGNETIC TIE LINE SURVEY OF FINLAND 1998

Juha V. KORHONEN, Maija Kurimo and Toivo Korja (all at Geological Survey of Finland, P.O. Box 96, FIN-02151 ESPOO, Finland Email: juha.korhonen@gsf.fi)

The first national aerogeophysical mapping programme of Finland was carried out in 1951-72 and covered 418,000 sqkm. In 1968-69 the relative magnetic intensities were tied to absolute values by tie lines, which were separated by 40 km from each other and were referenced to both Finnish magnetic observatories. Comparison with modern absolute magnetic surveys indicates a standard error less than 20 nT. The second national programme was started in 1972. The altitude was 40 m and track separations were 200 m. Eighty per cent of the Finnish land area was covered by 1998. The daily magnetic variation was corrected by one base station, which was located in the survey area. The measurements were reduced to absolute total intensity 1965.0 referencing the base station to magnetic observatories in

Nurmij_$B'S_(Bvi and Sodankyl. The accuracy of this procedure depends on the best homogeneity of magnetic field variation observed during each survey. The main source of error is nonlinear spatial change in total field, which can be corrected by denser net of magnetic base stations only. Comparisons with repeated measurements indicate, that the standard error of absolute level is better than five nT in a 25-year span. In 1998 the SVEKALAPKO BEAR experiment and IMAGE project in Fennoscandia (66 stations together) offered an opportunity to estimate spatial distribution of nonlinear drift in six weeks time and to use the network as base stations for tie lines, which were flown at 40 m altitude and with 100 km track separations. The aim was to use results in checking survey qualities, in future reduction of aeromagnetic measurements, in compilation of a Fennoscandian aeromagnetic map 1:1 mill and in interpretation of lithospheric magnetic sources. On display are the reduction procedure, results of comparison with elder magnetic measurements and the newest version of the aeromagnetic DGRF-65 anomaly map of Finland.

THE SWEDISH TIE-LINE PROJECT OF 1998: AN AIRBORNE MAGNETIC AND RADIOMETRIC RE-SURVEY

Soren Bystrom, Anders H. Linden and Gerhard SCHWARZ (Geological Survey of Sweden, Box 670, S-75128 Uppsala, Sweden, email: gerhard@sgu.se) Maija Kurimo and Juha V. Korhonen (Geological Survey of Finland, Box 96, FIN-02151 Espoo)

The first airborne geophysical measurements were done in Sweden about 40 years ago and today large parts of the country are surveyed by magnetic and radiometric measurements as well as partly by VLF-mappings. But, the huge amount of individual data sets taken over a longer period causes some problems in data treatment. When combining data sets that were measured in different years levelling errors may occur, both with the radiometric as well as with the magnetic data. Therefore, the Geological Survey of Sweden was doing an airborne magnetic as well as radiometric re-survey on a large scale all over Sweden, called the tie-line project. The project aims on compiling new magnetic and radiometric maps that consider all available airborne data. The airborne survey was flown by GTK of Finland during the summer of 1998. The distance between flight lines was about 18 km. At the same time the magnetotelluric array of the BEAR group of EUROPROBE's SVEKALAPKO project was in operation. Further information on the time varying magnetic field was provided by the IMAGE network, as well as by three to five total field moving base stations.
This scheme of fixed and moving base stations resulted in a distance between a ground station and the airplane not exceeding about 100 km. It allows to remove the time varying external magnetic field with better accuracy than in previous surveys. We will show maps compiled from the newly obtained magnetic and radiometric data. We will outline also strategies for further data treatment, e.g., fitting in airborne magnetic data from previous surveys into the newly obtained data, as well as considering the bias caused by electrical high conductivity zones.

CONSISTENT GEOMAGNETIC IMAGES WITHIN THE LOW DANUBE AREA. MAGLODAN PROJECT

Lucian Besutiu and Georgeta Besutiu (Geological Institute of Romania, 78344 Bucharest 32, sector 1, 1, Caransebes str., fax: +401 224.0404; e-mail: besutiu@igr.sfos.ro), Inna Pashkevich and Mikhail Orlyuk (Institute of Geophysics Kiev, 32, Palladin av., Ukraine, Marian Ivan (University of Bucharest, 1, Traian Vuia str., Romania), Vasile Neaga (Institute of Geophysics and Geology Chisinau, 3, Academiei str., Republic of Moldova)

MAGneticLOwDANube project represents the first step in a joint venture between the Geological Institute of Romania, Institute of Geophysics Kiev and Institute of Geophysics and Geology Chisinau in an attempt to join the national geomagnetic maps of Romania, Ukraine and Republic of Moldova. Based on a common international magnetic reference network, a consistent data set of absolute values of the total intensity scalar of the geomagnetic field was obtained for the whole Low Danube area. Total intensity scalar and geomagnetic anomaly maps were constructed. Horizontal gradient maps have been performed to check up the quality of the joining operation. Various local models of the reference field were used to achieve geomagnetic anomaly images. Regional and local effects are presented and discussed.

STRUCTURAL STUDY OF SEDIMENTARY BASIN USING AEROMAGNETIC DATA. CASE STUDY: THE TIN-SERIRINE SEDIMENTARY BASIN, HOGGAR ALGERIA.

Haydar BAKER (Departement de Geophysique, IST, USTHB, El-Alya, Alger, Algeria, email: djeddi@ccr.jussieu.fr) NasrEddine Bourenas (CREM, El-Biar, Alger, Algeria) Mohamed Hamoudi (Departement de Geophysique, IST, USTHB, El-Alya, Alger, Algeria,
email: hamoudi@ipgp.jussieu.fr)

The Tin-Seririne basin is situated in the SW of the Hoggar region in Algeria. It forms the continuity of the Ti-Merso-Iullmeden basin in the north of Nigeria. It is situated between the latitudes 8=B0 & 23=B0 and longitudes 20=B0 & 23=B0.
The interpretation of the magnetic anomalies and the results obtained from four regional gravimetric profiles suggest that the region has been subjected to intensive tectonic activities. Three principal fault systems have been differentiated in this work, namely the NS, the NNE-SSW and the NNW-SSE.
The NS fault system, which is essentially composed of three faults (along the latitudes 6=B015', 6=B050' & 7=B030' respectively) is considered to be the one responsible for the formation of the Tin-Seririne sedimentary basin during the late phase of the Pan-African orogenesis. The first phase of sinking is thought to have occurred along the seventh latitude, while the second phase is considered to have been associated with two important faults of the NNE-SSW system.
However, based on detailed geophysical and geological studies, a geodynamic model is given with six zones of distinctive geological characteristics.

ROLE OF AEROMAGNETICS IN THE DELINEATION OF THE GROSS STRUCTURAL FRAMEWORK OF GABAL MEATIQ AREA, CENTRAL EASTERN DESERT, EGYPT

Ahmed A, Amar, Said I. Rabie and Magdy A. GOUDA (all at Exploration Division, Nuclear Materials Authority, P.O.Box 530 Maadi, Cairo, Egypt) Nasser M. Abu-Ashour (Geophysics Dept., Faculty Of Science, Ain Shams Univ., Cairo, Egypt)

The delineation of the regional structure framework of Gabal Meatiq Area, Central Eastern Desert, Egypt, at the deep-seated and the near-surface levels, was achieved through the integrated application of some geophysical interpretation techniques to the aeromagnetic survey data reduced to the north magnetic pole (RTP) of the earth.
Two main average interfaces at depths 1.1 and 2.2 kms below measuring level were calculated through the application of the two-dimensional power spectrum. Isolation of the magnetic anomalies was conducted using filtering combined with analytical downward continuation at the two assigned interfaces. In addition, the magnitudes of the normalised total and horizontal magnetic vectors (gradients) of the field intensity were calculated at the two stated interfaces. Moreover, variations of the horizontal phase angle were calculated at the two fixed jnterfaces.
The information obtained from all the methods of interpretation were integrated to construct two interpreted magnetic basement structural maps at the two designated levels. These two maps show the gross structural framework of the area under study. The major delineated magnetic structural elements affecting the basement complex at the two appointed interfaces are faults and folds in the form of upfaulted blocks or anticlines and down-thrown blocks or synclines as well as dykes. Statistical trend analysis was executed, principally, for the defining the trend directions of the interpreted magnetic structural lineaments using the successive overlap technique.

AN AEROMAGNETIC SYNHTESIS OF THE ARABIAN SHIELD: GEOLOGICAL IMPLICATIONS

FAWZIA ASFIRANE HADDADJ, Pierre Nehlig, Antonin Genna, Philippe Bernard, Jean-Marc Miehe (BRGM, 3 Ave. C. Guillemin, B. P. 6009, 45060, Orléans cedex 02, France) and Abdallah Ahmed Showail (DMMR, USGS mission, P.O box 1488 Jeddah, 21431, Saudi Arabia)

In the frame of a global revaluation of the geology and metallogeny of the Arabian shield, a compilation of all the aeromagnetic surveys covering western Saudi Arabia has been completed (655000km2). Ten aeromagnetic surveys, carried out from 1962 to 1983, stored on magnetic tapes, realised at different terrain clearance (150 m, 300 m and 500 m) and different line spacing (800 m, 500 m and 2000 m) have been compiled in a 1 km elementary squared grid at an altitude of 300 m. In order to interpret the magnetic anomalies in terms of geological structures a reduction to the pole to replace the magnetic anomalies at the top of the sources has been achieved. A vertical gradient has been computed in order to underline the short wavelength anomalies which are associated to shallow sources such as the basaltic dykes due to the opening of the red sea. The resulting maps show magnetic anomalies, which are well correlated with geological features, which are constrained in terms of structures, lithology and geochronology. They shed new light on the accretion, the pan African tectonics and the intimate relationship between the N-S Nabitah belt and the NW SE Nadj faults system.

THE INTERPRETATION OF GRAVITY AND MAGNETIC ANOMALIES OF RUDAN AREA

Naser H. GUYA (Institute of Geophysics, Tehran University, P. O. Box 14155-6466, Tehran, I. R. Iran, email: nhzguya@chamran.ut.ac.ir)

Using magnetic and gravity data from a relatively small area close to Makran subduction zone in south-east Iran, we are trying to understand the complex geology of this area and say something about the plate tectonics of this part of the world. It has been suggested that the Iranian plateau has been compressed in south and south-west by the Arabian plate, and in south-east by the subduction of oceanic plate along Makran belt. This paper investigates the causes of observed anomalies and their relation to the tectonics of the area. The observed magnetic anomalies are mostly deep seated and show a north-south lineation. The gravity map also shows this lineation and a good correlation with magnetic data. We suggest that the north-east tectonic forces have stopped at the Sabzevaran fault and therefore the folding of basement in an east-west direction has occurred.

EVOLUTION OF THE CONCEPT OF MAGNETOTAIL RECONNECTION AS A SOURCE OF ENERGY FOR MAGNETOSPHERIC SUBSTORMS

Gordon ROSTOKER (Department of Physics, University of Alberta, Edmonton, Alberta, Canada T6G 2J1, email: rostoker@space.ualberta.ca)

Not long after the 1961 suggestion by J. Dungey that energy transfer from the solar wind to the magnetosphere was modulated by the direction of the interplanetary magnetic field with respect to the dayside terrestrialmagnetic field, it became clear that large scale enhancements of auroral and geomagnetic activity (termed magnetospheric substorms) were associated with frontside magnetic field merging and subsequent reconnection behind the earth in the magnetotail. Since the mid 1960's, the concept of neutral line formation in the magnetotail has been an integral part of most attempts to explain the most spectacular and explosive part of substorm development, the expansive phase. In this paper, I shall trace the evolution of neutral line models of substorm activity from both the observational and theoretical points of view. It will become clear from this presentation that a universally acceptable framework in which substorm activity can be understood has not yet materialized, and major changesin the dominant paradigm for understanding substorm activity have occurred from time to time even in the 1990's.

GA6.01/E/03-A5 0900

EDMOND HALLEY AND THE EARTH'S MAGNETIC FIELD

Alan COOK (Selwyn College, Cambridge, CB3 9DQ, UK, e-mail: ahc13@cam.ac.uk)

Three hundred years ago, at the end of June 1699, Edmond Halley returned from his first cruise to measure the magnetic declination around the Atlantic. In the middle of September, he sailed on his second cruise of nearly a year. The cruises, and the printed chart derived from them, set the course of geomagnetic studies for a century and more. Halley had first observed the magnetic declination as a schoolboy. He had proposed a model of the interior of the Earth to account for the westerly drift. In 1716 he showed that the patterns of aurorae matched those of the circumpolar geomagnetic field. So he posed three questions to which answers are only now appearing, the structure of the main field, the cause of the westerly drift, and the interaction of the solar wind with the geomagnetic field.
Halley stood on the shoulders of predecessors, of Petrus Peregrinus in the 13th century, William Gilbert in 1600, Gellibrand and Athanasius Kirchner early in the 17th century. His fundamental understanding of the geophysical implications of the nature of the field were his own. His successors, such as Sabine, improved and extended charts of the geomagnetic field. Halley realised that the large scale anomalies of the field must have deep lying sources, but a formal treatment had to wait for C F Gauss. Halley's ideas about the field and aurorae have been justified after three centuries by dynamo theory and by the discovery that the upper atmosphere is a plasma with its geometry controlled by the main geomagnetic field.

CAN SOLAR SEISMOLOGY ILLUMINATE TERRESTRIAL CLIMATIC CHANGES?

G.R. ISAAK (School of Physics and Astronomy, University of Birmingham, Birmingham, B15 2TT, U.K.)

Solar oscillations have now been monitored for over twenty years, a complete magnetic cycle. The completeness, quantity and quality of the acquired data has steadily improved and the resultant power spectra show a rich discrete and a continuum spectrum due to convective noise. The discrete spectrum is due to acoustic eigenmodes of the Sun and can be characterised by eigenfrequencies, amplitudes, splittings, line-widths and shapes: the acoustic analogue of the term values of an atom. The eigenfrequencies can now be measured to accuracies of a few parts per million and provide a superb probe of the interior of our Sun. Amplitudes and the other parameters are measured to only a modest precision. The eigenfrequencies and amplitudes are found to vary appreciably over the solar cycle, closely correlated with the solar irradiance. It would seem that the eigenfrequencies, at least, provide an excellent and readily measured proxy of the solar irradiance and, therefore, information on changes of the dominant term controlling the Earth`s climate.

GA6.01/W/02-A5 1055

THE EFFECT OF SOLAR VARIABILITY ON CLIMATE

Sofia SABATINO (Department of Astronomy, Yale University, P.O. Box 208101, New Haven, CT 06520, USA, email: sofia@astro.yale.edu)

Because the Sun supplies nearly the totality of the energetic input (photons and particles) in the Earth's environment, it is clear that any significant variation of the solar input should affect global change in general, and climate in particular. Here I will only address the effects of radiation. Variability of the total irradiance on timescales up to the activity cycle has been well determined, and understood. Its direct climate consequences are negligible. The larger fractional variability of the EUV-UV radiation affects the structure of the upper atmosphere of the Earth, in well-documented ways, but the energy content of radiation in this wavelength range is very small. It has been suggested that these variations may trigger processes, which indirectly cause climate change. It is fair to say, however, that none of the processes proposed to accomplish this has received wide acceptance. Finally, for timescales of several decades to centuries, direct measurements do not exist except for crude features, such as sunspot number. At the same time, various paleoclimatic data suggest the existence of a strong solar component. We propose in this paper the existence of a solar variability mechanism related to changes of the internal solar structure caused by the variable magnetic field due to the dynamo process. We present proxy data that support this view, and suggest additional work required to better understand the properties of this mechanism, and its implications for climate change.

GA6.01/E/02-A5 1120

RESPONSE OF THE LLN MODEL TO THE ASTRONOMICAL FORCING OVER THE QUATERNARY AND THE NEXT 130 THOUSANDS YEARS

A. BERGER, M.F. Loutre, X.S. Li (UCL, Institut d'Astronomie et de Géophysique G. Lemaître 2 Chemin du Cyclotron, B-1348 Louvain-la-Neuve, Belgium)

The LLN 2-D climate model has been used to reconstruct the long-term climatic variations over the Quaternary Ice Age. An atmospheric CO2 concentration decreasing linearly from 320 ppmv at 3 Myr BP (Late Pliocene) to 200 ppmv at the Last Glacial Maximum was used to force the model in addition to the insolation. Under such condition, the model simulates the intensification of glaciation around 2.75 Myr BP, the late Pliocene-early Pleistocene 41-kyr cycle, the emergence of the 100-kyr cycle around 900 kyr BP, and the glacial-interglacial cycles of the last 600 kyr. The hypothesis was put forward that during the Late Pliocene (in an ice-free - warm world) ice sheets can only develop during times of sufficiently low summer insolation. This occurs during large eccentricity times when climatic precession and obliquity combine to obtain such low values, leading to the 41-kyr period between 3 and 1 Myr BP. On the contrary in a glacial world, ice sheets persist most of the time except when insolation is very high in polar latitudes, requiring large eccentricity again, but leading this time to interglacial and finally to the 100-kyr period of the last 1 Myr. Using a reconstructed CO2 concentration over the last 600 kyr from a regression based upon SPECMAP, it has been shown that stage 11 and stage 1 request a high CO2 to reach the interglacial level. The insolation profile at both stages and modelling results tend to show that stage 11 might be a better analogue for our future climate than the Eem. Although the insolation changes alone act as a pacemaker for the glacial-interglacial cycles, CO2 changes help to better reproduce past climatic changes and, in particular, the air temperature and the southern extend of the ice sheets. Using the calculated insolation and a few scenarios for CO2, the climate of the next 130 kyr has been simulated. It shows that an interglacial will most probably last particularly long (50 kyr). This conclusion is reinforced if we take into account the possible intensification of the greenhouse effect, which might result from man's activities over the next centuries.

GA6.01/W/14-A5 1145

SOLAR VARIABILITY AND POSSIBLE RESPONSES IN THE TERRESTRIAL SYSTEM: THE EFFECTS OF SOLAR WIND VARIATIONS ON EARTH'S RATE OF ROTATION

Nils-Axel MOERNER (Paleogeophysics & Geodynamics, Sweden, e-mail: morner@pog.su.se)

The solar wind is known to interact with the Earth's own geomagnetic field which effects the Earth's shielding of incomming cosmic ray, measured by the in-fall of 10Be and the atmospheric production of 14C. The solar wind is also known to vary with the sunspot cycles. During the Spörer, Maunder and Dalton main sunspot minima, the solar wind decreased which weakened the shielding so that the 14C production increased like the in-fall of 10Be (less clear). A correlations has previously been observed between sunspot activity and variations in the Earth's rate of rotation. Because of a rough correlation with periods of cold climate – "Little Ice Ages" – in NW Europe, it has been proposed that solar irradiance (luminocity) decreased at the same time and that there exists a solar-terrestial climate linkage. However, I have been able to show that the Medieval warm period and the cold periods 1440-1460, 1687-1703 and 1808-1821 in NW Europe were all driven by changes in the distribution in the North Atlantic of warm surface water from the SW and cold arctic water from the N. These changes were driven by variations in the Earth's rate of rotation (in a feed-back coupling system). This affected the oceanic circulation so that the a major current like the Gulf Stream sent less warm equatorial water along its northern branch towards NW Europe at the same time as Arctic water penetrated furter south. This led to severe cold periods in the NW European region. In southern Europe and northern Africa the same periods were characterized by increased heat. This means that these periods represent changed distribution of the terrestrial energy. And this was driven by increased rate of rotation. In this scenario, we do not need to call for hypothetical large-scale variations in solar irradiance; only an influence of the solar wind variability on Earth's rate of rotation.

GA6.01/E/01-A5 1210

THE EARTH'S MIDDLE ATMOSPHERE AND THE SUN'S INTERIOR

Michael E. McINTYRE (Centre for Atmospheric Science at the Dept. of Applied Mathematics and Theoretical Physics, Cambridge CB3 9EW, UK, email: mem@damtp.cam.ac.uk)

The atmosphere used to be thought of using classical ideas about turbulence that looked back to analogies with gas kinetic theory, involving among other things an assumption that departures from spatial homogeneity are weak. This led to problematic notions like `negative eddy viscosity'. However, today's understanding of the global-scale atmospheric circulation, especially that of the middle atmosphere, recognizes --- as essential, leading-order features --- the strong spatial inhomogeneity of atmospheric turbulence together with the crucial role of wave propagation and wave breaking. The latter involves a phase-coherent interaction between the waves and (highly inhomogeneous) turbulence --- not pre-existing turbulence, but turbulence that owes its existence to the arrival of the waves, as with the familiar example of ocean-beach gravity waves. This description applies to all the wave types involved, from internal gravity to Rossby or potential-vorticity waves, provided that the term `wave breaking' is interpreted in a suitable way, consistent with the fundamentals of wave-mean interaction theory. The chirality of Rossby waves, tied to the sense of the Earth's rotation, results in an angular momentum transport that is intrinsically one-signed and therefore ratchet-like, producing via Coriolis effects an inexorable `gyroscopic pumping' of air systematically poleward that dominates, for instance, the global-scale transport of chlorofluorocarbons and other long-lived greenhouse gases in the stratosphere. Some of the same considerations apply to the fluid dynamics of the Sun's stably stratified radiative interior. Together with recent helioseismic data they are forcing us to a novel conclusion: the Sun not merely can, but must, have in its radiative interior a poloidal magnetic field that is strong enough to reshape, drastically, the circulation and differential rotation in the interior. This has far-reaching consequences for understanding solar spindown history and internal variability, and for performing helioseismic inversions.

NORTHERN LIGHTS RESEARCH IN SCANDINAVIA UP TO THE 19TH CENTURY

A. EGELAND, Department of Physics, University of Oslo, Norway, email: alv.egeland@fys.uio.no

Because nothern lights could be observed directly without scientific aids, it has stirred man's imagination, curiosity and fear as long as the Earth has been inhabited. The scientific name aurora was suggested 400 years after the Vikings have named this phenomenon Northern Lights. It is described in vivid details in the Norwegian chronicle Kongespeilet from around year 1200.
A close connection between aurora and the magnetic field was discovered by Hiorter and Celsius around 1730. They also strongly stressed the importance of accurate observations. Thus, already around 1750 it was suggested that the Northern lights formed a ring 10 to 20 degrees off the geographic pole. The first auroral atlas was published by Barhow in 1751.
In the period 1880 to year 1900 a number of ideas and theories of lasting importance in the field of auroral and plasma physics were advanced.

CHANGE-POINT DETECTION IN GEOPHYSICAL TIME SERIES

Raymond SNEYERS, Institut royal météorologique de Belgique avenue Circulaire, 3, B-1180 Bruxelles, Belgium Email: rsneyers@oma.be.

Besides the search for periodicities and autocorrelation, the statistical problem of change-point detection in geophysical time series is raised both for verifying homogeneity of data and for characterising the natural instability of the evolution of geophysical phenomena. In this paper, the used methodology is fully justified at the theoretical point of vue and an illustration is given by the example of the Global NH air and sea-surface temperature for annual and seasonal averages. Conclusions are derived from results in connection with the physics of the general atmospheric circulation.

GA6.01/W/11-A5 1425

TRANSIENT CLIMATE SIMULATION FORCED BY CHANGES IN SOLAR IRRADIANCE OVER THE LAST THREE CENTURIES

Cedric BERTRAND and Jean-Pascal van Ypersele (both at Institut d'Astronomie et de Geophysique G. Lemaitre, Universite catholique de Louvain, 2 chemin du cyclotron, 1348 Louvain-la-Neuve, Belgium, email: cedric@astr.ucl.ac.be)

Numerical experiments have been carried out with a two-dimensional sectorially-averaged global climate model in order to assess the potential impact of solar variability on the Earth's surface temperature from 1700 to now. In the absence of a full physical theory able to explain the origin of the observed total solar irradiance variations, four different total solar irradiance reconstructions have been used. A total solar irradiance change due to the photospheric effects incorporated in the Willson and Hudson (1988) parameterization, the reconstructed solar total irradiance variations from the solar models of Hoyt and Schatten (1993) and Lean et al. (1995), and the Reid's (1997) historical reconstruction.
Our results indicate that the modelled global warming due to the four inferred total solar irradiance reconstructions is insufficient to reproduce the observed 20th century warming. Nevertheless, our simulated surface temperature response to the changes in The Sun's radiant energy output suggests that the Gleissberg cycle solar forcing should not be neglected in explaining the century-scale climate variations.
Finally, spectral analysis seems to point out that the 10- to 12-year oscillations found in the recorded Northern Hemisphere temperature variations from 1700 could be unrelated to the solar forcing. Such a result could indicate that the eleven-year period which is frequently found in climate data might be unrelated to oscillations in the atmosphere or oceans, internal to the climate system.

GA6.01/E/13-A5 1440

CLIMATE VARIABILITY RELATED TO THE DOUBLE SOLAR CYCLE

Cornelius J.E. SCHUURMANS (Institute of Marine and Atmospheric Research, Utrecht University, P.O. Box 80.005, 3508 TA Utrecht, The Netherlands)

Winter temperatures in The Netherlands over the period 1634- 1977 (344 years) were, on average, found to be lower and more variable during odd solar cycles than during even solar cycles (Schuurmans, 1978). The two solar cycles which passed since this result was published confirmed this behaviour. Further analysis showed that also summer temperatures show a tendency to be slightly lower (and less variable) in odd, as compared to even solar cycles. Climate variations of this type can be explained in terms of decadal changes of the atmospheric circulation over the Atlantic- European area. Indeed, over the last 140 years the North Atlantic Oscillation (NAO) has varied on this time scale. Since the solar- climatic relation exists over more than 350 years, the question arises if the NAO- variability on this time scale possibly could be induced by solar activity?

GA6.01/W/18-A5 1455

CONSTRAINTS ON SUN-INDUCED CLIMATIC CHANGES OVER THE LAST 100 YEARS

Willie SOON, Sallie Baliunas (both at Harvard-Smithsonian Center for Astrophysics, 60 Garden Street, Cambridge, MA 02138, USA, email: wsoon.sbaliunas@cfa.harvard.edu); Eric Posmentier (Science Division, Long Island University, Brooklyn, NY 11201, USA, email: eposment@titan.liunat.edu)

Recent progress in monitoring the climate and the solar output, as well as modelling of the physical processes involved, is leading to improved understanding of the influence of solar variability on terrestrial climate change. We will present constraints on the solar total irradiance change on timescales of decades to centuries based on results from direct observations of the Sun and solar-type stars as well as modelling efforts. We will discuss another possible coupling mechanism through the interaction of the solar ultraviolet irradiance with stratospheric ozone and upper atmospheric clouds. We will also discuss the possible role of solar and cosmic ray charged particles in producing terrestrial climate change on timescales of months to years.

GA6.01/E/15-A5 1510

PATTERNS OF SOLAR PROTON EVENTS OVER FOUR SOLAR CYCLES

D.F. SMART and M.A. Shea (both at Air Force Research Laboratory, VSBS, 29 Randolph Road, Hanscom AFB, Bedford, MA 01731-3010, U.S.A., email: smart@plh.af.mil

We now have a solar proton event database for more than four solar cycles. A statistical study of the events having more than 10 particles/(sqcm-sec-ster) above 10 MeV indicates that the number of events as a function of time over the solar cycle exhibits a skewed Gaussian curve similar to the smoothed sunspot number. This result is somewhat surprising considering the extreme differences in the occurrence of these events for each individual solar cycle. Other results show a surprising consistency in the number of events per solar cycle recorded at Earth. In addition approximately 15% of the events each solar cycle contain relativistic solar protons. The solar proton events during the first two years of the 23rd solar cycle will be discussed in context with the events of the previous four solar cycles.

GA6.01/W/03-A5 1525

DESCEND TO AND ASCEND FROM THE MAUNDER MINIMUM

K. MURSULA (Department of Physical Sciences, University of Oulu, P.O. Box 3000, FIN-90401 Oulu, Finland, email: Kalevi.Mursula@oulu.fi), and I. Usoskin (Ioffe Physical Technical Institute, St. Petersburg, Russia)

We study the properties of solar cycles around the Maunder Minimum (MM) using the recently proposed group sunspot numbers (Hoyt and Schatten, Sol. Phys., 181, 1998) and the delayed component method. The method can be used to study the regularity of the solar cycle using a 2- or 3- dimensional presentation. The new sunspot group numbers cover a few cycles even before MM. We find that the last three cycles before the MM have a very different behaviour. The last cycle before MM is rather strong and has a regular 2-dimensional shape. The descend to MM undergoes very rapidly. Interestingly, the first cycle (SC –4) after MM is very regular despite its extremely low amplitude. This suggests that regular processes with approximately 11-year cycle can proceed in the Sun even during the great minima such as the Maunder Minimum.

GA6.01/E/14-A5 1600

SOLAR AND TERRESTRIAL SIGNALS IN THE PRECIPITATION AND TEMPERATURE IN ITALY FROM 1867 TO 1996

M. Brunetti (1), S. Cecchini (2), M. Maugeri (3), T. NANNI (1) (1) Istituto FISBAT-CNR – via Gobetti, 101 – 40129 Bologna; (2) Istituto TESRE-CNR – via Gobetti, 101 – 40129 Bologna; (2) Istituto di Fisica Generale Applicata – via Brera, 28 – I20121 Milano

We investigate the variability of annual and seasonal precipitations and temperatures in Italy during the last 150 years and their association with changes in solar (geomagnetic indexes, sunspots and aurorae) and terrestrial (NAO, SOI) time series. Significant correlations and common periodicities are discussed.

GA6.01/E/11-A5 1615

A MAGNETIC STORM - SIMULTANEOUSLY REGISTERED AT TWO SITES IN 1741

Olof BECKMAN (Dept of Materials Science, Uppsala University, Box 534, S-75121 Uppsala, Sweden, email: Olof.Beckman@angstrom.uu.se)

The daily variation in the magnetic declination was observed by George Graham in London in 1722. However, the connection between the aurora and sudden displacements of a magnetic needle was first observed by the Swedish astronomers Anders Celsius and Olof Hiorter in 1741. The aurora was known to occur high up in the atmosphere. In March 1741 Celsius wrote a letter to Graham asking him to observe the magnetic needle in order to find out if disturbancies might occur simultaneously in two so widely situated sites as London and Uppsala. Already on April 5th, 1741, such an event appeared, resulting in the very first documented simultaneous observation. Grahams data as well as Celsius's notes will be presented. The two recordings from London and Uppsala are quite similar in size (60 to 80 minutes of arc) and duration. The time difference between the events amounts to around 1 hour and 12 mins, which equals the difference in local solar time. Neither Celsius nor Hiorter have commented on this fact, however, which is remarkable since Celsius was very interested in time differences for longitude determination, an important problem of the time. Probably Celsius did not comment on this because he considered the aurora to be a terrestial phenomenon. Celsius determined the longitude difference between Uppsala and other sites such as Tornea, Københavnand Isle de Bourbon (Réunion) by help of eclipses of the moon and the Jupiter satellites. When Celsius visited Graham in 1735, they observed a total eclipse of the moon. At Uppsala Hiorter calculated the difference in longitude between Uppsala and Graham's garden in London to be 1 hour 11 mins and 50 secs. For longitude determination, one had to rely upon an event outside the earth (not the aurora).

GA6.01/L/02-A5 1630

HISTORICAL NOTES ON GEOMAGNETIC MEASUREMENTS IN AND AROUND ICELAND

Leo KRISTJANSSON and Thorsteinn Saemundsson (both at Geophysics Division, Science Institute, University of Iceland, Dunhaga 3, 107 Reykjavik, Iceland, email: leo@raunvis.hi.is. and halo@raunvis.hi.is)

Records of the use of a compass in Iceland reach at least as far back as the mid-17th century. Geodetic and hydrographic surveys using magnetic north as reference are known from about 1720. A source of disturbance in the geomagnetic field which is more serious in Iceland than in most other countries, is the strong magnetization of the bedrock which consists mostly of basalt lavas with little sediment cover. This and other problems of geomagnetic observations in the area, as well as the origin of the field, were discussed at length in publications by P. Lÿwenÿrn of Denmark who made many determinations of declination and some of inclination off the coast of Iceland in 1786. Daily magnetic variations in Iceland were studied in some detail by V. Lottin who participated in P. Gaimard's 1836 expedition on the corvette 'La Recherche': a temporary observatory was erected in Reykjavik where declination values were recorded at 15 min - 1 hr intervals during 10-28 Aug simultaneously with measurements in European observatories. French expeditions also carried out declination measurements in the seas around Iceland, at various times during the 19th century.
Continuous recordings of the geomagnetic field were made by Th. Thorkelsson in Iceland during much of the 1932-33 International Polar Year and again for four months in 1937. An observatory established by Th. Sigurgeirsson at Leirvogur near Reykjavik has operated continuously since 1957. Located in the auroral zone and bridging the gap between continents, this observatory has played an important role in the international network of observatories.
Some of the key methods and concepts employed in paleomagnetic research originated in the studies on reserved and transitional remanence directions in icelandic Tertiary lava sequences which were conducted by J. Hospers, Th. Sigureirsson and others during the 1050s.

GA6.01/E/21-A5 1645

LONG-TERM VARIATION OF SUNSPOT LATITUDES

Pentti J. PULKKINEN (Dept. of Physics, P.O.Box 0, FIN-00014, University of Helsinki, Finland, email: pentti.pulkkinen@helsinki.fi), John Brooke (Manchester Computing, University of Manchester, Oxford Road, Manchester, M13 9PL, United Kingdom; and Department of Mathematics, University of Manchester, Oxford Road, Manchester, M13 9PL, United Kingdom), Jaan Pelt (Tartu Astrophysical Observatory, Toravere 1-6, Tartu 202444, Estonia; and Astronomy Division, University of Oulu, P.O.Box 333, FIN-90571 Oulu, Finland), Ilkka Tuominen (Astronomy Division, University of Oulu, P.O.Box 333, FIN-90571 Oulu, Finland)

This work is based on a study(1), in which we use the whole time range of modern sunspot measurements (1853-1996), thus covering sunspot cycles 10 to 22. The data are combined with measurements by Carrington and Sporer and the Greenwich Photoheliographic Results. We first point out that the sunspot latitude is a measure of cyclic activity; the more active cycle the higher is the mean cyclic latitude per hemisphere. Further, if we calculate the global "centre of mass" of sunspots, we find variation over long period of time. The amplitude of this variation is 1.3 degrees and the period 34 000 days, or 93 years. Although we use the word "period", only the future measurements will confirm whether this variation is really systematic. This period of 93 years is of similar length than some other long-term periods found in sunspot data (Gleissberg cycle, north-south asymmetry variations by Verma(2) and Olivier & Ballester(3), or cycle length variation by Lassen & Friis-Christensen(4)). A possible explanation for this 93-year variation could be a mixed parity mode in which a quadrupolar component of the solar magnetic field is oscillating with this period. This phenomenon could also produce the observed asymmetry variations

GA6.01/P/06-A5 1700

REMARKS ON LIFE AND WORK OF JULIUS BARTELS

Hannelore and KARL-HEINZ BERNHARDT (Platz der Vereinten Nationen 3, D-10249 Berlin, Germany)

J. Bartels (1899-1964), who was president of IAGA (1954-57) and, later, vice-president of IUGG (1957-63), worked at the beginning of his academic career at the university of Berlin and at the forestry college of Eberswalde from 1927 to 1944. Bartels' activities during this period of his life as well as his relation to the Prussian Academy of Sciences are characterized based on archival records. Also most of his significant contributions to mathematical statistics in meteorology and geophysics, which are considered in some details as an important part of his versatile lifework, have been written in this time.
Following the doctor thesis (Göttingen, 1923), Bartels started in the fields of statistics with the study of cyclic variations of meteorological and geomagnetic parameters which are superimposed by strong non-cyclic components. The application of the synchronization method in this connection required to eliminate carefully the selection or curvature effect, which had often been misinterpreted formerly. Further, Bartels improved the methods of periodogram analysis and the statistical testing of their results on the basis of the contemporary theory of probability. Special attention was paid by him to problems of statistical testing in case of auto-correlated data as connected with the phenomena of persistence and quasi-persistence in meteorological and geophysical time series. Finally, he introduced special Monte Carlo like methods, as the shaking test, to test the signficance and the reliability of phenomena observed in time series. His rigorous criticism and the numerous remarks to avoid misleading conclusions from incorrect statistical data interpretation should be considered as exemplary also nowadays.

GA6.01/P/05-A5 1715

THE NAGYCENK GEOPHYSICAL OBSERVATORY AND ITS LONG DATA SERIES

Antal Àdám, Pál BENCZE and József Vero (Geodetic and Geophysical Research Institute, Hungarian Academy of Sciences, H-9401 Sopron, P.O.B. 5, Hungary, email: bencze@ggki.hu)

The Nagycenk Geophysical Observatory devoted to the study of the electromagnetic field of the Earth was opened in 1957. The favourable location of the Observatory due to the thick sedimentary overlay and undisturbed conditions enabled the achievement of long series of earth current, geomagnetic, atmospheric electric and ionospheric data. These long data series make possible the study of long period variations, or trends attributable to the change of the environment. In case of the earth current data e.g. the establishment of the attenuation of the pulsations during the solar cycles, regarding the geomagnetic data the study of the main field was posible. Furthermore considering atmospheric electricity, the long-term change of the charge transfer between the atmosphere and the Earth could be investigated, while the ionospheric measurements enabled the study of changes in the state of the lower ionosphere due to several solar activity effects.

GA6.01/L/03-A5 1730

CLIMATE EVOLUTION, AND MANKINGS ACTIVE AND PASSIVE ROLE AND RECORD THEY SYNERGISM BETWEEN EXACT SCIENCES AND HUMANISTIC DISCIPLINES

MICHELE COLACINO, Giovanni P. Gregori (both at IFA-CNR, via Fosso del Cavaliere 100, 00133 Roma, Italy, email: gregori@atmos.ifa.rm.cnr.it) and Wilfried Schroder (Hechelstrasse 8, 28777 Bremen-Roennebeck, Germany)

'History of Science' can be conceived according to 5 viewpoints: (1) dealing with the life of scholars who made science; (2) dealing with the impact of environment on mankind; (3) dealing with the impact of mankind on environment; (4) dealing with the history of ideas; and (5) dealing with the availability of observational records (either instrumental or proxy) got by means of the measuring instrument 'mankind'. The leading part of human civilisation was developed during the last several 104 years within the belt encompassing Sahara and Sahel, the Mediterranean, Middle East, Mesopotarnia, the Indus Valley, and the Silk Road. Such an entire area dramatically suffered by the profound desertification, and the anthropic factor is seriously suspected of being severely co-responsible for it. For example, if we want to understand the future consequence of an eventual deforestation of the Amazon basin, perhaps we should first understand the crucial role of mankind in Sahara's desertification. Using mankind as a proxy datum, however, implies assessing the athropological aspect of its time-varying understanding of the environment. hence, such an investigation requires an effective synergism between exact sciences and humanistic disciplines. The present subdivision of Earth's sciences into standard disciplines appears a substantial obstacle towars such a general cultural implementation. The present frontier ought to be rather concerned with extended interdisciplinary scenarios, with large team work, and with far-looking brain-storming.

GA6.01/L/04-A5 1745

CURRENT RESEARCH OF SOLAR-TERRESTRIAL PHYSICS IN EGYPT

M. A. Mosalam SHALTOUT, National Research Institute of Astronomy and Geophysics (NRIAG), Helwan – Cairo – Egypt, Phone (202)2630833 ; Fax (202)5548020 E-mail: mamshaltout@frcu.eun.eg

Solar-Terrestrial physics in Egypt start since more than sixty years ago, when Dr. Hurst, Director of Helwan Observatory, studied the influence of sunposts on Nile flooding. Starting from 1970 the effect of dark filament disappearance on the solar disk on the Geomagnetic components recorded at El-Messallat Geomagnetic Observatory in Egypt was studied. From world – wide Solar-Geophysical data many researches are carried out about the effect of solar flares in Geomagnetic storms and Sudden Ionosphere Disturbance at NRIAG. Also, the influence of sunspots, faculae, and solar constant in the climatic change and the Nile flooding for long periods by using the computers in time series analysis to obtain on short and long-term periodicities in solar activity and Nile flooding was performed. The current of research is about: 1-The influence of ultraviolet solar radiation EUV on the Ozone layer of Earth, 2-The periodicities in the Solar wind and its correlation with Geomagnetic storms, 3-The effect of solar proton flares on Radio communications, near satellites Orbits, high-latitudes electric grids, Ionosphere electric currents, and Polar Cap absorption. Also, there are some studies about Solar activity and its influence on trees rings and C14 abundance in the earth's atmosphere since thousands years. The variability of Solar constant measured from ground stations and artificial satellites and its influence on the earth's atmosphere was studied. The correlation between the old solar activity and the Nile flooding in the ancient Egypt and the periods of rising and falling of the civilization of the ancient Egyptians through seven thousands years was restudied on the base of long data of Nile flooding and C14 abundance. Most of the research published in National Scientific Journals, but some of them published in International Journals of Geophysics, Space Science, Solar and Astro-physics.

GA6.01/W/17-A6 0830

SOFT X-RAY VARIABILITY OF THE SUN FROM YOHKOH OBSERVATIONS

Hirohisa HARA (National Astronomical Observatory, 2-21-1 Osawa, Mitaka, Tokyo 181-8588, Japan, Email: hara@solar.mtk.nao.ac.jp)

Coronal activities from the maximum phase of cycle 22 to the rising phase of cycle 23 are presented from the Yohkoh soft X-ray observations. The variation of solar X-ray flux is investigated for two coronal components; active regions and the other dark features consisting of quiet regions and coronal holes. The X-ray flux from active regions is strongly dependent on the size of active regions and changes with the 11-year solar magnetic activity cycle in phase. We find that the X-ray flux from the other dark features also changes with the activity cycle, and that there is a strong correlation between the X-ray flux from the coronal dark features and the corresponding photospheric magnetic flux outside active regions. These show that the solar corona is heated in conjunction with the magnetic field, and there is no possibility of being due to the acoustic heating. The whole-sun X-ray flux does not monotonically decrease. Rather, there is a period of enhancement with about a one-year interval in the whole-sun X-ray flux. The activity appears as bright clusters in the butterfly diagram of the soft X-ray intensity and corresponds to the emergence of complexes of activity in the sunspot zones. We also find an intermittent activity with a time scale of about a year in the high-latitude regions.

GA6.01/W/04-A6 0850

THEORY OF THE SOLAR DYNAMO

Paul ROBERTS (Institute of Geophysics and Planetary Physics, UCLA, Los Angeles, CA 90095, USA, email: roberts@math.ucla)

The overshoot layer (OSL) at the base of the solar convection zone (SCZ) is often seen as the probable seat of the solar dynamo, and specific models have been proposed. These are hard to evaluate, since turbulence in the SCZ effectively masks the OSL from observation and interpretation. The role of turbulence above the OSL is poorly understood. What is its inductive effect? Does it assist or impede the OSL dynamo? The small length scales of the turbulence make it impossible to answer these questions by simulating the entire SCZ numerically, and two alternatives have been investigated. First, mean field electrodynamics has been generalized to turbulent magnetoconvection (mean field MHD!). Contentious issues have arisen, such as the quenching of the (effect by the mean field, but mean field models of the solar dynamo model have been constructed that have also aimed simultaneously to simulate the differential rotation that has been inferred helioseismically. Second, direct numerical simulations (DNS) of field and flow in small test volumes situated at different latitudes and depths in the SCZ have been performed. These not only provide a useful picture of the character of turbulence in the SCZ but also supply information about turbulent transport coefficients that is valuable to mean field theories. These and related issues will be described in this presentation.

GA6.01/E/06-A6 0920

THE INSTABILITY OF SOLAR MAGNETIC FIELDS

T. D. ARBER (Mathematical Institute, University of St. Andrews, St. Andrews, Fife KY16 9SS, Scotland, UK, email: tda@dcs.st-and.ac.uk)

Of all the physical processes active in the solar corona those which result from unstable magnetic field structures have the capacity to be the most abrupt and dramatic. It has been postulated that they could be responsible for triggering both two ribbon and simple loop flares. Considerable progress has been made over recent years in the magnetohydrodynamic (MHD) theory of such instabilities. While such theories at present only deal with simplified geometries and idealised physics they are none the less beginning to show some degree of correlation with observable features of the corona. This paper presents an overview of the current state of our understanding of such MHD instabilities, including a brief discussion of the nature of the magnetic field topology expected, how it may have evolved and why it suddenly becomes unstable.
Numerical simulations are now reaching a sufficient level of accuracy to be able to predict the observational signatures which should be present if simple flare loops are indeed caused by large scale MHD instabilities. These observational signatures are summarised and compared with those of transient brightening loops. The use of three dimensional simulations to fill the gap between theories of MHD instabilities and large scale observable properties is still in its infancy. Recent work is however encouraging and the paper ends with a sketch of the way forward in trying to determine whether MHD instabilities are indeed a major cause of solar flares.

GA6.01/W/09-A6 0945

REVIEW OF THE TWO DECADE LONG SPACE-BORNE IRRADIANCE MEASUREMENTS

Judit PAP (Department of Physics and Astronomy, University of California, Los Angeles, 405 Hilgard Ave., Los Angeles, CA 90095-1562, USA)

Solar irradiance (both bolometric and at various wavelengths) have been measured for two decades from several space platforms. Analyses based on these measurements have established conclusively that solar irradiance varies on various time scales: from minutes to the eleven year solar cycle. Although the overall pattern of the long-term irradiance variations is similar at various wavelengths, being higher during high solar activity conditions, remarkable differences exist between the magnitude and shape of the observed changes. These differences result from the different physical conditions in the solar atmosphere where the irradiances are emitted. In this paper we review the results of the two decade long space-borne measurements of solar irradiance integrated over the entire spectrum, hence total irradiance, and from EUV to the infrared portions of the solar spectrum. New techniques in solar irradiance modelling are also demonstrated to better understand the potential climate impact of solar variability over decades to centuries.

GA6.01/E/16-A6 1005

THE CLIMATIC INFLUENCE OF THE SUN AS A VARIABLE STAR

Edward HANNA (Department of Meteorology, University of Reading, Earley Gate, PO Box 243, Reading, Berkshire, RG6 6BB, UK)

Recent satellite observations have shown that solar output is intrinsically variable on many

spatial and temporal scales. The so-called "solar constant" (a misnomer) actually varies on the decadal timescale by ?0.1%, with substantially larger variations at ultraviolet wavelengths. Quasi-periodic secular changes several times greater drive interaction of the solar wind and cosmic rays with Earth's magnetosphere and ionosphere. Such effects may modulate stratospheric ozone and global climate, including cloud cover, planetary waves and atmospheric circulation patterns. Here I critically examine the historical solar and climatic records, and find much circumstantial evidence to support the hypothesis that our Sun, as a variable star, has a discernible influence on Earth's climate. Using stellar analogues from the broader astronomical scene, I argue that the Maunder Minimum and other well-documented solar anomalies in the historical record represent the Sun's natural and unremitting evolution between active (cycling) and quiet (non-cycling) phases. Some intriguing statistical evidence suggests that long-term (>11-year) solar activity cannot be overlooked as a potential cause of an appreciable part of twentieth-century global warming, and might in particular explain the latter's hiatus or even slight reversal between 1940-70. On this basis, I provide a forecast of future global temperature on the basis of projected solar activity. The role of the Sun should definitely be included in any consideration of Earth's continually changing climate, which is subject to natural as well as anthropogenic influences. The problem is that some of the former, including solar forcing, remain poorly defined in global climatic models.

INTENSIFICATION OF THE GLOBAL UPPER OCEANTEMPERATURE RESPONSE TO CHANGING SOLAR IRRADIANCE BY POSITIVE FEEDBACKS FROM WATER VAPOR AND CLOUDS

Warren B. WHITE, Michael D. Dettinger, and Daniel R. Cayan

Abstract. Global-average upper ocean temperature fluctuated in fixed phase with changing solar irradiance on decadal timescales over the past 100 years, but its amplitude was 50 to 100% larger than expected from the Stefan-Boltzmann radiation balance (White et al., 1997, 1998). The latter yields a temperature sensitivity for the Earth of 0.3°K per Watt m-2 of changing surface radiative forcing. Examination of the global patterns of upper ocean temperature response indicates that the Earth's temperature does not respond passively to changing solar irradiance; rather, natural variability on decadal timescales is either excited by or brought into phase with the solar signal. This has the potential for intensifying Earth's temperature response as simulated already in Earth climate system model experiments (e.g., Rind, 1998). We have combined analyses of upper ocean temperatures, atmospheric moisture content and clouds from SIO, COADS, NCEP, and TOVS, finding the warm upper ocean temperature response to peak solar irradiance associated with increased global tropospheric moisture content and decreased global cloud cover. The surface radiative forcing associated with these internal responses will be presented, used to quantitatively assess Earth's net temperature sensitivity to changing solar irradiance on decadal timescales.

THE SOLAR NEUTRINO PROBLEM

L. PATERNO' (Istituto di Astronomia, Universita' di Catania, Citta' Universitaria, 95125 Catania, Italy, Email: lpaterno@alpha4.ct.astro.it)

Helioseismology has demonstrated that the standard solar model is accurate within 0.5%, therefore the solar neutrino problem, namely the huge discrepancy between predicted and measured neutrino fluxes, can hardly be attributed to a wrong modelling of the solar interior. It is shown that unordered changes in the properties of the physical processes operating in the Sun's interior are needed for reducing the predicted neutrino flux to the observed one. However, such changes produce dramatic changes in the internal stratification of the Sun, which are incompatible with the very accurate results of helioseismic data inversions. Non standard neutrino properties, which require massive neutrinos, have been proposed as a suitable solution for the observed neutrino deficit. The solution relies upon the change of neutrino flavour in the path from the solar core to the Earth, which renders the emitted electron neutrino undetectable by the experiments. Various possibilities, such as vacuum oscillations, MSW resonant transition in the matter and spin-flip, are discussed in the framework of the results of the neutrino experiments presently in operation. The potentialities of the future neutrino experiments are also discussed.

GA6.01/L/01-A6 1130

SOLAR NEUTRONS

J.F. VALDES-GALICIA (Instituto de Geofisica, UNAM, 04510, Mexico, D.F., MEXICO)

Observations of neutrons from solar flares are providing important new information on particle acceleration in solar flares and on the flare process itself. They are produced directly by nuclear interactions of the flare- accelerated protons and heavier ions with ambient gas in the solar atmosphere. Thus they yield the most direct information available on different aspects of the flare region. Neutrons were first observed from the flare of 21 June 1980 and since then a number of solar neutron events were detected with instruments on board satellites and also with ground based cosmic ray neutron monitors. I will briefly review the rich variety of neutron emission that has been observed from solar flares over the past two decades. I then will discuss what we have learned from these observations and how solar neutrons can be considered as a manifestation of the Solar Variability. Finally I will discuss some recent work to understand the transport of high energy neutrons in the Earth's atmosphere.

GA6.01/W/13-A6 1150

THE EXTENDED CORONA AND SOLAR WIND

G. NOCI

The observations with the instruments on board the SOHO spacecraft have greatly increased our knowledge of the solar corona. They have concerned the morphology as well as the space distribution of physical parameters, such as densities, temperatures, element abundances, outflow velocity. The SOHO findings, with particular attention given to the data from the Ultraviolet Coronagraph Spectrometer, are discussed, focussing on the problem of the coronal expansion. They are compared with the results from the Ulysses spacecraft.

GA6.01/W/19-A6 1210

VARIABILITY OF THE SOLAR WIND AND ITS COMPOSITION

R. VON STEIGER and J. Geiss (International Space Science Institute, Bern, Switzerland); G. Gloeckler (Dept. of AOSS, Univ. of Michigan, Ann Arbor, USA, and Dept. of Physics, Univ. of Maryland, College Park, USA)

The solar wind seems to be a continuous and ubiquitous phenomenon. Ancient solar wind can be found as inclusions in meteorites and in the lunar regolith. On historical time scales it can be inferred from the existence of comet tails. During the last few decades the solar wind has been observed by in situ spacecraft and its variations were measured on time scales from a solar cycle down to minutes.
The composition of the solar wind provides us with a nearly unaltered sample of the material that constituted the protosolar nebula. Moreover, it is a powerful diagnostic tool for decoding the solar wind origin and acceleration: The charge states of heavy elements are indicative of the coronal temperature and its profile, whereas the elemental abundances probe the conditions and the processes in the chromosphere and lower transition region.
The Solar Wind Ion Composition Spectrometer (SWICS) on the Ulysses mission has now given us routine measurements of the abundances of 8–10 elements in up to 30 charge states at nearly all heliographic latitudes over the past 8 years. This data set provides the baseline solar wind composition and its variability during the time of decreasing and minimum solar activity. We will present an overview of the implications on the source regions of the solar wind and the processes active at these sites as inferred from the composition.

NEW IDEAS AND TRADITIONAL VIEWS IN EARTH SCIENCES FROM MIDDLE AGE TO RENAISSANCE

Giancarlo SCALERA (Istituto Nazionale di Geofisica, via di Vigna Murata 605, 00143 - Roma, Italy)

The different degree of tolerance and/or intolerance about a series of basic earth science topics at the passage from middle age to modern age has bees examined. Starting from the first scholastic criticisms to the Aristotelian system, which were needed because of the incompatibility of the infinity of the time compared to the Biblical Genesis, an attitude to extend the criticisms to other aspect of the Greek science diffuses among the intellectual class of the time. The discussion about the motions of the planet Earth and the Copernican heliocentrism, which initially was held also in presence of open mind Vatican hierarchies, suffers an involution towards sometime dramatic upshot after the conclusion of the Council of Trento. Both the earth mobility and the findings of marine fossils on the top of mountains were in contradiction with the biblical myth, but a less conflictual story of relations with the exponent of the dogmatic view was reserved to people which refuse to explain the marine fossils on the heights a…

SOME HISTORICAL NOTES ON THE SOLAR-TERRESTRIAL PHYSICS IN THE UNIVERSITY OF ISTANBUL (INCL. THE WORKS OF GLEISSBERG AND OTHERS)

Ferhat ÖZÇEP (1), Naci ORBAY (1), Hüseyin MENTESE (2) and Adnan OKTEN (2) (1-University of Istanbul, Faculty of Engineering, Department of Geophysical Engineering, Division of Earth's Physics, 34850, Istanbul TURKEY, E mail: ferozcep@istanbul.edu.tr; 2- University of Istanbul, Faculty of Science, Department of Astronomy and Space Sciences)

In the University of Istanbul, the studies on the solar-terrestrial physics can be investigated in two parts. One of these is the studies in the Astronomy Departmnent. Seconed one is in Geophysical Department. The first geophysical and astronomical department for educational and scientific purposes was established in Istanbul Darülfünunu (University of Istanbul) by Fatin Gökmen in 1926 as "the Institute of Astronomy and Geophysics". In the same year, first geophysical lecture was given as a " Lesson of Meteorology and Geophysics" at the same Institute. University of Istanbul was reorganized in 1933. By this year, Prof. Dr. Freunlich, he was the director of Einstein Institute (Berlin, Potsdam) and Astrophysical Observatory of Berlin, invited for the reorganization of the Department of Astronomy. Later, to assist to himself, Dr. Gleissberg was invited to the Department of Astronomy in 1934. Dr. Gleissberg initiated an expanded program of sunspot observation and continued his researches at the Astronomy Department up to his deperture in 1958. Today, solar photospheric observations are still continued as well as chromospheric observations in the same Department. During Gleissberg term as director of the Department, six students completed their PhD works on the subject of the lifetime and perspective foreshortenning of sunspot groups, relative number (or Wolf number) curves of sunspot cycles, and the latitudinal distribution of sunspot groups under his supervision. The most important contribution to the sunspot research of the Gleissberg is to show the existence of secondary cycle of about eighty years duration within the long term sunspot records. Today, this long-period is known as the Gleissberg Cycle in the literature. By the 1952, Geophysical Institute of University of Istanbul was strongly reestablished in Faculty of Science by the contributions of Prof. I. Özdogan, M. Fouche, Coulomb and J. Barthels in this time. At the same department, by the 1960, Ionospheric Research Center was established and the Center began the Ionospheric Data. In the same year, Prof. Dr. Rikitake was invated to the Department for educational and scientific aims. He had one Ph.D. student and he gave "Seismology", "Physics of Earth's Interior" and "Physics of Upper Atmosphere" Lectures in 1960-1961 Semester.

JOHANN VON LAMONT - FIRST YEARS OF GEOMAGNETIC RESEARCH IN MUNICH, 1836 - 1845

Martin BEBLO and Heinrich Soffel (both at Geophysical Observatory Fuerstenfeldbruck, University of Munich, Ludwigshoehe 8, D-82256 Fuerstenfeldbruck, Germany, Email: magnetic@fur.observatory.uni-muenchen.de).

Johann von Lamont started with sporadic geomagnetic observations in Munich in 1836. Since 6 o'clock in the morning on August 1st, 1840, he run regular observations with variometers built by Gauss and Meyerstein in Goettingen. In May and June 1841 Lamont replaced the Gauss variometers (suspended magnets with a weight of 25 lb - 11.4 kg) by instruments of his own design using very small and light magnets. These instruments improved significantly accuracy and sensitivity of geomagnetic measurements and made geomagnetic surveys possible. Some years later Lamont developed his travel thodolite and distributed 45 instruments of this type for scientific work worldwide. His instruments became international standard for geomagnetic instruments for more than 50 years.

JOHANN VON LAMONT - FIRST REGIONAL MAGNETIC SURVEYS 1850 - 1858

Martin BEBLO and Heinrich Soffel (both at Geophysical Observatory Fuerstenfeldbruck, University of Munich, Ludwigshoehe 8, D-82256 Fuerstenfeldbruck, Germany, Email: magnetic@fur.observatory.uni-muenchen.de).

In the 1850s Johann von Lamont started to make regional magnetic surveys at about 250 points in the kingdom of Bavaria. Probably no other country in the world was equipped with such an early and dense survey net. Lamont extended his survey into many European countries and documented the results in voluminous maps, 1856 for France, Spain and Portugal and 1858 for northern Germany, Belgium, Holland and Denmark. His central European maps with isolines of the geomagnetic elements are parts of the classical literature. Many of Lamonts's reference points can still be used today.

AN ADJOINT METHOD OF CALCULATION OF ENERGETIC SOLAR-PARTICLE-EVENT EFFECTS ON THE EARTH'S ATMOSPHERE

K. O'Brien, Noethern Arizona University, Flagstaff, AZ 86011, USA; Herbert H. Sauer, CIRES, University of Colorado, Boulder, Co 80303, USA, NOAA Space Environment Center, Boulder, CO 80303, USA

High-energy solar particles, produced in association with solar flares and coronal mass ejections, occasionally bombard the earth's atmosphere, resulting in radiation intensities additional to the already-present cosmic-ray dose rates. Access of these particles to the earth's vicinity during times of geomagnetic disturbance are not adequately described by using static geomagnetic field models. These solar fluxes are also often distributed non-uniformly in space, so that fluxes measured by satellites obtained at great distances from the earth and which sample large volumes of space around the earth cannot be used to predit fluxes locally at the earth's surface. We present here a method which uses the ground-level neutron monitor counting rates as adjoint sources of the flux in the atmosphere immediately above them to obtain solar-particle dose rates as a function of position over the earth's surface. We have applied this approach to the large September 29-30, 1989 event (GLE 42) to obtain the magnitude and distribution of the dose rates from an atypically large event. This approach could easily be adapted to the calculation of other atmospheric quantities of interest, such as ionization and energetic primary and secondary particle fluxes.

RELATIONS BETWEEN SOLAR, GEOMAGNETIC AND CLIMATE VARIABILITY

Václav Bucha (Geophysical Institute, Czech Academy of Sciences, 141 31 Praha 4 Sporilov, Bocni II, Czech Republic, email: bucha@ig.cas.cz)

Historical records of long and short-term solar variability and climate contribute to the study of cyclic changes which were observed both in solar and geomagnetic activity and temperature as well as in t4C anct have a similar trend. It is shown that the external geomagnetic forcing has a strong effect also on short-term meteorological processes. This justifies our suggesting a hypothesis for explaining Sun-weather relations. Several very similar cycles are clearly detectable not only in yearly but also in daily variations of both solar and atmospheric variability. A composite curve was suggested roughly representing basic cycles of geomagnetic and solar activity, temperature and 14C during the past millenia as well as their possible trend for the next centuries.

THE ORIGIN OF THE METEOROLOGICAL OBSERVATIONS IN ROME

M. COLACINO (Istituto di Fisica dell Atmosfera, CNR, Via del Fosso del Cavaliere, 100 - 00133 Roma, Italy, email: colacino@atmos.ifa.rm.cnr.it)

As it it well known the origin of the Meteorology as science based on the observations and measurements dates back to the second half of XVII century. In that period many pupils of Galileo, pursued, in the frame of the "Accademia del Cimento", the setting up of different meteorological instruments. They began to use thermometers, barometers, hygrometers in order to study the physical properties and motions of the atmosphere. Being aware that the atmosphere must be studied not only locally, but at larger scale, they sustained the creation of a meteorological network that was sponsored by Granduke of Tuscany and realised in 1656. The network collected data for about ten years: after more or less a century its heritage was assumed by the "Meteorological Societas Palatina" created by Prince Carl Theodorus in1780. This Society was aimed to diffuse the meteorology in Europe and this goal was pursued by creating a network, which included more than 30 stations covering all the Continent. In Italy were involved the observatories of Bologna, Padova, Roma and Chioggia where some meteorological observations were already carried out. The official series of measurements dates in Rome from 1782, year in which the network began its activity, in the observatory of "Collegio Romano" that was managed by Jesuits.In the present work after a short recall of different meteorological data series collected in Rome, the history of "Collegio Romano" station from the origin till the end of XIX century is presented, stressing the role that this institution had in promoting the meteorology in Italy.

THE UNPUBLISHED CORRESPONDENCE BETWEEN NOBILE AND EREDIA DURING THE PREPARATORY PHASE OF THE ARCTIC EXPEDITION OF 1928

M. COLACINO (Istituto di Fisica dell Atmosfera, CNR, Via del Fosso del Cavaliere, 100 – 00133 Roma, Italy, email: colacino@atmos.ifa.rm.cnr.it); O. FERRANTE , M.R. VALENSISE (Segreteria Antartica, CNR, Viale Markx, 15 – 00137 Roma, Italy, Tel: +39 06 86090308)

The 70th anniversary of the Nobile expedition with the Dirigible Italia has been celebrated in 1998. The expedition was characterised also for the scientific objectives and involved scientists and geophysicists well known as Finn Malgram (Sverige), Aldo Pontremoli (Italy), Francesco Behounek (Cecoslovacchia). The history of the expedition is well known, but new insights could be brought by the examination of a very important archive, not yet examined, composed by more than 3000 documents and presented for the first time during the above said celebration. The preliminary work, now under development, consists in a catalogation and a first interpretation of the documents. Among them particularly interesting is the correspondence between Nobile and Professor Eredia, who had been charged to study the meteorological aspects of the travel in order to cross the Alps in the course Milano-Friederichshafen and to give a description of the climatology of the Svalbard islands from which the Dirigible Italia should start to reach the Pole. In addition Eredia was requested of a specific advise in order to cross the Carso, that was believed dangerous not only for the meteorological conditions, but also for the lacking of meteorological data and information. The rich correspondence (16 letters) is important not only as unpublished documents, but gives a detailed picture of the care paid in preparing the expedition and represents an useful reference in order to analyse the development of the meteorology in Italy after the first world war.

WITHIN- AND AMONG-SOLAR-CYCLE (S) VARIATIONS AND HUMAN MORPHOLOGY, PHYSIOLOGY AND PATHOLOGY

G. CORNELISSEN, R.B. Sothern, L. Gheonjian, T. Paatashvili, Y. Watanabe, T. Breus, F. Halberg (Univ. of Minnesota, Minneapolis, MN 55455, USA; e-mail: halbe001@maroon.tc.umn.edu); Wilfried Schroeder (Hechelstrasse 8, D-28777 Bremen-Roennebeck, Germany)

An increase in myocardial infarctions (MI) after magnetic storms, among other effects of interest to space life science, was validated on 85,819 cases added to those reviewed by Dubrov and Gamburtsev. But even dense or long samples show that the solar cycle number and stage may lead to different associations. Heart rate measured automatically around the clock every ~half-hour over 11 years was positively correlated with Wolf's numbers (WN) during the ascending (r=0.535; P=0.001) but not during the descending stage (r=0.078; P=0.556). Heart rate, self-measured up to 6 times a day for 31 years, was positively correlated with WN during the descending stage of one solar cycle (Jan 1970-Dec 1975: r=0.398; P=0.001) and negatively during the next 2 descending stages (Jan 1982-Dec 1985: r=-0.427; P=0.002 and Aug 1991-Jul 1996: r=-0.450; P<0.001). A remove-and-replace approach (with 7-day components in solar wind present or absent) also revealed solar amplification of about 7-day cycles in heart rate, a result in keeping with more prominent about- weekly variations in mortality from MI in Tbilisi, Georgia, during high vs. low solar activity. For each biological rhythm, notably when desynchronized from the obvious socio-ecologic light-dark and temperature cycles of the habitat niche, a more remote as well as proximal physical match or near-match should be sought and vice versa. Consistent relations found over several solar activity cycles in heart rate variability (gauged by the standard deviation), mood and blood pressure, vs. WN or Kp, may be informative. Physical and physiological series should then be aligned, to gauge by cross- spectral coherence, superposed epochs and remove-and-replace approaches, life's past and/or present interactions with environments near and far, via feedsidewards (multiple interactions), revealing biological associations with two "master" switches, helio-geomagnetics and light, as they behave over several solar cycles.

THE CLIMATE CHANGE IN PAST 600 YEARS AND ITS RELATION WITH SOLAR ACTIVITY

Xiaoqing GAO(Lanzhou Institute of Plateau Atmospheric Physics, Chinese Academy of Sciences, Lanzhou 730000, P.R.China, email: xqgao@lzu.edu.cn) Giovanni P Gregori(Istituto di Fisica dell'Atmosfera, CNR, Rome 00133, Italy, email: gregori@atmos.ifa.rm.cnr.it)

The solar-terrestrial relationship is always the hot topic in geoscience. There are two ways in which the sun can influence the Earth environment. One is from up to down (by radiation process), another is from down to up (by geodynamo process). In this paper the focus is on the latter one. The geomagnetic model for past 600 years was used for computing the variation of geomagnetic field. There were two abrupt changes in geomagnetic field, which related to the solar activity. The climate on the Earth also experienced two low temperature periods in the same time. It suggests that solar activity, geomagnetic field change and climate change are related in some way. We know that the climate can be influenced by heat flux coming from the Earth. And Joule heat is produced by geodynamo and is varing in time. It is possible that the geothermal releasing is the key to solar-terrestrial relationship.

DOES THE 155-DAY PERIODICITY OF THE SUNSPOT AREA FLUCTUATIONS DURING THE PERIODS OF THE MAXIMUM OF THE 11-YEAR CYCLES REALLY EXIST?

Ryszarda Getko, Astronomical Institute, University of Wroclaw 51-622 Wroclaw, Kopernika 11

The problem discussed in this article concerns the issue of the short-term periodicities of the daily sunspot area fluctuations from July 1923 to September 1933. For these data the correlative analysis indicates negative correlation for the periodicity of 155 ± 10 days but the spectral analysis indicates a statistically significant peak in this time interval. Thus, in this paper, a new method of the diagnosis of an echo effect in spectrum (MDE) was proposed. On the basis of this method it was stated that the 155-day periodicity is a harmonics of the periodicities from the interval of [400, 500] days.
The comparison of autocorrelation functions for the fluctuations of Sunspot areas of the one rotation time interval on the both hemispheres, separately for the whole solar cycle 16 and for the maximum period of this cycle, shows no differences, especially in the interval of [120,180) days, what proves against the thesis of the existence of strong positive fluctuations of the 155 ± 10-day interval in the maximum period of the solar cycle 16.

CHRONOASTROBIOLOGY- AND CHRONOBIOASTRONAUTICS-AGENDA INVOLVING MONITORING THE BIOSPHERE AND COSMOS: THE BIOCOS PROJECT

Franz HALBERG, Germaine Cornelissen, Othild Schwartzkopff (University of Minnesota, 420 Washington Ave. SE, Minneapolis, MN 55455, USA; e- mail: halbe001@maroon.tc.umn.edu); Wilfried Schroeder (Hechelstrasse 8, D-28777 Bremen-Roennebeck, Germany)

A statistically highly significant ~9-hour lead of about-daily (circadian) rhythmic murine hepatic RNA formation before DNA synthesis corresponds to a lesser statistically significant lead of RNA over DNA contents of Euglena. Both leads support, before our DNA world, an RNA-world wherein RNA could replicate itself. In a broader comparative physiologic context, these sequences may provide evolutionary information. Changes in relative prominence of about-weekly (circaseptan) vs. circadian rhythms during the development of individuals and species, features of adaptive integration, may dif- ferentiate between sites of life's origins. On the ocean floor, without daily alternating light with darkness, geomagnetic disturbance may prevail: it has a circaseptan component, noted as a broad band by Vernova, demonstrated by us as a narrow spectral band around 6.7 days, confirmed by physicists, quantified by circaseptan- to-circadian amplitude ratios. On the earth's surface, circadian rhythms are prominent. Immediately after birth the circaseptan amplitude is larger in humans, pigs, rats, crayfish and some short series on Euglena. Acetabularia, E. coli and cyanobacteria require further study, but their circadians predominate in currently too- short series. Half-yearly changes in nocturnally circulating

melatonin point to a corresponding helio- and/or geomagnetic signature as a second "master" switch complementing yearly changes in light and temperature. About 10.5- and about 21-yearly changes in human morphology, physiology and pathology are at least numerically associated with solar activity cycles as documented by data covering up to 112 years of neonatal weight, height, and circumference of head, chest and abdomen, revealing in the same babies numerical associations of one variable with 10.5- and another with 21-year cycles. From monitoring for chronoastrobiology blood pressure and heart rate as gauges of biosphere effects from solar activity variation, critical information may be obtained for risk reduction in chronobioastronautics and vice versa.

HELMHOLTZ AND THE AGE OF THE SUN'S HEAT

Herbert Hörz (Leibniz-Sozietät, Hirtschulzstr 13, 12621 Berlin, Germany,
email: Herbert.Hoerz@t-online.de)

In the second half of the nineteenth century in connection with Darwin!s theory of evolution scientists discussed the age of the sun's heat. In 1854 Hermann von Helmholtz (I 821-1894) in a lecture about new insights in physics defended the hypothesis of Kant-Laplace about the evolution of the planetary system. He explained the shrinking of the sun as the source of heat generating. His theory was fifty years the foundation of cosmogonic thinking about the sun's heat. In his lecture in 1871 about the evolution of planetary system Helmholtz spoke about the beginning and the end of the energy of the sun as the source of living systems on the earth. William Thomson (1824 - 1907), the later Lord Kelvin, gradually switched from the meteoric theory to the position of Helmholtz. How Helmholtz was able to found such a long-living theory? Four reasons are described. Firstly his position of the universality of natutral laws and secondly he was thoroughly convinced that the conservation of energy is such a law. Thirdly he was an evolutionary thinker in the tradition of Kants hypothesis and fourthly the new insights in physics with the spectroscopical methods showed him the truth of his general philosophical position about laws. Discoveries in nuclear physics in our century brought cosmogony to new theories on the sun's heat.

MATHEMATICAL MODEL OF SOLAR ACTIVITY TAKING INTO ACCOUNT NON-LINEAR PROCESSES IN SUNSPOT FORMATION

Lev Tsirulnik, Tamara KUZNETSOVA, Viktor Oraevsky (all at IZMIRAN, Troitsk, Moscow region, 142092, Russia, email: tsyrul@izmiran.rssi.ru)

A method of nonlinear spectral analysis (called the method of global minimum: MGM) has been used to find periodicities in annual Wolf sunspot numbers (W) during the period 1700-1997. The study harmonics with time-varying phase and amplitude allows to detect time intervals of development of nonlinear processes in sunspot formation. An additional new and important result, manifested by MGM is a non-stationary behavior of some of the harmonics during the studied period. The powerest spectral triplet at period T~204 yr. testifies to the existence of the slowest non-stationary processes in sunspot formation during the studied interval. Time behavior of the triplet shows depressions in long term solar activity during periods known as Dalton's and Gnevishev's minima in solar physics. Our analysis excludes interpreting such cycle anomaly as Maunder minimum in terms of stochastic behavior and demonstrates that solar activity is not discontinuously changed at the end of the period: these changes are connected with decline and rise phases of the over long non-stationary triplet. The second power spectral peak at T=82 yr. is a non-stationary doublet, period of which coincides with period T~80 yr. found by Gleisberg in Schove's set of polar aurora for 16 centuries The calculated model confirms our previous conclusion concerning a non-stationary triplet at T=37.8 yr. that we associate with period T~ 36-37 yr. found by Brieckner in historical sets of hydrometereological phenomena from 1700 and by Clough in drought data in Europe from 1200. This period was discussed in the solar physics (solar or not). We for the first time derived it in sunspot data and consequently showed it's solar origin. These results demonstrate long term synchronous variations in solar and terrestrial phenomena. Long and short term variability in the solar and terrestrial phenomena are discussed.

HIERARCHY OF CYCLIC CHANGES IN SUNSPOT ACTIVITY

Alexander V. MORDVINOV, Georgy V. Kuklin (Institute of Solar-Terrestrial Physics, Russian Academy of Sciences, P.O. Box 4026, Irkutsk, 664033, Russia, email: avm@iszf.irk.ru)

Energetic and phase wavelet analyses were applied to study cyclic behaviour of sunspot activity. Energetic wavelet spectra of both the relative sunspot numbers and numbers of sunspot groups clearly show the cyclic mode, which varies its amplitude and period at about 11-yr timescale. Long-term changes are also seen in the spectra at about 50-100 yr timescale. Phase wavelet spectra of sunspot indices clearly show cyclic structure even if amplitudes of temporal changes are small. It is remarkable that the phase spectra resemble a picture of period doubling intrinsic for a fractal process. Phase wavelet spectra and the skeleton of zero-phase lines show fork-like structures of period-doubling bifurcations at various timescales. Separate 11-yr cycles are combined in pairs to make up complete magnetic cycles.
The phase spectra show three different regimes in solar activity behaviour. Regime of low activity for 1645-1715 known as the Maunder Minimum was changed to more-or-less regular cyclic variations with irregular amplitude alternation from even cycle to the odd one for 1745-1855. Since 1855 the cyclic mode of solar activity has been established with regular amplitude alternation according to the Gnevyshev-Ohl rule: every odd cycle exceeds the previous even cycle in amplitude. According to this scheme, if the amplitude of coming cycle 23 turn out to be lower than that of the preceding cycle, this might imply that a new regime of solar dynamo begins to operate.

THE FIRST PHOTOGRAPHICAL RECORD OF TERRESTRIAL MAGNETIC PULSATIONS IN 1896 BY M. ESCHENHAGEN AND THE REGISTRATION OF A PASSING ELECTRICAL CIRCULATING CURRENT

Wilfried SCHRÖDER and Karl Heinrich WIEDERKEHR

As pulsations and circulating currents are caused by the activity of the sun, I'd like to begin with a short survey of the way to the recognition about solar influences on terrestrial magnetism, particularly about the hypotheses of Balfour Stewart and the two treatises of Arthur Schuster about the daily variations. In meteorology and geomagnetism photographic self-registering apparatuses were already early developed in Greenwich and Kew. E. Mascart and M. Eschenhagen continued this line. With the help of his "Feinregistriergerät" (quick-run magnetograph) Eschenhagen could record pulsations for the first time more precisely. Through short-time simultaneous observations suggested by him the course of a terrestrial magnetic disturbance could be pursued. This disturbance was identified by A. Schmidt in 1899 as a moving circulating current in the upper strata of the atmosphere.

A NOTE ON THE SUGGESTED VARIABILITY OF THE LENGTH OF THE SOLAR CYCLE DURING RECENT CENTURIES AND SOME CONSEQUENCES

Wilfried Schröder and Hans-Jürgen Treder, Geophysical Station, Hechelstrasse 8, D-28777 Bremen Germany

It is shown that there exists neither physical explanation nor plausible mechanism which could initiate or support any variability in the length of the solar cycle. Furtermore, any suggestions concerning a relationship with terrestrial climate are questionable and without any supporting physical evidence.

THE EVALUATION OF THE SOLAR ACTIVE REGION NO. 6555 DURING MARCH 1991

M. A. Mosalam Shaltout, National Research Institute of Astronomy and Geophysics, Helwan, Cairo, Egypt.. Phone: (202) 2630833; Fax (202) 5548020 E-mail: mawshaltout@frcu.eun.eg

In 22 March 1991 during the declining phase of solar cycle 22, a very high energetic solar flare was released at UT 22h 47m from NOAA/SESC active region No. 6555. The proton flux of particles had energies > 10 Mev was 43,000 particle flux units (pfu), measured by GOES space craft. It is the highest measured one during the solar cycles 21 and 22. The flare was associated by microwave great burst of level 36,000 sfu on IO cm wavelength, and type II meter radio burst. The data used have been obtained from "Solar - Geophysical Data" Prompt Reports No. 560 and 561, and comprehensive reports No. 561 and 591, published by NOAA, Boulder, Colorado, USA.
One of our method for forecasting the high energetic solar proton flares depend on increasing of the ratio of microwave flux on two wavelengths emitted from the solar disk. The Air Weather Services Sagamom Mil (SGMR) observations are selected. The solar microwave flux adjusted to I Astronomical Unit, and Calibrated to bursts. The ratio of 269S MHz flux to 8800 MHz flux, and the ratio of 4995 MHz flux to 8800 MHz flux are represented for March 1991. The spectral type of the great outstanding microwave bursts associated with the high energetic solar proton flare of 22 March was determined using the solar radio emissions measured at frequencies 80000, 35000 and 7000 MHz of Nobeyama station (NOBE), and the solar radio emissions measured at frequencies 15400, 8800, 4995, 2695, 1415, 610, 410, and 245 MHz of Learmonth station.

SOLAR ULTRAVIOLET RADIATION AND ITS INFLUENCE ON THE OZONE LAYER

M. A. Mosalam Shaltout and A. Okasha, National Research Institute of Astronomy and Geophysics, Helwan, Cairo, Egypt , Fax: (202) 5548020, Phone (202)2630833
E-mail: mamshaltout @ frcu.eun.eg

It is confirmed that the method of Health and Schlesinger for the core to wing ratio of Mg II h and k lines at 280 nm in solar emission was a good measure for the relative temporal variation of UV fluxes in the range 170 - 295 nm and chromospheric UV and EUV fluxes at shorter wavelengths.
Short and long-term variability of the Ultraviolet Solar Radiation is very important factor for the variations in the earth's stratospheric ozone. Measurements of the solar ultraviolet radiation in Mg II h and k lines band were performed by the artificial satellites Nimbus 7 and NOAA 9, and the daily data of Mg II center to wing ratio for the period from November 1978 to December 1988 were published in the comprehensive reports of Solar - Geophysics Data Edited by NOAA, Boulder, Colorado, USA. Also the concentration of ozone in the stratosphere of the Earth's atmosphere observed by Nimbus 7 from November, 1979 to December, 1992. Power spectra analysis of the solar UV radiation and ozone concentration show periodicity close to 27 days (period of the sun rotation) and the period of revolution of Earth in ecliptic orbit around the sun (solar year). Other periodicities similar to 13 days and 6 months are clear in the power spectra diagram.

POWER SPECTRA ANALYSIS FOR INTERPLANTARY HIGH ENERGETIC CHARGED PARTICLES MEASURED BY GOES FROM JANUARY 1987 TO JUNE 1998

M. A. Mosalam Shaltout and S. El-Genedi, National Research Institute of Astronomy and Geophysics, Helwan, Cairo, Egypt, Phone: (202) 2630833; Fax (202) 5548020 E-mail: mamshaltout@frcu.eun.eg

The proton fluence in the interplanetary medium is measured by GOES of NASA at three different energetic levels as > IMev, > IOMev, and > I OOMev. The data for the period (January I987-June1998) are published in "Solar - Geophysical Data",of NOAA, Boulder, Colorado, USA.'The data are provided merely as a tool to distinguish when events occur. Where, during the period of January 1987 - June 1998 more than seventy solar proton events affecting the earth environment are recorded by the GOES Space Craft at Geosynchronous orbit, for energies > I 0 Mev. Also, in 22 March 1991 during the declining phase of solar cycle 22, a very high energetic solar proton flare was released at UT 22h 47m from NOAA/SESC active region No. 6555. The proton flux of particles had energies > IO Mev was 43,000 particle flux units (pfu), measured by GOES space craft. It is the highest measured one during the solar cycle 21 and 22. The power spectra analysis are applied on the time series of the daily proton fluence measured by GOES for the period (January 1987 - June 1998) for the three energetic levels. The results show a variability in the proton fluence as short and long-term periodicities close to the periodicities of the solar activity.

QUASI-BI-DECADAL CLIMATE OSCILLATIONS RELATED TO SOLAR ACTIVITY

Zhongwei YAN (Institute of Atmospheric Physics, Beijing 100029, China email: yzw@ast590.tea.ac.cn)

Climate variations of decadal time-scales behave variously in different regions, thus forming the complexity of global change. This study tried to recognize the mentioned scale signals that are of global significance. The Morlet wavelet method was applied to global 5 longitude X 5 latitude grid monthly temperature series. In the global mean case of the last 100 years, besides the 4-5-year variations, the bi-decadal ones showed strong power. Although they might not be dominant everywhere, these two signals were of global significance. If the short scale signal could be conventionally related to ENSO, the bi-decadal one remained less known. It was noted that the bi-decadal oscillations decayed since the 1960s. The precipitation in northern China of the last 100 years were also analyzed. Besides the strong interannual fluctuations, the quasi-bi-decadal variations were of strong power. They also decayed suddenly since the 1960s, when a long-term dry phase began in northern China. The temperature difference between southern and northern China has the similar spectra with a prominent peak around the bi-decadal scale. At this time-scale, the larger the temperature difference, the more the regional precipitation, thus performing some climatological 'front' effect. Similar oscillations also existed in northern America, where the higher the temperature, the less the precipitation. This regional relation seemed broken since the 1960s, when the quasi-bi-decadal signal decayed and a long-term warming and wetting trend occurred. The reason for the prevalence of the quasi-bi-decadal oscillations in climate remained unsolved. It was interesting that the same time-scale variations existed in the sunspots' umbra/penumbra ratios and more interesting that they decayed during the late half of this century.

EFFICIENCY FACTORS IN THE SOLAR-TROPOSPHERIC RELATIONS

Andras LUDMANY and Tunde Baranyi (both at Heliophysical Observatory, H-4010 Debrecen P.O.Box 30. Hungary, email: ludmany@tigris.klte.hu)

Two basic paradigms of solar-tropospheric relations are reviewed and compared in the report. They are based on different energy transfer mechanisms: the irradiance and the solar corpuscular radiation. It used to be widely accepted for a long time that the solar impact affects the troposphere through irradiance variations. It turned out, however, that under certain circumstances the impact of the particle flux variations may be more efficient than that of the irradiance. The efforts of the Debrecen Observatory are devoted to study both paradigms in a parallel and comparative way, both approaches need long-term datasets. On one hand the irradiance studies are supported by our sunspot catalogues, the Debrecen Photoheliograph Data which is a catalogue of sunspot positions and areas (like the Greenwich Photoheliograph Results), and a new, ambitious project in preparative state, the Historical Solar Image Database, which will contain full disc white light images of the Sun for every day since the beginnig of the regular observations, the present contribution provides the first report about it to the solar-terrestrial community. On the other hand the paradigm of corpuscular impacts is also investigated by using long-term datasets of the surface temperatures and the aa-index. These latter studies revealed several previously unknown regularities in the terrestrial responses to the incoming solar effects, they are mainly of vectorial nature which is a clear signature of corpuscular influence. The atmospheric response depends on 1) the polarity of the main solar magnetic dipole field (22-yr modulation), 2) the mutual attitudes of the Sun-Earth axes (semiannual fluctuation), 3) the solar origin of the plasma flow (polar or equatorial), and 4) the terrestrial hemisphere (eastern or western). It is not appropriate to treat any of these paradigms in an exclusive way, we provide their brief comparison in order to overview their relevance.

ACTUAL STATUS OF GEOMAGNETISM IN DEVELOPING COUNTRIES

Luiz Muniz Barreto Observatorio Nacional. Rua General Bruce,586. 20921-400, Rio de Janeiro,RJ. Brasil e-mail : barreto@on.br

Besides its mathematical and physical approaches, Geomagnetism is substantially a natural science. Its results and conclusions must be made after methodic enquiries to the Nature : observations are essential. Geomagnetic phenomenon embraces our planet and a great region around it. For this reason, among some important requirements for good observed data, two conditions must be considered first : an homogeneous and adequate distribution of permanent observing stations, and a continuous operation for a very long time. Both conditions are difficult to be accomplished, because we must keep in mind that about 70% of the terrestrial surface is covered by oceans and seas, and in the remaining 30% the situation is not satisfactory, mainly for cultural and economical reasons, because a great part of land area is represented by the Developing Countries (DC). However, there are in DC areas some important geomagnetic field patterns, such as the EEJ and the SAGA, typically scientific questions, that need to be addressed. Despite the clear evidence of the importance of DC for Geomagnetism, there are many problems to be solved. To install new stations with modern instruments is only a part of a satisfactory solution. It is necessary to train observers, to improve local scientific research and, above all, to convince local authorities about the importance of our Science. Some fruitfull examples could be given, for instance the African French speaking countries, Latin-America, India, China, Vietnam. In all these examples the presence of an international cooperation has been a source of the success.

GA7.01/P/04-A6 **0930**

EVIDENCES OF SEVERAL CURRENT SYSTEMS GENERATING THE MAGNETIC FIELD SUPERPOSED ON QUIET DAYS EQUATORWARD OF THE SQ FOCUS

C. Agodi ONWUMECHILI (4813 Lackawanna Street, College Park, Maryland 20740, USA, email: agodi onwumechili@yahoo.com)

The horizontal magnetic field, SPMF(H), superposed on the monthly mean Sq(H) to compose the diurnal profile of Sq(H) on a given quiet day, has been found to be complex. Its diurnal pattern varies from day to day and can be different at two stations on the same longitude. However, the pattern is normally very similar at all the stations in the equatorial electrojet (EEJ) zone and very similar at all the stations in the worldwide part of Sq (WSq) zone outside the influence of the EEJ. The 9 possible categories of SPMF in the EEJ zone vis-a-vis the WSq zone to be expected if the intensities of EEJ and WSq vary independently have all been found. Only one category occurs preferentially. In particular, variations of the intensities of the EEJ and WSq current systems in phase and in antiphase respectively are found to occur with equal frequency. These independent variations of the EEJ and WSq current systems explain the lack of correlation between the Sq(H) in EEJ and WSq zones. The particular types of SPMF that cause abnormal phase quiet days (APQDS) in the EEJ zone and in the WSq zone respectively are also found. In the EEJ zone it is generated by a current system resembling the counter equatorial electrojet (CEJ) current system but in the WSq zone it is generated by the single vortex current (SVC) system.

GA7.01/P/03-A6 **0945**

CORRELATIONS OF SQ HOURLY AMPLITUDES AND THEIR IMPLICATIONS FOR LOW LATITUDE IONOSPHERIC CURRENTS

C. Agodi ONWUMECHILI (4813 Lackawanna Street, College Park, Maryland 20740, USA, email: agodi-onwumechili@yahoo.com)

The investigation of the correlation of DH at all local time hours of the day has given a lot more information on the correlation of the ionospheric current intensities and their changes than is obtainable from daily ranges. It is found that the correlation coefficients of all pairs of stations in night-time are positive, very high and independent of the distance separating the two stations. It is explained that the small-amplitude variations at night being correlated arise from magnetospheric sources even on very quiet days. The correlation coefficients at two stations (called E stations) in the equatorial electrojet (EEJ) zone or at two stations (called L stations) in the worldwide part of Sq .(WSq) zone outside the influence of the EEJ are positive, very high and remain fairly steady at all hours of the day. This is because each pair of stations is under the same current systems. The correlation of L-L pair of stations in daytime decreases with the distance separating the stations because the ionospheric parameters that determine ionospheric current intensity and its changes are different at the two stations. The correlation coefficients of E-L pairs of stations fall drastically from very high values at night-time to very low and often insignificant values in daytime. This is principally due to the differences in the ionospheric parameters that determine the current intensities of the EEJ and WSq current systems in the different environments of the two stations. However, there is evidence that the counter equatorial electrojet (CEJ) current system occasionally modulating the EEJ current system and the single vortex current (SVC) system occasionally modulating the WSq current system make their minor contributions.

REGIONAL SQ VARIABILITIES TO BE STUDIED AT INDIVIDUAL OBSERVATORIES

Naoshi FUKUSHIMA (Dept. of Earth and Planetary Physics, University of Tokyo, Tokyo 113-0033 Japan. email: fukusima@nipr.ac.jp)

A general seasonal tendency of the geomagnetic Sq-field is to show a maximum intensity in local summer (June-July in the northern hemisphere) and a minimum in local winter over the world. However, we find some regional modifications of the Sq intensity observed on the ground throughout the year; for example:

(1) The Sq intensity is usually strongest in the end of August in the western Pacific countries in the northern hemisphere;
(2) At some Indian stations the Sq intensity is maximum in September;
(3) At Argentine stations the Sq maximum is seen at both vernal and autumnal equinoxes, and so forth.

These interesting regional features of the geomagnetic Sq-field must be studied extensively in the near future, with international cooperation in data exchange and analysis. It is hoped also that some more examples of the regional dependence of the Sq-field will be found to contribute eventually to the understanding of the air motion and the resulting electric current in the ionospheric region.

STUDY OF GEOMAGNETIC VARIATIONS AT EQUATORIAL STATIONS SITUATED ON TWO CLOSELY SEPARATED LONGITUDINAL PROFILES

NALIN B. TRIVEDI, Severino L. G. Dutra (Instituto Nacional de Pesquisas Espaciais-INPE , C.P.-515, São Jose dos Campos, SP 12201-970, Brazil, email: trivedi@dge.inpe.br); José M. Da Costa (Universidade de Taubate-UNITAU, SP 12020-270, Brazil, email: dacosta@dge.inpe.br)

During September and October 1994 we had recorded geomagnetic daily variations at several stations near the magnetic equator on 45º West meridian (three stations) and on 60º West meridian (six stations). The equatorial electrojet (EEJ) and counter electrojet (CEJ) characteristics were studied using H, D and Z data for 10 quiet days (Ap less or equal to 6) of the above mentioned period. The results of the analysis regarding longitudinal differences in the daily range in H and ionospheric current system associated with the equatorial counter electrojet (CEJ) are presented and discussed.

OVERVIEW ON EQUATORIAL GEOMAGNETISM (INVITED TALK)

R.G.RASTOGI, Department of Physics, Gujarat University and Physical Research Laboratory, Ahmedabad 380 009, India e-mail: parvs@prl.ernet.in

The discovery of equatorial electrojet immediately led to the two important features of the ionosphere (1) equatorial sporadic E layer (2) Equatorial ionization anomaly. Later it was found the Spread F is also related to the special features of the equatorial electric field. The long

series of HF Ionospheric Drift observations at Thumba led to the first time a close relation between the electrojet field and the Interplanetary Magnetic Field. Today the new results of equatorial geomagnetic storm effects are redefining the global magnetic disturbance phenomenon. The paper would define the role of electrojet in ionosphere, space physics and in the solar wind magnetospheric relationships. It is a rewarding opportunity for developing countries to contribute significantly to global science through electrojet studies.

GA7.01/E/06-A6 1130

CEJ RELATED EQUIVALENT CURRENT SYSTEM: A CASE STUDY ALONG INDIAN SECTOR

BALDEV R. ARORA and S.K. Bhardwaj (Indian Institute of Geomagnetism, Colaba, Mumbai 400 005, India, email: bra@iig.iigm.res.in)

The method of Principal Component Analysis (PCA) is applied to geomagnetic daily variations in H and D along the Indo-Russian chain of stations to establish spatial-temporal structures of the source currents on normal and counter electrojet days. It is found that first two principal components (PCs) are able to describe the characteristics of CEJ related field variations within and outside the equatorial belt. The first PC depicts the well-known latitudinal behaviour of Sq variations. Second PC describes the salient perturbations at low and middle latitudes accompanying the large negative excursion in H field at equatorial stations. When the perturbation in H and D components are combined, the nature of deduced flow path of source current favours superposition of additional current system caused by some global tidal modes in the dynamo region. The CEJ related current system, marked by intense westward current flow in equatorial belt, is shown to close its path by forming a clockwise loop extending up to mid-latitudes, with a well defined focus around 10 (degree) dip latitude. Their comparison with numerically simulated current system, due to various tidal modes, emphasize the significance of semidiurnal symmetric tidal modes in the generation of CEJ events.

GA7.01/E/11-A6 1145

GROUND-BASED DD DIURNAL VARIATIONS IN THE EQUATORIAL ELECTROJET INFLUENCE AREA IN AFRICAN

VAFI DOUMOUYA (Universite de Cocody, UFR-SSMT, BP 582, Abidjan 22, Ivory Coast, email: doumouv@syfed.ci.refer.org) Jacques Vassal (CETP, 4, Avenue de Neptune, 94107 Saint-Maur, France, email: jacques.vassal@cetp.ipsl.fr) Yves Cohen (IPGP, Laboratoire de Geomagnetisme, 4, place Jussieu, 75252 Paris Cedex 05, email: cohen@ipgp.jussieu.fr); Michel Menvielle (Physique de la terre, Bat.504, Universite Paris Sud, 91405 Orsay Cedex, France).

During the International Equatorial Electrojet Year (IEEY), the DH, DZ and DD daily variations of the geomagnetic field have been recorded in a network of ten stations across the dip-equator, along the 50W meridian in West-Africa. For a former experiment in Central Africa, these same variations were recorded from 1968 to 1970. In this paper, we describe and make an attempt to interpret the DD variations as observed during these two experiments.
The DD diurnal pattern is characterized by a very strong day to day variability. But some days, it presents a fairly regular structure in the northernmost and southernmost stations. In the light of the data from the Central African experiment, we have shown that DD displays four distinct zones with opposite signs: a positive northern area and a negative southern area in the morning; a negative northern area and a positive southern area in the evening. This structure has been interpreted as related to a meridional current system which converges in the morning and diverges in the evening. As this current system seems to be close to the dip-equator, we analyze and discuss its likely origins and relations with the equatorial electrojet.

GA7.01/E/08-A6 1200

VARIATIONS OF THE LUNAR GEOMAGNETIC TIDE IN THE INDIAN REGION

R.J. Stening (School of Physics, University of New South Wales, Sydney 2052, Australia, e-mail: R.Stening@unsw.edu.au) and R.G. Rastogi (Physical Research Laboratory, Ahmedabad 380 009, India, e-mail: parvs@prl.ernet.in)

Hourly magnetic field values from several observatories in the Indian region have been analysed for lunar tides using up to ten years of data. The average form of the seasonal variation of the lunar geomagnetic tide is descibed and also year-to-year changes are shown in the phase of the tide and in the position of the current system focus (when there is one).

GA7.01/E/13-A6 1215

ANOMALOUS BEHAVIOUR OF SQ CURRENT SYSTEM ALONG 75 (DEGREE) E MERIDIAN

S.K. Bhardwaj and BALDEV R. ARORA (both at Indian Institute of Geomagnetism, Colaba, Mumbai - 400 005, INDIA, email: bra@iig.iigm.res.in)

Analysis of Sq variation along the Indo-Russian chain of observatories has shown disappearance of the northern hemispheric 'Sq Vortex' during winter months. In order to understand the possible source and whether this anomalous feature persists in southern hemisphere, the Sq behaviour at a few stations in southern hemisphere are examined through the method of Principal Component Analysis (PCA). It is seen that Sq(H) at mid-latitude stations, confined between longitude slice of 25-90 (degree) E, exhibits markedly different daily pattern than those recorded at comparable latitudes outside this longitudinal belt. PCA of Sq(D) variations also indicates the presence of two distinct patterns, one corresponding to regular Sq and the other associated with second component which has similar waveform both in northern and southern hemispheres. This component, indicative of the presence of strong inter-hemispheric currents, undergoes much stronger seasonal variability than the first component. It is deduced that the magnetic effects associated with these currents tend to dominate the weak wintertime Sq dynamo effects, accounting for the disappearance of Sq vortex in the northern hemisphere. This longitudinal sector is also marked by an anomalous pattern in vertical component of Earth's main magnetic field. The contours of isolines, instead of following the circle of latitudes, tend to align north-south in this longitudinal belt in the southern hemisphere. A possible effect of this main field anomaly on the dynamo mechanism is discussed, among other feasible factors, as a possible source of the peculiar behaviour of Sq along this longitude sector.

GA7.01/W/05-A6 1230

THE SIGNATURE OF THE 18.6 YEARS MN LUNAR TIDAL EFFECT OVER HUANCAYO EQUATORIAL MAGNETIC OBSERVATORY

GIANIBELLI, Julio C.Dep. of Geomagnetism and Aeronomny, Faculty of Astronomical and Geophysical Sciences, La Plata University, Paseo del Bosque s/n, 1900 La Plata, Argentina, email: jcg@fcaglp.fcaglp.unlp.edu.ar

The lunar wave of 18.6 year on the monthly mean values of the geomagnetic elements recorded during 70 years at Huancayo magnetic observatory is determined. It is supposed that this very long term signal is important on the modulation of aeronomic effect.
The methodology used is the non-linear Maximum Entropy Method (MEM) with a switch of 90% in all the error predictor filter (fpe) longitudes.#

MAGNETIC REPEAT STATION NETWORK IN VIETNAM (FROM J = 80N TO J = 230N)

N T K THOA, H D Chau and N V Giang (Institute of Geophysics, Box 411 Buudien Boho Hanoi Vietnam, email: thoa@igp.ncst.ac.vn) Daniel Gilbert (Institut de Physique du Globe de Paris, 4 place Jussieu 75252 Paris Cedex 05, France)

During the years 1990-1991 and 1997 in the frame of the project of cooperation between Hanoi Institute of Geophysics and Institute of Earth's Physics in Paris, the absolute measurements of total intensity of geomagnetic field (T) with its components in 56 points, distributed sparsely all over the territory of Vietnam (from j = 80N to j = 230N) were carried out. With the instruments having a high degree of precision as proton magnetometer ELSEC for the measurement of total intensity of geomagnetic field (T), magnetic theodolite FLUXGATE for the measurement of declination (D), inclination (I), and from it, calculate the horizontal (H) and vertical components (Z). Repeat measurements at 56 points in 1997 were carried out with the same degree of precision. The error of measuring and reducing is 1' for D, 9 nT for H and T and 4.5 nT for Z. The precise methods were used to correct time variation *T with the attention to strong influence of Equatorial Electrojet, in order to reduce the measured values to the epoch 1991.5 and 1997.5 (00h of July 1st, 1991 and 1997). The values of measurements of geomagnetic field in the territory of Vietnam for two epoch are follow: 1991.5 1997.5 41100 nT £ T £ 45700 nT 41 200 nT £ T £ 46 000 nT 38300 nT £ H£ 41300 nT 38 200 nT £ H £ 41 300 nT 0nT £ Z £ 24000 nT, 500nT £ Z £ 25 500 nT 0o £ I £ 35o, 0o £ I £ 34.5o -1.2 o £ D £ 0o -1.2 o £ D £ 0o 1. INTENSE SOLAR FLARE EFFECTS AND STORM SUDDEN COMMENCEMENTS IN THE INDIAN CHAIN OF OBSERVATORIES

R.G.Rastogi (Physical Research Laboratory, Ahmedabad 380 009 India, email: parvs@prl.ernet.in) B.M.PATHAN and D.R.K.Rao(both at Indian Institute of Geomagnetism Colaba, Mumbai 400 005, India, email: bmpathan@iig.iigm.res.in)

With the close network of thirteen magnetic observatories along the Indian longitudinal sector from 0 deg to 70 deg dip latitudes, it has been possible to identify the Sfe and SSC at the same local time.
First, the direction of Sfe vector is found to be identical with the pre-flare Sq vector suggesting that the meridional currents causing changes in declination flow in the same altitude range as that of Sq current at low and middle latitudes. The daily variations at low latitudes are not due to the field line currents as these high altitude currents would not be affected by the solar flares. Extraordinarily large electro- magnetic induction efects are observed in the vertical component at the equatorial stations. The latitudinal profile of SSC in H during nighttime shows a small decrease in amplitude at stations near the magnetic equator. These observations are explained as due to the concentration of the low latitude induced currents in the conducting layers inside the earth around the Palk Strait between India and Sri Lanka forming an intense band current flowing westward.

GA7.01/W/04-A6 1430

EQUATORIAL ENHANCEMENT OF STORM TIME PC5-6 GEOMAGNETIC PULSATIONS

Pathan B.M., N.G.Kleimenova, O.V.Kozyreva, D.R.K. Rao and R.L.Asinkar

The geomagnetic Pc5-6 range (1-4 mHz) pulsations during several magnetic storms have been analyzed using ground observations at array of 5 Indian stations from 0.8ø to 25ø dip. latitude and two pairs of low-latitudes (~20ø) - near equator (~4-5ø) stations, located at ~4 hours to the West and East from this profile. The pulsations were occurred as separate wave packets and characterized by similar spectra at all stations with two dominate bands of frequencies: ~1.5-2.0 mHz and ~2.5-4.0 mHz. Very strong daytime equatorial enhancement of the waves intensity has been noted. The higher enhancement was observed in the noon-afternoon times and the same is reduced to the morning and evening times. The polarization of both frequency bands at the equator is noticed to be almost linear, mainly along the H-direction. The amplitude in the D-component of the pulsations is found to decrease as one approaches the dip equator. The mechanism of day time equatorial enhancement of long period geomagnetic pulsations obviously is connected with the influence of the Cowling conductivity effects in the vicinity of the dip equator.

GA7.01/E/05-A6 1445

A METHOD FOR REDUCTION OF MAGNETIC MEASUREMENTS IN THE AREA OF INFLUENCE OF EQUATORIAL ELECTROJET

H D CHAU (Hanoi Institute of Geophysics, Box 411 Buudien Boho Hanoi Vietnam, email: chau@igp.ncst.ac.vn)

Magnetic repeat station network in Vietnam has just been built from 1990 -1991. The measurements of the geomagnetic field were carried out in 1991 and 1997. The errors of absolute measurements are 1' for D, 9 nT for H and T and 4.5 nT for Z. When reduce the data measured into a certain epoch, the authors have to overcome the difficulties follow: The territory of Vietnam is elongated from 8 dgr.N to 23 dgr.N latitudes and Southern Vietnam lies under the influence of Equatorial Electrojet, so diurnal geomagnetic variation in this region is very complicated. For correcting and reducing to an epoch, the data of a station which is near to the observatory, one can use directly the variation data of this observatory. But when the station is far from the observatory, one will commit big errors. The errors of reducing from variations can be very big, especially if the measurements are carrying out at maximum and minimum of solar activity. We managed to resolve this problem, using the magnetic variation data recorded in 4 magnetic observatories distributed sparsely over the territory of Vietnam: Chapa (22 dgr.21'N, 103 dgr.50'E), Phu Thuy (21 dgr.02'N, 105 dgr.57'E), Da Lat (11 dgr.57'N, 108 dgr.29'E), Bac Lieu (09 dgr.17'N, 105 dgr. 44'E). The Bac Lieu observatory is lied just under the band of Equatorial Electrojet, and Da Lat observatory at its edge. The station data are corrected according to the observatory magnetograms and reduced to the midnight base.

On the hypothesis that the amplitude of the diurnal magnetic variation between two observatories (for example Phu Thuy and Da Lat) change linearly with the latitude, one can calculate the this amplitude in a point between two observatories by interpolation. This hypothesis was very carefully checked by the measurement data for many years. This method has given the precisions enough for the elaboration of the magnetic charts in Vietnam.

GA7.01/W/02-A6 1500

LOW LATITUDE IONOSPHERE- MAGNETIC STUDIES DURING STRONG MAGNETIC STORM OF MARCH 13,1989, BASED ON OBSERVATIONS IN PHUTHUY, VIETNAM

T Q Hao, N T K THOA, P V Tri (Institute of Geophysics, Box 411 Buudien Boho Hanoi, Vietnam, email: thoa@igp.ncst.ac.vn), N G Kleimenova (Institute of Physics of the Earth, Bolshaya Gruzinskaia 10, D-242, Moscow, Russia)

Strong magnetic storm of March 13-14,1989 started at 01.27 UT with Kp=9, maximal value of Dst = - 578 nT, Ap = 246. The comparison between ionospheric and magnetic records at the observatory Phuthuy, Vietnam (j= 21002, l=105057) showed that in the main phase of storm (11UT 13.03.1989 - 06UT 14.03.1989) the sudden fluctuations of h'F occurred simultanously but in the antiphase with the magnetic disturbances. The increase of h'F from ~240 km at 14 UT 13.03.1989 to ~450 km at 15 UT 13.03.1989, the strong decrease of the frequency of F layer in the correlation with magnetic activity confirm the apperance of additional source in the ionosphere during the night time at low latitude.

GA7.01/W/01-A6 1515

PC3-5 STUDY OF GEOMAGNETIC MICROPULSATIONS AT VERY LOW LATITUDE, IN BRAZIL

Ademilson ZANANDREA , Severino L G Dutra and Nalin B Trivedi (all at Instituto Nacional de Pesquisas Espaciais-INPE, São José dos Campos, SP, 12201-970, Brasil, e-mail: ademil@dge.inpe.br); José M Da Costa (Universidade de Taubaté-UNITAU, Taubaté, SP, 12020-270 and at Instituto Nacional de Pesquisas Espaciais-INPE, São José dos Campos, SP, 12201-970, Brasil, e-mail: dacosta@dge.inpe.br); K Yumoto, T Kitamura, M Shinohara and H Tachihara (Kyushu University,Fukuoka 812, JAPAN, e-mail: yumoto@geo.kyushu-u.ac.jp)

This present study is aimed at the understanding of source mechanisms and propagation modes of Pc3-5 micropulsations at very low and equatorial latitudes. It used simultaneous data measured with a chain of 10 geomagnetic stations in Brazil using high sensitive fluxgate magnetometers. Multiple tapered spectral estimation method based on Fast Fourier Transforms (FFT) was used to obtain micropulsation power spectra, polarization parameters and phases. It was observed an increase on the occurrence of highly polarized Pc3-5 pulsations, reaching maxima close to local noon (14:00 and 15:00 UT) in the stations nearest to the magnetic equator. The dynamic spectra showed the occurrence of 81 simultaneous events of Pc3-4 pulsations with high degree of polarization, mainly during daytime. The diurnal events showed increases in the polarized power density of 3,2 times for pulsations observed at stations close to the magnetic equator in comparison to the more distant ones. The phase of the pulsations observed at station close of the magnetic equator showed a delay of 48° and 62° in relation to the most distant one. This effects is clearly related to the increase of ionospheric conductivity and equatorial electrojet intensity. The amplitude of north-south component is much larger than the west-east one (poloidal mode oscillation). This result could be an evidence that field line resonance mechanism does not explain Pc3-5 micropulsations observed at very low and equatorial latitudes. The propagation of compressional waves may excite the trapped compressional made or the compressional global mode. The resulting phenomenon, field lines forced oscillations in the plasmasphere, may be a possible source mechanism for Pc3-4 pulsations at very low latitudes.

GA7.01/W/07-A6 1530

ULF FIELD GEOMAGNETIC OBSERVATIONS ASSOCIATED WITH ELECTRICAL ATMOSPHERIC STORMS IN BRAZIL

José M DA COSTA (Universidade de Taubaté-UNITAU, Taubaté, SP, 12020-270 and Instituto Nacional de Pesquisas Espaciais-INPE, São José dos Campos, SP, 12201-970, Brasil; e-mail: dacosta@inpe.dge.br); Severino L G Dutra, Nalin B Trivedi, Ademilson Zanandrea and Nelson Arai (all at Instituto Nacional de Pesquisas Espaciais-INPE, São José dos Campos, SP, 12201-970, Brasil; e-mail: dutra@inpe.dge.br); José R S Souza (Universidade Federal do Pará - UFPA, Belém, PA, Brasil)

An experiment to verify the influence of atmospheric electrical storms on ULF geomagnetic micropulsations parameters was conducted at low latitude stations as Belém (1.4°S, 48.4°W), Cuiabá (15°S, 56°W) and Cachoeira Paulista (22.7°S, 45°W), in Brazil. The geomagnetic field was monitored with high sensitive low noise fluxgate magnetometers in the DC-1Hz frequency range. The thunderstorm sensors could detect atmospheric electrical activity within a radius of 180km from the station. The local atmospheric electrical activity was also confirmed by the analysis of a sequence of satellite cloud cover data. The data analysis shows increases on the amplitudes of some Pc3 and Pc4 micropulsations events in association with electrical thunderstorms.

GA7.01/W/03-A6 1615

PLASMA DIAGNOSTIC EXPERIMENTS ON BOARD THE BRAZILIAN SCIENTIFIC APPLICATIONS SATELLITES SACI-1 AND SACI-2P

MURALIKRISHNA, M.A. Abdu, S. Domingos, J.A.C.F. Neri (all at Instituto Nacional de Pesquisas Espaciais - INPE/MCT, C.P. 515, 12201-970, São José dos Campos - SP, Brazil, email: murali@dae.inpe.br) and Koh-Ichiro Oyama (Institute of Space and Astronautical Science, 3-1-1, Yoshinodai, Sagamihara 229-850, Japan, email: oyama@bochan.ted.isas.jp)

A set of three plasma diagnostic experiments, are proposed to be launched on board the two Brazilian Scientific Applications Satellites SACI-1 and SACI-2 to investigate the phenomenon of ionospheric plasma bubbles, known to exist in the ionospheric region over a wide range of latitudes. While the micro satellite SACI-1 is going to be put in a near polar (98 degree inclination) orbit SACI-2 is going to be put in a low inclination orbit. Their launches are presently scheduled for this year, SACI-1 being programmed for launch in the middle of this year. The two plasma diagnostic packages will be practically identical in functioning but will be different in the mechanical mounting of the sensors on board. It is intended to make measurements of the density, temperature and spectral distribution of the irregularities, of the plasma using (1) a High Frequency Capacitance Probe for measuring the plasma density, (2) a fixed-bias Langmuir Probe for measuring the electron density profile and the spectral distribution of plasma irregularities, and (3) an Electron Temperature Probe for measuring the kinetic temperature of the ionospheric electrons. In the High Frequency Capacitance Probe a metallic sensor in the form of a sphere of about 60mm diameter, mounted at the extremity of one of the solar panels is used as a capacitance element in the tank circuit of a "Clapp" type oscillator. In the fixed bias Langmuir Probe a metallic sensor, similar to that used in the HFC experiment, is mounted at the extremity of another solar panel and the sensor potential is selected using telecommands. In the Electron Temperature Probe two semicircular metallic sensors in the form of a circular disc, mounted at the extremity of a third solar panel is used to determine the kinetic temperature of the ionospheric electrons. The experiment details along with details of the data acquisition system, on board processing of the LP ac data etc. are presented here.

GA7.01/E/04-A6 1630

DEVELOPMENT OF A FABRY-PEROT INTERFEROMETER TO STUDY THE THERMOSPHERIC DYNAMICS OF THE UPPER ATMOSPHERE

G.K.Mukherjee Indian Institute of Geomagnetism Colaba, Mumbai 400 005 India
e-mail:gkm@iig.iigm.res.in

A pressure scanning Fabry-Perot Interferometer has been fabricated under AICPITS programme sponsored by DST, Govt.of India. The interferometer has been installed at a low latitude station, Kolhapur (16.8 deg N, 74.2 deg E, dip latitude 10.6 deg N) in India. The high resolution spectrometer consists of a pair of etalons of 150 mm in diameter(IC Opt sys,UK) and is used to monitor temperature and horizontal winds in the thermosphere from the Doppler broadening and shift of the peak of [OI] 630.0 nm emission line in the night airglow. This is the largest aperture interferometer operating in the country.

Salient features of the spectrometer and preliminary data obtained are presented here.

GA7.01/E/07-A6 1645

COORDINATION OF GROUND BASED AND ROCKET BORNE STUDIES OF EQUATORIAL ELECTROJET

R.G.RASTOGI, H.Chandra, H.S.S.Sinha and Som Sharma Physical Research Laboratory, Ahmedabad 380 009, India, e-mail: parvs@prl.ernet.in

The discovery of the longitudinal variation of equatorial electrojet current strength from IGY data still remains a unsolved problem. The second problem to be solved is the association of electrojet with Sq. A study has been made to coordinate the ground based magnetic data, vertical incident ionospheric data and the rocket borne current profile data in Indian and American longitudes. The longitudinal inequality is sufficiently reduced when the ground data are calibrated with rocket data. It is concluded that many of the longitudinal variations of equatorial geomagnetism and aeronomy are due to corresponding variation of the horizontal electric field in the equatorial E region of the ionosphere.

GA7.01/E/14-A6 1700

EQUATORIAL F2 PEAK ENHANCEMENTS AND THE BRAZILIAN F3 STRATIFICATIONS

E. Sambou (UCAD Dept de physique, Dakar-Fann, Senegal); R. Fleury (FT/CNET DMR/TSI, 22307 Lannion Cedex,France); P.M. VILA (CETP/CNRS StMaur-des-Fosses 94107, France)

We compare the Brazilian F3 phenomenon of 1995 ionograms (Fortaleza, 4.5° South mag. latitude) interpreted by Balan et al.(1998), with the morning crest and dome events documented from the 1993-94 West African ionosonde series (Sambou et al., 1998). Although the two features have much in common, a new scrutiny of their morphologies and physical conditions shows clear distinctions. We bring about auxiliary results to help discussing the respective mesoscale dynamics acting in the two longitude sectors, quite different despite their geographic vicinity.

GEODESY SECTION 1, POSITIONING: SECRETARY'S REPORT

Yehuda BOCK (Scripps Institution of Oceanography, La Jolla, CA 92093-0225, USA, e-mail: ybock@ucsd.edu)

The section has sponsored 5 special study groups during this last 4-year period (1996-1999) dealing with important topics and issues in geodetic positioning:
SSG 1.154: Quality Issues in Real-Time GPS Positioning, Chris Rizos (Australia),
SSG 1.155: Active GPS Networks Hiromichi Tsuji (Japan),
SSG 1.156: Advanced GPS Analysis for Precise Positioning, Geoffrey Blewitt (United Kingdom),
SSG 1.157: GPS Ambiguity Resolution and Validation, Paul J. de Jonge (The Netherlands)
SSG 1.158: GPS Antenna and Site Effects, Jan M. Johansson (Sweden)
SSG 1.159: Use of GPS Positioning for Atmospheric Monitoring, Michael Bevis (USA)
We summarize briefly the major findings of these groups and discuss positioning issues for consideration in the next 4-year period, in particular, new developments and applications with an enhanced Global Positioning System.

G1/L/06-A3 0850

REPORT OF THE IAG COMMISSION 10 ON GLOBAL AND REGIONAL GEODETIC NETWORKS

Claude BOUCHER (IGN/LAREG, 2 Avenue Pasteur B.P. 68, 94160 Saint-Mandé, France, email: bock@ign.fr)

This presentation provides a summary of the report on the activities of the IAG Commission 10 on Global and Regional Geodetic Networks (GRGN) for the period 1996-1999. This includes a survey of the activities of its working groups and subcommissions, as well as the works achieved by participating countries. Some views for the future contributions of GRGN are then presented, with a particular focus on three topics: the developing use of ITRF, GPS versus other systems and the development of a global vertical datum.

G1/E/49-A3 0910

REALIZATION OF A TERRESTRIAL REFERENCE FRAME FOR LARGE-SCALE GPS NETWORKS

Detlef ANGERMANN, Juergen Klotz, Christoph Reigber (GeoForschungsZentrum Potsdam, Telegrafenberg C2, 14473 Potsdam, email: dang@gfz-potsdam.de)

The GFZ Potsdam established GPS networks for geodynamic studies in South America (SAGA), Central Asia (CATS) and South-East Asia (GEODYSSEA), in cooperation with various organizations in the host countries, as well as in Europe and North America. This presentation concentrates on the datum definition of these networks.
The GPS data of the large-scale networks were processed simultaneously with data of the IGS station network using the GFZ software EPOS. The mean station coordinate residuals between our global network solutions and the ITRF96 coordinates are 1cm horizontally and 1-2 cm vertically. With respect to a regional reference frame the mean station coordinates residuals are in the range of 2-5 mm horizontally and below 1 cm for the height. For the interpretation of our network results we focus on regional tectonics and relative plate motions. To achieve this goal we define the datum of the station velocities in a regional frame. We present results for the datum definition of the SAGA and CATS network.

G1/E/46-A3 0930

THE EUROPEAN REFERENCE SYSTEM COMING OF AGE

J. Adam, W. Augath, C.Boucher, C. Bruyninx, P. Dunkley, E: GUBLER, W. Gurtner, H. Hornik, H. van der Marel, W. Schlüter, H. Seeger, M. Vermeer, J.B. Zielinski (members of the EUREF-Technical Working Group)

Ten years ago, the advantages of GPS technology were recognised and a first GPS campaign covering the western part of Europe was organised in order to establish a uniform European Reference Frame (EUREF). Through successive GPS campaigns, the network has been extended towards eastern parts of Europe and various countries have undertaken densification campaigns. This International co-operation within Europe has resulted in the establishment of a high accuracy, 3 dimensional geodetic network with links to global and national reference systems.
Strategies and guidelines have been developed for network densification, observation procedures, data flow and data analysis. This has resulted in today's permanent GPS network comprising in excess of 75 stations, a data handling service and supported by 12 analysis Centres. The results show an accurate and consistent network (+/- 3mm in the horizontal component, +/- 6mm in the height component).
Since 1995, emphasis has been placed on the height component, resulting in an extended and improved adjustment of the United European Levelling Network (UELN) and the establishment of the European Vertical GPS Reference Network (EUVN). Today, the EUREF Network contributes towards multi-disciplinary activities such as the estimation of meteorological parameters and links to tide gauges.

G1/E/38-A3 0950

A NATIONAL NETWORK OF CONTINUOUSLY OPERATING GPS RECEIVERS (COGRS) FOR THE UK

Alan DODSON, Richard Bingley, Leighton Symons, Nigel Penna (IESSG, University of Nottingham, Nottingham, NG7 2RD, UK, email: alan.dodson@nottingham.ac.uk)

A national network of COGRs can provide a temporal and spatial density of continuous GPS data which can greatly expand the potential use of IGS data. For example, flood defence monitoring on a national scale can be related to the mean sea level monitoring carried out on a global scale.
Similarly, the use of data from a national network, supplemented with data from the IGS global network, will permit detailed studies of tropospheric and ionospheric activity. The potential of COGRs has already been recognised by four UK government organisations, namely the Environment Agency (EA), the Meteorological Office (MO), the Ministry of Agriculture Fisheries and Food (MAFF) and the Proudman Oceanographic Laboratory (POL). By the end of 1998, a national network of thirteen COGRs was effectively in place in the UK. These thirteen COGRs will be supplemented by the Ordnance Survey of Great Britain, who have recently announced the establishment of a number of COGRs as active survey reference stations. In order to optimise the use of COGR data by the environmental community, the IESSG is in the process of establishing a national centre responsible for the transfer, archiving, processing and analysis of data from all COGRs in the UK, which could include about thirty stations by mid 1999. This presentation intends to discuss how the national data archive will be structured at the IESSG and illustrate preliminary results from a number of UK government funded projects.

G1/L/23-A3 1010

QUALITY CONTROL ISSUES IN REAL-TIME GPS POSITIONING

Chris RIZOS, Shaowei Han (both at School of Geomatic Engineering, The University of New South Wales, Sydney NSW 2052, Australia, email: c.rizos@unsw.edu.au, s.han@unsw.edu.au)

Real-time carrier phase-based GPS positioning techniques are now increasingly used for many surveying and precise navigation applications on land, at sea and in the air. Quality control (QC) issues are becoming more important for all applications. QC has been addressed at different stages of the GPS positioning process, for example, data collection, data processing and data display. In this paper, the quality control procedures or methodologies for the following critical operations are discussed:
- Measurement quality control for single receiver data, concerned with issues such as failured satellites, ionospheric scintillation, multipath and cycle slips.
- Quality assurance for data communication and data transmission delay.
- Quality control of the position modelling procedure, related to systematic error mitigation and stochastic modelling.
- Ambiguity resolution and validation procedures.
- Additional constraints for particular applications.

As examples, the proposed quality control procedures implemented in the Singaporean multi-base station network and the GPS-based volcano deformation monitoring system in Indonesia are described and future or unresolved considerations are outlined.

G1/L/17-A3 1100

ARE GPS DATA NORMALLY DISTRIBUTED?

Christian TIBERIUS (Delft Univ. of Technology, The Netherlands,
email: c.c.j.m.tiberius@geo.tudelft.nl); Kai Borre (Aalborg Univ., Denmark, email: borre@kom.auc.dk)

In precise relative GPS positioning, like in many geodetic applications, the data are routinely processed using a least-squares algorithm, either in batch or in recursion mode as a Kalman filter implementation. The least-squares principle requires the specification of a functional relation between observations. The full probability density function of the observed data is not needed for estimating the parameters. This function, however, is needed to interpret the precision of the estimators. Next, a statistical testing procedure for integrity monitoring to spot outliers and cycle slips in the data does rely directly on the probability distribution. And thirdly, also making probabilistic inferences for resolution of the ambiguities requires knowledge of the probability density function of the data. In this contribution we will analyse the probability distribution of GPS data. The analysis is based on the least-squares residuals, as a time-series at 1-second rate, per channel (satellite), per epoch and per observation type, from a coordinates and ambiguities constrained solution. We consider data from several state of the art geodetic receivers, used in different experiments like a zero baseline and an ordinary baseline in the field. Statistical tests known from literature are used to indicate and quantify by the level of significance, whether the normal probability density function is a reasonable model for the distribution of GPS code and phase data. The preliminary conclusion is that fortunately, this seems to be the case indeed, although the conclusion's validity may be restricted to certain circumstances. In addition the findings will be supported by some graphical analysis.

G1/W/42-A3 1120

ON THE ACCURACY AND RELIABILITY OF NEAR REAL-TIME GPS PHASE OBSERVATION AMBIGUITIES

Hansjoerg KUTTERER (University of Karlsruhe, Geodetic Institute, Englerstrasse 7, D-76128 Karlsruhe, Germany, email: kutterer@gik.uni-karlsruhe.de)

During the past decade the integer fixing of the GPS carrier phase ambiguities has been studied in a variety of papers. The available techniques are more or less sophisticated regarding the selection of the possible solutions contained in the ambiguity search space and, consistently, of the reduction of the observation epochs necessary for the unique solution. As incorrect solutions may occur, it is indispensable to study their impact on the coordinate estimates and accuracies. Thus, quality issues concerning the ambiguity resolution techniques are both of practical and theoretical interest.
The paper focuses on the theoretical aspects of the near real-time case with short baseline lengths. The float ambiguity solution is restudied giving new insight in the composition of the ambiguity search space. In addition, an approach is outlined for describing the accuracy of the ambiguities regarding their integer nature. Finally, reliability aspects are considered taking possibly incorrect ambiguity solutions into account.

G1/L/07-A3 1140

APPLICATION OF GEODESY TO ENGINEERING - NEW TRENDS

O. Univ.-Prof. Dr.-Ing. Heribert KAHMEN (University of Technology Vienna, Institute of Geodesy and Geophysics, Dept. of Applied and Engineering Geodesy, Gusshausstrasse 27, 29/E128/3, A-1040 Vienna, email: Heribert.Kahmen@tuwien.ac.at)

Rapid developments in engineering have greatly changed both intrumentation and methodology in engineering geodesy. To document the body of knowledge in this field and to encourage new developments, IAG Spec. Com. 4 was established. To accomplish these objectives working groups did research work in areas of current interest. This paper presents some highlights of the activities.
Multi sensor systems have become an emerging trend in mapping applications because they allow a task-oriented implementation of geodetic concepts at the measurement level. To fullfil the need for up-to-date inventory and georeferenced data along transportation routes two developments are of especial interest: Digital imaging and precise navigation with respect to geodetic reference systems.

Concepts for new structures-bridges, towers, buildings - break barries of scale in span or hight. Technically, the lateral and vertical deflections and the dangerous vibrations must be studied. Therefore, another topic dealt with the development of georeferenced measurement systems and the investigation of the mathematical and physical models of the kinematic systems.
Another challenging topic was: Traffic and guidance control and autonomous vehicle navigation. Digital maps are a key technology all traffic information and navigation systems. In the future an information service provider for accurate complete up-to-date and in time available information with precise geometrical attributes will be of great interest.

G1/L/11-A3 1200

RE-WEIGHTING OF GPS BASELINES FOR VERTICAL DEFORMATIONS ANALYSIS

Henk DE HEUS, Marcel Martens, Hans van der Marel (Delft University of Technology, Thijsseweg 11, 2629 JA Delft, The Netherlands, email: H.M.deHeus@geo.tudelft.nl)

In the Netherlands GPS is used to monitor subsidence caused by extraction of natural gas. GPS campaigns are organised on a yearly basis. Each campaign consists of GPS observations on 30 to 60 points, using typically 5 dual frequency GPS receivers. The duration of a session is between one and two hours, but as every point is observed several times, up to 56 sessions have been observed for each campaign. The area is about 75 by 60km, resulting in an average baseline length of 10 km. The GPS data is processed using a stepwise - iterative - approach. First the GPS data is processed session by session. Then the sessions are combined, using their full co-variance matrix in a network adjustment. The network adjustment is used to estimate the proper variance of the GPS observations. This involves removal of outliers using statistical procedures, estimation of variance components, re-scaling and reprocessing of the GPS sessions. The best results are obtained using L1 and L2 phase data with an ionospheric constraint determined from the network adjustment, and using distinct weighting factors for the horizontal and vertical components. The precision of the heights after the network adjustment is on the average 6 mm for individual campaigns. This has been confirmed by independent levelings.

G1/E/62-A3 1220

STOCHASTIC MODELLING OF THE IONOSPHERE FOR FAST GPS AMBIGUITY RESOLUTION

Dennis ODIJK (Department of Mathematical Geodesy and Positioning, Delft, University of Technology, Thijsseweg 11, 2629 JA Delft, The Netherlands, email: D.Odijk@geo.tudelft.nl)

Integer carrier phase ambiguity resolution is the key to precise GPS positioning. For baselines with a length up to 100km the errors due to the ionosphere are a limit for the ability to resolve the integer ambiguities within the shortest observation time span. One can of course estimate the ionospheric delays, but due to the extra unknowns in the model the shortening of the time span will be limited. On the other hand very short time spans can be reached by not estimating the delays at all, but only if the ionospheric delays in the data are within certain bounds.
In this contribution the effect is investigated of a priori weighting of the ionosphere on integer ambiguity resolution with LAMBDA. Stochastic modelling of the ionosphere can mathematically be regarded as the addition of pseudo observations to the model of GPS obervation equations, together with a variance matrix in which the uncertainty of the ionospheric delays is modelled. Note on the one hand that if "infinite" weights are used for these ionospheric pseudo observables, we get the model in which no ionospheric delays are estimated. On the other hand if these observables are not weighted at all, the model in which the ionospheric delays are estimated is obtained. Stochastic modelling in a way interpolates between these two "extreme" models and for a medium-length baseline it will be shown that with this technique it is possible to get the correct integer ambiguities within a shorter time span than with the model in which the ionospheric delays are considered as completely unknown.

FINAL REPORT BY SSG 1.158: GPS ANTENNA AND SITE EFFECTS

Jan JOHANSSON (Onsala Space Observatory, Chalmers University of Technology, SE-49392 Onsala, Sweden, email: jmj@oso.chalmers.se)

The improvement in precision obtained in GPS observations over recent years has revealed some problems related to the local conditions at the GPS site. In order to further improve precision investigations of site dependent effects and GSP antennas are required. The objectives for Special study group 1:158 were to provide information and recommendations regarding; the characteristics of different GPS based on measurements in anechoic chambers, field experiments, and numerical evaluation; the influence of electromagnetic scattering (including multipath) on the antenna characteristics; the effects of using different types of antennas in the same network; design and testing of new GPS antennas; elimination of radio interference; monumentation and establishment of permanent stations including construction of pillars and monitoring of their long-term stability; glassfiber radomes used to protect permanently installed antennas; the influence of snow, rain, and local atmospheric conditions. Here, we review some of the problems associated with site-specific errors and present recommendations on how to eliminate or minimize these effects.

G1/E/34-A3 1420

THE IMPACT OF GPS ANTENNA PHASE CENTER VARIATION ON HEIGHT ACCURACY

Chun-Sung CHEN (Department of Civil Engineering, National Chiao Tung University, Hsinchu 30050, Taiwan, R.O.C., email: ccs@cc.nctu.edu.tw); Yi-Jau Chen (Department of Civil Engineering, National Chiao Tung University, Hsinchu 30050, Taiwan, R.O.C.)

The precise point of a station whose position is being measured using GPS surveying is generally assumed to be the phase center of the GPS antenna. However, the phase center of a GPS antenna is neither a physical point nor a stable point. For any given GPS antenna, the phase center is varied according to the direction of the signal from a satellite. Therefore, the variation of the GPS antenna phase center is very complicated. Besides, the phase center variations are antenna-type-dependent. This effect has to be carefully modified when different types of antennas are used simultaneously. Ignoring these phase center variations can lead to serious (up to 10 cm) vertical errors that are independent on the baseline length. Even if the same types of antennas are used, the main effect is a scale factor up to about 0.015ppm. In this study, the antenna phase center drifts and variations using GPS data will be estimated. The results of GPS height measurements with phase center corrections and no corrections will be compared. Besides, a feasible method to calibrate antenna phase center and a correction model is suggested.

G1/W/28-A3 1440

MITIGATING MULTIPATH ERROR USING SEMIPARAMETRIC MODELS FOR HIGH PRECISION POSITIONING

Minghai JIA, Maria Tsakiri, Mike Stewart (all at School of Spatial Sciences, Curtin University of Technology, GPO Box U 1987 Perth WA 6845, Australia, email: jia@vesta.curtin.edu.au)

Multipath delay is a dominant error source of the double differential GPS observation data in short distance GPS models. Although important progresses to feature and mitigate the impact of the multipath errors on the positioning results, more practicable mathods need to be developed.
A major obstacle to mitigate the multipath errors is how to model those errrors. Since the multipath errors results from the mixture of many reflected signals, it is very difficult to model those error with the existing parametric methods. We have developed a semiparametric model to model and mitigate those error. Semiparametric model is a new mathematical tool developed in the last decade. In the semiparametric model, the multipath errors can be considered as a complicated function without caring the parameters and the pattern of the function. Using penalised least squears principle, the function and other parameters, such as site coordinates, can be estimated simultaneously. Trial results have shown that the multipath errors can be efficently estimated and can be reduced to the level of the receiver noise.

THE IMPACT OF THE ATMOSPHERE ON WADGPS

Stefan SCHAER, Markus Rothacher (both at Astronomical Institute, University of Berne, Sidlerstrasse 5, CH-3012 Berne, Switzerland, email: stefan.schaer@aiub.unibe.ch); Urs Wild, Adrian Wiget (both at Federal Office of Topography, Seftigenstrasse 264, CH-3084 Wabern, Switzerland, email: urs.wild@lt.admin.ch)

The Swiss Federal Office of Topography is currently building up the Automated GPS Network for Switzerland, called AGNES. This GPS network will serve various purposes, like national surveying, engineering surveying, navigation, meteorology, and research. For Wide-Area Differential GPS (WADGPS), in particular precise real-time positioning using the GPS phase data of one or more reference stations of the AGNES network, one may expect that atmospheric refraction plays the crucial role, since the reference stations may be rather widely separated in Switzerland, typically by 50-100 kilometers. In the time period of the next solar maximum, the ionospheric refraction will probably be the most crucial error source, in particular for resolving the initial phase ambiguities, which is mandatory when aiming at accuracies on the centimeter-level. Nowadays, global and regional total electron content (TEC) maps, like those produced by the Center for Orbit Determination in Europe (CODE), are available and may be used to model the mean ionospheric refraction. However, on time scales of few minutes, ambiguity resolution usually suffers from short-term ionospheric fluctuations which are not accounted for by such TEC maps. Significant height differences with respect to the nearest reference stations may also occur, especially in mountainous areas like Switzerland.This implies that mismodeled tropospheric refraction may cause biases too. Therefore, we will monitor ionospheric as well as tropospheric biases, study their impact on WADGPS results, and investigate whether it is possible to extract atmospheric information from the AGNES network for correcting the data of mobile GPS receivers in (near) real time.

IMPROVING THE MODELLING OF ATMOSPHERIC DELAY USING METEOROLOGICAL DATA ASSIMILATION MODELS

D. S. MacMILLAN (NVI, Inc./Goddard Space Flight Center, Greenbelt, MD 20771, USA, email: dsm@leo.gsfc.nasa.gov); C. Ma (NASA Goddard Space Flight Center, Greenbelt, MD 20771, USA)

We have investigated using meteorological data assimilation models to correct tropospheric delay models in space geodetic analysis. We considered two sources of modelling error: the mapping function that gives the elevation dependence of the delay and the gradient model that describes the azimuthally asymmetric part of the delay. From analysis of radiosonde profile raytracings, the uncertainty of the site vertical due to current mapping functions is about 5-9 mm for the hydrostatic and about 3-4 mm for the wet assuming a wet delay of 10 cm. To more accurately determine the mapping function and its short-term variation, it is necessary to have information about the atmospheric profile above a site. We have therefore determined site-dependent mapping functions by raytracing atmospheric profiles derived by interpolation of gridded global data assimilation data. The hydrostatic mapping functions were then applied in the analysis of VLBI data. On tests with VLBI data from 20 CONT94 R&D experiments (January 1994), the baseline length repeatabilities were improved by about 0.2 ppb from 0.7 ppb. Raytracing of atmospheric data is not always practical, for example, in the analysis of daily GPS data from hundreds of sites. We consider site-dependent seasonal models derived from the assimilation model data and various approximations to full raytracing of atmospheric profiles.
Unmodeled atmospheric refractivity asymmetries can produce large errors in geodetic analysis. Typically gradient estimates from VLBI data, which typically have rms variations of about 45 mm at a 5 deg elevation angle, are correlated with gradients computed from data assimilation models with correlation coefficients of about 0.5-0.6. We investigate the use of the assimilation model gradients as an a priori estimate in the geodetic analysis.

ACHIEVEMENTS, TRENDS AND RESEARCH OPPORTUNITIES IN POSITIONING

Fritz K. BRUNNER, (Engineering Surveying and Metrology, Technical University of Graz, Steyrergasse 30, A-8010 Graz, Austria, email: brunner@aig.tu-graz.ac.at)

Currently Positioning is concerned with the scientific aspects of the following topics: measurement and analysis of regional and global geodetic networks, satellite and inertial positioning and applications of geodesy in engineering. Tremendous advances of GPS surveying have occurred especially in precision and applicability. Furthermore, GPS measurements have shown the potential to be used as a remote sensing tool of atmospheric parameters.
Traditionally the research in Positioning has been driven by the needs of National Survey Organisations and the geodetic community. However, it appears that the availability of better hardware and the nearly unlimited computational capabilities of today, allow the development of new geodetic methods for novel applications. Geodetic GPS arrays are already the backbone of crustal motion studies, development of new survey systems, deformation monitoring systems, and remote sensing systems of water vapour and electron content in the atmosphere. Fusion of data from GPS and other sensors will allow the development of new monitoring and positional control systems for engineering applications. A scenario for the future of Positioning and associated research opportunities will be discussed.

EFFECTS OF AURORAL IONOSPHERIC DISTURBANCES ON DGPS POSITIONING ACCURACIES

Susan SKONE (Department of Geomatics Engineering, University of Calgary, 2500 University Dr. NW, Calgary, Alberta T2N 1N4, Canada, email: sskone@ensu.ucalgary.ca); M. Elizabeth Cannon (Department of Geomatics Engineering, University of Calgary, 2500 University Dr. NW, Calgary, Alberta T2N 1N4, Canada, email: cannon@ensu.ucalgary.ca)

GPS satellite signals must travel through the dispersive ionosphere prior to being received at the Earth's surface, causing ranging/positioning errors dependent on both the given signal frequency and ionosphere electron content. This effect is the single largest source of GPS positioning error (up to tens of metres), outside of Selective Availability (errors intentionally imposed by the U.S. military). Ionosphere range errors may be mitigated through the use of differential GPS (DGPS) positioning algorithms, where range corrections are calculated at reference stations and transmitted to remote users. Accuracies of such differential techniques depend on the spatial decorrelation of ionospheric TEC, which can be significant in regions characterized by geomagnetic storm and substorm events, such as the auroral zone. These effects are expected to increase in the next few years, approaching solar maximum, with corresponding degradations in DGPS positioning accuracies. In this paper the spatial decorrelation of ionospheric range delay errors, and corresponding effects on DGPS positioning accuracies, are investigated during several recent geomagnetic substorm events at high latitudes. These events are representative of intense effects at solar maximum. Periods of auroral disturbances are identified from ground-based and space-borne magnetometer measurements and ultraviolet images. GPS observations are provided by the Natural Resources Canada wide area network, allowing extensive coverage of the auroral region.

IONOSPHERIC CALIBRATION CONSIDERING THE SATELLITE AND RECEIVER L1/L2 DIFFERENTIAL DELAY EFFECT ON SINGLE FREQUENCY GPS USERS

Caijun XU (School of Geo-Science & Surveying Engineering, Wuhan Technical University of Surveying and Mapping, 129 Luoyu Road, Wuhan, 430079,China, email: cjxu@hpb1.wtusm.edu.cn); Yong-qi Chen (Dept. of Land Surveying & Geo-Informatics, The Hong Kong Polytechnic University, Hung Hom, Kowloon, Hong Kong, email: lsyqchen@polyu.edu.hk); Jingsong Huang (Engineering Research Center for Satellite Positioning System, Wuhan Technical University of Surveying and Mapping, 129 Luoyu Road, Wuhan, 430079, China, email: huang@public.wh.hb.cn)

Since the ionosphere acts as a dispersive medium to GPS signals, dual-frequency(L1 at 1575.42MHz,L2 at 1227.60MHz) GPS receivers can eliminate(albeit to the first order) ionospheric delay through a linear combination of the L1 and L2 observations. However, this option is not available to single-frequency GPS receiver users. This kind of users needs an ionospheric model or ionospheric delay from GPS dual-frequency receiver at reference station in order to eliminate the ionospheric delay from the single-frequency measurement. However, both the satellite and receiver differential delay biases introduce error in the measurement of TEC or ionospheric delay (Coco et al., 1991,E. Sardon et al., 1994, Wilson, 1994, L.-S.Lin et al., 1996). They may result in an error of 9 TECU and 30 TECU respectively (Wilson et al., 1994). Without calibrating for this satellite and receiver differential delay, it is impossible to obtain precise TEC and ionospheric delay estimation from GPS measurements. Considering this factor, the satellite-plus-receiver (SPR) differential delays and ionospheric delay in real time at the DGPS universal reference stations in Hong Kong area are calculated, and they are applied to single-frequency GPS measurements in mobile stations. These mobile stations are used to gather GPS raw data, their distances to the DGPS universal reference stations are about 10km to 37km, the span time of gathering GPS data are about one hour to two hours. The results of ionospheric calibration considering SPR differential delay effects on single-frequency GPS positioning are discussed in the paper.

THE IMPACT OF RADOMES ON GPS HEIGHT ESTIMATES

Klaus KANIUTH, Klaus Stuber (Deutsches Geodaetisches Forschungsinstitut, Marstallplatz 8, D-80539 Muenchen, Germany, email: kaniuth@dgfi.badw.de)

GPS height estimates are sensitive to a number of modelling and processing strategy variations. These include the adjustment cut-off angle setting, the troposphere prediction model in combination with the applied mapping function and the selected antenna phase center variation model. In addition, during the past few years some time series of GPS position determinations showed significant jumps in the height estimates of up to several centimeters as a consequence of setting up or dismounting an antenna radome.
In order to contribute to the understanding of the interaction between protective radomes and the height estimation, we analyze in this paper the data set of a dedicated experiment as well as data collected by some permanently operating GPS stations. The analysis comprises several modern geodetic receiver/antenna systems and radomes either supplied by the manufacturers or individually designed by scientific institutions.

GPS AT TIDE GAUGES: IS MULTIPATH DUE TO WATER SURFACES A CONCERN?

Volker Janssen, Chris Rizos, Shaowei Han (School of Geomatic Engineering, The University of New South Wales, Sydney, AUSTRALIA)

A geodetic application receiving increased attention these days is the use of the GPS technology to survey tide gauge benchmarks in support of studies relating to sea level change. While such an application can be addressed using "conventional" GPS Geodesy techniques, whereby dedicated survey campaigns are carried out to collect epoch data subsequently processed using scientific GPS software, proposals have been made to install permanent GPS receivers at the tide gauge sites themselves. However, rather than monitor the tide gauge benchmark itself (which is generally located some distance from the tide gauge sensor), it has been suggested that the GPS antenna be installed right next to the tide gauge sensor. In such a configuration the antenna is often surrounded by the water surface. This paper presents the results of a study on how a GPS receiver, equipped with choke ring antenna, is affected by reflected signals from the water surface. Such multipath affects may need to be accounted for if ultra precise height estimates are to be obtained using the GPS technology.

AMBIGUITY RESOLUTION FOR PRECISE GPS/GLONASS POSITIONING

Jinling WANG, Mike Stewart, Maria Tsakiri, Troy Forward (School of Spatial Sciences, Curtin University of Technology, GPO Box, U1987 Perth, WA 6845, Australia,
email: Wang@vesta.curtin.edu.au)

When processing GLONASS or GPS/GLONASS carrier phases, the standard double-differencing (DD) procedure cannot cancel receiver clock errors due to the multiple frequencies of the GLONASS carrier phases. Consequently, the resulting normal matrix becomes singular. To deal with this problem, some methods have been proposed in the literature. These methods, however, rely on the use of pseudo-ranges. As contaminated by multi-path and hardware delays, biases in the pseudo-ranges are significant and may result in unreliable ambiguity resolution. This paper will address some critical issues in GPS/GLONASS ambiguity resolution. Firstly, both existing mathematical and stochastic modelling methods are critically reviewed and feasible modelling methods are identified. Secondly, a new approach for GPS/GLONASS ambiguity resolution is presented. Thirdly, a quality control procedure for GPS/GLONASS ambiguity resolution is discussed. Testing results of ambiguity resolution for GLONASS and combined GPS/GLONASS positioning will be demonstrated.

THE GIL NETWORK OF CONTINUOUS GPS MONITORING IN ISRAEL FOR GEODETIC AND GEOPHYSICAL APPLICATIONS

Shimon WDOWINSKI (Department of Geophysics and Planetary Sciences, Tel Aviv University, Ramat Aviv, Israel, email: shimon@geo1.tau.ac.il); Yehuda Bock (Institute for Geophysics and Planetary Physics, Scripps Institution of Oceanography, University of California, San Diego, USA, email: ybock@ucsd.edu); Yosef Forrai, Yosef Melzer (both at Survey of Israel, 1 Lincoln St., Tel Aviv, Israel, email: forrai@soi.gov.il, melzer@soi.gov.il); Gideon Baer, Dov Levitte (both at Geological Survey of Israel, 30 Malchai Israel St., Jerusalem, Israel, email: baer@mail.gsi.gov.il)

GIL (GPS in Israel) is a network of 10 continuous GPS stations, in which 7 stations are operating and the additional 3 stations will be operative before 8/2000. The network is built, maintained, and operated by researchers from Tel Aviv University, Scripps Institution of Oceanography, the Survey of Israel and the Geological Survey of Israel and is funded by the Israel Space Agency and by the Survey of Israel. It provides a reference network for precise GPS measurements in Israel and serves basic and applied research, including (1) monitoring plate motion and crustal deformation across the Dead Sea Fault, and (2) mapping atmospheric water vapor content. Preliminary results from 18 months of continuous GPS measurements reveal that the current displacement rate between Tel Aviv and Katzerin (Golan) is 2.3+-0.9 mm/yr, reflecting interseismic deformation across the Dead Sea Fault due to 5-6 mm/yr of relative motion between the Sinai and Arabian plates. Further collection, processing and analysis of the GIL network data can verify the preliminary results in a higher confidence level and will provide a detailed description of the current deformation pattern along the Dead Sea Fault.

SYSTEMATIC EFFECTS IN GPS DOUBLE DIFFERENCE PHASE RESIDUALS

Juan MOIRANO (Facultad de Ciencias Astronomicas y Geofisicas, Universidad Nacional de La Plata, Paseo del Bosques s/n, 1900 La Plata, Argentina, email: jmoirano@fcalp.fcalp.edu.ar); Klaus Kaniuth (Deutsches Geodaetisches Forschungsinstitut, Marstallplatz 8, D- 80539 Muenchen, Germany, email: kaniuth@dgfi.badw.de)

Compared to the precision resulting from the least squares adjustment or from solution repeatabilities the accuracy of GPS positioning estimates may be worse by up to one order of magnitude. This degradation is due to modelling errors which will not show up in the adjustment results as long as network geometry, processing strategy and models remain unchanged. However, systematic structures in the adjustment residuals may be indicators of modelling errors and may help identifying the responsible error sources. Therefore, this paper analyzes a large number of double difference phase residuals series resulting from adjustments using the Bernese GPS software 4.0. The analysis comprises most of the presently available geodetic receiver and antenna systems and data sets acquired in regional and local networks in Europe and South America. Particular emphasis is put on identifying troposheric refraction asymmetries, mapping function errors as well as phase center variation model discrepancies.

THE AUTOMATED GPS NETWORK FOR SWITZERLAND (AGNES)

Urs WILD, René Hug, Thomas Signer, Adrian Wiget (Swiss Federal Office of Topography (S+T), Seftigenstrasse 264, CH-3084 Wabern, email: urs.wild@lt.admin.ch)

The Swiss Federal Office of Topography (S+T) is establishing a network of permanent GPS track-ing stations in Switzerland, named the Automated GPS Network for Switzerland (AGNES). The main goals of AGNES are:
- Reference for national and engineering surveys
- Reference for differential navigation applications
- Research (geodynamics, atmosphere)

Currently 9 stations are already operating and the network will be densified according to the needs for real-time kinematic (RTK) applications using an adapted WADGPS approach for phase observations.
The poster outlines the general concept of AGNES, describes the station hard- and software and gives first results of the daily geodetic processing (including the estimation of troposphere parameters) as well as of the first field tests for RTK applications using GSM mobile phones.

PRECISION GPS/GLONASS GEODETIC ANTENNA CALIBRATIONS

Thomas A. CLARK (Laboratory for Terrestrial Physics, NASA/GSFC, Greenbelt MD 20771 USA, email: clark@tomcat.gsfc.nasa.gov); Bruce R. Schupler (AlliedSignal Technical Services Corp., Lanham, MD 20706, USA, email: schuplb@thorin.atsc.allied.com)

For a number of years, we have used the microwave anechoic chamber at GSFC for a series of calibrations of antenna parameters which impact the accuracy of GPS geodetic observations. These include the geometric location of the antenna's phase center, amplitude and polarization responses, and the effects of objects in the vicinity of the antenna. Last year, the indoor antenna range was completely refurbished with new microwave instrumentation, data acquisition system, and a more stable antenna positioner. We report on measurements

made with the new antenna range and compare them to our earlier published results.
The new capabilities have allowed us to extend the frequency coverage to span the entire 1.2-1.6 GHz band used by GPS and GLONASS. We report on the measured phase center variations of standard "DM" geodetic choke ring antennas (designed by JPL and used at many permanent IGS GPS stations) over the full ~40 MHz bandwidth of L1 and L2 GPS and GLONASS signals, and at the possible new L3 frequencies.
Our earlier presentations included measurements designed to understand effects of "real world" conductive and dielectric objects in the near-field of the antenna such as mechanical mounting fixtures, protective radomes, and the antenna's mounting pier. We report on new measurements of these effects that our new anechoic chamber capabilities have allowed us to emulate.

A SOLUTION OF THE ON-THE-FLY DUAL-AMBIGUITY-PROBLEM FOR LONG BASELINES

Stefan LEINEN (Institute of Physical Geodesy, Petersenstr. 13, 64287 Darmstadt, Germany, email: stl@ipgs.ipg.verm.tu-darmstadt.de)

Kinematic applications of GPS, aiming at highest accuracy, require a reliable ambiguity resolution On-the-Fly. In case of long baselines (25 km and more) the ionosphere free linear combination of phases has to be applied to remove the major error effect, namely the ionospheric refraction. Before this the dual-ambiguity-problem has to be solved completely.
By a complete solution of the dual-ambiguity problem the determination of the ambiguities of both the L1- and L2-phases is meant. In case of long baselines this is usually done in two steps: at first the correct set of wide lane ambiguities is identified by some kind of search algorithm. Keeping these widelane ambiguities fixed the common approach is to resolve the narrow lane ambiguities in the second step. This step is the critical and limiting aspect of this approach due to large residual error effects in the observable compared to to wavelenght.
In this presentation a discussion of this narrow lane problem and the inherent error effects will be given. A mathematical model revealing the drawback of this narrow lane method compared to other phase linear combinations will be presented. This leads to an alternative strategy with solving for the ambiguity of a phase linear combination better suited than the narrow lane. Additionally the superiority of the new method will be shown by results of various experiments and real data evaluations.

IONOSPHERE-INDUCED-RAY-PATH BENDING EFFECTS IN PRECISION SATELLITE POSITIONING SYSTEMS

Victor H. RIOS (Laboratorio de Técnicas Satelitales, Instituto de Física, UNT. Avenida Indepen-dencia 1800 -(4000), San Miguel de Tucumán, Argentina); Norbert Jakowski (DLR/DFD Remote Sensing Station , Neustrelitz, Germany)

In precise satellite-based positioning systems, propagation errors represent a major factor in the measurement accuracy. Due to the dispersive properties of the ionosphere, first order effects may easily be eliminated with dual frequency receivers.
The aim of this paper is to discuss refraction-induced errors due to ray path bending. Although relatively small, such errors may play a certain role in geodetic applications particularly since they are not completely compensated by linear difference methods commonly used.
Numerical ray-tracing methods were used to determine the excess path length as a function of both, geometrical -as well as medium-describing parameters. The analysis takes into account a large number of samples covering a wide range of variability in geometry and ionospheric behaviour. The derived quasi-empirical formulas for estimating the excess path length need only a few parameters.The results are discussed in relation to their possible use in satellite navigation systems such as NNSS, DORIS, and GPS over Argentina.

G1/W/29-A3 Poster 1620-12

PRECISE REAL TIME POSITIONING IN REGIONAL GPS REFERENCE STATION NETWORKS UNDER THE INFLUENCE OF INCREASING IONOSPHERIC ACTIVITIES

Stefan WILLGALIS (Institut fuer Erdmessung, University of Hannover, 30165 Hannover, Schneiderberg 50, Germany, email: willgalis@mbox.ife.uni-hannover.de); Cord-Hinrich Jahn (Landesvermessung + Geobasisinformation Niedersachsen, 30659 Hannover, Podbielskistr. 331, Germany, email: jahn@lgn-3.h.uunet.de)

Within the research project HPPS II a network of DGPS reference stations with an average spacing between 40 and 60 km is being set up in Lower Saxony. Carrier phase based precise differential (PDGPS) corrections are provided in real time. Targeting the 1 cm accuracy, this reference network is built to satisfy the precise positioning needs for land and cadastral surveys as well as for precision navigation in various applications. Critical for precise real time positioning are ionospheric disturbances. The upcoming maximum of solar cycle 23 predicted for 2000/2001 will make this situation even worse. Depending on the distance from the nearest reference station, the positioning accuracy will be degraded, and ambiguity fixing in real time will be impeded - if not impossible. To minimize the ionospheric error, as well as other distance dependent errors, the reference stations are interlinked, i.e. the differential corrections are exchanged, coefficients for network correction are computed, and transmitted to the user. Results of measurements in the Lower Saxony test network, which show the influence of ionospheric activities, will be presented. Solutions derived from standard differential corrections will be compared with positioning results obtained from network corrections.

G1/W/30-A3 Poster 1620-13

THE DESIGN AND APPLICATION OF DATA PROCESSING AND SOFTWARE FOR THE GPS AUTOMATIC MONITORING SYSTEM FOR DAM DEFORMATION

Jingnan LIU, Shaoquan Xu, Zhenghang Li, Kongzhe Chen, Weiping Jiang, Liwen Dai (School of Geoscience and Surveying Engineering, Wuhan Technical University of Surveying and Mapping, 129 Luoyu Road, Wuhan 430079, China, email: jnliu@wtusm.edu.cn)

This article expounds a general method of designing GPS automatic monitoring system for the external deformation of concrete dam in hydroelectric power stations, especially the design scheme of automatic data acquisition, processing, management, analyzing and relevant systemic software. It introduces an important example of the application of this scheme: in one of the crucial branches of Yangtse River - Qingjiang River in Hubei Province - a GPS automatic monitoring system for external dam deformation has been established in the Geheyan reservoir there. After 18 months of continuous operation, especially during the period of the unusual flood in Yangtse River in 1998, it is testified that this design scheme can meet the request of technical specification for dam deformation monitoring. With this scheme, the availability can reach 99.95%, and the reliability can reach 96%. The accuracy for determination of horizontal deformation is higher than ¡Á1mm, and the accuracy for determination of vertical deformation is higher than ¡Á1.5mm, based on 2 hours of GPS static monitoring data. The response time of automatic data processing and analyzing is less than 10 min. This GPS automatic monitoring system for dam deformation has played a key role in the unusual flood of Yangtse River in 1998. Under its continuous real time monitoring, sluice level of Geheyan was 4 meters higher than prescriptive water level and the external dam deformation reached 16mm, which is still within the security limitation after examination. Thus it insured the sequent over-water-level sluice in Geheyan reservoir and the success of staggering the overlap of the two flood peaks in the Qingjiang River and in Yangtse River.

VARIABILITY OF GPS ERRORS ON-SITE - INVESTIGATIONS OF ANTENNA PCV AND MULITPATH TOWARDS A STATION CALIBRATION

Volker BOEDER, Falko Menge, Guenter Seeber (Institut fuer Erdmessung, Universitaet Hannover, Schneiderberg 50, D-30167 Hannover, Germany, e-mail: boeder@mbox.ife.uni-hannover.de); Gerhard Wuebbena, Martin Schmitz (Geo++® GmbH, Steinriede 8, D-30827 Garbsen, Germany, e-mail: geopp@ibm.net)

The Institut fuer Erdmessung (IfE) and the Geo++® company extensively carry out research in the field of GPS antenna calibration. With the improving GPS precision the whole error budget 'on-site' demands increased attention, especially to antenna behavior and to multipath. One task is the absolute calibration (here done in the field) of the phase center variations (PCV) of the used antenna types. These results must be site- independent in order to have a model as precise as possible for a certain antenna type, which hence can be used everywhere. With the knowledge of PCV the next task is the verification and determination of multipath effects and its variability on 'on-site' observables and coordinates, which might be input for an adequate station dependent model. Since the results should be precise, consistant, reliable and be fast attainable, an automation is desirable. Therefore, the use of a robot is currently implemented for the field work. In this poster, several investigations and results concerning the variability of site dependent errors and steps towards a station calibration are presented.

G1/W/33-A3 Poster 1620-16

DEFORMATION MONITORING USING SINGLE-EPOCH GPS DATA

Mike STEWART (School of Spatial Sciences, Curtin University of Technology, GPO Box U 1987, Perth WA 6845, Australia, email: stewart@vesta.curtin.edu.au); Maria Tsakiri (School of Spatial Sciences, Curtin University of Technology, GPO Box U 1987, Perth WA 6845, Australia, email: tsakiri@vesta.curtin.edu.au)

Precise measurement of displacements of large structures is one of the most important activities in engineering surveying as results can indicate subtle damage that could be of concern to public safety. The use of permanent GPS positioning arrays can provide continuous and timely monitoring of deformations of multiple points but with a prohibitive cost for implementation if many localised points must be monitored. Instead, it is desirable to conduct episodic occupations of the points of interest whilst retaining many of the advantages of continuous monitoring. In practice, episodic monitoring using kinematic GPS techniques can be undertaken for a fraction of the expense of running a typical permanent antenna array but at the cost of a loss of the information and precision which may be obtained from permanent local arrays. This paper explores the resolution of single epoch GPS data for the episodic monitoring of large, slowly moving structures. Single epoch GPS data are supplemented by knowledge of the a priori location of the monitoring points and the mode of deformation to aid ambiguity resolution, solution quality and reliability. Data from an episodic GPS deformation monitoring regime on the North Dandalup dam in Western Australia is analysed. Since 1995, some 60 points have been monitored using GPS and conventional surveying techniques. The time interval between surveys has been aproximately three months. Results using single epoch GPS carrier phase data are presented and compared with results from the conventional surveys.

G1/W/35-A3 Poster 1620-17

PLANNING OF KINEMATIC GPS INCLUDING REALISTIC OBSTACLES DESCRIPTION

Domenico SGUERSO, Paolo Zatelli (Dpt. Ingegneria Civile e Ambientale, Università degli Studi di Trento Via Mesiano 77, 38050 Trento, Italy, email: domenico.sguerso@ing.unitn.it, paolo.zatelli@ing.unitn.it)

A good planning is a key factor for the success of a GPS survey. A realistic forecast of the DOP requires to take into account the obstacles that can hide part of the sky. This is specially true in a mountaneous region (natural obstacle) and in the urban area (artifact obstacle). In practice it is relatively easy to take into account the various obstacle in the planning of a static survey, but it is more difficoult to do the same for a kinematic survey. In the present work an authomatic procedure for the planning of a kinematic survey has been realized with a dedicated procedure inside a GIS. The realized procedure is interfaced with the almanac, a DHM for the planning in M.A. and a carthographic data base for the planning in urban areas (still in project) and computes the DOP with the standard algorithm for the points in a given trajectory.

G1/W/40-A3 Poster 1620-18

RTK GPS POSITIONING USING MULTIPLE REFERENCE STATIONS

Jinglin WANG, Mike Stewart (School of Spatial Sciences, Curtin University of Technology, GPO Box, U1987 Perth, WA 6845 Australia, email: Wang@vesta.curtin.edu.au)

Real-time kinematic (RTK) GPS positioning techniques have being widely used in surveying and navigation. In RTK GPS positioning, both measurement bias elimination and integer ambiguity resolution are critical issues. For short-range kinematic positioning, differencing GPS measurements collected from both roving and reference receivers can virtually cancel many measurement biases, such as satellite orbital bias, ionospheric and trospheric biases,

and thus, integer carrier phase ambiguities can be easily identified. For long-range kinematic positioning, however, integer ambiguities become increasingly difficult to resolve as the residual biases in the differenced measurements are significant. To efficiently reduce the magnitude of residual biases, a RTK positioning strategy using multiple reference stations has been developed. Basic idea behind this positioning strategy is combining the measurements from precisely determined multiple reference stations to estimate and then correct the measurement biases.
Following a critical review of the existing methods, this paper will present a new approach to RTK positioning using multiple reference stations. An advantage of this proposed approach is that it fully exploits the intrinsic relationship between reference stations and thus, has an optimal performance in practical applications. Some preliminary results will be presented.

G1/E/01-A3 Poster 1620-19

PHASE CENTRE VARIATIONS IN HIGH PRECISION KINEMATIC GPS SURVEYS

Fritz K. BRUNNER, H. Hartinger, A. Wieser (Engineering Surveying and Metrology, Technical University of Graz, Steyrergasse 30, A-8020 Graz, Austria, email: brunner@aig.tu-graz.ac.at)

For high precision kinematic GPS applications the phase centre variations (pcv) have to be taken into account. In general the pcv values depend on the horizontal and vertical angle-of-arrival of the signal with respect to the antenna, however, they are assumed to be equal for the same antenna type. In kinematic applications the orientation of the rover antenna in relation to the reference antenna may change and thus the pcv differences need to be considered. We present an experimental field set-up to verify whether two antennas have the same pcv and to measure the azimuthal pcv variations of antennas having different orientations. The pcv values are determined as single differences using a special GPS sensor system which allows the elimination of the receiver clock errors. The results of the experimental determination of the azimuthal pcv of several antenna types shall be presented.

MITIGATION OF SIGNAL DIFFRACTION EFFECTS ON PRECISE GPS-POSITIONING

Lambert WANNINGER, Volker Frevert, Steffen Wildt (Geodetic Institute, Dresden University of Technology, D-01062 Dresden, Germany, email: Lambert.Wanninger@mailbox.tu-dresden.de)

GPS signal diffraction is a common error source in precise GPS positioning if obstructions exist above the antenna horizon. It occurs whenever the direct signal is obstructed but nevertheless a diffracted signal is received and processed. The longer propagation time of the diffracted signal causes carrier phase errors of up to several cm. A common characteristic of all diffracted signals is their weaker signal power as compared to the corresponding direct signal.
We have tested several weighting and selection algorithms for mitigation of signal diffraction effects on GPS data processing, i.e. on ambiguity resolution and on coordinate estimation. They are based either on the observed signal power level (e.g. the SIGMA-Delta weighting algorithm suggested by Brunner et al. 1998) or on the estimated observation residuals. The ability to automatically detect diffraction effects and to process the observation data accordingly significantly improves ambiguity resolution and GPS position accuracy.

RAPID GPS AMBIGUITY RESOLUTION OVER MEDIUM RANGE DISTANCES

Paul DE JONGE, Yehuda Bock (both at Scripps Institution of Oceanography, University of California, San Diego, La Jolla, CA 92093-0225, USA, email: deJonge@lox.ucsd.edu)

Resolving the phase ambiguities is the key to fast high precision GPS positioning. The main factor preventing a successful estimation of the integer ambiguities, is the delay experienced by the signal while traveling through the ionosphere; more specifically, it is the difference in delay at the two end points of the baseline that is important. Some factors that may influence the size of the ionospheric delay are: geographical location, orientation of the baseline, diurnal cycle, 11-yearly sun spot cycle, and the length of the baseline.
In this contribution we show how different circumstances influence the ambiguity resolution for a number baselines in Southern California with lengths of up to 100 km. The analysis was done using the MIT/SIO GPS processing software (GAMIT). The existing algorithm to form orthogonal observables from the phase observables and ionospheric pseudo-observables was extended to include also pseudorange observables to enable instantaneous positioning. For the integer estimation of the ambiguities, the Least-squares AMBiguity Decorrelation Adjustment method (LAMBDA) was implemented.

PRECISE POSITIONING WITH THE USE OF JPS LEGASY GPS/GLONASS RECEIVERS AT THE REMOTE SITES OF RUSSIA

Javad ASHJAEE, Viktor Iodis, Andrey Maiorov, Konstantin Saliy, Pavel Tolkachev (all at Javad Positioning Systems, 1731 Technology Drive, San Jose, CA 95110, email: javad@javad.com); Gleb Demianov, Vladimir Kaftan, Viktor Kashaev, Nikolay Makarenko, Vladimir Zubinsky (all at Central Research Institute of Geodesy, Aerial Surveying and Cartography, Onezhskaya 26, 125413 Moscow, Russia)

Several JPS Legasy receivers were installed at the remote Russian sites Ekaterinburg, Yakutsk, Magadan and Petropavlovsk-Kamchatsky situated in Ural, Siberya and Far Eastern regions. GPS/Glonass observations were performed during the latest part of the IGEX98 field campaign in severe climate conditions. The observation points covered the large part of Russian territory which enabled to improve the homogeneity and global distribution of the IGEX98 stations. Some practical and instrumentation recommendations were made. The coordinate determination results are also discussed.

THE ANTENNA CALIBRATION OF THE FINNISH PERMANENT GPS NETWORK (FINNREF)

Antti Kylkilahti, Hannu KOIVULA, Markku Poutanen (Finnish Geodetic Institute, P.O.Box 15, 02431 Masala, Finland, email: hannu.koivula@fgi.fi, markku.poutanen@fgi.fi)

The Finnish permanent GPS network (FinnRef) was established mainly to study the crustal deformations in Finland by the Finnish Geodetic Institute (FGI). One big unmodelled error source is the antenna phase centre variation. It contains of two components: phase centre offset and antenna phase centre variation (PCV). The purpose of this study was to determine the zenith angle dependent PCV and the vertical phase centre offset of nine stations of the FinnRef using the field calibration method. During summer 1998 FGI performed a test campaign and an actual field campaign to calibrate 9/12 antennas of the FinnRef. Data processing the Bernese GPS software 4.0 was used. We describe both the test campaign and the field calibration campaign and show the results of the calibration.

COMPARISON OF INDEPENDENTLY DERIVED ATMOSPHERIC PARAMETERS

Dirk BEHREND, Antonio Rius (both at Institut d'Estudis Espacials de Catalunya, Edif. Nexus-204, Gran Capita 2-4, 08034 Barcelona, Spain, email: behrend@ieec.fcr.es); Lubomir P. Gradinarsky, Ruediger Haas, Jan M. Johansson (all at Onsala Space Observatory (OSO), Chalmers University of Technology, SE-439 92 Onsala, Sweden, email: geo@oso.chalmers.se); Stephen J. Keihm (Mail Stop 246-101, Jet Propulsion Laboratory, 4800 Oak Grove Drive, Pasadena, CA 91109, USA, email: Stephen.J.Keihm@jpl.nasa.gov)

Atmospheric parameters can be estimated using different space geodetic and remote sensing techniques. The stations Madrid (Spain) and Onsala (Sweden) have colocated equipment for space geodetic measurements using Very Long Baseline Interferometry (VLBI) and the Global Positioning System (GPS) and are equipped additionally with Water Vapor Radiometers (WVR).
Observations using these three micro wave techniques are affected by the atmospheric propagation delay of radio waves. Simultaneous observations with the three techniques allow the comparison of atmospheric parameters derived from each of the techniques.We will present a comparison of zenith wet delay and horizontal North and East gradients for simultaneous observation epochs for Onsala and Madrid. The GPS data will be analyzed using different software packages (GIPSY, GAMIT, Bernese). The results will be intercompared and compared to the results of other techniques. Apart from this an additional comparison with meteorological models will provide an independent check of the parameter retrieval.

INTEGER AMBIGUITY SEARCH IN THE COORDINATE AND AMBIGUITY DOMAINS USING CONDITIONED ADJUSTMENT

Guochang XU (National Survey and Cadastre - Denmark Rentemestervej 8, DK-2400 Copenhagen NV, Denmark)

An integer ambiguity search method based on conditioned adjustment theory is proposed in this paper. This method has been implemented in a GPS software KSGSoft (Kinematic/Static GPS Software, developed in GFZ Potsdam) and used for extensive real data processing of EU project AGMASCO. The search can be carried out in coordinate domain or in ambiguity domain or in both domains by using this technique. The most published least squares ambiguity search methods are a special case of this algorithm, if only ambiguity search domain is selected and without considering the uncertainty of ambiguity. A general criterion for ambiguity searching is then obtained to ensure an optimal search result. Detailed formulas are derived and their usages are outlined.

PRECISE REAL-TIME POSITIONING IN WADGPS NETWORKS

Günther RETSCHER (Department of Applied and Engineering Geodesy, Vienna University of Technology, Gusshausstrasse 27-29 E128/3, A - 1040 Wien, AUSTRIA, email: gretsch@pop.tuwien.ac.at); C H Jason Chao (Department of Land Surveying and Geo-Informatics, The Hong Kong Polytechnic University, Hung Hom, Kowloon, HONG KONG, e-mail: lschchao@polyu.edu.hk)

Local DGPS services have been established all over the world for many different kind of applications. However, the main disadvantage of Local Area DGPS Systems (LADGPS) is that position accuracy of a user degrades as the reference-to-user separation increases. Therefore Wide Area DGPS Systems (WADGPS) are being developed to overcome the main drawbacks of LADGPS. The spatial decorrelation of the error sources, i.e. the atmospheric propagation and satellite orbit errors, are the main causes for the degradation of position accuracy. The combination of the measurements of several reference stations can be used to model these error components separately. To achieve position accuracies better than 5 m (95 %) the satellite orbits have to be determined with an accuracy of the order of 10 m using pseudorange data from three different reference stations and atmospheric models need to be estimated. For real-time positioning the orbit and atmospheric models need to be predicted ahead.
The covered area of the LADGPS system is also limited by the perceived range of the used HF/MF radio systems. Satellite based DGPS systems became both commercially and technically feasible with the introduction of broadcasting via geostationary satellites at the start of the decade; available services are e.g. Fugro OmniStar and Racal LandStar. A annual subscription service charge for the receiving of corrections has to be paid. Most users are completely satisfied with code DGPS services for horizontal positioning. However, for special applications and for vertical positioning accuracies on the decimetre or few centimetre level are required. Therefore real-time kinematic positioning with carrier phases and OTF (on-the-fly) ambiguity resolution strategies have to be applied.

EXTRACTING IONOSPHERIC INFORMATION USING GPS MEASUREMENTS

Claudio Brunini (Facultad de Ciencias Astronómicas y Geofísicas, Universidad Nacional de La Plata, Buenos Aires, Argentina, email: claudio@fcaglp.fcaglp.unlp.edu.ar); María Andrea Van Zele (Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires y CONICET, Buenos Aires, Argentina, email: avanzele@tango.gl.fcen.uba.ar); Amalia Meza (Facultad de Ciencias Astronómicas y Geofísicas, Universidad Nacional de La Plata, Buenos Aires, Argentina, email: ameza@fcaglp.fcaglp.unlp.edu.ar); Mauricio GENDE (Facultad de Ciencias Astronómicas y Geofísicas, Universidad Nacional de La Plata y CONICET, Buenos Aires, Argentina, email: mgende@fcaglp.fcaglp.unlp.edu.ar)

Signals from GPS satellites received at the surface of the earth have passed through the terrestrial atmosphere and are therefore affected by refraction in the ionosphere and the lower neutral atmosphere. In Geodesy and in Astrometry these refraction effects are typically seen as a nuisance and are removed from the measurements using appropriate models. The complementary point of view is that the refraction effects in GPS measurements contain useful information accumulated by passing through the atmosphere. In this scenario, the ionospheric and tropospheric delay are seen as remotely sensed data related to atmospheric parameters, with the possibility to recover some or all of these parameters through proper data analysis.
The main goal of this kind of ionosphere research is to make use the capability of these observations to continuously and routinely ionosphere monitoring at global scale. In particular, we will focus in the estimation of parameters describing the distribution of free electrons in the ionosphere and their changes along time. We describe the algorithms used to produce ionospheric global maps automatically. We analyse the GPS observations collected in some years by around forty earth stations globally distributed and we discuss the correlation between some estimators obtained from the ionospheric model and the geomagnetic and solar activity.

FAST AMBIGUITY RESOLUTION USING THE GPSEQ SOFTWARE

Joco Francisco Galera MONICO, Wagner Carrupt Machado (both at Department of Cartography, Sco Paulo State University UNESP, Presidente Prudente, CEP 19060-900, BR, email: galera@prudente.unesp.br)

GPSeq is a software under development at the Department of Cartography, FCT/UNESP, to process GPS data. At the present stage, it allows to process GPS baselines taking into account single frequency data only. A recursive processing algorithm with outliers detection was applied. The double differences of phase and pseudorange are the basic observables. For ambiguity resolution, the LAMBDA method, developed at the Delft University of Technology, is used. It is intended that in the future the software can also allow the processing of double difference receiver data, using broadcast or IGS predicted orbits. At such a case, instantaneous ambiguity resolution is possible. Some experiments were carried out using GPSeq. GPS data files collected in Brazil, forming baselines of up to 10 km were processed. The results have shown that the ambiguities can be solved within four minutes period of data collection at 15 seconds sample rate. In this paper, a brief description of the software is presented, together to the description of the several tests carried out. Additionally, the quality control approach used to evaluate the results is presented, as well as the future plans to upgrade the software

USING GPS OBSERVATIONS TO DETERMINE VERTICAL REFRACTION IN ZENITHAL OBSERVATIONS

Jorge PINTO, Helena Ribeiro (Instituto Português De Cartografia E Cadastro, Rua Artilharia 1 , nº 107, 1070 Lisboa, Portugal, email: jtpinto@ipcc.pt, lenarib@ipcc.pt)

The great precision and accuracy that nowadays is ensured by the GPS technique provide an interesting mean to estimate the vertical refraction in classical theodolite ground to ground vertical observations, which is the limiting factor of using simultaneous and reciprocal zenithal distances observations, as a tool to determine geoidal ondulations height differences. The authors conceive and realize some experiences that shows the possibility to evaluate, with enough precision, the refraction angle in both stations and so, to estimate the existing geoidal height difference between the both stations. This experiences were made in Geobase, Estremoz, which is a precise geodetic test network facility, existing in South Portugal, near the Spanish border. The test facility provide distances that ranges between some hundreds meters to 15 kilometers. Due to terrain constraints, lack of time and also financial problems only a short number of sides were observed, but the experiences made were quite impressive, leaving no need to perform more to validate the method. The range can easily be, with the appropriate instrumentation, widened to greater distances, than the 15 kilometer provided by Geobase. Actually, as greater the distance and the height difference between the stations, as smaller the relative error in the vertical angle refraction determination.

PROGRESS IN TRIAL STUDY ON RAINFALL ESTIMATION BY GPS TECHNOLOGY

Li YANXING, Hu Xinkang, Wang Min (First Crustal Deformation Monitoring Center, China Seismological Bureau, Tainjin, 300180, P.R. China, email: dzjl@shell.tjvan.net.en); Xu Baoxiang, He Ping, Yang Hongmei (Chinese Meteorological Seientific Research Institute, Beijing, P.R. China)

In the paper, a new model for atmospheric refraction delay, a Tm calculation model and a model for calculating the precipitation of atmospheric column height have been established by the authors. Cooperated with Chinese Meteorological Scientific Research Institute, storm observation test by GPS technology was carried out on three meteorological stations in South China from May to June däl 998. The test results indicate that the precipitation value calculated from GPS data is very close ,In the value calculated from the data observed by meteorological sounding; The highperiod precipitation calculated from GPS data is highly interrelated to the actual rainfall process; For a heavy rainfall, the precipitation generally has an increasing process before the rainfall and a decreasing process when the rainfall is ended; Before the occurrence of a sudden storm, the precipitation is often to increase abruptly by a big margin; Before a heavy storm, there is a very obvious developing period lasting for a rather long time.

OPTIMAL INTERPOLATION OF IONOSPHERIC DELAY FOR A VIRTUAL GPS STATION

Inseong Song, H. VAN DER MAREL (Delft University of Technology, Thijsseweg 11, 2629 JA Delft, The Netherlands, email: H.vanderMarel@geo.tudelft.nl)

In the Netherlands a network of five permanent GPS receivers is operated. The data from the permanent stations is sent every hour to a computing centre, from where the data can be downloaded using an a flexible World Wide Web interface. A new feature is the so-called virtual GPS station. In this innovative approach the network of GPS stations is used to generate data for a non-existing receiver at a location selected by the user. The purpose of the virtual station is to let the user benefit from all the advantages of a network approach, including reduced observation times, without changing the processing from the user point of view. In order to compute virtual station data, atmospheric delays must be computed at the virtual station. This is done by an optimal least squares interpolation method. The method has been tested on the slant ionospheric delays computed from dual frequency GPS phase measurements from the network of reference stations. The interpolation routine is able to handle double differenced ionospheric delays, or the appropriate estimable functions in case of undifferenced processing.

TRANSFORMATION OF THE CLASSIC TRIANGULATION IN POLAND INTO EUREF REFERENCE SYSTEM

L. JAWORSKI, J.B. Zieliński (Space Research Centre, Polish Academy of Sciences, 00-716 Warsaw, Poland, email: leszek@cbk.waw.pl); S.Gelo (National Office of Geodesy and Cartography, Warsaw, Poland)

The classic triangulation network in Poland has been constructed over many decades, using data from different sources and different measurement campaigns. Number of solutions was produced, among them the solution which was part of the unified eastern block geodetic network adjustment. All these solutions are compared with the modern GPS solution named POLREF, which is part of the European Reference Frame EUREF. It allowed assessing the quality of old solutions and after transformation to include large part of the old network in the modernised network. No important errors were found in old solutions but some weak segments of the network could be identified. The comparison with the last classic solution gives the scaling factor equal to 0.9999997 and the average deformation on the level of 10 cm.

INVESTIGATION OF SITE DISPLACEMENTS DUE TO TIDAL LOADING EFFECTS FOR GPS ARRAY IN TAIWAN

Chia-Chyang CHANG (Department of Surveying and Mapping Engineering, Chung Cheng Institute of Technology, Tahsi, Taoyuan 335, Taiwan, email: ccchang@cc04.ccit.edu.tw)

High precision GPS measurements are always required for many scientific applications, such as the establishment of national geodetic control networks, geodetic observations for the monitoring of crustal movement, deformation monitoring of main engineering structures, and the determination of global sea level changes. It is also essential to develop some strategies and techniques for GPS observation and data processing, in order to effectively enhance the accuracy of coordinates based on GPS measurements. One of the GPS error sources, based on the effects of tidal loading, can theoretically cause significant site displacements during the GPS observation. The effects of tidal loading, thus, have to be investigated if a higher level of GPS positioning accuracy is expected. It can be achieved through the use of a set of model tested with GPS data and defined for the tidal loading corrections.
Site displacements caused by the tidal loading effects, in terms of the polar tides and atmospheric pressure loading, are practically investigated in this paper in order to realise their influence on GPS positioning. These tidal loading models, also used by the IERS, have been tested with the auxiliary data required and the GPS data collected at the GPS tracking stations in Taiwan. The results show that the polar tides can reach the average displacements of 8 mm in height and 2 mm in plan coordinates over a time scale of one year. Moreover, the variations of vertical displacements caused by the atmospheric pressure loading can be as large as 10 mm for data observed in different seasons, and up to 25 mm for data collected at different sites in Taiwan area.

CHTRF98: THE FIRST RE-OBSERVATION OF THE SWISS GPS CONTROL NETWORK

Adrian WIGET, Elmar Brockmann, Dieter Schneider, Thomas Signer (Swiss Federal Office of Topography, Seftigenstr. 264, CH-3084 Wabern, email: adrian.wiget@lt.admin.ch)

Between 1988 and 1994 the Federal Office of Topography established a new GPS-based control network called LV95. This high-precision network, integrated in EUREF, consists of 104 main points and approx. 60 densification points. It realizes the reference frame (CHTRF95) for the new national geodetic reference system CHTRS95. The nationwide accuracies (1 sigma) of the coor-dinates relative to the SLR station Zimmerwald are better than 1 cm for the horizontal and 3 cm for the vertical components. However, modern high-precision geodetic networks are no longer static. The concept for the determination of a kinematic model for CHTRS95 (called CHTKM95) includes permanent measurements of the Automated GPS Network for Switzerland (AGNES) as well as periodic re-observations of LV95. In 1998 this network (plus some additional reference points in neighbouring countries) were re-observed for the first time using the 9 permanent AGNES stations and 14 mobile GPS receivers. The measurements were collected in a total of 15 night sessions and were processed with the Bernese GPS Software 4.1. Results of a kinematic analysis of the two sets of coordinates (CHTRF95 and CHTRF98), partly bridging a timespan of ten years, will be pre-sented. Further goals of the re-observation were: to determine a new set of coordinates (CHTRF98), thus improving the reliability of the existing CHTRF95 coordinates (in particular the ellipsoidal heights) to check the stability of the LV95 points and to verify the quality of the monumentations to combine LV95 with the AGNES and the EUREF permanent networks to improve the connections with modern GPS networks in neighbouring countries to provide a more homogeneous and more precise reference for future kinematic studies at the earliest time possible.

THE USE OF GPS TO ESTABLISH A ZERO-ORDER GEODETIC DATUM IN MALAYSIA

Zarina AHMAD-BERGER, Chris Rizos, A. H. W. Kearsley (at School of Geomatic Engineering, The University of New South Wales, Sydney, AUSTRALIA, email: z8635633@student.unsw.edu.au, c.rizos@unsw.edu.au, w.kearsley@unsw.edu.au); Peter Morgan (at School of Computing, University of Canberra, Canberra, AUSTRALIA, email: pjm@mawson.canberra.edu.au)

Over the last decade, precision GPS positioning has been used to strengthen the Malaysian geodetic datum. Several problems have been identified with the existing geodetic framework. For example, there is no homogeneous adjustment of the current levelling network. Also, the use of the existing tide gauge network as the basis for the vertical datum needs revisiting, and the Malaysian geodetic network needs to be transformed to an ITRS-based datum. Such "problems" have several consequences. For example how does one deal with the apparent sea surface slope between the east and west coast of the Peninsular Malaysia? Should the geodetic network be considered a one-off activity, or be subject to regular "maintenance" and be a dynamic datum? Such matters have an important impact on the allocation of material and human resources to Geodesy in countries such as Malaysia, which may not be able to justify the same level of investment as countries which are more prone to earthquake and other such natural hazards which can be monitored by geodetic observations.
At the heart of modern geodesy is the reconciliation of GPS Geodesy, a powerful technique for the definition of modern geometric datums, and gravimetric geodesy, which is required to transform GPS heights into orthometric heights and to define the vertical reference surface in a physically meaningful manner. The Department of Mapping and Surveying Malaysia (DSMM) in late 1998 established a permanent network of approximately 12 GPS stations throughout Malaysia. This paper considers what roles such a network could play in defining and maintaining the precise Geodetic Network, supporting mean sea level/tide gauge studies as well as providing the means of integrating the conventional leveling networks with gravimetric geoid models. In particular, the issue of how DSMM GPS processing may be meaningfully integrated with regional and global GPS networks using the "ITRF densification via SINEX files" approach will be addressed.

THE DETERMINATION OF COASTLINE VARIATION WITH GPS

Cláudia Pereira KRUEGER (Graduate Program in Geodetic Sciences, Federal University of Paraná, Centro Politécnico, CP. 19001, Curitiba, Paraná, Brazil, 82531-990, email: ckrueger@cce.ufpr.br); Carlos Roberto Soares (at Marine Studies Center, Federal University of Paraná, Avenida Beira-Mar s/n, CP 43, Pontal do Sul, Paraná, Brazil, 83255-000, email: soaresc@aica.cem.ufpr.br)

At the Paraná state coast can be observed many areas (like Mel island and Pontal do Sul resort) where the coastline is changing in response to progradation or retreat processes.

These variations can be detected by differentes alternatives: aerial photographies, satellite imagery, surveying with theodolites, levels and total stations and actually with GPS. The GPS has a simple application, continue availability and independence of weather conditions, becoming an atractive praticity. Since 1996 GPS has been used in the monitoring of some areas of the Paraná coastline, with the kinematic positioning. Initially the raw data was collected with Ashtech Z-XII receiver and post-processed with GEONAP-K software. Actually is being applyed the GNRT-K software, which permits results in realtime with high precision. The overlay of preliminary results allows the detection of the progradation and retreat areas, and the rates of these processes, which have variantions from centimetric to metric level.

IMPROVEMENTS IN INSTRUMENTATION, PERFORMANCE AND POSITIONING OF THE SLR TRACKING STATION AT SAN FERNANDO, SPAIN

Isabel VIGO-AGUIAR, Jose M. Ferrandiz (Dpt. Applied Mathematics, EPS, University of Alicante, E-03080-San Vicente, Alicante, Spain); Carmelo Belza, Jorge Garate, Jose Martin Davila, Manuel Quijano (Real Instituto Y Observatorio de la Armada, 11110- San Fernando. Cadiz. Spain); Dave Rowlands (Space Geodesy Branch, Code 926, NASA Goddard Space Flight Center, Greenbelt, Maryland 20771, USA)

The Royal Astronomical Observatory (RAO) of the Spanish Navy at San Fernando is strategically located near the Gibraltar Straight, by the boundary between the Eurasia and African tectonic plates. A satellite laser ranging (SLR) station, a Global Positioning System (GPS) station and a set of atomic clocks are co-located at this site. While routinely contributes to laser ranging to several satellites as well as the international time service, the San Fernando SLR station is engaged in an improvement process. We have made a complete overhaul of its electronics and its optics, enabling routine tracking of LAGEOS at about 200 successful LAGEOS night passes per year, while at the same time doubled the number of successful night passes for lower orbit satellites. With the substitution of the old dome for a new one, we are now in the process of improving the quality of the measurements. We have reduced the pulse width to 50 pcsecs. Currently we are in the process of installing a Single Photon Avalanche Diode (SPAD), we have already got, for the reception system. We are building a new calibration system, we have rebuilt some parts of the station control software, and we are investiating the time counter behaviour. On the other hand, we are automating the focusing and trying to smooth the telescope movements with a new control system. We hope that this work enable our station to get high quality performances. At the same time, better determinations of the site position have been obtained using the NASA software GEODYN. We obtain the solutions by fitting 10-day arc data from LAGEOS I in terms of normal points from the global SLR tracking network. Past determinations of the station coordinates with respect to ITRF had root-mean-square(RMS) values on the order of as large as 6 centimeters, hindering a representative contribution to the determination of satellite orbits and plate motions, as well as related geodetic studies. Now combining 3 months of data between March and May 1998, we derived a San Fernando station position with RMS bellow 3 centimeters. It is expected that more data will yield further and better adjustments of the station position.

POSITION CHANGES DUE TO RECENT CRUSTAL DEFORMATIONS ALONG THE CARIBBEAN - SOUTH AMERICAN PLATE BOUNDARY DERIVED FROM THE CASA GPS PROJECT

Klaus KANIUTH, Hermann Drewes, Klaus Stuber, Herbert Tremel (Deutsches Geodaetisches Forschungsinstitut, Marstallplatz 8, D-80539 Muenchen, Germany, email: kaniuth@dgfi.badw.de); Napole¢n Hern ndez (Servicio Aut¢nomo de Geograf¡a y Cartograf¡a Nacional, Edif. Camejo, Esqu. Camejo CSB, Piso 2, oficio 216, Caracas 1010, Venezuela, email: hernandez.sagecan@conicit.ve); Melvin Hoyer and Eugen Wildermann (La Universidad del Zulia, Apartado Postal 10311, Maracaibo, Venezuela, email: mhoyer@europa.ica.luz.ve); Hans-Gert Kahle and Alain Geiger (Eidgenoessische Technische Hochschule, HPV G 52, CH-8093 Zuerich, Switzerland, email: kahle@geod.ethz.ch)

The Central And South America (CASA) GPS project aims at monitoring crustal deformations in the tectonically complex area of interaction of the Caribbean, Cocos, Nazca and South American plates. Since its initialization in 1988 several GPS campaigns were performed by various institutions, unfortunately not always covering the whole area simultaneously.
This paper concentrates on presenting the latest estimates of deformations along the Caribbean - South American plate boundary as covered by the Venezuelan part of the project. The Venezuelan network has been regularly observed from early 1993 on. The eastern part suffered from an earthquake of magnitude 6.9 in July 1997 and a subsequent seismic activity culminating in another earthquake of magnitude 4.5 in December 1998. Our analysis comprises GPS data collected up to spring 1999 and provides estimates of linear horizontal velocities as well as discontinuous displacements in a global reference frame. The processing strategy for deriving velocities is outlined and the accuracy and reliability of the results is discussed.

SIMULATED ANNEALING - OPTIMISATION METHOD FOR GPS SURVEYING NETWORKS

Hussain SALEH, Peter Dare (Applied Geodesy Research Unit, School of Surveying, University of East London, Longbridge Road, Dagenham, Essex, RM8 2AS, UK, email: Hussain2@uel.ac.uk)

For Global Positioning System (GPS) epoch surveys, m receivers (m>1) are placed in a sequential manner on the n ground points whose coordinates are required. If n>m, as is usually the case in epoch surveys, then receivers will have to move between points to ensure that all points have been visited. When m receivers are observing simultaneously, this defines a session. When n>m, more than one session will be required to connect the points together to form a network. The list of sessions required to form the network is known as the schedule. Determining the best order of the sessions (i.e., determining the cheapest schedule) is not a trivial task and this paper describes an analytical approach to determining the optimal schedule given a list of sessions and the cost of moving receivers between points.
The approach is based upon the development of a Simulated Annealing (SA) heuristic technique for the optimisation of the scheduling of GPS receivers and gives examples of its application. In the design of GPS surveying networks there are difficulties in establishing good schedules for the network observation. The optimal schedule can be determined for relatively small networks using exact methods. Generally, however, solving large networks to optimality requires impracticable computing time. To avoid this, the SA technique provides near-optimal solutions for large networks within an acceptable amount of computational time when parameter values for the SA algorithm are correctly chosen.
Currently, an experienced surveyor in GPS surveying performs this task manually. In this research, the problem has been formulated as a Combinatorial Optimisation Problem (COP) and solved by making use of the SA algorithm. This technique enables the surveyor to generate an observation schedule for the whole network in an efficient manner. The developed SA algorithm is found to be very effective for solving schedule design problems and has been coded in Visual C++ under Windows NT. Computational results indicate that the SA heuristic technique, which has been validated using real data, consistently provides significantly better GPS receiver schedules than those established manually. The speed of the SA technique enables near-optimal solutions to be produced in a real-time environment.

A DETAILED MODELLING OF THE SOLAR RADIATION PRESSURE ACTING ON ERS SATELLITES

F. VESPE (Agenzia Spaziale Italiana-Centro di Geodesia Spaziale -Matera, Italy); R. Devoti, V. Luceri (Telespazio-Centro di Geodesia Spaziale -Matera, Italy)

In the last few years the weakening and deflection of the solar radiation through the atmosphere has been deeply investigated. An empirical model based on star light observations is proposed that combines both the geometric and physical effects of the penumbra transitions. The weakening and deflection of the solar radiation caused by the atmosphere are treated using the observed atmospheric data for the extinction and deflection of the star light that are usually collected during an astro-photometric calibration. These data are used to formulate the empirical relationship between the atmosphere's extinction and deflection and the height measured from the Earth's surface.
This model can be useful in enhancing the orbit modelization of Earth satellites of complex shape such as ERS-1 and ERS-2. A validation of the model is performed analysing the orbital residuals of both ERS satellites using SLR and PRARE data during the eclipses transitions.

OCEAN-LOADING DEFORMATIONS DERIVED FROM GPS OBSERVATIONS

M.S. SCHENEWERK (NOAA, SSMC3 1315 East-West Highway Silver Spring, MD 20910, USA, email: mark@tony.grdl.noaa.gov); T.M. van Dam, O. Francis (Observatoire Royal de Belgique, Avenue Circulaire, 3 B-1180 Bruxelles Belgium, email: tonie@oma.be)

The proliferation of continuously operating GPS tracking sites and improvements in estimating the vertical component of a site's position from GPS measurements presents a unique opportunity to directly observe the effects of ocean tidal loading. The long, continuous record from these permanent sites permits the coherent accumulation of observations with respect to the driving tidal forces. Techniques like this defeat atmospheric, geometrical, and multipathing effects which can have a comparable magnitude, but do not have the same periods as the ocean-loading signals.
A project is underway to estimate ocean-loading effects at selected sites in North America. Agreement with a priori estimates of height variation generated from existing models is excellent. This presentation will describe the technique used, results and the feasibility of extending this processing globally. The significance of these results for local, regional, and global GPS data processing will be discussed.

REALIZATION OF THE VERTICAL REFERENCE SYSTEM IN VENEZUELA

Hermann DREWES, Wolfgang Bosch, Klaus Kaniuth (all at Deutsches Geodaetisches Forschungsinstitut, Marstallplatz 8, D-80539 Muenchen, Germany, email: drewes@dgfi.badw-muenchen.de); Napoleon Hernandez (Servicio Autonomo de Geografia y Cartografia Nacional, Av, Este 6, C.S.B., Edif. Camejo, Piso 2, Caracas 1010, Venezuela, email: hernandez.sagecan@conicit.ve); Melvin Hoyer, Eugen Wildermann (both at Escuela de Ingenieria Geodesica, La Universidad del Zulia, Maracaibo, Venezuela, email: mhoyer@luz.ve)

The height reference system of Venezuela is defined by the La Guaira tide gaugein the central part of the caribbean coast. The mean sea-level at this site during theepoch of definition was considered to coincide with the geoid. Recent models of sea surface topography as derived from Topex/Poseidon altimetry present a quite heterogeneous pattern along the Venezuelan coast-line. Long-term tide gauge records at La Guaira, at Carupano (about 400 km east of La Guaira), and at Amuay (about 400 km west of La Guaira) show a quite different behaviour of sea-level changes ranging from -2 mm/a decrease to +2 mm/a increase. The ellipsoidal heights of those three tide gauges (Amuay, La Guaira, and Carupano) have been determined repeatedly over six years by precise GPS observations.
They are reduced by the (quasi-) geoid heights from different models and compared with the sea surface topography from satellite altimetry. The differences are analyzed in order to define a height reference system which refers to the (quasi-) geoid instead of the zero mark of the tide gauge. The height variations are discussed with regard to eventual recent crustal movements.

THE ESTABLISHMENT AND MAINTENANCE OF THE TWD97 GEODETIC REFERENCE FRAME

Ming YANG, Ching-Liang Tseng, Jyh-Yih Yu (all at Department of Surveying Engineering, National Cheng Kung University, Tainan 701, Taiwan, email: myang@mail.ncku.edu.tw)

Taiwan is located in an active seismic region on the boundary of the Eurasian plate and the Philippine plate. Severe crustal movements at rates of greater than 5 centimeters per year have been recorded in the area. For the time period from 1995 to 1998, the Global Positioning System (GPS) had been used to establish a geodetic reference frame in Taiwan, the Taiwan Datum 1997 (TWD97), which includes 8 GPS permanent tracking stations and 726 1st- and 2nd-order control points. TWD97 has the following major properties in its establishment and future maintenance: (1) connection with the International Terrestrial Reference Frame (ITRF); (2) incorporation of velocity field models in various regions. In order to retain the required accuracy for the control network, remeasurements of selected points are scheduled, depending on the associated velocity fields of different regions.

TESTS FOR THE MAINTENANCE OF FUNDAMENTAL GPS NETWORKS IN TAIWAN

Chia-Chyang CHANG (Department of Surveying and Mapping Engineering, Chung Cheng Institute of Technology, Tahsi, Taoyuan 335, Taiwan, email: ccchang@cc04.ccit.edu.tw); Hung-Chih Chen (Land Survey Bureau, Taiwan Provincial Government, Taichung 400, Taiwan,
email: ccandrew@mail.lsb.tpg.gov.tw)

The "new" type of national reference system, consisting of one set of 3-D coordinates accurately defined in the ITRF for those well-distributed GPS control stations in the fundamental networks, has become possible to effectively carry on the maintaining work. The fundamental GPS networks composed of 8 permanent GPS tracking stations, 105 first-order, and 621 second-order GPS control stations in Taiwan area had been established during 1993 to 1997. As the facts that Taiwan is located at the fringes of two different tectonic plates, and

many geodetic observations have shown the significant crustal deformation of up to 3-8 cm/yr at most of the monitoring sites in this area, it is particularly required to carry on the maintenance for the GPS control stations in Taiwan.
This paper is aimed at investigating some of the related effects on the maintenance of the fundamental GPS networks, in order to provide one set of 3-D coordinates with the reliable accuracy. The results based on the simulation tests are analysed and discussed for the following topics: (1) Coordinate variations of the GPS tracking stations related to the update of the ITRF; (2) Coordinate variations of the first- and second-order GPS control stations estimated using velocity fields decided by the GPS tracking stations; (3) The effective period of maintenance required to provide high quality of coordinates for the GPS control stations; (4) The optimal operation procedure designed for re-occupying or re-building the GPS control stations whose sites or coordinate accuracies were found to be damaged or assessed to be degraded.

ON THE USE OF LOW COST INERTIAL SYSTEMS IN AIRBORNE SURVEYING

Sérgio CUNHA (Electric Eng. Dpt., Porto University, Portugal, email: sergio@fe.up.pt); Phillip Tomé, Telmo Cunha, Luisa Bastos (Astronomical Obs., Porto University, Portugal, email: phillip@oa.fc.up.pt, telmo@oa.fc.up.pt, lcbastos@oa.fc.up.pt)

Geodetic airborne surveys such as gravimetry and altimetry require the determination of precise aircraft position and attitude. The first can be most successfully obtained using carrier phase differential GPS, reaching decimetre level accuracy. By integration with low cost inertial units, precise attitude and robust position measurements can be achieved. The combined use of these two sensors can, however, be also employed to estimate the gravity anomaly.
The methodology to compute position, attitude and gravity anomaly from a system based on a low cost inertial device and two GPS receivers (with access to GPS reference station data) is focused. The presented approach is supported by data selected from an extensive airborne gravimetric and altimetric survey that took place in the Azorean area in 1997. The correlation between sensor errors and the resulting position, attitude and gravity anomaly estimation errors is discussed.

G1/W/41-A3 Poster 1620-46

THE VERTICAL REFERENCE SYSTEM OF ARGENTINA

Klaus KANIUTH, Wolfgang Bosch, Hermann Drewes (all at Deutsches Geodaetisches Forschungsinstitut, Marstallplatz 8, D-80539 Muenchen, Germany,
email: kaniuth@dgfi.badw-muenchen.de); Claudio Brunini, Juan Moirano, Maria Paula Natali (all at Facultad de Ciencias Astronomicas y Geofisicas, Universidad La Plata, La Plata, Argentina, email: claudio@fcaglp.fcaglp.edu.ar)

The classical height reference system of Argentina is defined by the fundamental station at Tandil which was determined in the fourties by a precise spirit levelling to the 120 km distant tide gauge at Mar del Plata. The mean sea level at Mar del Plata averaged over a few months at that time was considered to coincide with the geoid. Recent models of sea surface topography derived from Topex/Poseidon altimeter data show not only the deviations of the mean sea surface from the geoid but also a significant sea surface variability with dominant annual oscillation.
The ellipsoidal heights of the fundamental station Tandil as well as of the Mar del Plata tide gauge were determined in December 1998 and repeatedly in 1999 by precise GPS observations. They are reduced by height anomalies in order to obtain the corresponding normal heights. The results are compared with the sea surface heights resulting from satellite altimetry in order to detect systematic effects.

NATIONAL PREPARATION FOR THE USE OF THE GLOBAL REFERENCE FRAME

Martin LIDBERG (Geodetic Research Division, National Land Survey, 801 82 Gavle, Sweden, email: martin.lidberg@lm.se)

The paper describes the project RIX95 from a technical point of view. The aim of the project is preparation for the use of the Global Reference Frame (WGS84/ITRF/EUREF89), increase accessibility of the national network, and connect numerous local geodetic networks (with an extension of some 10th of km) to the National and Global Reference Frames. To do so, a new network is established including all points in the national horizontal network, and principal points in regional networks. A number of points in the first order levelling network are also included. The new network is also connected to the 21 permanent GPS stations in the SWEPOS network, where the Global Reference Frame has been realised.
The origin of the project is the wish to take advantage of the possibility for increased efficiency in surveying, coming from the rapid development in satellite geodesy. The high accuracy over long distances, the new infrastructure with continuously operating reference stations, the efforts towards real time cm level positioning services can be mentioned as some examples.
The most interesting subjects in the project from a scientific point of view are the method for densification of a geodetic network from the SWEPOS stations, the handling of several co-ordinate systems, and strategies for future reference networks.

USE OF OBJECT-ORIENTED PROGRAMMING IN PARTICLE ACCELERATOR ALIGNMENT

Catherine M. Le COCQ (Stanford Linear Accelerator Center, Stanford University, P.O. Box 4349, MS21, Stanford, CA 94309, USA, email: lecocq@slac.stanford.edu)

Aligning particle accelerator components presents specific characteristics that force data treatment programs to be very modular, extensible and feature-rich. Spending the time and effort to design a software framework, both efficient and open, has proven to be well worth the investment in the long run.
The history of LEGO, the latest geodetic adjustment package in use at Stanford Linear Accelerator Center (SLAC), is a good illustration of how certain concepts of object-oriented programming (OOP) can be used to make a product flexible and portable. Started as a simple C program designed to handle laser tracker observations, LEGO has evolved into a multi-instrument, multi-platform, and multi-model C++ package. It has been successfully used for different tasks such as final adjustment of the B-Factory storage ring integrating laser tracker, theodolite and precise level observations simultaneously, feasibility test of a high resolution digital camera and simulation of a two-story network in the National Ignition Facility project.
The first part of this paper describes how LEGO benefits from OOP design. An overview of the different C++ object definitions involved (called "classes") demonstrates how portability is achieved. The description of the relationship between the classes highlights one of the strengths of OOP: data hiding. This is the key for safe and quick implementations within various environments. Other OOP concepts such as encapsulation, base classes and virtual functions are detailed. They have been introduced during the adaptation of LEGO to the new types of measurements and treatments needed for faster and better quality surveys in particle accelerator centers. The second part of this paper starts from the analysis of the limitations of the existing package. It then proposes an object-architecture for the next generation of SLAC alignment package under study for the Next Linear Collider project.

LINK OF BRAZILIAN VERTICAL DATUM TO SIRGAS NETWORK

Sílvio R.C. DE FREITAS (Graduate Program in Geodesy, Department of Geomatics, University of Paraná, 81531-990, Curitiba, Brazil, email: sfreitas@cce.ufpr.br); Jucilei Cordini (Department of Civil Engineering, University of Santa Catarina, 88040-900, Florianópolis, Brazil, email: cordini@mbox1.ufsc.br); Eduardo Marone (Centro de Estudos do Mar, University of Paraná, 83255-000 - Pontal do Sul, Brazil, email: maroned@cce.ufpr.br)

The present activities of the SIRGAS project in South America are mainly directed to the connection of the different national height systems in a coherent continental network linked to the South American geodetic geocentric frame. This frame is one of the most recent and precise realizations of ITRF in the world. The WG III of SIRGAS established some recommendations related to the steps for this purpose. The definition of the geocentric position of the different national vertical Datum was pointed as a fundamental step for the intended connection. The Graduate Program in Geodesy, University of Paraná, established a 315 km long continental profile of observation in Southern Brazil with three stations, devising to establish the geocentric position of the Brazilian vertical Datum, placed at the Imbituba harbour. The first station was located at Imbituba itself, being the second one 50 km away from the sea (in the city of Blumenau), and the third one 80 km inland (in Curitiba -SIRGAS station). In each one of them dual-frequency GPS receivers were installed, plus a gravimeter for observation of gravity tide, and air pressure and temperature sensors. Two IGS stations were also used (Santiago and Brazilia). The results of these observations considering the GPS data processing, using fiducial techniques and the dynamical effects coming from gravity tides, meteorological and ocean indirect effects, are discussed in the presentation.

PRESENT-DAY TECTONICS IN WESTERN TURKEY BASED ON GPS OBSERVATIONS

Yüksel ALTINER, Hermann Seeger (both at Bundesamt für Kartographie und Geodäsie, Frankfurt, Germany, email: seeger@igs.ifag.de); Mustafa Ocak, Ali Türkezer (both at General Command of Mapping, Ankara, Turkey); Mustafa Ergünd, Müjgan Salk (both at the University of the 9th September, Izmir)

For the determination of the complex movements in the western part of the Anatolian plate in 1992 a GPS network of 35 stations around the rivers Gediz and Büyük Menderes was established. In this network from 1992 to 1997 four GPS-campaigns were carried out. For the processing of these data the Bernese Software was used. The magnitude of the horizontal velocities relative to the SLR station Yigilca (north of the North Anatolian Fault Zone) varies from 1 cm/yr to 3 cm/yr, increasing from east to west. The stations in the eastern part move in east-west direction while those in the western part turn to the west-south. The results of a deformation analysis based on the analytical surface deformation theory indicate that the western part of the investigation area (Gediz Graben System) may be characterized as compression and the southern part as extension (Büyük Menderes Graben System). Both regions are separated from each other by a region of very small deformation.

A NATION-WIDE GPS GEODETIC NETWORK IN CHINA

Ziqing WEI, Duan Wuxing (both at Xian Research Institute of Surveying and Mapping, 1 Yanta mid-road, Xian, Shaanxi 710054, P.R.China, email: ziqingw@public.xa.sn.cn)

A nation-wide GPS geodetic network has been set up in China. Its primary purposes are threefold: first, to control and strengthen the astro-geodetic network; second, to refine the geoid in this region; third, to establish the regional geocentric coordinate system. The whole network was subdivided into the first order network and the second order one; both are nation-wide and laid out in the form of overall continuous network. The station spacings is about 700 km for the first order network and 150-200 km for the second order network. The first order network was observed from May 1991 to April 1992 using MINI-MAC 2816 receivers, with the data processing conducted in 1994. It was shown that the accuracy of baseline components reaches 0.03 ppm and the accuracy of geocentric coordinates ranges from 0.3 to 0.5 metres. For the second order network the field operation was carried out between 1992 and 1997 mainly employing Ashtech Z12 receivers, and the data processing was performed in 1998 by means of the GAMIT software developed by MIT and SIO. It was exhibited that the accuracy of geocentric coordinates is better than 0.1 metres, and the accuracy of baseline components is mostly at the 0.02 ppm level.

G1/E/13-A3 Poster 1620-53

INFLUENCE OF GPS SATELLITE ORBITS' QUALITY ON POSITIONING PRECISION

A. KRANKOWSKI (Institute of Geodesy, Olsztyn University of Agriculture and Technology, 10-957 Olsztyn, POLAND, e-mail: kand@moskit.art.olsztyn.pl)

In the paper, results of analysis of the influence of the CODE orbits' quality on positioning precision were presented. The following orbits were taken into account:
- final orbits
- 1-day orbits, accessible with 3 days delay,
- rapid orbit, accessible with 16 hours delay,
- predicted orbits (24 and 48 hours prediction).

Using mentioned above orbits the repeatability of the following vectors were monitored: Lamkowko-Borowa Gora, Lamkowko-Borowiec, Lamkowko-Metsahovi, Lamkowko-Matera. Results were referred to those obtained using IGS final orbits. As results of investigations the following conclusions can be stated:
1. Very good agreement between final IGS and CODE orbits permits to use both in geodynamic investigations.
2. One-day and rapid orbits can be used for high precision engineering works (postprocessing).
3. Orbits predicted one day ahead can be used for precise real time positioning.

SWEPOS - DESIGN, APPLICATIONS AND FUTURE DEVELOPMENT

Gunnar Hedling, Bo JONSSON (National Land Survey of Sweden S-80182 G E4vle, Sweden, email: gunnar.hedling@.lm.se, bo.jonsson@lm.se)

The presentation describes the design of the Swedish network of GNSS reference stations, SWEPOS and the goals for the network. SWEPOS consists of 21 stations and has been in operation since 1993, during the latest 1 BD year as a real time network. Each station hosts two high-precision dual frequency PS-receivers and on some stations combined GPS/GLONASS dual-/single-frequency receivers are also installed. GPS-data is transmitted once a second from the stations to the control centre to be forwarded to real-time distributors and stored for post-processing applications. The data flow, experiences from the operation and statistics for the data availability and data quality are shown. The purpose of SWEPOS is to provide data both for scientific applications, e. g. studies of crustal movements and production applications, e. g. surveying and navigation. A summary of the SWEPOS applications today is given in the presentation. SWEPOS is also a national realisation of the Global Reference Frame. An overview of development activities for integrity monitoring of RTK-data and new applications where the network is used is also presented. Onsala Space Observatory, Teracom and the National Land Survey are working together in the Ciceron project to develop a RTK service with centimetre accuracy, covering the whole Sweden. In another project SWEPOS data is going to be used to compute the atmospheric water vapour content over Sweden.

THE CATALAN GPS PERMANENT NETWORK

Julià TALAYA, Miquel Àngel Ortiz, Ernest Bosch, Carme Parareda (Institut Cartogràfic de Catalunya, Parc de Montjuïc, Barcelona 08038, Spain, email: talaya@icc.es)

Since 1992 the Institut Cartogràfic de Catalunya is deploying a network of GPS permanent stations for covering an area of 30000 square km. At present the network consists in 8 stations equipped with dual frequency receivers and four of them with meteorological measurement systems. The data collected by the stations is of public domain and can be accessed via ftp (ftp.icc.es). The GPS stations are also used for generating and monitoring code corrections (RASANT system) that are transmitted via RDS (Radio Data System, a subcarrier of commercial FM transmissions). We are working on the broadcasting of phase observations from the stations via DAB (Digital Radio System, the new digital radio standard) that will allow RTK positioning all over Catalunya. Future developments will include the transmission of the data observed by the receivers in real time to the ICC headquarters using VSAT platforms (Very Small Aperture Terminal, a satellite based communications technique).
This network is used by the scientific community to monitor the crustal deformation of the Pyrenees area, some of the stations belongs to the IGS and EUREF networks and the stations that collect meteorological information are used by different scientific groups for computing water vapour contents of the atmosphere.

THE DEVELOPMENT AND IMPLEMENTATION OF NEW ZEALAND GEODETIC DATUM 2000

Don GRANT, Graeme Blick, Merrin Pearse (all at Land Information New Zealand, PO Box 5501, Wellington, New Zealand, email: dgrant@linz.govt.nz); John Beavan (Institute of Geological and Nuclear Sciences, PO Box 30368, Lower Hutt, New Zealand, email: john.beavan@gns.cri.nz); Peter Morgan (University of Canberra, PO Box 1, Belconnen, ACT 2616, Australia, email: peterm@ise.canberra.edu.au)

There has been clear evidence in recent years that New Zealand Geodetic Datum 1949 is inadequate for some current and emerging applications. A new geocentric datum, New Zealand Geodetic Datum 2000 (NZGD2000), designed and built during 1998, is realised through ITRF96 and uses the GRS80 ellipsoid. Coordinates for 29 primary 1st Order 2000 network stations, were generated at an epoch of 1996 using data from 5 repeat GPS surveys made between 1992 and 1998. Data from these and other repeat surveys are used to generate a velocity model to account for crustal deformation across New Zealand, primarily due effects of plate tectonics. The velocity model has been used to generate coordinates at epoch 2000.0 (the reference date for the new datum of 1 January 2000) for the 1996 dataset. The velocity model will also be used to ensure that Land Information New Zealand can generate epoch 2000 coordinates from observations made at other times and to allow other specialised users to generate up-to-date coordinates for times other than the reference epoch. As the geodetic network is densified, new marks will be incorporated into the new datum. The new datum will be implemented in conjunction with the implementation of the New Zealand Survey and Title Automation Programme, Landonline. A description of the new datum, its design, and implementation will be presented.

DENSIFICATION OF THE EUREF NETWORK IN FINLAND

Matti OLLIKAINEN, Hannu Koivula, Markku Poutanen (Finnish Geodetic Institute, Geodeetinrinne 2, FIN-02430 Masala, Finland, email: FinnRef@fgi.fi)

During the years 1996 and 1997 the FGI measured a GPS network of 100 points over Finland in order to densify the network of EUREF points. The network was measured using the 12 permanent GPS stations of the FGI as initial points. Four of these stations belong to the network of permanent EUREF stations.
The main part of the observation sites were First-Order triangulation points, however, in order to connect the GPS network to the national height system (N60), some tide gauge sites as well as precise levelling benchmarks were included in the network. The observations were processed in ITRF96 (Epoch:1997.0). Finally, the coordinates were transformed to ETRF89 (Epoch 1997.0).
The GPS solution of the network was performed using the Bernese v. 4.0 software. In the final adjustment the RMS values of the coordinates, which were computed according to the discrepancies between different observation sessions, were ±2mm, ±2mm, ±6mm in North, in East and in Up component, respectively.
The 7-parameter transformation parameters were solved between EUREF-FIN coordiantes and terrestrial systems (e.g. ED50, DE87). The residuals of the solutions show the deformation of the old triangulation network. The largest residuals were more than 2 meters. The desification of the network was continued in 1998 when 190 points, located in the Southern part of the country, were connected to the network observed in 1996-97. The new points were observed in order to improve the availability of the EUREF points for further GPS determinations.

GEODYNAMICAL RESEARCH IN THE VENEZUELAN ANDES: NEW RESULTS OF LAST ANALYSIS OF THE APARTADEROS-SIERRA-NEVADA-GEOTRAVERSE

Klaus LINKWITZ (University of Stuttgart, Stuttgart, Germany); Heinz Saler (Fachhochschule Karlsruhe, Karlsruhe, Germany)

Induced by a co-operation since 1970 of partners in Venezuela and Germany below, sponsored by the Volkswagen-Foundation, Hannover, the project Apartaderos Sierra Nevada Geotraverse could start in 1980 and ended intermediately in 1995 with a final analysis and evaluation of different -including earlier field campaigns between 1970 and 1993. Objective of the project were precise geodetically orientated investigations within a selected part of the Bocono Fault about 50 km. East of the town of Merida, not very far from the Pico Bolivar (5100 m). The very unusual topographical environment, the crystal clear air in the dry weather period between December and March (the Astro-Observatory of Merida lies directly in the traverse), the apparent visibility of the Bocono Fault, and a comparatively easy accessibility give this region the character of an open air laboratory not readily found elsewhere. The other, also extraordinary characteristic of the investigations is the fact, that all field campaigns unto 1987 still used the classical geodetic methods of triangulation and trilateration, comple-mented intensively by astronomical and gravimetrical observations. However, the campaigns 1991 and 1993 used also differential GPS and were (minor) part of the large international project CASA DOS extending far in to the Caribbean Sea and its islands. Consequently, the analysis and evaluation had to develop and use an extended model, combining the heterogeneous classical geodetic observables and the new GPS observables. As a result of the extended and complex analysis a number of thesis about the kinematic properties of the Fault in the area of investigation can be formulated of which some are contrary to original expectations and therefore surprising. This is dealt with in detail in the paper processed in ITRF96 (Epoch: 1997.0). Finally, the coordinates were transformed to ETRF89 (Epoch 1997.0).
The GPS solution of the network was performed using the Bernese v. 4.0 software. In the final adjustment the RMS values of the coordinates, which were computed according to the discrepancies between different observation sessions, were ± 2 mm, ± 2 mm ± 6 mm, in North, in East and in Up component, respectively. The 7-parameter transformation parameters were solved between EUREF-FIN coordinates and terrestrial systems (e.g. ED50, ED87). The residuals of the solutions show the deformation of the old triangulation network. The largest residuals were more than 2 metres.
The densification of the network was continued in 1998 when 190 points, located in the southern part of the country, were connected to the network observed in 1996-97. The new points were observed in order to improve the availability of the EUREF points for further GPS determinations.

THE NEW STANDARD BASELINES MEASURED BY THE FGI

Jorma JOKELA (Finnish Geodetic Institute, Geodeetinrinne 2, FIN-02430 Masala, Finland; email: Jorma.Jokela@fgi.fi)

The Finnish Geodetic Institute is one of the National Standard Laboratories in Finland, being responsible (among other things) for length standards in geodetic applications. In 1998 we measured two new Vaisala baselines in very special places: One of them is indoors under the main building of the Helsinki University of Technology. The other is an old calibration baseline, not originally planned for interferometric measurements, near Chengdu in China. We present results and experiences of these and other recent projects. In addition to white light interferometry, we have used high precision EDM instruments, like Kern Mekometer ME5000, in our metrological projects.
At the new baselines the Vaisala baseline benchmarks and the equipment for calibration measurements are on the same observation pillars, contrary to general standard baseline design. We discuss the advantages and possible drawbacks of the new system, especially in the stability control and projection measurements needed to combine the interferometric and other geodetic measurements.

APPLICATION OF REAL-TIME KINEMATIC GPS TECHNOLOGY TO MANNED MODELS SHIPHANDLING SIMULATION USING VIRTUAL PORT PRESENTATION

Janusz BOGUSZ, Lech Kujawa, Jerzy B. Rogowski (all at Institute of Geodesy and Geodetic Astronomy, Warsaw University of Technology, 00-661 Warszawa, POLAND, email: jb@gik.pw.edu.pl); Miroslaw Korcz (Gdynia Maritime Academy, POLAND); Wojciech Leszczy ski (Institute of Meteorology and Water Management, Warsaw, POLAND); Marcin Szoucha (Topographic Service of Polish Army General Staff, Warsaw, POLAND)

This paper presents an application of RTK methods for simulation and monitoring ships' slow speed manoeuvres while manoeuvring in the harbour as well as on approaching to the quay. It describes results of tests, which were performed using manmanned models of Ferry and VLLC in Ship Handling Research and Training Centre in I awa, Poland. Trimble and Ashtech RTK systems were used and compared with kinematic method and DGPS in real time based on mobile telephones for reference data transmission. The paper discusses the successful implementation of RTK method for the simulation of ship manoeuvres in virtual port.

DETECTION OF SUBCENTIMETRE DEFORMATIONS WITH GPS

H. Hartinger, Fritz K. BRUNNER (Engineering Surveying and Metrology, Technical University of Graz, Steyrergasse 30, A-8020 Graz, Austria, email: hartinger@aig.tu-graz.ac.at)

Frequently, the capability of deformation monitoring systems based on conventional surveying instruments is decreased by weather effects which prevent line-of-sight measurements. GPS observations are not restricted to the line-of-sight, however, presently the attainable accuracy of GPS measurements is not as high as that of the conventional deformation monitoring systems. The final goal of this research project is a subcentimetre, near realtime GPS deformation monitoring system which is generally applicable. Each station consists of a choke-ring antenna, a GPS receiver and a data transmission unit. The measurements of all stations are simultaneously transmitted to a control station which stores and processes the original GPS data. The most difficult research area for achieving subcentimetre accuracy in local GPS deformation monitoring systems are systematic errors, mainly multipath. This difficulty is even amplified in near realtime systems because of the low frequency characteristics of multipath. This poster reports about the development of the GPS hardware and software of a monitoring system which performs at a 3 to 5 mm accuracy range. Several strategies have been investigated for the reduction of systematic errors and the results shall be presented. In a first practical application the GPS system was used to monitor the motions of a landslide area. The results show that an accuracy of 2 mm in position is achievable for a time resolution of 3 minutes using the appropriately filtered raw GPS data.

EVALUATION OF THE HIGH PRECISION GPS POINT POSITIONING USING GPS DATA FROM BRAZIL

Joco Francisco Galera MONICO (Department of Cartography, Sco Paulo State University UNESP, Presidente Prudente, CEP 19060-900, BR, e-mail: galera@prudente.unesp.br)

Point positioning is generally referred to the estimation of station/receiver parameters by the use of the pseudorange data, constraining the satellite parameters to the values given in the navigation message. The quality of the results is affected by the Selective Availability (SA), which degrades the orbits and clocks of the satellites and by the quality of the observable (pseudorange), which precision is of the order of 1 m. In the high precision point positioning, besides the pseudorange observable, the carrier phase one is also included in the processing. Additionally, in order to eliminate the effects of SA, one has to use precise ephemeredes, which are obtained in a pos-processing approach. Additionally to the satellite orbits, the precise ephemeredes also provide the corrections to the satellite clocks. Results documented in the GPS literature refer to daily precision of the order of few millimeter in the horizontal components and centimeter in the vertical.
GIPSY-OASIS II software, developed at Jet Propulsion Laboratory, provides means of performing high precision point positioning. In order to evaluate the quality of the results of this approach in Brazil, data from the Brazilian continuos GPS network (RBMC) was processed using this software. The results of this strategy besides being compared to those obtained from the network approach, they were analyzed using the concept of repeatability. Preliminary results agree with the quality claimed in the literature. The basic fundamentals of the precise point positioning approach and the description of the GPS data used, together to the quality control applied will be the main topics of this paper.

CONNECTION OF THE COLOMBIAN VERTICAL DATUM TO THE GEOCENTRIC REFERENCE SYSTEM

Laura SANCHEZ, William Martinez, Juan Florez (all at Instituto Geografico Agustin Codazzi, Carrera 30, No. 48-51, Santafe de Bogota, Colombia, email: lsanchez@igac.gov.co); Hermann Drewes, Klaus Kaniuth, Herbert Tremel (all at Deutsches Geodaetisches Forschungsinstitut, Marstallplatz 8, D-80539 Muenchen, Germany, email: drewes@dgfi.badw.de)

The classical Colombian vertical datum is defined by the Buenaventura tide gauge at the Pacific coast. The mean sea level at this tide gauge is assumed to coincide with the geoid. All the official Colombian height values derived by spirit levelling refer to this datum. Recent comparisons of ellipsoidal heights derived from GPS observations and corrected by geoid undulations (regional geoid for Colombia based on EGM 96 with local refinements), show a systematic offset of about 2 meters.
To verify this discrepancy, the ellipsoidal height of the Buenaventura tide gauge was determined by a dedicated GPS survey and corrected by the sea surface topography as derived from satellite altimetry. The geoid height obtained in this way is compared with that of the regional geoid for Colombia and allows some estimates of a systematic offset in EGM 96. To control the offset, two other tide gauges at Tumaco (south of Buenaventura) and Cartagena (Carribean coast) are observed in the same way and confirm the results.

IMPROVEMENT OF PRECISE AND RELIABLE KINEMATIC GPS POSITIONING IN REAL-TIME OVER LONG DISTANCES

Rock SANTERRE (Centre de recherche en giomatique, Universiti Laval, Ste-Foy, Quibec, G1K 7P4, Canada, email: Rock.Santerre@scg.ulaval.ca); Claude St-Pierre (VIASAT Gio-Technologie, Montrial, Quibec, H2S 1Z2, Canada, email: cstpierre@viasat.qc.ca)

This research project, which is part of the Canadian GEOID (Geomatics for Informed Decisions) Network of Centres of Excellence, is dedicated to the improvement of the methodology and the algorithms to achieve more precise and more reliable kinematic GPS positioning (which implies more reliable and efficient phase ambiguity resolution) over distances even longer than 75 km: for the support, but not exclusively, of bathymetric surveys in real-time. This research will lead to added-value for the customized software already developed for the Canadian Coast Guard (CCG) and this will consequently further support the modernization and the cost-effectiveness of bathymetric operations. To reach these goals, different research avenues will be considered. The main avenues are: 1) GPS relative positioning with multiple reference stations, 2) the improvement of ionospheric modelling, 3) the use of precise real-time orbits, 4) the integration of Glonass observations and 5) radio-communication management (which includes the problem of time latency).
In this presentation, first results related to the interpolation of relative ionospheric delays will be presented. Ionospheric information is extracted from the reference stations - about 125 km apart in our case, along the St. Lawrence river. It is shown that this significantly improves the success rate of ambiguity resolution of phase observations collected by a GPS receiver onboard a survey ship navigating midway between two reference stations.

STATUS AND DEVELOPMENT OF THE EUROPEAN HEIGHT SYSTEMS

J. Adam, W. Augath, F. Brouwer, G. Engelhardt, W. Gurtner, B. G. Harsson, J. IHDE, D. Ineichen, H. Lang, J. Luthardt, M. Sacher, W. Schlüter, T. Springer, G. Wöppelmann (members and associated members of the EUREF-Technical Working Group)

After a break of ten years, the work on the United European Levelling Network (UELN) resumed in 1994 under the name UELN-95. The objectives of the UELN-95 project being to establish a unified vertical datum for Europe at the one decimeter level with the simultaneous enlargement of UELN as far as possible to include Central and Eastern European countries. More than 3000 nodal points were adjusted, constraint-free, in geopotential numbers linked to the reference point of UELN-73 (gauge Amsterdam). The new heights in the system UELN-95/98 are available for more than 20 participating countries.
The European Vertical GPS Reference Network (EUVN) is designed to contribute to the UELN project along with the connection of European tide gauge benchmarks as contribution to monitoring absolute sea level variations, the establishment of fiducial points for the European geoid determination. The EUVN includes 195 points all over Europe. At every EUVN point, three-dimensional coordinates in ETRS89 and levelling heights primary in the system of the UELN-95 have to be derived. The GPS computations are finalised, though some levelling connections still have to be realised. At the tide gauge stations of EUVN additional sea level observations have to be included.
The height systems will be developed as a combination of GPS permanent observations, levelling, and geoid information under consideration of well-known vertical movements towards a European kinematic height reference system.

EFFECTS OF IMPLEMENTATION OF GEOCENTRIC DATUM UPON INTEGRAL DEVELOPMENT OF GEOMATIC ENGINEERING

LU ZHIPING, Li Hui, Li Baoli (Department of Geodesy, Zhengzhou Institute of Surveying and Mapping, Zhengzhou 450052, China)

Since 1993, National Geodetic Coordinate System 1980 has been put into effect in China as the datum of mapping and other engineering applications in order to gradually substitute Beijing Geodetic Coordinate System1954. However, the regional reference coordinate system is only an outcome of traditional Geodesy. In the age of modern geodetic surveying, the implemented reference datum should facilitate various uses and coincide with international geodetic datum under the global integration circumstance. Along with the progress in science and technology and the change of user's needs in datum, the regional reference datum is bound to be substituted by kinematic, continuing and highly accurate geocentric datum. This is the inevitable of the integral development of geomatic engineering.
The paper expresses that it is inevitable development to implement geocentric datum in China by analyzing requirements of user's in geomatic engineering, development of geodesy and investigating international trends on adoption of datum. The implementation of National Geodetic Coordinate System 1980 at present maybe well result in that all Chinese geo-information don't refer to a single, homogeneous, geodetic datum. So it is necessary to implement geocentric datum in China as soon as possible.

USING ON-LINE ATMOSPHERE MODELS AND PRECISE PREDICTED ORBITS FOR RTK-GPS POSITIONING IN THE SATVB REFERENCE STATION NETWORK

Helmut TITZ, Johannes Boehm (both at Department of Advanced Geodesy, University of Technology Vienna, Gusshausstr. 27-29, A-1040 Vienna, Austria, email: htitz@luna.tuwien.ac.at)

In August 1997 the BEWAG, a local power supply company in Austria, established in cooperation with the Department of Advanced Geodesy in Vienna a network of 4 permanent GPS reference stations called the SATVB network (Satellitenvermessung Burgenland). The reference stations are interconnected by means of a wide area token ring network which allows for the computation of atmospheric models and correction parameters for distance dependent errors in realtime. Mobile rover stations making use of the correction models are able to do a faster and more reliable ambiguity resolution. Future extensions will also make use of precise predicted orbits (IGP) transmitted to the rovers over the air link.
In addition to the realtime measurements all GPS observations are recorded in RINEX format. This observation data has been processed at a daily basis since January 1998. The resulting time series allow for investigations concerning the ionospheric and tropospheric behaviour as well as for multipath effects. Comparisons between realtime and postprocessing solutions are possible.

SPECTRAL ANALYSIS FOR TRANSFORMATION PARAMETERS DETERMINATION: THE COLOMBIAN CASE

Laura Sanchez, William MARTINEZ, Juan Florez. (Instituto Geografico Agustin Codazzi, Carrera 30 No. 48-51, Santafe de Bogota, Colombia. email: lsanchez@igac.gov.co)

The new Colombian reference frame MAGNA (Marco Geocintrico de Referencia Nacional) has been established by the Instituto Geografico Agustmn Codazzi (IGAC) as the realization of the SIRGAS datum in Colombia. MAGNA has replaced the old classical network defined on Bogota Datum to which all of the cartographic surveys made in the country have been tied.
In order to make consistent the current cartography with the GPS technique, IGAC computed some sets of transformation parameters using the Bursa-Wolf method, Molodenskyi-Badekas formulae and Helmert transformation. However, they can not take account local deformations of the old frame.
To determine both, sistematic and aleatory changes between the Colombian frames, IGAC has proposed a solution that involves spectral techniques. In this way, it is possible to evaluate different sources of deformation, e.g. geometrical weaknesses in the old network, the non-rigorous adjustment, crustal deformations and the poor definition of a geoid model before the 90s.

FLIGHT STATE MONITERING OF AN AIRBORNE REMOTE SENSING SYSTEM BY USING GPS

G. XU (National Survey and Cadastre, Rentemestervej 8, DK-2400, Copenhagen, Denmark); L. Bastos (Astronomical Observatorium, Monte da Virgem, 4430 V.N.Gaia, Portugal; R. Forsberg, L. Timmen (GeoForschungsZentrum Potsdam, Telegrafenberg A17, D-14473 Potsdam

Using GPS for flight state monitoring of an airborne remote sensing system has been carried out in Europe within the EU project AGMASCO. About two Months of kinematic GPS flight data and static data have been collected in four campaigns during the past of three years. Several GPS softwares have been used for the extensive real data processing. In this paper, the general scenario of the campaigns is briefly outlined. The strategies and principle of the data processing are discussed and detailly given. The multiple static reference data are used for kinematic positioning to strengthen the geometric stabilities. Static results are used as conditions for reducing the unknown number and modifying the ambiguity resolution in the kinematic positioning. Multiple kinematic GPS data are evaluated simultaneously for flight state monitoring. Constraints of known distances between antennas fixed on the airplane are introduced into the data processing. Results, precision estimation and comparison are outlined.

A NEW ADAPTIVELY ROBUST FILRTERING FOR KINEMATIC GEODETIC POSITIONING

Yuanxi YANG Xi'an (Research Institute of Surveying and Mapping, No.1 Mid-Yanta Road, 710054 Xi'an, P.R. China)

The Kalman filter has been applied extensively in the area of kinematic geodetic positioning. The reliability of the linear filtering results, however, will degrade when the kinematic model noise is not accurately modeled in filtering or the measurement noises at any measurement epoch are not normally distributed. A new adaptively robust filtering is proposed based on the robust M (Maximum likelihood type) estimation. It consists in weighting the influence of the updated parameters in accordance with the magnitude of discrepancy between the updated parameters and the robust estimates obtained from the kinematic measurements and in weighting individual measurement at discrete epoch. The new procedure is different from functional model error compensation, it changes the variance matrix or equivalently changes the weight matrix of the predicted parameters to cover the model errors. A general estimator for adaptively robust filter is developed, which includes the estimators of classical Kalman filter, adaptive Kalman filter, robust filter, sequential least squares (LS) adjustment and robust sequential adjustment. The procedure can not only resist the influence of outlying kinematic model errors, but also control the effects of measurement outliers. In addition to the robustizing properties, feasibility in implementation of the new filter is achieved through the equivalent

weights of the measurements and the predicted state parameters. A numerical example is given to demonstrate the ideas involved.

THE COLOMBIAN NATIONAL GEOCENTRIC REFERENCE FRAME

Laura SANCHEZ (Instituto Geografico Agustin Codazzi, Carrera 30, No. 48-51, Santafe de Bogota, Colombia, email: lsanchez@igac.gov.co); Herbert Tremel, Hermann Drewes (both at Deutsches Geodaetisches Forschungsinstitut, Marstallplatz 8, D-80539 Muenchen, Germany, email: mailer@dgfi.badw.de)

The Colombian National Geocentric Reference Frame (Marco Geocentrico de Referencia Nacional, MAGNA) is realized by a GPS base network of 60 stations covering the entire country. The network includes the five Colombian stations of the South American Geocentric Reference System (SIRGAS) and 16 points of the Central and South American (CASA) geodynamics network. It was observed by three GPS campaigns in 1994, 1995 and 1997.
The results presented here are based on a data processing using the Bernese software version 4.0. In a first step, "free network" adjustments of the partial (annual) networks were done using the IGS precise orbits. The internal precision estimated from daily repeatabilities is in the centimeter-level. In the second step, the partial networks are transformed to the SIRGAS stations providing the geocentric orientation. The position accuracy is estimated to be in the order of a few centimeters.
For an external quality check, the MAGNA coordinates are compared with the SIRGAS and the CASA coordinates. Some discrepancies are explained by recent crustal movements, which are very large in this area. A soon repetitive observation of the MAGNA network is necessary to determine the corresponding station velocities.

LONG BASELINE OF KINEMATIC GPS

Andy EVANS, Gethin Roberts, Vidal Ashkenazi (IESSG, University of Nottingham, Nottingham, NG7 2RD, UK, email: isxaje@isn1.iessg.nottingham.ac.uk)

It is well established that static GPS surveying using the carrier wave of the GPS code signal can achieve relative positions at a resolution of a few millimetres suitable for geodetic work. Past developments to improve geodetic positioning solutions in terms of reliability and speed of results has allowed techniques to emerge for the positioning of moving receivers with solutions approaching geodetic accuracies. There are two important areas of consideration when positioning with the carrier wave, these are ambiguity resolution and the modelling of observation errors. On-the-fly (OTF) kinematic GPS is a method specific to carrier wave relative positioning. Over short baselines (<10 kilometres) millimetric accuracies are achievable and thus a viable method for numerous engineering applications. Due to the short baseline constraint observation errors between receivers are negligible and so effective ambiguity resolution is the primary factor. As the baseline length increases so the accuracy degrades as observation errors have greater effect. The focus of this work is to examine methods for increasing the workable baseline length whilst maintaining short baseline accuracy and quick ambiguity resolution. The areas of investigation are the use of multiple reference stations (MRS) to improve the ambiguity resolution process and the modelling of observation errors in the received signals.

ATMOSPHERIC LOADING EFFECTS IN GPS VERTICAL TIME SERIES

Marijke Brondeel, Tonie M. van Dam (Royal Observatory of Belgium, Ringlaan 3, B-1180 Brussel, Belgium, email: Marijke.Brondeel@oma.be, Tonie.vanDam@oma.be); Mark SCHENEWERK (NOAA, SSMC3, 1315 East-West Highway, Silver Spring, MD, 20910, U.S.A., email: mark@ness.grdl.noaa.gov)

Atmospheric pressure loading is known to generate noise in GPS vertical time series. Even weekly solutions of GPS determined vertical coordinates are correlated with atmospheric loading in more than 70% of the stations investigated. A recent investigation of these effects indicates they are larger than previously observed. First, we investigate the reason for the larger signal by comparing solutions using the different meteorological data sets (ECMWF, NCEP Reanalysis, and NMC). Second, we present an analysis of the loading effect in one year of GPS heights from 1) Europe (CODE daily solutions), 2) Globally (CODE weekly solutions and 3) Globally (JPL daily solutions). Preliminary results indicate that the loading effects are more significant in the global solutions, presumably due to the fact that for smaller networks the loading is coherent over the station spacing in the network. Furthermore, we compare the Two Coefficient Correlation Equation Method with the Convolution Method for calculating the atmospheric loading effects. Finally we will consider the effects of the loading on GPS orbit determination by calculating orbits with and without pressure loading corrections for one month of GPS data.

THE INTEGRATION OF BRAZILIAN GEODETIC SYSTEM INTO TERRESTRIAL REFERENCE SYSTEMS

Sonia Maria Alves COSTA (Department of Geodesy, IBGE, Av. Brasil 15671, Parada de Lucas, Rio de Janeiro, RJ, Brazil, 21241-000, email: soniamaria@ibge.gov.br); Marcelo Carvalho dos Santos (Graduate Program in Geodetic Sciences, Federal University of Parana, CP. 19001, Curitiba, Pr, Brazil, 82531-990, email: mcsantos@geoc.ufpr.br); Camil Gemael (Graduate Program in Geodetic Sciences, Federal University of Parana, CP. 19001, Curitiba, Pr, Brazil, 82531-990, email: cgemael@geoc.ufpr.br)

The motivation for the work described here is on the integration between geodetic reference systems. To begin with, a global and simultaneous adjustment of the Brazilian geodetic network into South American Geocentric Reference System (SIRGAS) was carried out. SIRGAS is considered as the most accurate realisation of ITRF in South America. It is an example of regional network integration based on ITRF/IGS products. In this adjustment, GPS and classical networks are combined on a simultaneous adjustment using Helmert Blocking technique and three-dimensional modelling.
As a second step, these results are integrated into ITRF's versions. The establishment of the Brazilian Network for Continuous Monitoring of GPS (RBMC), with 9 stations in operation since 1997 (the same ones occupied during the SIRGAS campaign), has provided all information for the integration of Brazilian geodetic system into ITRF. The intention is to estimate a velocity field for the RBMC stations, as well as to compare between GPS results and the global plate motion model recommended by the IAG, namely the NNR-NUVEL-1A. For the estimation of velocity field, 4 epochs of GPS data comprising 15 days will be processed with software Bernese version 4.0.

PRELIMINARY RESULTS OF THE GPS BUOYS DATA PROCESSING IN THE NORTH WESTERN MEDITERRANEAN SEA

M. MARTINEZ-GARCIA (Dept. Applied Mathematics and Telematics, Universitat Politecnica de Catalunya, c/ Jordi Girona 1-3, 08034 Barcelona, Spain, e-mail: marina@mat.upc.es); J.J. Martinex-Benjamin (Dept. Applied Physics, Universitat Politecnica de Catalunya, c/ Jordi Girona 1-3, 08034 Barcelona, Spain, e-mail: benjamin@grace.upc.es); G.L.H. Kruizinga (Satellite Geodesy and Geodynamincs Systems Group, Jet Propulsion Laboratory, Caltech, Pasadena, California, U.S.A., e-mail: Gerhard.Kruizinga@jpl.nasa.gov)

Preliminary results are presented on GPS buoy positioning in the North Western Mediterranean Sea in support of the absolute range altimeter calibration for the US/French altimeter satellite TOPEX/POSEIDON.
The experiment was conducted in March 1999 off the coast near Begur Cape (Catalonia, Spain). The objective is to compare the sea level derived from GPS buoys and TOPEX/POSEIDON and to calibrate the satellite altimer system. The experiment consisted out of two reference GPS stations on shor2e and two GPS buoys underneath the TOPEX/POSEIDON ground track. Local tide gauge measurements were used to correct GPS buoy heights to estimate the Mean Sea Surface height along the TOPEX/POSEIDON and ERS-1/2 ground tracks. An analysis of the different techniques and software used in the GPS data processing will be presented.

PROSPECTIVE USE OF WIDE AREA AUGMENTATIONS IN THE SOUTHERN HEMISPHERE

Marcio Aquino, Vidal Ashkenazi, Terry MOORE (IESSG, University of Nottingham, Nottingham, NG7 2RD, UK, email: marcio.aquino@nottingham.ac.uk)

The footprint of the Inmarsat 3 series of satellites enables the transmission of augmentation corrections, provided by EGNOS and WAAS, to southern hemisphere regions such as Africa and South America. The integrity and availability functions of both EGNOS and WAAS will be valid worldwide, regardless of the location of the service area where they have been derived, but the same does not apply to the WAD (Wide Area Differential) function. The latter includes orbital and the atmospheric corrections that will best correlate to the area where the corresponding ground network is placed. A regional WADGPS system has been developed at the University of Nottingham, which may overcome this drawback and complement either of the existing augmentation services with regard to the provision of WAD corrections. The "orbit relaxation" technique, in conjunction with improved atmospheric models, form the background for the proposed system. This technique is simpler and less costly to implement than alternative methods of orbit improvement, such as the dynamical orbit determination. Generation of WAD corrections and their application by the user, within the context of the new approach, have been evaluated as part of the project. Initial results of this study were presented at the IAG-97 scientific assembly, primarily relating to tests carried out with simulated data. This paper presents the latest outcome of the investigations. Further validation tests with simulated data were performed and were followed by real data tests. The presentation concentrates on extensive processing of data collected at a Brazilian permanent GPS tracking network. Results are presented and discussed, with a special view to a possible application of the system in Brazil.

COORDINATE TRANSFORMATIONS FROM WGS84 TO THE MAPPING DATUM IN IRELAND

Chris HILL, Vidal Ashkenazi, Richard Bingley, Wu Chen, Terry Moore (IESSG, University of Nottingham, Nottingham, NG7 2RD, UK, email: chris.hill@nottingham.ac.uk)

This paper describes two recent projects carried out by the IESSG under a joint contract to the Ordnance Survey of Ireland and the Ordnance Survey of Northern Ireland. The first project was on the design, computation and implementation of a Zero Order GPS based ETRF89 Reference Framework for the whole of Ireland, and its Densification. The methodology used and the results obtained were presented to and accepted by the EUREF Technical Working Group in 1996. The second project established a transformation between the mapping datum (Ireland 1975) and the new GPS-based coordinate reference system. The project investigated three different coordinate transformations. Each was assessed against a series of criteria, such as transformation accuracy, invertability/reversibility, conformality, extensibility, and uniqueness. Based on this analysis, two dedicated transformation methods were identified to transform coordinates from Ireland 1975 to ETRF89, and vice-versa. This paper briefly outlines the principles and algorithms for the three transformation methods, and the steps taken to evaluate each method against the required criteria.

STUDY OF REFRACTION VARIATION OBSERVATION USING VIDEO THEODOLITS

Ismail Kabashi, Günther RETSCHER (both at Department of Applied and Engineering Geodesy, Vienna University of Technology, Gusshausstrasse 27-29 E128/3, A-1040 Wien, AUSTRIA, email: ikabashi@pop.tuwien.ac.at, gretsch@pop.tuwien.ac.at)

Optical observations over long distances are significantly affected by the refraction of the signal. In a research study at our department the observation of refraction variations with video theodolits is currently being analysed. In this paper the results of a series of test measurements will be presented. Thereby observations with the video theodolite are taken between two buildings of the Vienna University of Technology over an about 400 to 500 m long distance at changing weather conditions. The angles are observed with sampling rates of up to 10 Hz, i.e. 10 observations per seconds. In comparison this baseline is also observed with GPS.

TRANSFORMATION BETWEEN GEODETIC SYSTEMS WITH RESIDUAL MODELLING

Marcelo Carvalho dos SANTOS (Universidade Federal do Parana, Departamento de Geometica, C.P.19001, Curitiba, Pr, Brazil, CEP: 82531-990, email: mcsantos@geoc.ufpr.br); Moises Ferreira Costa (Universidade Federal do Paran, Departamento de Geometica, C.P.19001, Curitiba, Pr, Brazil, CEP: 82531-990, email: mfcosta@geoc.ufpr.br)

A methodology intended to allow transformation between geodetic systems in which the distortions of the networks are taken into account is described and tested. Typically, only a similarity transformation is used, resulting in 7 parameters that portray the relationship between the systems. In our approach, the distortions are accounted for by treating the residual field (entries of the residual vector) as a mathematical surface. Therefore,besides the 7 parameters,

corrections are applied for each and every coordinate allowing a point-to-point transformation. The methodology was tested for transforming between two realisations of the Brazilian Geodetic System (BGS). Only a part of the BGS was used, in an area covering the State of Parana. A comparison between the application of the 7 parameters transformation only with the referred methodology (7 parameters transformation plus residual modelling) has shown an 84% improvement when applying the methodology. In this study, the residual field was approximated by a fourth order polynomial.

REAL TIME GPS MONITORING OF RIVER LEVELS

Terry MOORE, Gethin Roberts, Kefei Zhang (IESSG, University of Nottingham, Nottingham NG7 2RD, UK, email: terry.moore@nottingham.ac.uk), Vidal Ashkenazi, Mark Dumville (Nottingham Scientific Ltd, University Park, Nottingham, NG7 2RD, UK), Gareth Close (Science Systems (Space) Ltd, Bristol, UK); Roger Moore (Institute of Hydrology, Wallingford, UK)

This paper presents current progress of the project "River Level Monitoring Using GPS Heighting (RiGHt)" conducted at the University of Nottingham in partnership with Science Systems (Space) Ltd and the Institute of Hydrology, awarded by the British National Space Centre (BNSC), under the UK Government's Space Foresight Programme. The aim of the project is to demonstrate how space technologies may be used to address the problem of continuously monitoring river heights at any point in the world, from a remote platform. This paper presents a space-based real-time river level monitoring system using kinematic GPS, satellite communication and GIS techniques. A GPS receiver is mounted on a river buoy together with other sensors for water quality sampling and attitude determination of the buoy. Communication satellites are used for the datalink between the buoy and the GPS reference stations. The system architecture, configuration and instrumentation of such a comprehensive river level monitoring system are described, and operation and applications of such a buoy are discussed. Field trials have been conducted using both a buoy simulator and a prototype integrated positioning system onboard a buoy. Preliminary results show that a consistent millimetre precision of the RTK GPS water level measurements can be achieved. The continuing investigation will also be described, with the aim of developing a reliable and practical system. The ultimate goal is to remotely monitor river levels in real-time, in a cost-effective manner and with high precision.

DEVELOPMENT AND MAINTENANCE OF GEOCENTRIC REFERENCE FRAME IN THE CZECH REPUBLIC AND ITS USE FOR MODERNIZATION OF TERRESTRIAL GEODETIC CONTROL

Jan Kostelecky, Jaroslav SIMEK (Research Institute of Geodesy, Topography and Cartography, Geodetic Observatory Pecny, 251 65 Ondrejov 244, CZ, email: gope@asu.cas.cz)

Starting with November 1991, the EUREF reference frame was established with the help of BKG Frankfurt am Main and a little later densified by a sequence of EUREF post-campaigns performed by the Czech National Geodetic Agencies in 1992-1994, to the present density 1 point/400 km sq. The geodetic frame, formed in this way, was used together with existing S-42/83 for an essential modernization of the obsolete civilian system S-JTSK for its new version S-JTSK/95. In addition to it so called "Basic Geodynamical Network" which integrates precise GPS, levelling and gravity measurements, was established in 1996 and since that time has been periodically re-measured several times. Research Institute of Geodesy is also taking an active part in further development of EUREF by operating in Local Analysis Center of EUREF Permanent Network, EUVN pre- processing and analysis center and by continual evolution of time series of observations of a number of European permanent GPS stations. Methods used for merging different EUREF post-campaigns in the Czech Republic and procedures related to creating new civilian system S-JTSK/95 are described in more detail as well as some results stemming from new projects. An outlook is attached describing present activities towards further densification of the EUREF frame and integration of horizontal and vertical geodetic control.

GEOIDAL GEOPOTENTIAL AND WORLD HEIGHT SYSTEM

Working Group Global Geodesy Topics: Satellite Altimetry Applications (WG GGT): Milan Bursa (Astronomical Institute, Academy of Sciences of the Czech Republic, Prague, CR, email: bursa@ig.cas.cz); Jan Kouba (Geodetic Survey Division, Natural Resources Canada, Ottawa, Canada, email: kouba@geod.emr.ca); Muneendra KUMAR, Scott A.True (National Image and Mapping Agency, St.Louis, MO 63118-3399 USA, email: KumarM@nima.mil, TrueS@nima.mil); Achim Muller (Federal Armed Forces, Geographic Office, Euskirchen, Fed.Rep. of Germany, email: amil-geo@t-online.de); Karel Radej, Viliam Vatrt, Marie Vojtiskova (Topographical Service of the Army of the Czech Republic, Topographical Institute VTOPÚ, Dobru_ka, CR, email: vatrt@vtopu.army.cz,;vojtiskova@vtopu.army.cz)

The geoidal geopotential value of W0 = 62 636 855.6 ± 0.5m2s-2, determined from 1993-1998 TOPEX/POSEIDON altimeter data, can be adopted for the practical definition and realization of the World Height System. The W0 - value can also uniquely define the geoidal surface.The W0 - value is required for a number of applications, including the General Relativity in precise time keeping and time definitions. Furthermore, the W0 value provides a scale parameter for the Earth that is independent of the tidal reference system. All of the above considerations make the geoidal potential W0 ideally suited for official adoption as one of the fundamental constants, replacing the currently adopted semi-major axis a of the mean Earth ellipsoid. Vertical shifts of the Local Vertical Datum (LVD) origins can easily be determined with respect to the World Height System (defined by W0), using the recent EGM96 gravity model and ellipsoidal height observations (e.g. GPS) at leveling points. Using this methodology the LVD vertical displacements for the NAVD88(North American Vertical Datum 88), NAP (Normal Amsterdamsch Peil), AHD (Australian Height Datum), KHD (Kronstadt Height Datum), and N60 (Finnish Height Datum) were determined with respect to the proposed World Height System as follows: -59.1 cm, -14.9 cm, +38.3 cm, -15.5 cm and -2.2 cm, respectively.

GPS PRECISE POINT POSITIONING (PPP): REPEATABILITY EXPERIMENTS

Paulo C.L. SEGANTINE (Sao Carlos Engineering School, Univ. of Sao Paulo, Brazil, email: seganta@stt.eesc.sc.usp.br); S. Witchayangkoon (Dept. of Civil Engineering, Faculty of Engineering, Thammasa Univ., Thailand, email: witchay@spatial.maine.edu)

Since the establishment of IGS with the multi-international cooperation in 1993, the accuracy of IGS products has been imporved dramatically, particular the GPS orbits and clock information. JPL as one of IGS Analysis Centers has recently launched automated service for analyzing single station observations using the GIPSY-OASIS II software. JPL orbits are at the same accuracy, or slightly better than JPLs. However, JPL clock information is better than that of IGS. JPL Auto service uses its information for Precise Point Position (PPP) analysis. PPP provides solutions as centimeter level for dual-frequency observation. PPP has been proven to be computational efficient since the engagement to a network is avoided, in addition to base satellite and base receiver. The result of the analysed position is free of network distortion and is in the OTRF96 reference frame rather than a relative position.
This analysis experiments with repeatability of different length of observation data in PPP. The accuracy of PPP depends upon given approximate position as well as observation length. GPS observation data with 1-, 2-, 3-, 4-, 8-, 12-, and 24-hour length is tested. The accuracy of 1cm seems to be stabilized after x hours of observation. Sub-centimeter accuracy absolute positioning is obtained for more than 12-hour data.

GPS - AN IMPORTANT TECHNOLOGY IN CARTOGRAPHIC BASES GEOCODING

Paulo C.L. SEGANTINE, Maurício Roberto Veronez, Eliana Ederle Dias Chaves, Reginaldo Macedônio da Silva (São Carlos Engineering School, EESC/USP, Department of Transportation, Post office box 359, CEP 13560-250, São Carlos, São Paulo, Brazil, email: seganta@stt.eesc.sc.usp.br)

Nowadays, with the progress of the computer science, some activities began to appear in a preoccupying way. It is the case of the establishment of a Geographic Information System - GIS without the necessary attention with the cartographic base quality. It is essential in case of GIS for the manipulation of spatial data. The quality of a cartographic base is directly related with the scale and with the reference system of the map. The geocoding of a cartographic base is only possible using coordinates transformation parameters. This paper has the intention to show the importance of the use of the GPS system in the cartographic base geocoding through a study of case through two simulations. In the first one it was considered that the study area is not associated to any reference system, that is, just related with a local topographical system. In the second one, the base is geocoded in UTM system (Hayford) and through a transformation Afin this base also went compatible with the local topographical system. In both simulations, the validity of the proposals methodologies was tested in function of 15 controls points distributed in the whole study area and very identifiable in the land and in the map.

EFFECTS OF SOFTWARE-NOISE AND REFERENCE-NETWORK-NOISE ON GPS-RESULTS, SHOWN FOR AN EXTENDED GPS NETWORK IN ANTARCTICA

W. NIEMEIER, H. Salbach (Technical University Braunschweig, Pockelstraße 4, D-38106 Braunschweig, Germany); R. Dietrich, R. Dach, J. Perlt (Technical University Dresden, Germany); H.W. Schenke, T. Schöne (Alfred-Wegener Institut, Bremerhaven, Germany); G. Seeber, F. Menge, C. Völksen (University Hannover, Germany); K. Lindner, M. Mayer (University Karlsruhe, Germany)

In 1995 and 1998 large-scale GPS – Campaigns could be realized for the Atlantic Sector of Antarctica, a region of special interest for geosciences. This Antarctic network was tided into the ITRF-IERS terrestrial reference frame by including several well-spread ITRF stations in the southern hemisphere into the processing of the data and embedded into the IGS by using precise IGS-orbits. The campaigns were coordinated by the Scientific Committee of Antarctic Research (SCAR) and were only possible by extensive international support and participation. Each group had processed the data separately, applying its own software package, using its own selection of fiducial stations and defining its own strategy to determine the solution. In this paper the following items will be pointed out: Basics for the establishment of this network to serve for various scientific activities.

MEDIUM-RANGE GPS POSITIONING TECHNIQUES AND THEIR APPLICATIONS

Shaowei HAN, Chris Rizos (School of Geomatic Engineering, The University of New South Wales, Sydney NSW 2052, Australia, email: s.han@unsw.edu.au, c.rizos@unsw.edu.au)

Continuously operating GPS networks are increasingly being established to support surveying, mapping, or navigation applications, often with reference receiver separations of the order of 100 or more koilometres. Carrier phase-based, medium-range GPS kinematic positioning can potentially provide centimetre accuracy trajectories even when the separation between the mobile receiver and reference receiver(s) is many tens of kilometres. Such a technique is based on a linear combination functional model, formed from the single-differenced functional equation for baselines from the mobile receiver to three or more reference receivers. The orbit bias and ionospheric delay can be eliminated, and, in addition, the tropospheric delay, multipath and observation noise can be significantly reduced. In this paper, further test results are described for the following scenarios:
1 Medium-range, single-epoch GPS positioning using state-of-the-art GPS receivers.
2 Medium-range, rapid static positioning for geodetic network densification using low-cost, single-frequency GPS receivers.
3 Establishment of a high precision, high density geodetic network using low-cost, single-frequency GPS receivers, for example, to determine the spatial characteristics of crustal deformation across an area of interest.
Three examples: (a) the single-epoch GPS kinematic positioning experiment, (b) the Taiwan geodetic network densification, and (c) the Indonesian GPS-based volcano monitoring network, are described, and further comments are given with regard to future implementation scenarios.

A GEODETIC NETWORK FOR MONITORING CHANGES IN REGIONAL GROUND LEVEL IN THE THAMES ESTUARY AND GREATER LONDON

Richard BINGLEY, Simon Booth, Nigel Penna, Vidal Ashkenazi (IESSG, University of Nottingham, Nottingham, NG7 2RD, UK, email: richard.bingley@nottingham.ac.uk)

Small ground movements can have major strategic or economic significance in certain regions of the world, for example in low lying river estuaries and coastal regions susceptible to flooding. One such region where small ground movements are exhibited is the Thames Estuary and Greater London, warranting the construction of tidal defences, such as the Thames Barrier.
In 1996, the UK Environment Agency initiated a project involving the IESSG and the British Geological Survey. The objective was to develop a generic strategy for monitoring changes in regional ground level using GPS and the ITRS, and providing an interpretation of such changes in terms of local and regional geology. The strategy developed is based around the use of a small number of continuously operating GPS receivers, acting as reference stations for a dense network of monitoring stations, observed using episodic GPS measurements. The strategy has been tested in the Thames Estuary and Greater London region, and the presentation will give details of the establishment of the monitoring network and the results from the first two years of measurements.

MODELLING AND CORRECTION OF GPS/GLONASS OBSERVATION DATA USING TIME SERIES METHODS FOR IMPROVING SURVEYING PRECISION

Minghai JIA, Maria Tsakiri, Mike Stewart (all at School of Spatial Sciences, Curtin University of Technology, GPO Box U 1987 Perth WA 6845, Australia, email: jia@vesta.curtin.edu.au)

Since the observation data from GPS/GLONASS are contaminated by multiple complicated error sources, the GPS/GLONASS observation errors rarely subject to a normal distribution. Even specific techniques to reduce the observation errors, such as diverse differential methods, have been widely used, there still exist some patterns in the observation errors in some circumstances such as the multipath delay errors in the monitoring of open pit walls and the residual ionospheric refraction errors in the processing of the long baselines.
In this study, time series methods have been used for the modelling and correction of diverse GPS/GLONASS observation data including the non-differences and the diverse differences of pseudorange and carrier phase data as well as their different frequency combinations. The developed procedure has been merged into the GPS/GLONASS software developed by Curtin University of Technology.
Trial results for the data sets from different circumstances have shown that the developed procedure can build reliable models for the data sets. An ARMA (1, 2, 0) model, for example, to all visible satellite is applicable for a specific non-difference carrier phase data set at a sampling rate of 1Hz. Using the developed procedure, some errors such as the multipath delay errors and the residual ionospheric refraction errors can been largely modelled and corrected, and also, the slips of one to two cycles in GPS observation data been detected and corrected. Improvement of the modelling rate is expected for perfecting the developed procedure.

REAL TIME POSITIONING BY DIFFERENTIAL GPS IN THE WESTERN MEDITERRANEAN SEA

S. KAHLOUCHE, A. Zeggai, A. Ayouaz, S. Touam, H. Abbas, S. Benahmed Daho (Geodetic Laboratory, National Centre of Spatial Techniques, CNTS BP 13, Arzew 31200, Algeria); H. Mouheb (Office National de Signalisation Maritime, 9 Bd Amirouche, Algiers 16000, Algeria)

The setting up of the three DGPS emitting stations (Oran, Algiers and Jijel) for maritime applications in the south basin of the western Mediterranean sea needed a choice of site implantation for the optimal covering of the Algerian coast.
The geodetic configuration, initially based on the ADOS (African Doppler Survey) network with a metric accuracy, was carried out by the establishment, in the WGS84 system of a precise absolute network determined from the TYRGEONET (Tyrrhenian Geodetic Network) network established for regional geodynamical studies in the western Mediterranean. The GPS observing campaigns, using the Ashtech Z-12 receivers, are processed with PRISM software and provided a centimetre accuracy of the stations.
The use of the emitting stations (range of 800 Km) permit, from the differential corrections elaborated, a real time positioning (every 0.6 s) with a metric (2 m) accuracy. The maritime applications in the local reference system (Nord Sahara) needs the determination of the transformation parameters from the establishment of a coastal network.

THE NEW NATIONAL HEIGHT SYSTEM (LHN95) OF SWITZERLAND

A. Schlatter, U. MARTI (both Federal Office of Topography, Seftigenstrasse 264, CH-3084 Wabern, Switzerland. email: Andreas.Schlatter@lt.admin.ch, Urs.Marti@lt.admin.ch)

The existing old height system of Switzerland (LN02) consists of purely levelled heights without considering gravity measurements. This causes difficulties in the application of modern techniques such as GPS for height determination in mountainous areas and in the data exchange with neighbouring countries. Therefore, a new rigorous height system LHN95, based on geopotential numbers and the corresponding geoid, is being determined at the Federal Office of Topography (L+T) in collaboration with the Federal Institute of Technology at Zurich. LHN95 not only serves as the new National Height Network but it also fulfills the demands of large engineering projects. LHN95 is treated as a kinematic network with respect to the Alpine uplift which reaches amounts of up to 1.5 mm/year. The corresponding relative vertical movements are determined by repeated observations of the first and second order levelling lines. For LHN95, it was decided to use ortho-metric heights. This implies the use of the geoid as the reference because it has a smooth surface and can be interpolated easier than the quasigeoid.
First results can now be presented from these extensive computations. Of special interest is the information obtained on recent vertical movements in Switzerland resulting from a dense network of repeated measurements. From the comparison of LHN95, the new geoid for Switzerland (GEOID98, Marti) and the repeated observations of the new satellite-based national control survey (LV95), informative conclusions may be drawn concerning the possibilities of absolute height determination in Alpine regions with height differences of over 2000 m.

- Software Noise: The effect of different software packages and strategies on the results of the GPS data processing
- Reference network noise: The effect of a different number of fiducials and differences in their stochastics on the resulting coordinates.

SATELLITE GEODESY ON CURVED MANIFOLDS

SCHWARZE

A consistent model for satellite geodetic observations is developed within the framework of general relativity at post-Newtonian level. The theoretical model consists of three parts. The first part considers the motion of some satellite vehicle, the second the propagation of electromagnetic waves and the third the definition of observable quantities.
The satellite vehicle, the electromagnetic wave and the observer are considered to move on a curved four-dimensional manifold of pseudo-Riemann type. The impact of the relativistic model on the geodetic adjustment process is considered by the simulation of several satellite based positioning scenarios involving several differencing techniques (single-, double- and triple-differences).

FUTURE DIRECTIONS OF THE NATIONAL CORS SYSTEM

WESTON

The National Geodetic Survey (NGS) continues to enhance the continuously operating reference station (CORS) system, thereby improving people's ability to use Global Positioning System (GPS) data for positioning points with cm-level accuracy throughout the United States and its territories. People also use CORS data to develop geographic information systems, to monitor crustal deformation, to determine the distribution of water vapor in the atmosphere, to support remote sensing applications, and to monitor the distribution of free electrons in the ionosphere. To enhance the CORS system, NGS is steadily increasing its spatial coverage by adding an average of 3 new CORS sites per month. (In December 1998, the system contained 145 sites.) In addition, NGS plans to regularly upgrade its user-friendly CORS information server, making CORS data and related information (descriptive text, site positions and velocities, GPS ephemerides, selected meteorological data etc.) more readily accessible via the Internet. Also the agency is:

- generating digital models of: antenna-phase-center variation, crustal motion, total electron content in the ionosphere, and geoid heights;
- supporting research to develop a reduced multipath GPS antenna;
- investigating the possibility of providing nationwide digital maps of pertinent meteorological data to enable more rigorous GPS processing;
- striving to produce and provide accurate GPS ephemerides and digital models more rapidly so that the users can determine accurate point positions in a timely manner.

Moreover, NGS is continuing to study how enhancements to the CORS system impact positioning accuracy and its dependence on the distance to the nearest CORS site and the duration of an observing session.

A NEW QUALITY CRITERION FOR GPS MEASUREMENTS

Kerstin WIENHOLZ (TU Berlin, Str. d. 17. Juni 135, D-10623 Berlin, Germany,
email: wienholz@inge3.bv.tu-berlin.de)

The GPS signal can be disturbed by cycle slips, multipath and refraction effects. These factors can influence the ambiguity fixing. The resulting coordinates are therefore affected by the accuracy and reliability of the determination of ambiguities. Especially for networks with longer baselines the computation of ambiguities is still an unresolved problem. Today, the average user has no other choice than to trust the results of the GPS phasemeasurements. The only available additional information (besides coordinates) is restricted to the P-DOP value, which represents the quality of the geometrical configuration of satellites.
This study introduces a supplementary criterion based on further sources of disturbance. For this we need a trustworthy preprocessing of GPS data to obtain cycle slips and a new method for the ambiguity fixing. The necessary parameterization of the observation equations is being presented. This parameteriziation contains also an elimination of several unknowns. Using the resulting quality factor the user can decide between a longer observation time or stopping the measurements. This is especially important in GPS realtime measurements because the observer gets coordinates and their quality estimate at the same time. In the future, a broader range of the radio transmission of the information from the base station to the rover will make realtime phaseobservations within larger areas possible. Than the demonstrated method can become an important part of the realtime processing.

THE UNIFICATION OF GLOBAL VERTICAL DATUMS

KEARSLY

Since at least the mid-1970's, a unified global vertical reference system has been the desire of many geodesists, and the subject of successive IAG Special Study Groups. These have been formed to study, inter alia, "methods for the determination of a unique global vertical reference surface", and "strategies for developing and implementing a World Vertical Datum". With the advent of GPS, other space-based techniques, and the development of the ITRF and regional GPS super-control networks, we now have the means to link vertical datums geometrically. Some campaigns have had as their specific aim the strengthening of the regional vertical datum (e. g., EUVN; NAVD). However, for most of these networks the vertical component has been of secondary, if any, interest - their primary intent was to provide control for GPS surveys, superior geodetic infra-structure for regional GIS's (e.g., APRGP97), or a means of tracking horizontal deformation (e. g., GEODYSSEA). Nevertheless, it is possible to make use of these latter campaigns, as they provide an invaluable source of vertical data. We now also have with the production of superior global geopotential models (e. g., EGM'96), a globally recognised physical reference surface. We thus have the capacity to bring to a full realisation the goals of those earlier Study Groups. In this presentation I will be proposing a strategy which, by involving national and regional authorities, national vertical datums can be tied into the regional GPS super-control networks and, indirectly or directly, onto the ITRF. The properties desired of such tie points will be proposed, and the problems associated with such ties, (e. g., distortions in a national vertical datum) foreshadowed, with possible solutions proposed.

THE SINGAPOREAN GPS REFERENCE RECEIVER NETWORK: AN "OPEN AIR" LABORATORY FOR INNOVATIVE HIGH PRECISION GPS TECHNIQUES

Chris RIZOS, Shaowei Han (both at School of Geomatic Engineering, The University of New South Wales, Sydney, Australia, email: c.rizos@unsw.edu.au, s.han@unsw.edu.au); Pong Chai Goh, Tam Khoon Tor (both at School of Civil & Structural Engineering Nanyang Technological University, Singapore, email: cpcgoh@ntu.edu.sg, cpcgoh@ntu.edu.sg)

Continuously operating GPS networks have been used for many years to address two types of positioning applications. The first, perhaps the best known application, is in support of geodetic goals such as the determination of crustal motion on a variety of spatial scales - from the measurement of the broad kinematics of tectonic plates to deformation monitoring of local areas. Currently, hundreds of permanent GPS stations around the world are now formally part of the global network known as the International GPS Service (IGS). The second class of applications that have traditionally been addressed by continuously operating GPS receiver networks are those that require real-time, differential GPS (DGPS) services over many hundreds of kilometres, to determine coordinates to accuracies of the order of a few metres. The DGPS corrections to pseudo-range data are determined at groups of permanent GPS stations which service wide continental or oceanic regions, using a positioning technique generally referred to as Wide Area DGPS.
The population of continuously operating GPS receivers is growing. Some are being established to address a single application, while others are designed for multi-functional use. In some countries permanent GPS stations are intended to support local surveying users. However, the GPS reference receivers, because of their high cost, often cannot be established in a dense enough configuration to satisfy all user requirements. For example, GPS surveying typically requires receiver separations of less than 30km (and even <20km for OTF-kinematic and rapid static positioning techniques). In this paper, several new static and kinematic GPS techniques for user positioning which are optimised for GPS baseline lengths of the order of 50-100km are described, and the role of the Singaporean GPS reference receiver network in the development and testing of such techniques is highlighted.
One implementation is a form of "densification" of a network of dual-frequency GPS receivers

in which a permanent array of single-frequency GPS receivers is deployed to increase the basic network spatial resolution. Such an implementation would benefit deformation monitoring applications. Another implementation is analoguous to the "rapid static" GPS surveying technique, but using a network of base receivers. An enhanced (single-epoch) OTF-kinematic technique suitable for real-time positioning applications is also described. What makes the Singaporean network unusual is that the permanent GPS reference receivers are linked by high speed datalinks to a single control station in a manner analogous to the WADGPS systems, simplifying testing and simulating a real-time operational environment for such techniques.

TRANSFORMATION OF WGS84 CO-ORDINATES IN LOCAL DATUM USING GPS BASELINES

A. ZEGGAI, S. Touam, B. Ghezali, N. Nabed (Geodetie Laboratory, National Centre of Spatial Techniques, BP 13 Arzew, 31200, Algeria)

The co-ordinates transformation models between geodetic reference systems (Bursa-Wolf, Molodensky-Badekas, Veis) are generally the most used to compute the transformation parameters if both systems are identical. The accuracy obtained depends on the accuracy of the co-ordinates used.
In the case of Algeria, the parameter computation remains altered by the total absence of information of the geoid undulation above astro-geodetic ellipsoid (Clarke 1880 A). The planimetric solution proposed from the computation of the geodetic baselines (azimuth, geodetic length) can give better results if we consider azimutal correction and scale Variation bei between both lengths (in both systems). This problem is particularly important for geodetic and cadastral works in the south region of ALGERIA (Sahara) where the geodetic data are not sufficiently available (GPS and National bench marks, spirit levelling, etc). An experimental network based on GPS baselines measurements with bifrequency receivers, was observed in the south west of ALGERIA (Oran - Bechar). The accuracy given from preliminary results is about 2 to 3 cm for short baselines 2 to 15 kilometres) and metric for long baselines (500 kilometres).

GPS SATELLITE ORBIT PERTURBATIONS DUE TO THE SOLAR WIND: INITIAL RESULTS

Marek ZIEBART, Peter Dare (both at Applied Geodesy Research Unit, School of Surveying, University of East London, Longbridge Road, Dagenham, Essex RM8 2AS, UK, email: marek@uel.ac.uk, peter@uel.ac.uk)

Orbit reresentation customarily uses time-tagged position and velocity vectors. These are determined by solving the satellite's second order differential equation of motion. The non-gravitational forces modelled include solar radiation pressure (SRP). Empirical scaling factors for the SRP models are usually applied to compensate for modelling errors. Accelerations due to the solar wind, have previously not been modelled. Most of the solar wind is deflected away from the Earth at 6-10 earth radii, whereas at the magnetic poles particles from the solar wind spiral down to lower altitudes. This flux may act as a perturbing acceleration to the GPS orbit. Variations in the SRP scaling factors are considered. Time-tagged scaling factor data is used to compute a fourier series for each satellite. This data is used to map the satellite ground tracks, colour graduated with the SRP scaling factor. An algorithm is also developed to compute the orientation of the satellites' solar panels with respect to a simplified model of the Earth's magnetic field. There appears to be a correlation between the satellite attitude and the magnitude of the SRP scaling factors which may be due to the flux of the solar wind particles in the magnetic field interacting with the satellite. Orbit analysis is carried out using GIPSY-OASIS II.

ON THE PERMANENT EARTH TIDES

Wenke SUN, Lars E. Sjoberg (both at Royal Institute of Technology, Department of Geodesy and Photogrammetry, S-10044 Stockhom, Sweden, e-mail: sunw@geomatics.kth.se)

The tidal deformation caused by the luni-solar potential includes not only a periodic part, but also a time-independent part, called the permanent tide. How to deal with the tidal correction in gravimetric observations, especially the treatment of the permanent tide, has been discussed for a long time (e.g. Honkasalo 1959; Heikkinen 1979; Ekman 1989), since some practical and physical problems exist anyhow. To avoid the problems, Ekman (1979) and Groten (1980) proposed that the permanent tidal attraction of the Moon and the Sun are eliminated, but the permanent tidal deformation of the Earth is maintained. This is called zero gravity and the geoid associated with it is the zero geoid. This concept was accepted in a resolution of IAG in 1983. As to the crust deformation, Poutanen et al. (1996) suggested that coordinates should be reduced to the zero crust, i.e. the crust that includes the effect of the permanent tide. This research shows that horizontal components of the permanent earth tides, which have never been considered up to now, is also important in GPS positioning and geoid determination. Since the tide-generating potential can be expanded into harmonics and divided into two parts: geodetic coefficients and the group of harmonic waves, the permanent earth tides can be easily obtained by multiplying the amplitude of the zero-frequency wavelength by the corresponding geoid geodetic coefficient. Results show that the vertical permanent crust change reaches -12 cm at the poles and 6 cm at the equator. The horizontal permanent crust displacement and geoid deflection also reach as much as 2.5 cm and 8.9 cm, respectively. According to the solution of IAG (1983), the permanent vertical components are kept in GPS positioning and geoid computation. Thus, it is natural to include the horizontal components correspondingly.

THE METHOD OF IMITATING BLOCK MOTION IN ESTABLISHING REGIONAL GEODETIC DATUM

Lu ZHIPING (Department of Geodesy, Zhengzhou Institute of Surveying and Mapping, Zhengzhou, 450052, P.R.China); Liu Jingnan (Wuhan Technical University of Surveying and Mapping, 39 Luoyu Road, Wuhan, 430070, P.R.China)

The high-density and high-precision GPS geodetic network in China, called the scientific engineering "China Crustal Movement Observation Network", is carrying out since 1998, which is the occasion of establishing Chinese practical reginal kinematic geodetic datum.
In order to make practical application convenient, we define kinematic datum parameters(e.g., rotation of block), which is similar to static datum parameters(e.g. ellipsoid and orientation parameters). And the added paramerers are corresponding to a certain block, not corresponging to a point such as velocity parameters in ITRF. So a group of kinematic parameters can be resolved using multi-point observed data in the same block. In practice, the coordinates change so slow that they would not affect engineering application such as digital mapping for 20-30years. But once considered, the time dependency of the datum established in this method can ensure the continuity of datums in different periods and make relative positions unchanged within the block.
The concrete processes of the method are as follows: First, dividing the tectonic blocks which can be reflected by observed data. This will refer to geological and geomorphic models, but completely determined by the precision and time-scale of observed data. Second, resolving the motion parameters of each block by the combined adjustment. The concrete types of motion models led into adjustment model are determined through model tests before the adjustment.

VELOCITY FIELD ESTIMATION FOR GEODETIC NETWORKS USING METHOD MODIFIED KALMAN FILTERS

Wu CHEN, Cahit Tagi Celik, Richard Bingley, Vidal Ashkenazi (IESSG, University of Nottingham, Nottingham, NG7 2RD, UK, email: wu.chen@nottingham.ac.uk)

The use of permanent GPS networks has been expanding rapidly over recent years, providing great opportunities for geodynamics research. With long-term observations, horizontal and vertical movements on the Earth can be precisely measured and used to form coordinate time series. Kalman filtering techniques can then be used as an efficient way to estimate station velocities from these coordinate time series. However, any short-term local motion (eg due to an earthquake) or inconsistencies in the coordinate time series (eg due to GPS equipment changes) can contaminate the velocity estimates for a significant period when using a conventional Kalman filter. In order to overcome this problem, two types of modified Kalman filter have been developed and implemented. The first tries to reduce the velocity estimate error by modifying the covariance matrices, and the second uses an adaptive filter to estimate the local movement separately.
The performance of these two modified Kalman filters has been tested using a real/simulated data set, based on the effect of the 22 November 1995 earthquake on a geodetic network in the East Mediterranean. The presentation will give details of the modified Kalman filters and will compare their performance, based on the results obtained using the real/simulated data set.

REVIEW OF THE REALIZATIONS OF THE INTERNATIONAL TERRESTRIAL REFERENCE SYSTEM AND CURRENT RESULTS

Zuheir ALTAMIMI, Claude Boucher, Patrick Sillard (all at IGN/ENSG/LAREG, 6-8 Avenue Blaise Pascal, 77455 Marne-la-Vallee, France, email: altamimi@ensg.ign.fr)

Since the creation of the IERS in 1988, the International Terrestrial Reference System (ITRS) is realized nearly yearly through the International Terrestrial Reference Frame (ITRF). A review of these realizations are presented in this paper, focused on their quality as well as the progress achieved to improve the ITRF implementation. Specific attention is given to the most recent ITRS realizations, namely ITRF96 and ITRF97 which represent the "starting point" of new generation of ITRF solutions based on more rigorous physical and statistical combination modelling. The most current results and analysis of ITRF are presented in this paper.

G1/C/G5/E/15-A3 Poster 1620-102

IGS REALIZATIONS OF ITRF, AN UPDATE

R. FERLAND, D. Hutchison, Y. Mireault (all at 615 Booth Street, Ottawa, Ontario, Canada, K1A 0E9, e-mail: ferland@geod.nrcan.gc.ca, hutch@geod.nrcan.gc.ca, mireault@geod.nrcan.gc.ca)

The objectives of the International GPS Service (IGS) realization of the International Terrestrial Reference Frame (ITRF) are to provide an accurate, consistent and unique set of station coordinates, velocities and Earth Orientation Parameters (EOP). The consistency is ensured by simultaneously combining the station coordinates and EOP using their variance-covariance information. The Analysis Centers (AC) compute a new solution every week containing station coordinates and daily EOP. The Global Network Associates Analysis Centers (GNAAC) combine these AC solutions. The final results are based on a unique combination of the GNAAC weekly solutions. The IGS realization of ITRF is accomplished by aligning the solutions to a carefully selected set of 47 reference frame stations. There are currently more than 180 stations in the network with an objective of 200 to 250 well distributed stations. Over 3 years of weekly solutions have been combined. Weekly geocenter estimates are extracted. The formal sigma weekly time series on the geocenter indicates a gradual improvement in the solutions. The geocenter Z component shows an annual period with amplitude of about 25 mm. The RMS residuals at the reference frame stations are 3-4 mm horizontally and 9-10 mm vertically. A spectral analysis of the residuals shows the presence of a small annual and/or semi annual period at some stations mainly in the vertical component. EOP comparisons will also be analyzed.

G1/C/G5/W/18-A3 Poster 1620-103

INVESTIGATION OF A GPS PROCESSING STRATEGY FOR THE AFRICAN CONTINENT

Cara LINDSAY, Peter Dare (both at Applied Geodetic Research Unit, School of Surveying, University of East London, Longbridge Road, Dagenham, Essex, RM8 2AS, UK, Email: c.l.wilson@uel.ac.uk)

Processing of GPS data is increasingly being adapted to benefit crustal dynamic applications, however, the results depend on the processing strategy adopted. The key objective of this paper is the establishment of an analytical procedure to study the plate kinematics of the African continent. This enables the rates of displacement to be determined to a precision of millimetres between reference points. Data will be drawn from a globally distributed network of high precision receivers maintained by the International GPS Service (IGS). The IGS data used covers a three year period, where weekly solutions are computed using the GIPSY-OASIS II suite of programs. The flexibility, yet complexity of the software lends itself well to this project. Three primary vectors that span the African plate have been selected. This set of vectors has been computed using varying strategies. Different models are used to distinguish the most effective method for gaining significant results. These include modelling for the wet tropospheric delay, phase centre variation and resolving for integer ambiguities. Additional IGS stations are included in the processing to tie the overall solution into the International Terrestrial Reference Frame. These span the Eurasian and Arabian plates, including stable SLR and VLBI sites. Limited crustal dynamic work has been carried out on the African continent, thus reducing the agreement or disagreement with other global plate motion models, e.g. NUVEL 1A and the work by M.B.Heflin. Comparison of results from the different strategies gives an initial understanding of the components that need to be considered for the African continent.

AN EXTENDED WEIGHT MODEL FOR GPS PHASE OBSERVATIONS

Andreas Wieser, Fritz K. BRUNNER (Engineering Surveying and Metrology, Technical University of Graz, Steyrergasse 30, A-8020 Graz, Austria, email: wieser@aig.tu-graz.ac.at)

The accuracy of GPS based point determinations in small scale engineering applications is mainly limited by multipath and signal diffraction. Often the observation sites are determined by positional requirements rather than by ideal observation conditions, which increases the probability of obstructions and signal distortions. In order to improve satellite geometry and reduce the required observation time, low elevation data is included in the processing, but this increases noise and systematic errors. Thus careful weighting of the phase observations is needed. The measured carrier-to-noise-power-density ratio (C/N0) has proven to be an excellent tool for the estimation of the random errors of the phase observables. Due to the strong correlation between the satellite elevation and the C/N0, a template function can be determined to derive the expected C/N0 for a certain elevation angle and receiver-antenna combination. The difference (Delta) between the C/N0 observation and the template value is an indicator for systematic signal distortion, which is also shown a posteriori by the residuals of the phase data. In this paper an extended weighting model is presented, which combines the information inherent in C/N0, Delta and the residuals in order to take random errors and diffraction effects properly into account. A comparison of the proposed method with equal weighting and elevation dependent weighting shows a significant reduction of the signal distortion influence on baselines up to a few kilometers. Consequently, accuracy and ambiguity resolution are improved and the required observation time can be minimized.

DATA PROCESSING AND ACCURACY ANALYSIS OF THE SECOND-ORDER GPS NETWORK IN CHINA

ZHA MING and Xu Bilin (Xi'an Technical Division of Surveying and Mapping, 36 Xiyinglu,Xi'an, Shaanxi 710054, P.R.China) Duan Wuxing and Tang Yingzhe (Xi'an Research Institute of Surveying and Mapping, 1 Zhongduan, Yantalu ,Xi'an, Shaanxi 710054, P.R.China)

The nationwide GPS geodetic network comprised the first-order and the second-order network in China has been established. It will play an important role in strengthening an astro-geodetic network, refining a geoid and realizing a regional geodetic terrestrial reference frame.
The first-order network involving 44 stations was measured during the period from late May 1991 to early May 1992. Based on the first-order network, the field survey of the second-order network including 534 stations was performed in 1992,1993,1994,1995 and 1997. Now the data processing of the second-order network has been complished. Fiducial Point Technology has been used for the data processing. The coordinates of a regional distributed set of IGS tracking stations are constrained weightily to force the second-order network refers to ITRF96. GAMIT GPS analysis software was used for baseline processing. The software VECADJ was developed to make the network adjustment. According to the accuracy analysis of the adjustment results, it has been shown that the absolute positional accuracy is better than 0.1m and the relative positional accuracy is better than 0.1ppm.

SOME ERROR SOURCES IN HIGH PRECESSION INTERFEROMETRIC AND ELECTRNIC DISTANCE MEASUREMENTS

Yuriy GALKIN (Department of Physics, Moscow State Forestry University, Mytischi-5, Moscow reg., 141005, Russia, email: galkin@mgul.ac.ru)

It is shown that, besides anomalous refractivity, the non-linearity of the dispersive behavior of the refractive index of air, particularly near the absorption lines of the atmospheric components, affects measured lengths as a sistematic error. This is prticularly important for interferometry in metrology and very high accuracy laser EDM. The magnitude of the error depends on the specific device and measurement conditions. The results of computer simulations are presented.

SPACE GEODETIC TECHNIQUES

Reiner Rummel (IAPG, Techn.Univ.Munich, Arcisstrasse 21, D-80290 Muenchen, Germany, email: rummel@step.iapg.verm.tu-muenchen.de)

Again the past four years brought about considerable advances in space geodesy. GPS applications were extended to atmospheric sounding, continuous tracking of LEO's, earth rotation time series with high resolution. Precise orbits for GLONASS satellites will come soon and IGS plays a prominent role on all of the above. CSTG established services for VLBI and laser ranging very similar to that for GPS. VLBI and satellite laser ranging are still progressing in terms of efficiency, automation, precision and reliability, as do the tracking systems DORIS and PRARE. A further milestone is the prospect of a series of dedicated gravity field missions. They will change the face of geodesy and its role in Earth sciences. There remains the big challenge of really combining geodetic space techniques so as to form one integrated "instrument" encompassing our planet.

G2/L/02-A2 **0945**

HIGHLIGHTS OF RECENT DEVELOPMENTS IN THE INTERNATIONAL GPS SERVICE AND PERSPECTIVES FOR FUTURE DIRECTIONS

R. Neilan (1), Ch. Reigber(2), T. Springer(3), G. Beutler(3), J. Kouba(4) 1. IGS Central Bureau, Jet Propulsion Laboratory/Caltech Pasadena, CA, USA 2. GeoForschungsZentrum Potsdam, Germany 3. Astronomical Institute University of Bern, Switzerland 4. Natural Resources of Canada, Ottawa, Canada

In December 1998, the IGS Governing Board officially changed the name of this IAG service from 'International GPS Service for Geodynamics' to simply the 'International GPS Service'. This change of name reflects the fact that today the IGS supports numerous scientific projects outside the traditional geodetic and geodynamic disciplines. A number of IGS projects and working groups have been established, each concentrating on a particular science application, such as the ionosphere, atmosphere, reference frame, precise time transfer, etc. These activities are enabled and stimulated by the IGS and directly contribute to the continuing development of the service. The IGS is currently poised to respond to evolving user requirements that focus on timeliness and reliability of data and products, particularly in support of a slate of Low Earth Orbiter missions over the next decade.
Perspectives on the future of the IGS will be developed based on current directions as well as anticipated external influences, such as GPS satellite modernization, GLONASS, availability of global communications, and plans for the European GALILEO (Global Navigation Satellite System - GNSS). We will address development of user friendly interfaces and IGS product tutorials.

THE CONTRIBUTION OF THE WEGENER PROJECT TO AN INTEGRATED MONITORING OF THE EARTH SYSTEM

Susanna Zerbini (email: zerbini@astbo1.bo.cnr.it), Hans-Peter Plag and Bernd Richter

The Special Commission 6 of IAG Section II, the WEGENER Project, has promoted the development of scientific space-geodetic activities in the Mediterranean and European area for the last fifteen years and has contributed to the establishment of geodetic networks designed particularly for Earth science research. The WEGENER Project has three main objectives: 1) to study the three-dimensional deformations and gravity along the African-Eurasian plate boundaries and in the adjacent deformation zones in order to contribute to a better understanding of the associated geodynamical processes; 2) to monitor the three-dimensional deformations in a large region centered around Fennoscandia in order to determine the magnitude and extent of the present-day postglacial rebound in that area, thereby extending our knowledge about the viscoelastic properties of the Earth; 3) to investigate height and sea-level variations in order to identify and separate the processes contributing to these variations. However, WEGENER activities include contributing to improvements of the measurement techniques, testing of new technological means, proposals for new missions and providing syntheses of observable quantities and inversion of the observations for geodinamically relevant parameters.
The WEGENER Project is conscious of the importance of contributing to the implementation of the principle of sustainable development and, in this context, is now trying to develop an effort, at European scale, which addresses the need to realize an integrated multi-purpose network for the acquisition and availability of long-term, continuous, high-quality spatial and in situ measurements. WEGENER intends to specifically contribute, among other objectives, to the definition of a high-precision network of permanent GPS stations in the European area, to the availability of the data collected by the stations for scientific exploitation and to lay the basis for the realization of an infrastructure where the different partners involved in the establishment and operation of permanent space-geodetic networks can meet, plan and organize the activities in a coherent, cost-effective manner. Such a network would also provide a significant contribution to the detection and understanding of climate change, to asses impacts at global, regional and local scale and would provide fundamental observations to validate models.

DEDICATED GRAVITY FIELD MISSIONS

Karl Heinz ILK (Institute of Theoretical Geodesy, University of Bonn, Nussallee 17, D-53115 Bonn, Germany, email: ilk@theor.geod.uni-bonn.de)

The investigation of the Earth's gravity field will enter a new era at the turn of the millenium. After three decades of careful preparation of various spaceborne gravity field mission concepts there are excellent chances to realize all three of them. These three mission concepts are high-low SST, low-low SST and SGG. CHAMP and GRACE will be launched in the years 2000 and 2001 with an overlapping mission period of two years. These two missions will provide the gravity field of the Earth with unattained accuracy and an eventual time dependency at least of the long-wavelength part of the gravity field. ESA's satellite gravity gradiometry mission concept GOCE has an excellent chance to become the first Earth Explorer mission. It is a dedicated high resolution gravity field mission concept and will open a completely new range of spatial scales of the earth's gravitational field spectrum down to 100km wavelength. Careful investigations have shown that the characteristics of the three mission concepts are rather complementary than competitive. Together with complementary geophysical data, satellite gravity data represent a "new frontiere" in studies of the system Earth.

SAR INTERFEROMETRY TECHNOLOGY

ROLAND KLEES (Department of Geodetic Engineering, Delft University of Technology, Thijsseweg 11, 2629 JA Delft, The Netherlands, email: klees@geo.tudelft.nl)

The main objective of the SSG 2.160 SAR Interferometry Technology was (1) to make significant contributions to the development of SAR Interferometry (InSAR) as a technique for topographic mapping and surface change detection and (2) to promote the implementation of InSAR into geodetic and geodynamic work. This has led to the following major research topics of the SSG: (1) data processing strategies, (2) quality description and validation, (3) applications in Earth sciences, (4) limitations to InSAR.
We will give a review of the SSG-research according to the classification mentioned before: ad (1) phase unwrapping strategies, filter techniques, ad (2) nature of noise, coherence estimation, comparison with GPS and levelling, ad (3) detection of tectonic deformations, post- and co-seismic deformation measurements, volcano monitoring, glacier and ice sheet monitoring, monitoring of local subsidence due to anthropogenic activities, and atmospheric tomography for operational meteorology; ad (4) decorrelation and atmospheric disturbances in SAR interferograms. The presentation will finish with an outlook on future work in the field of InSAR.

SPACE BORNE ATMOSPHERIC GNSS SOUNDINGS

Christian Rocken ,COSMIC and GST Programs, UCAR 3300 Mitchell Lane Boulder, CO 80301, USA, E-mail: rocken@ucar.edu

The international research community has achieved significant progress in space borne atmospheric limb sounding with GPS. Most high-quality data from the GPS/MET proof-of-

concept mission have been analyzed, archived, and made available to the research community. Statistical validation of these results confirmed the high theoretically expected equivalent temperature accuracy of approximately 1 K from near the surface to 40 km. It was further demonstrated that accurate water vapor profiles can be retrieved when ancillary temperature data are available. The occultation sounding data have also been used for the measurement of accurate (~ 10 meters) geopotential heights and for the study of gravity waves. Perhaps the most important meteorological result from GPS/MET was that the agreement with numerical weather prediction (NWP) models is noticeably better in data dense than in data poor regions. This means that occultation data assimilated into NWP models should improve the weather forecast. In the ionosphere the data were used for electron density profiling. Comparison with the global ionosonde network showed ~15% rms agreement in the critical plasma frequency foF2. Techniques for tomographic analysis of the occultation data in combination with ground based observations have been developed. Two space missions carrying Jet Propulsion Laboratory-developed GPS occultation receivers have been launched in early 1999, and at least 6 more missions with limb sounding receivers have been funded and are scheduled for launch in the next 3 years. The goals of these missions ranges from limb sounding technology improvement to demonstrating the impact of this technology on weather prediction, space weather prediction, and climate monitoring. This presentation will highlight key limb sounding results obtained during the last 4 years and describe the scientific goals of planned future missions.

CSTG DEVELOPMENT IN THE TIME PERIOD 1995-1999

Gerhard BEUTLER (Astronomical Institute, University of Bern, Sidlerstrasse 5, CH-3012 Bern, Switzerland, email: beutler@aiub.unibe.ch) Hermann Drewes (Deutsches Geodaetisches Forschungsinstitut, Marstallplatz 8, D-80539 Munich, Germany,
e-mail: mailer@dgfi.badw-muenchen.de)

International Coordination of Space Techniques for Geodesy and Geodynamics (CSTG) is Commssion VIII of the International Association of Geodesy (IAG) and Sub-Commission 2.B of the Commission for Space Research (COSPAR).
According to its charter, CSTG has to develop links between various groups engaged in the field of of space geodesy and geodynamics by various techniques, to coordinate the work of these groups, elaborate and propose projects implying international cooperation, follow their progress, and report on their advancement and results.
In the time period 1995 to 1999 CSTG the commission's structure was considerably changed through the creation of two new services, the ILRS (International Laser Ranging Service) and the IVS (International VLBI Service) as successors of the the SLR/LLR subcommission and the VLBI subcommission of CSTG. CSTG was also the lead organization of the first global GLONASS tracking and analysis experiment, the IGEX-98. Four issues of the CSTG Bulletin fully document the work performed by the Commission in this time period.
We highlight the essential developments within CSTG of the past four year period and we address the future of the Commission in view of the changes that took place in the time period 1995-1999.

G2/L/09-A2 1200

FROM THE VLBI SUBCOMMISSION TO THE IVS: SCIENTIFIC HIGHLIGHTS AND PERSPECTIVES

W. SCHLUETER (Bundesamt fuer Kartographie und Geodaesie, Wettzell, Germany, email: schlueter@wettzell.ifag.de), N. Vandenberg (Goddard Space Flight Center/NVI, Inc., Greenbelt, Maryland, USA, email: nrv@gemini.gsfc.nasa.gov), J. Campbell (Geodetic Institute University of Bonn, Bonn, Germany, email:campbell@sn_geod_1.geod.uni-bonn.de), T. Clark (Goddard Space Flight Center, Greenbelt, Maryland, USA, email: clark@tomcat.gsfc.nasa.gov)

The International VLBI Service for Geodesy and Astrometry (IVS) was established over the last two years under the leadership of the International Association of Geodesy (IAG) Commission VIII, the International Coordination of Space Techniques for Geodesy and Geodynamics (CSTG).
The IVS was the third service to be established, following the International GPS Service (IGS) and the International Laser Ranging Service (ILRS). The objectives of IVS are:
- to intensify the international cooperation of the responsible agencies,
- to encourage new contributions from the international community,
- to provide an international umbrella for all participating groups, and
- to ensure the world wide service for provision of the required products from the VLBI technique for the terrestrial and celestial reference frames and the Earth orientation parameters needed for research and applications.

This paper summarizes the events leading up to the establishment of the IVS, points out its components and structure, and gives current information on the scientific perspectives and highlights of the IVS.

INTEGRATED EARTH OBSERVATION MODEL

SCHWARZE, Volker (Stuttgart University Department of Geodetic Science
email: schwarze@gis.uni-stuttgart.de)

Geodetic space techniques like Very Long Baseline Interferometry or Lunar Laser Ranging as well as satellite based systems give deep insight into the system behaviour of the Earth. To use the full physical and geometrical information of the geodetic sensors all types of observations have to be combined within a consistent physical, geometrical and stochastical model.
The physical model is developed consistently within the framework of general relativity at post-Newtonian order. This part contains the motion of extended bodies as well as the description of the physical properties of the Earth.
The geometrical part contains the definition and connecting of geodetic coordinate systems as well as the definition of observable quantities on a curved four-dimensional manifold of pseudo-Riemann type.
The combination of heterogenous observations leads to the problem that the components of their variance-covariance matrix has to be determined from an adjustment procedure. Several estimators to fulfil additional optimazation conditions are given and extensively discussed.

G2/W/07-A2 1430

CONTRIBUTIONS OF LASER RANGING TO THE GOALS OF SPACE GEODESY

Richard EANES (Center for Space Research, University of Texas at Austin, 3925 W. Braker Lane, Suite 200, Austin, TX 78759-5321, USA, email: eanes@csr.utexa.edu)

Laser ranging to artificial satellites and to the Moon is one of theprimary techniques of space geodesy. The principle advantages of laser ranging (LR) are: 1) the effects of the earth's atmosphere and ionosphere can be modeled to few mm accuracy; 2) delays in the ground segment can be calibrated to few mm accuracy; 3) the delay at the target can be modeled to few mm accuracy; 4) appropriate targets are available from low-Earth orbit (LEO) to the moon, 5) the LEO targets provide a link of the crust-fixed TRF to the origin of the local inertial frame located at the Earth's center of mass. The LR technique's major weaknesses are its high cost per station (relative to GPS) and its vulnerability to weather. These disadvantages have kept the number of LR observatories low and have resulted in less than optimum spatial and temporal distribution of observations, but the strengths of the LR more than compensate and ensure that the technique will continue to be a significant component in the Integrated Global Geodetic Observing System. Laser ranging has contributed to several broad areas of geodynamics research including: determination of the mean gravitational field of the Earth (including GM) and its temporal variations due to redistribution of mass in the atmosphere, hydrosphere, and cryosphere; determination of motions of crust-fixed observatories relative to the center of mass of the planet; orbit determination of and calibration of altimetric satellites; and tidal and non-tidal variations of earth orientation parameters. While presenting the contributions of laser ranging to geodynamics research I will highlight the complementary contributions of the other space geodesy techniques that were required for success.
The future of laser ranging looks bright. The establishment of the International Laser Ranging Service (ILRS) was completed in September 1998 and should rapidly lead to improved coordination of the network of laser ranging observatories, increased cooperation among the analysis community, and more effective promotion of ideas for new satellite missions and new scientific applications of the technique. Remotely operated satellite laser ranging systems have already been successfully deployed and the design of advanced systems with nearly complete automation is well underway and should significantly lower the cost of LR. Two new systems with dual lunar and satellite laser ranging capability are currently operating in enginering status, and several excellent mobile stations are available for deployment to areas that will improve the geographic distribution of the technique. These advances ensure that laser ranging will play an important role in the integrated space geodesy measurement system of the future.

G2/W/10-A2 1445

ICESAT PRECISION ORBIT DETERMINATION

Hyung-Jin RIM, Charles Webb, and Bob E. Schutz (Center for Space Research, University of Texas at Austin, Austin, TX 78712, USA, email: rim@csr.utexas.edu)

The Ice, Cloud and land Elevation Satellite (ICESat) is scheduled for launch on July 2001 as a part of the NASA Earth Science Enterprise missions. The Geoscience Laser Altimeter System (GLAS) will be carried on the ICESat to measure ice-sheet topography and associated temporal changes, as well as cloud and atmospheric properties. To accomplish the ICESat science objectives, the position of the GLAS instrument in space should be determined with an accuracy of 5 cm and 20 cm in radial and horizontal components, respectively. This knowledge will be acquired by the Precision Orbit Determination (POD) activities using the data collected by the GPS receiver on ICESat and the ground-based satellite laser ranging (SLR) data.
The predicted radial orbit errors at the ICESat orbit (600 km altitude) based on recent gravity models, such as JGM-3 and EGM-96, are 15-20 cm, which exceeds the 5 cm requirement. Gravity model improvement effort for the ICESat mission (gravity tuning) will be carried out during the Verification Phase (first 90-120 days from launch) using the collected GPS and the SLR data. Since the scheduled launch date of the ICESat is near the next solar maximum, the drag model errors will be the limiting factor for a successful gravity tuning and for the ICESat POD.
The results of an in-depth simulation study to assess the ICESat POD accuracy are summarized in this paper. Effects of the drag model errors on the gravity tuning and the POD are examined. Experiments on how to minimize the effect of drag model errors are summarized.

G2/W/05-A2 1500

ADVANCED SPACE TECHNOLOGIES FOR GEODESY OF THE MOON: SELENODETIC MISSIONS IN SELENE AND SELENE2

Kosuke HEKI, H. Hanada, T. Tsubokawa, N. Kawano and M. Ooe (National Astronomical Observatory, 2-12 Hoshigaoka,Mizusawa, Iwate 023-0861, Japan, email: heki@miz.nao.ac.jp) N.Namiki (Kyushu University, Fukuoka, Japan) T.Iwata (National Space Development Agency, Japan)

SELENE, the Japanese lunar explorer to be launched in 2003 July, involves three missions of lunar geodesy, VRAD, RSAT and LALT(laser altimetry). Two radio transmitters on board the lunar orbiter and lander (VRAD) are used as radio sources for differential VLBI from the Earth. Its combination with conventional R&RR measurements enables three dimensional measurement of the satellite position and lunar gravitational acceleration. The relay satellite at a high eccentric orbit (RSAT) relays Doppler signals from the main orbiter to perform first direct gravimetry of the lunar farside. Feasibility study has started for the next project SELENE2 toward the launch in ~2006. There we are proposing a selenodetic mission aimed at the lunar rotational dynamics, "In-situ Lunar Orientation Measurement (ILOM)"; a small optical telescope is deployed near the lunar pole, fixed toward the celestial pole, star positions (accurate to <0.1") are recorded with a CCD camera. Year-long star trajectories are analysed to determine amplitudes and phases of major components of forced librations of the Moon, as well as to detect its free librations.

G2/C/G5/W/23-A2 1515

CORE: ACCURACY OF VLBI UT1 AND POLAR MOTION

D S MacMillan (NVI, Inc./Goddard Space Flight Center, Greenbelt, MD 20771, USA, email: dsm@leo.gsfc.nasa.gov) C. Ma and T. A. Clark (both at NASA Goddard Space Flight Center, Greenbelt, MD 20771, USA)

VLBI is one of the most important techniques measuring Earth orientation parameters (EOP). Measurements of EOP can provide constraints on geophysical models of the solid Earth, the atmosphere, and the oceans. Recognizing the importance of EOP measurements, the international VLBI community is engaged in a program to make continuous EOP measurements beginning in 2001, ramping up from four 24-hour sessions per week during 1999. This campaign is called CORE (Continuous Observations of the Rotating Earth). One of the principal problems with high precision VLBI measurements is determining its accuracy. In the CORE program, EOP measurements will be made with several networks, each operating on a different day. It is therefore important to determine whether there are systematic differences between EOP derived from different networks. The basic test for accuracy is to examine the differences between simultaneous measurements of EOP from independent VLBI measurements. From the history of VLBI sessions from 1980 to the present, there are about 300 such simultaneous sessions. These comparisons imply that the formal EOP errors should be increased by a factor of 1.5-2.0. The EOP precision of these measurements varies over a wide range (by about a factor of ten compared to current precision) so that it is difficult to determine whether the differences are due to random or systematic errors. To determine current accuracy and to prepare for the CORE program, we have run a series of VLBI experiments that are either simultaneous (CORE-A) with the weekly NEOS network or on adjacent days (CORE-B). These experiments began in 1997 and continue to the present time. Analysis of 70 simultaneous experiments again indicates that the formal errors are too small by a factor of 1.5-2.0. However, there are large systematic differences between the networks, which are much larger than the expected average differences. The cause of these differences is under active investigation.

G2/W/13-A2 1530

ESTIMATION OF TROPOSPHERIC DELAY FROM VLBI DATA

Oleg TITOV (Astronomical Institute of Saint-Petersburg University, Bibliotechnaya sq., 2, Petrodvorets, Saint-Petersburg, 198904, Russia, email: oleg_titov@usa.net)

Temporal instability of troposphere leads to loss of accuracy at VLBI data adjustment. Conventionally, all scientists wish to reduce an influence of troposphere on more important geodetic and geodynamic parameters (station coordinates, polar motion, length-of-day, etc.). Nevertheless, it is possible to estimate the variations of troposphere delays directly from VLBI data. Least squares collocation technique allows to obtain time series with temporal resolution up to 3-5 minutes for any VLBI station. Special covariance function based on theoretical consideration and large set of measurements has been used as a priori information. Results of adjustment of two-weeks VLBI experiment CONT'94 are presented. All calculations made using OCCAM software. Comparison of the time series with independent measurements by WVR (water vapor radiometry) made at the Onsala Space Observatory (Sweden) shows that VLBI has a strong potential for the problem solution. It allows to reduce a costs for WVR equipment installation and service.

G2/E/02-A2 1545

SATELLITE GRAVITY GRADIOMETRY WITH GRACE ?

Wolfgang KELLER (Geodetic Institute, University Stuttgart, Geschwister-Scholl-Str. 24/D,70174 Stuttgart,GERMANY, email: wolfgang.keller@gis.uni-stuttgart.de)

The GRACE mission will be a satellite-to-satellite-tracking (SST) mission. Compared to SST, a satellite-gravity-gradient (SGG) mission is expected to provide a higher resolution.
The paper presents a simulation study about the accuracy of artificially generated gravity gradients, which can be derived from GRACE range-rate data. It will be shown that the accuracy is comparabel to the accuracy of planned SGG missions, provided the GPS derived satellite positions and velocities have a sufficient quality. Two independend methods for the recovery of the gravity field from artificial SGG data are investigated.
Both methods give almost identical resolutions

G2/L/10-A2 1630

FROM THE SLR/LLR SUBCOMMISSION TO THE ILRS: SCIENTIFIC HIGHLIGHTS AND PERSPECTIVES

Michael Pearlman John DEGNAN, Carey Noll, and Erricos Pavlis, Van Husson, Scott Wetzel, Peter J. Dunn and Mark H. Torrence

With the endorsement of the IERS and theCSTG in April, 1998, the International Laser Ranging Service (ILRS) was created to support geodetic, geophysical, and lunar research activities and to provide the IERS with timely, high quality products important to the maintenance of an accurate International Terrestrial Reference Frame (ITRF). Patterned in part after the highly successful International GPS Service (IGS), the ILRS is responsible for the development of the standards and specifications necessary for product consistency and the encouragement of international adherence to its conventions. The ILRS, which started officially on November 1, 1998, collects, merges, analyzes, archives and distributes satellite and lunar laser ranging data to satisfy a variety of scientific, engineering, and operational needs and encourages the application of new technologies to enhance the quality, quantity, timeliness, and cost effectiveness of its data products. The ILRS is organized into permanent components: (1) a Governing Board, (2) a Central Bureau, (3) Tracking Stations and Subnetworks, (4) Operations Centers, (5) Global and Regional Data Centers, and (6) Analysis, Lunar Analysis, and Associate Analysis Centers. The Governing Board, with broad representation from the international SLR and LLR community, sets policy and defines the service philosophy while the Central Bureau oversees and coordinates the daily service activities. In addition, the Governing Board has established four standing working groups: (1) Missions, (2) networks and Engineering, (3) Data Formats and Procedures, and (4) Analysis. These Working Groups draw operational and technical expertise freely from the SLR community in order to better exploit current capabilities and challenge the ILRS membership to keep pace with evolving user needs. The ILRS currently tracks 25 retroreflector-equipped satellites and the Moon and is conducting four specialized campaigns in support of specific scientific or engineering studies.

SPACE GEODETIC EXPERIMENTS BETWEEN COLLOCATED STATIONS

Taizoh YOSHINO, H. Kunimori, F. Katsuo, J. Amagai, K. Sebata, M. Furuya, T. Otsubo, Y. Takahashi, and H. Kiuchi (Communications Research Laboratory, 4-2- 1 Nukui-kita, Koganei, Tokyo 184-8795, Japan, e-mail: yosh@crl.go.jp) T. Kondo, R. Ichikawa, and Y. Koyama (Kashima Space Research Center, Communications Research Laboratory, 893-1 Hirai, Kashima, Ibaraki 314-0012, Japan)

Modern geodetic observations are performed using the several space techniques. Each technique has strength and weakness. In Japan, a geodetic observing network around Tokyo (the Key Stone Project) is working regularly for a study of crustal deformation. The network consists of four collocated stations, which has VLBI, SLR and GPS facilities. Intercomparison of the geodetic results are performed using these independent techniques. To compare the global position and its time variations of the stations, the K-4 type VLBI system (256Mbps recording) is transported to Wettzell stations in 1999 which is also an ideal collocated station. SLR and GPS data is exchangeable. The results from the experiments between collocated station will not only contribute the terrestrial reference frame, but will help to understand the systematic error sources which is invisible from an observation using only one technique.

GLOBAL COORDINATES OF VLBI/SLR/GPS COLLOCATED KEYSTONE STATIONS - INITIAL RESULTS

Toshimichi OTSUBO (NERC Satellite Laser Ranging Group, Monks Wood, Abbots Ripton, Huntingdon PE17 2LS, UK, email: t.otsubo@ite.ac.uk, on leave from Communications Research Laboratory, Japan)Yasuhiro Koyama and Ryuichi Ichikawa (both at Kashima Space Research Center, 893-1 Hirai, Kashima, Ibaraki 314-0012, Japan, email: koyama@crl.go.jp and richi@crl.go.jp)

The Communications Research Laboratory, Japan, has developed four geodetic stations around Tokyo utilizing the space geodetic technologies - VLBI, SLR and GPS. They have been worked as the VLBI regular measurement of the regional crustal deformation since 1994, and they can now act as the collocation between the independent three technologies. We derived the global station co-ordinates in ITRF96. In the VLBI analysis, the position of the four Keystone antennae were connected, through a series of tie experiments, to the Kashima 34m antenna whose co-ordinates are listed in ITRF96. In the precise SLR global orbit determination, only the Keystone station co-ordinates were solved for, while the other global stations were fixed to ITRF96. For GPS, the co-ordinates of Keystone and some others were freely estimated, whilst constraining some IGS points to ITRF96. An initial analysis showed that the SLR and GPS co-ordinates agreed with the VLBI co-ordinates within +/- 3 cm in the horizontal components and within +/- 4 cm in the vertical components, after the correction of local ties.

Since more than 20 years, the French geodynamics site located near Grasse, France has participated to the tracking of many geodynamic, geodetic, and oceanographic satellites. The Satellite- and Lunar Laser Ranging stations (SLR fixed and mobile, and LLR) are the main systems, but special efforts have been made during the 90's to combine different space geodetic and gravimetric techniques such as : GPS, DORIS, GLONASS, Laser, VLBI, and absolute gravimetry. The aim was to search for systematisms and unstabilities in the measurements and the positioning in order to improve the accuracy of different tracking systems. In this poster, the purpose is to summarize the results of different collocation experiments. We present a cross-analysis of laser measurements made on geodetic satellites (especially Lageos 1 and 2) and on the GPS and GLONASS constellations. Methods of data comparison are proposed as well as techniques for orbit quality control. Correlations between the laser residuals computed for different orbits and instruments (SLR and LLR) are shown to provide some evidences of the objective quality of the stations, and their positioning. Then a comparison between the absolute positioning resulting from the different techniques (SLR, GPS, DORIS, and g measurements) is presented.

LUMPED COEFFICIENTS - A MEANS FOR ORBIT SENSITIVITY ANALYSIS

CH. SCHAEFER and E.W. Grafarend (Geodetic Institute of the University of Stuttgart, Geschwister-Scholl-Strasse 24/D, D-70174 Stuttgart, Germany)

A possible concept for a orbit sensitivity analysis will be presented, based on the concept of lumped coefficients and Fourier- / frequency investigations of the satellite's orbit data. The method will be set up taking into account the needs and mission specifics of the German satellite mission CHAMP, which is due to be launched in autumn 1999 for the determination of the Earth's gravitational field, besides other goals. The main aim of the presented analysis is to get an idea on the sensitivity of the mission layout with respect to gravitational filed determination and thus to reduce the number of relevant unknowns to be estimated from the tracking data.

THERMAL FORCE EFFECTS ON SATELLITES

Jânia DUHA (Departamento de Geomática, Universidade Federal do Paraná, UFPR, Curitiba, Brasil, email: jduha@geoc.ufpr.br) Germano B. Afonso (Departamento de Física, Universidade Federal do Paraná, UFPR, Curitiba, Brasil, email: afonso@fisica.ufpr.br)

The precision of satellite orbit determination has continually increased, in the past years, because of the improved tracking technologies and increasing density of high-quality tracking stations. Subtle dynamical effects of non-gravitational origin become apparent, and as a result, a considerable effort has been devoted to the analysis of non-gravitational perturbations. A satellite heated up by a thermal energy source (sun, earth, etc.) have one hemisphere preferentially heated over the other. After a characteristic time the thermal radiation is re-emitted by the satellite's surface. The photons emitted by the hotter hemisphere carries away more momentum than the ones emitted by the colder hemisphere, so that the satellite is subjected to a thermal thrust.
In this work, we propose an improved thermal model that presents the total thermal effect as the sum of the summer-winter and the "generalized" day-night effects. We show that a unified model (J. Duha, M. Sc. Degree, 1996) may take into account the sin q' term for the day-night force component (longitudinal) and the cos q' term (where q' is the co-latitude of the thermal energy source) for the summer-winter force component (latitudinal). These terms yields from temperature variations on the satellite's surface due to its movement around the thermal energy source and allow to the simultaneous application of these two effects resulting in a unified total thermal effect. Thus, the total thermal force has two components: the summer-winter force, in the satellite spin axis direction (z), and the generalized day-night force, in the satellite equatorial plane (x,y).
We calculate the along-track accelerations for a test-satellite (parameters based on the LAGEOS satellite data) obtaining an averaged along-track acceleration equal to -3.46 x 10-13 m s-2, for the day-night effect, and -2.85 x 10-12 m s-2, for the summer-winter effect. That leads to a residual orbit decay of nearly 1.08 mm d-1.
Finally, we analyze the behavior of the averaged radial and along-track accelerations, and the thermal lag angle, as a function of the satellite altitude, and show the "selective law" (J. Duha, M. Sc. Degree, 1996) that control the satellite orbit decay, and associate the maximum thermal effect to the radius and altitude of the satellite.

GLONASS ORBIT COMPARISONS FROM THE IGEX FIELD EXPERIMENT

Robert WEBER, Elisabeth Fragner (both at Department of Advanced Geodesy, University of Technology Vienna, Gusshausstr. 27-29, A-1040 Vienna, Austria, email: rweber@luna.tuwien.ac.at)

In September 1998 the IGEX (International Glonass Experiment) field campaign has been started in order to set up a global Glonass observation network and to determine Glonass orbits in the ITRF with a quality of about one meter or even better. IGEX is an international project sponsored by CSTG (Coordination of Space Techniques for Geodesy and Geodynamics), IGS (Int. GPS Service), ION (Institute of Navigation) and the IERS (Int. Earth Rotation Service).
In January 1999 the IGEX steering committee decided, that the field campain will be prolonged at least till end of April 1999. Besides that, the first author has been appointed to act as IGEX Data Analyses Coordinator, responsible e.g. for orbit comparisons and the documentation of the orbit processing methodologies in use. This presentation characterizes the current status of the IGEX campaign, summarizes results of the orbit comparisons obtained so far and discusses strategies for the combination of the orbit submissions.

A SINGLE FREQUENCY IONOSPHERIC CORRECTION FOR GPS

Yuriy GALKIN, Victor Kharchenko, Daniil Zakharov (all at Department of Physics, Moscow State Forestry University, Mytischi-5, Mosciw reg.,141005, Russia, email: galkin@mgul.ac.ru)

It is shown that the non-linearity of the dispersive form of the refractive index of the medium affects a propagating radio signal in a complicated manner. This effect depends on the signal form and the dispersive properties of the medium. Computer simulations demonstrate that the GPS signal and the dispersive properties of the ionosphere allow to determine a new parameter in the received signal that is a function of the total electron content in the propagation path of the radio wave.

CORRECTION OF THE WATER VAPOUR ABSORPTION LINE EFFECT FOR EDM WITH INFRARED EMITTING DIODES

Yuriy GALKIN (Department of Physics, Moscow State Forestry University, Mytischi-5, Moscow reg., 141005, Russia) Ruben Tatevian (Department of Metrology and Standartisation, Central Research Institute of Geodesy, Air-Survey and Cartography, 26 Onezhskaya Street, Moscow, 125413, Russia) Lev Blank (Scientific Research Centre "Geodynamics", 4 Gorokhovskii side-street, Moscow, 103064, Russia)

The theory of the anomalous refraction and the spectral absorption effects are shown for wideband emission and amplitude modulated signal as in used by electronic distance meters with emitting diodes in near infrared spectral region. Software is being developed for correction of 6714 water vapour absorption lines (taken from HITRAN, between 750 and 1000 nm) on EDM with a Gaussian emitted spectrum. This correction has already been estimated for many conditions and found to reach magnitudes of several ppm of distance on occasions.

AUTOMATION OF THE VLBI DATA ANALYSIS USING A KNOWLEDGE-BASED SYSTEM

Wolfgang SCHWEGMANN and Harald Schuh (both at: Deutsches Geodätisches Forschungsinstitut (DGFI), Marstallplatz 8, 80539 München, Germany, email: schwegmann@dgfi.badw.de)

VLBI is an extremely precise modern space geodetic technique for monitoring the Earth rotation and for the realization of the global reference system. However, there is still a delay of at least one week between the time of observation and the availability of results and the data analysis requires a lot of manual operations. An important contribution to the acceleration of the VLBI procedure is a faster and semiautomatic data analysis, which is in particular needed in view of the increasing amount of VLBI data to be processed in the next years. Most of the tasks in the VLBI data analysis are very complex and their automation requires typical knowledge-based techniques. A concept for the automation of one of the most widely used VLBI software packages the MarkIII Data Analysis System was already presented. Now, an intelligent assistant for support and guidance of the analyst is being developed using the workbench BABYLON, which is based on methods of artificial intelligence. First the knowledge acquisition has to be carried out. Then the concept and design of the knowledge-based system has to be completed by the formalization and the representation of the knowledge using rules, objects, etc. Additionally an explanation-component is going to be developed as a part of the system to check its decisions. This component can also be used as a teaching-system for less experienced analysts. This would be very helpful, because there is a shortage of qualified experts and the analyst's training takes a long time. Examples will be given about the current status of the project, e.g. it will be shown how knowledge-based methods can be used to automate the final selection of parameters in the VLBI data analysis.

VLBI DATA ANALYSIS WITH A FULL VARIANCE-COVARIANCE MATRIX

Harald SCHUH and Volker Tesmer (both at: Deutsches Geodätisches Forschungsinstitut (DGFI), Marstallplatz 8, 80539 München, Germany, email: schuh@dgfi.badw.de)

The complete model of least squares adjustment contains the full variance-covariance matrix. Its diagonal elements can be computed from the a priori errors of the observables; the off-diagonal elements can be derived from the a priori errors and from the correlation coefficients between each pair of observables. However, in all present standard VLBI solutions, only the variances of the observed time delays are introduced, whereas no a priori correlations between the observables of a VLBI-session are taken into account, i.e. the covariances are set to zero. The causes of such correlations will be pointed out: They are in particular due to imperfections of the models used in VLBI data analysis. The determination of empiric correlation coefficients has shown that they depend on the geometry of the network and on the time of the observations, i.e. are relatively high for temporally close observations. There are also other reasons for correlations, e.g. observations of the same radio source may be correlated due to systematic influences of the source position and of the source structure. In a first attempt, the correlation coefficients determined empirically will be entered into the VLBI data analysis. The results will be compared with those of an uncorrelated approach. The OCCAM 3.4 VLBI software, which is used by several international VLBI groups, was modified for that purpose by introducing the full variance-covariance matrix, and was applied for the investigations.

THE COMPARISON OF VLBI AND GPS STATION MOVEMENTS AND THEIR VARIATIONS LONGER THAN ONE MONTH

Yukio TAKAHASHI, Hitoshi Kiuchi, Akihiro Kaneko, Yasuhiro Koyama, Noriyuki Kurihara, Mamoru Sekido, Tetsuro Kondo, Ryuichi Ichikawa, Taizoh Yoshino, Jun Amagai, Masato Furuya and Kouichi Sebata (Communications Research Laboratory, 4-2-1 Nukui-kita-machi, Koganei, Tokyo 184-8795, Japan, Email: takahashi@crl.go.jp)

We compared the station movements obtained by VLBI and GPS data in the domestic observation network. CRL constructed the KSP (the Crustal Deformation Monitoring System for Tokyo Metropolitan Area) with 4 stations which have VLBI, SLR and GPS facilities. In the KSP, the daily VLBI observations started since January, 1995. There are some GPS stations of GSI located near KSP stations. The KSP is a good test bench for comparing the results of VLBI, GPS and SLR. The current reliability of VLBI was almost the same as that of GPS. The dispersions of measurements in one-day experiments were about 2 mm and 10 mm for horizontal and vertical movements, respectively. The variations longer than one month for the station movements measured by both VLBI in KSP and GPS were 0.5-1 mm and 2-5 mm for horizontal and vertical movements, respectively. However, their variations of VLBI data were different from those of GPS data. The station velocities obtained by VLBI data in KSP agreed well with those by GPS data.

ATMOSPHERIC GRADIENT EFFECTS ON THE COMPACT VLBI NETWORK AROUND THE TOKYO METROPOLITAN AREA

Tetsuro KONDO, R. Ichikawa, Y. Koyama, M. Sekido, and N. Kurihara (Kashima Space Research Center, Communications Research Laboratory, 893-1 Hirai, Kashima, Ibaraki 314-0012, Japan, e-mail: kondo@crl.go.jp) T. Yoshino, J.Amagai, and K. Sebata (Communications Research Laboratory, 4-2-1 Nukui-kita, Koganei, Tokyo 184-8795, Japan)

Regular measurements on the compact VLBI network consisting of the four stations (Kashima, Koganei, Miura, and Tateyama; the longest distance between any two stations is about 135 km) around the Tokyo metropolitan area shows a good repeatability such as a 2-mm level in baseline length.
However the repeatability tends to be degraded in summertime. A correlation analysis between measured baseline lengths and surface meteorological data was made and it was suggested that an apparent position change of Kashima occurred according to the change of weather condition. Considering from the location of the station and the general characteristics of weather condition in Japan, this apparent position change is supposed to be caused by the atmospheric gradient, in particular by the wet component. We evaluate the effect of atmospheric gradient on the baseline length measurements quantitatively. Results will be presented at the meeting.

RAPID UT1-UTC ESTIMATION USING REAL-TIME VLBI TECHNIQUE.

Yasuhiro KOYAMA, Tetsuro Kondo (both at Kashima Space Research Center, Communications Research Laboratory, 893-1, Kashima, Ibaraki 314-0012 JAPAN, email: koyama@crl.go.jp, kondo@crl.go.jp), Jun Amagai, and Kouichi Sebata (both at Communications Research Laboratory, 4-2-1 Nukui-kita, Koganei 184-8795 JAPAN, e-mail: amagai@crl.go.jp, seba@crl.go.jp)

Communications Research Laboratory has established four space geodetic observation sites in and around Tokyo, Japan under the Key Stone Project. Regular geodetic VLBI experiments are currently performed every two days with the duration about 24 hours by using four 11m antennas. The observed data are transfered to a correlator system over high speed ATM network and data from four VLBI stations are processed in real-time. The data analysis procedures are fully automated and the results are generated immediately after each experiment. Usually, the data are analyzed to estimate precise positions of the VLBI sites, but we successfully demonstrated the capability of the data for estimating UT1-UTC by fixing a-priori site positions. The uncertainties of the estimated UT1-UTC are typically 0.1 msec. The accuracy of the estimation can be improved by expanding the baseline lengths between observation sites and we are currently investigating a possibility to connect existing VLBI sites by a high speed communication link.

WORLDWIDE FREQUENCY AND TIME COMPARISONS USING GPS CARRIER PHASE

G. PETIT, C. Thomas and Z. JIANG (Bureau International des Poids et Mesures Pavillon de Breteuil, 92312 Sevres CEDEX, France, email: gpetit@bipm.fr, cthomas@bipm.fr, zjiang@bipm.fr)

Recently-developed frequency standards state an accuracy well below 1x10-14, so comparing their frequency over a sufficiently short interval is a challenge for existing time and frequency transfer techniques. In this aim, we study the use of carrier phase and code measurements from Ashtech Z12-T receivers, a version of the usual geodetic Z12 which has been specially modified to meet the stability requirements of time and frequency comparisons. Over baselines of a few meters, it has been shown that the relative frequency stability between two independent systems is below 1x10-16 for averaging durations of half a day. We have carried out frequency comparisons between hydrogen masers over baselines ranging from a few kilometres to several thousand kilometres.
For these experiments, the Z12T data have been included in a larger set of measurements from a geodetic GPS data base maintained by the International GPS Service for Geodynamics (IGS). We study the impact of different processing strategies, regarding the treatment of troposphere and ambiguity parameters and the characteristics of the session processed, on the frequency comparison between remote hydrogen masers. In order to be used also for time transfer, these receivers should be calibrated to obtain the true values of the hardware delays and their variation with the environment. We discuss preliminary results of an exercise of absolute calibration of the Ashtech Z12-T receiver carried out using a GPS signal simulator.

TEMPORAL VARIATIONS OF OCEAN TIDAL TERMS IN UT1-UTC

Oleg TITOV (Astronomical Institute of Saint-Petersburg University, Bibliotechnaya sq., 2, Petrodvorets, Saint-Petersburg, 198904, Russia, email: oleg_titov@usa.net)

Global redistribution of mass water causes a variations in Universal Time. VLBI technique allows to detect and estimate the corresponding oceanic tides with periods near 12 and 24 hours. Usually, scientists obtain the estimates using global set of VLBI data. Possibility of the tides variations from year to year is considered this paper. About 500 VLBI experiments (NEOS-A, CONT'96, etc.) from 1991 till 1998 year were analyzed. All reductional calculations have been made using OCCAM software. Least squares collocation method (LSCM) provides us the time series of UT1-UTC variations with high temporal resolution (one point for 3-5 minutes). The full number of points exceeds 100.000. Therefore the standard deviation of yearly estimates is reasonable. Variations of UT1-UTC obtained using the LSCM are in a good agreement with ones recommended by IERS Conventions. Estimates of main tidal terms in UT1-UTC independently for every year as well as for full set of data are presented. It is shown that the yearly estimates are slightly differ from each other. The various reasons of the effect are discussed.

EARTH ROTATION PARAMETERS AND TERRESTRIAL REFERENCE FRAME REALIZATION FROM LAGEOS-1 AND LAGEOS-2 1983-1998 SLR DATA ANALYSIS

Sergei RUDENKO (Main Astronomical Observatory, National Academy of Sciences of Ukraine, Golosiiv, Kiev 252022, Ukraine, email: rudenko@mao.kiev.ua)

A homogeneous series of the Earth rotation parameters and a realization of the Terrestrial Reference Frame have been derived by the joint processing of Lageos-1 and Lageos-2 SLR data acquired by the global network of stations since September 1, 1983 until December 15, 1998. Lageos-1 data consists of 939,134 normal points obtained by 109 stations and Lageos-2 data represents 370,861 normal points acquired by 72 stations. The data analysis has been performed using KIEV-GEODYNAMICS 5.2 software which basically follows the IERS Conventions (1996). Among the estimated parameters are: satellite orbital elements - at 15-day orbital arcs, Earth rotation parameters (Xp, Yp pole coordinates, UT-UTC) - at 3-day arcs, geocentric cartesian coordinates of 109 stations and velocities of 65 stations located at 42 sites at the whole 15-year span. The formal errors of station coordinates and velocities are 0.1-1 cm and 0.2-5 mm/y, respectively, for the majority of stations. The formal errors of ERP are 0.19 and 0.17 mas for Xp and Yp pole coordinates and 0.015 ms for UT. The derived station coordinates and velocities have been compared with ITRF96, and the ERP values wer compared with EOP(IERS)C04 series. Our solution SSC(GAOUA)99L01 has 89 common stations with ITRF96. The coordinates of many stations given by our solution are at a few cm level in agreement with ITRF96. The transformation parameters between two these solutions are presented. Discussion on the residuals in the coordinates and velocities of some stations given by two these solutions is also given in the paper.

ON COMPUTATION OF DAILY AND SUBDAILY SLR EOP SERIES

Zinovy MALKIN (Institute of Applied Astronomy RAS, nab. Kutuzova 10, St.Petersburg 191187, Russia, e-mail: malkin@quasar.ipa.nw.ru)

In spite of GPS provides determination of EOP with impressive accuracy and operativity, SLR EOP results are very important for combined IERS solutions for improvement of systematic accuracy of the final IERS products. Unfortunately, EOP series produced by SLR analysis centers are not so unified as GPS products which makes difficult their comparison and combination. In the paper possible ways of computation of daily EOP series form the SLR observations are discussed and attempt to choice optimal strategy have been made.
The main problems with computation of daily EOP series are discussed. These are densification of SLR EOP series without loss of accuracy (from usual 3-5 days to daily solution), computation strictly daily series (for 0h every day instead of more or less accident fraction of day depending on distribution of observations) and computation of UT series from LOD one.
Special strategy is proposed to improve accuracy of operational solution. As results of operative determination of EOP depend on initial value of EOP, this effect was investigated in various ways. To eliminate it in routine operative computation special iterate procedure have been developed. In particular, it requires accurate short-time prediction of EOP. Improved method of EOP prediction is advanced. Proposed strategy have being used in routine daily EOP computation in the IAA and shows good density (one day), accuracy (0.2-0.3 mas for Pole coordinates and 0.02-0.003 ms for LOD) and operativity about 2 days (if sufficient number of observations are present) of EOP results.
A possibility to get more dense SLR EOP series (12 and 6 hours) was investigated. Unfortunately, accuracy of these determination evidently is not sufficient to make substantial contribution to research of high-frequency variations of the Earth's rotation. Nevertheless, combination of SLR and VLBI observations for this purpose seems interesting.

GEOID AND SEA LEVEL OF THE NORTH ATLANTIC REGION FROM MULTI MISSION AND MULTI CHANNEL REMOTE SENSING DATA

P. Knudsen, O. B. ANDERSEN, T. Knudsen, O. Leeuwenburgh (all at National Survey and Cadastre, Copenhagen NV, Denmark, email: pk@kms.dk) A. A. Nielsen, K. B. Hilger (both at IMM, Technical University of Denmark, Lyngby, Denmark) C. C. Tscherning, N. K. Højerslev, G. Moreaux (all at University of Copenhagen, Geophysical Department, Copenhagen OE, Denmark); E. Buch, V. Hues (both at Danish Meteorological Institute, Copenhagen, Denmark).

The interdisciplinary project GEOSONAR (funded by the Danish Earth observation programme) analyses multi-disciplinary contributions to sea level and its variations on different time scales. This includes geodetic, oceanographic and meteorological effects on sea level, focussed in the North Atlantic and particularly the North Sea.
In addition to traditional geodetic remote sensing techniques, such as altimetry, this project also involves the use of multi-channel scanning radiometers data, in the visible and infrared wavelengths. Data have been obtained from the Sea-viewing Wide Field-of-view Sensor (SeaWIFS), as well as from the NOAA advanced very high resolution radiometer (AVHRR), and the ERS along track scanning radiometer (ATSR).
The project and initial results are presented. One of these results is a new enhanced cloud removal technique for SeaWIFS data. This technique is based on maximum auto-correlation factors analysis (MAF). Extracting geodetic and oceanographic signal from these merged multi-channel data sources is non-trivial, however, the MAF analysis tool has also proven to valuable in the interpretation of the data.

THE IGES CROSS OVER ADJUSTMENT WITH A NEW SOFTWARE FOR THE SST IN THE MEDITERRANEAN SEA

A. Piatti and G. VENUTI (both at DIIAR Politecnico di Milano - Facolta' di Como - p.le Gerbetto, 6 - Como - email: giove@ipmtf4.topo.polimi.it)

Having in mind to determine the Mediterranean stationary SST from the radar altimetric observations an ad hoc procedure was built up. After a trackwise collocation filtering on the repeat mission data from both T/P and ERS1/2 to determine the stationary SST from the fully corrected altimetric observations, a local cross-over adjustment is needed to model the residual radial orbital error and the tidal error. The main characteristics of the proposed cross-over adjustment are: the possibility to merge data from different satellite missions and to allow a stepwise adjustment in which a set of tracks is capt fixed, playing the role of reference system. We will present the main feature implemented to search the cross-over positions and to fix the rank defect of the adjustment model. As a result we will show the stationary SST obtained by applying this procedure to T/P and ERS1/2 data in the Mediterranean area.

IMPROVED TIDE MODEL FROM TOPEX/POSEIDON AND GEOSAT ALTIMETRY OVER SHALLOW SEAS

Xiaoli DENG and Dingbo Chao (School of Geo-science of Engineering Surveying, Wuhan Technical University of Surveying and Mapping, 39 Luoyu Road, Wuhan 430070, P. R. China, email: dxl@ultra2.wtusm.edu.cn)

TOPEX/POSEIDON (T/P) data and Geosat ERM data have been used to extract errors in major diurnal and semidiurnal tidal constituents of the CSR3.0 model over the Western Pacific. Due to spatial complexity of tides in shallow seas, the coarse bin technique, which is necessary to overcome tidal aliasing problems in altimetry, does not be performed to avoid considerable distortion of the tidal signal. Using the harmonic analysis, this has been done here from over 4.5 years of T/P data along the ground track and Geosat ERM data at crossover locations with both ascending and descending track data. Comparison of simulated tides to the CSR3.0 model shows that more accurate information about tides in shallow water can be obtained from along-track T/P data, and that tides at crossover locations can be improved from both ascending-track and descending-track of Geosat data which have a shorter data record than T/P. They both contribute to the local region studied where resolution is more important than regular spacing.

GPS-ALTIMETRY TESTS – MEASURING GPS SIGNAL REFLECTED FROM THE SEA SURFACE

P. Knudsen, H. Olsen, G. Xu Natinal Survey and Cadastre - Denmark (KMS) Rentemestervej 8, DK-2400 Copenhagen NV, Denmark

Several so-called GPS-altimetry tests have been carried out at the National Survey and Cadastre - Denmark (KMS) for measuring the GPS signal reflected from the sea surface. The purpose of such tests is to see if it is possible to use downwarded GPS antenna to receive the reflected GPS signal for applications such as sea surface or ice sheet topography determination. Usually, in satellite altimetry or airborne altimetry, profiles of footprints over the sea surface are measured, however, by using GPS-altimetry, every measured profile of footprints has a bandwidth. So that such GPS-altimetry can be used for sea surface or ice sheet topography coverage. This paper describes the details and the intention of our tests. An upwarded antenna and a downwarded antenna are used, one for positioning the antenna platform and the other for the reflection surface measurement. Results of the GPS data analysis are given. Theoretical basis is discussed and outlined.

SIMULATION OF GOCE ORBIT DETERMINATION AND GRAVITY FIELD RECOVERY

J. VAN DEN IJSSEL, R. Koop and P. Visser (Delft Institute for Earth-Oriented Space Research, Delft, The Netherlands, email: jose.vandenijssel@lr.tudelft.nl) A. Selig, P. Hoyng and M. Smit (SRON, Utrecht, The Netherlands) N. Sneeuw, J. Mueller and R. Rummel (IAPG, Muenchen, Germany)

The Gravity field and steady-state Ocean Circulation Explorer (GOCE) is one of 4 ESA candidate missions in the Earth Explorer Mission program. Its main mission objective is a high-resolution, high-accuracy and homogeneous determination of the static Earth's global gravity field. To this aim GOCE will be equipped with a gradiometer providing Satellite Gravity Gradiometry (SGG) measurements, a GPS/GLONASS (GRAS) receiver providing Satellite-to-Satellite Tracking (STT) measurements and a Drag Free Control (DFC) to compensate non-conservative forces. The gravity field recovery of the GOCE mission will be based on both SST and SGG measurements. The gradiometer is particularly sensitive to the medium and high frequency gravity field information and the GRAS receiver will be used for the long and

medium wavelengths. In the framework of the preparations for this mission and parallel to the phase A development a simulator facility is being developed. The main purpose of this simulator is to show how all system aspects of the satellite affect both the SGG and SST measurement accuracy and hence the final achievable gravity field recovery accuracy. To this end orbit recovery simulations are conducted to determine realistic values for the achievable orbit accuracy in the presence of error sources like e.g. measurement noise, dynamic modelling errors for the gravity and tides model and tropospheric correction errors. Furthermore, software is developed for the least-squares estimation of geopotential coefficients from SGG and SST data from GOCE. The procedure is based on an iterative, semi-analytical approach with a block-diagonal normal matrix. Recent progress in the development of the simulator will be shown.

GENERALIZED SPHERICAL HARMONIC ANALYSIS OF SATELLITE GRADIOMETRY

Zhang CHUANDING and Wu Xiaoping (Department of Geodesy, Zhengzhou Institute of Surveying and Mapping,66 Longhai Road, Zhengzhou 450052 Henan , P. R. OF CHINA)

This paper mainly focuses on the generalized spherical harmonic series representation of satellite gradiometry and on the generalized spherical harmonic analysis of satellite gradiometry. Using the form of generalized spherical harmonics, the combination of several components of satellite gradiometry can be represented as in series of generalized spherical harmonics, which are several subset of larger group of orthogonal functions: the D-functions. If the observations are preprocessed by averaging to form a constant radius, equiangular grid, we can easy obtain good formulae for high degree and order global spherical harmonic analysis from D-functions as eigenfunctions. This paper secondary aims to the realization of D-functions or d-functions. d-functions are homogeneous polynomial and are given explicitly by Wigners formula, but it is too complexly to compute. By using the relations of d-functions (third index m=0,1,2) and the k (k=0,1,2) order derivatives of Legendre functions, a new recursive methods for calculations of d-functions (third index m=0,1,2) is presented. We conclude if we view upon the data set as being a set of observations distributed in some way in three dimensional space, a regular, global of observations in geocentric cartesian system or in local geocentric spherical coordinate system is more convenient for recovery of spherical harmonic coefficients, and if we consider the data set as a times series, the observations given in subsequent points along a satellite orbit, the observations in geocentric cartesian system or in orbital coordinate system is more convenient for computation of spherical harmonic coefficients.

RECENT RESULTS IN THE SIMULATION OF THE GRAVITY FIELD MISSION GOCE

Juergen MUELLER, Helmut Oberndorfer and Nico Sneeuw (Institut fuer Astronomische und Physikalische Geodaesie, Technische Universitaet Muenchen, D-80290 Muenchen, Germany, email: jxmx@alpha.fesg.tu-muenchen.de); Martijn Smit (Space Research Organisation Netherlands, NL-3584 CA Utrecht, NL) Radboud Koop and Pieter Visser (Delft Institute for Earth Oriented Space Research, Delft University of Technology, NL-2629 JA Delft, NL)

GOCE (Gravity Field and Steady-State Ocean Circulation Explorer) is one of the dedicated gravity field missions of the next years. Its main objective is the determination of the Earth's gravity field with high spatial resolution and with high homogeneous accuracy by applying: Satellite-to-Satellite Tracking (SST) in high-low mode for the orbit determination and for the retrieval of the long-wavelength part of the gravity field, and Satellite Gravity Gradiometry (SGG) for the derivation of the medium/short-wavelength parts.
For a realistic simulation, the various errors (e.g. misalignments, drag coupling or S/C rotation) as well as the interactions between the sensors/actuators (e.g. for attitude control) have to be considered and their effect on the scientific end-products (e.g. spherical harmonics, geoid heights or gravity anomalies) has to be investigated. The simulation is performed by different techniques using different mathematical tool boxes whose results are compared.
Our preliminary results show that the aspired accuracy level of 10^(-3) Eoetvoes/sqrt(Hz) can be achieved which enables to derive a gravity field up to degree and order 250.

A NEW TECHNIQUE FOR ENHANCEMENT OF SAR INTERFEROMETRIC IMAGES IN VOLCANIC AREAS

Libero Bertucco and Giuseppe Nunnari, (Dipartimento Elettrico, Elettronico e Sistemistico, Università di Catania, Viale A. Doria, 6, 95125, Catania, Italy, email: gnunnari@dees.unict.it) Pierre Briole Institut de Physique du Globe, 4, Place Jussieu, 75252, Paris, France, e-mail: briole@sismo15.ipgp.jussieu.fr Jean-Luc Froger UMR 6524, OPGC-CRV, 5, Rue Kessler, 63000, Clermont-Ferrand, France, e-mail: froger@opgc.univ-bpclermont.fr Giuseppe PUGLISI (Istituto Internazionale di Vulcanologia, Consiglio Nazionale delle Ricerche Piazza Roma, 2, 95123, Catania, Italy, tel. +95 448084, fax +95 436801, email: geo@iiv.ct.cnr.it)

Synthetic Aperture Radar (SAR) is a high-resolution imagery system for remote sensing. We propose a new technique for enhancement of wrapped interferometric SAR images. The aim of filtering is to reduce the noise in wrapped images before unwrapping step. The reasons of this work rise from the need to have low-noisy images for the parameters inversion of ground deformation sources. The volcanic areas represent a good test site because the SAR images relevant to these areas often show breaks in the continuities in the SAR interferometric phase. There are many sources of these phenomena; for instance, the typical cone-shape of the relief that give rise to large lay-over or shadow phenomena or the juxtaposition of fresh lava and vegetated areas having large difference in coherence give small scale breaks. The images examined to validate the proposed algorithm are differential interferometric images acquired from ERS-1 and ERS-2 satellite systems. The technique, called MPSF (Median Phase Shift Filter) is essentially based on two steps. First step is a particular median filtering based on phase shift; second step is based on the analysis of the neighborhood of every pixel of the image. The results obtained on test-images shown a appreciable improvement of the processed images.

THE DEVELOPMENT OF THE ISGN: STATUS AND PERSPECTIVES

Hermann DREWES, John Bosworth, Tom Herring

The Working Group on the establishment of an International Space GeodeticNetwork (ISGN) was created during the IAG Scientific Assembly in Rio deJaneiro in a joint meeting of CSTG, IERS and IGS. Its installation was anoutcome of the previous Working Group on the IUGG Fundamental Referenceand Calibration Network (FRCN). The main objectives of the ISGN WG were: - to define the criteria for including a station into the ISGN, and - to install a better cooperation between theindividual techniques.The criteria defined by the ISGN WG include the sites criteria, theanalysis criteria, and the IERS requirements. They were presented to andaccepted by the CSTG Executive Committee and the IERS Directing Board inApril 1998. In the next step, all those stations of the existing spacegeodetic sites were selected, which fulfill these criteria. They are thecandidates for the new ISGN to be installed in the next months.

HORIZONTAL SITE DISPLACEMENT DUE TO ATMOSPHERIC LOADING

Tadahiro SATO, Yuki Hatanaka and Shin'ichi Miyazaki, Seiichi Shimada

Atmospheric mass loads the Earth and deforms its surface. Temporal variations of atmospheric mass distribution lead to site displacement. Atmospheric loading effect is large in high latitude, at inland area and in winter season. Vertical component of atmospheric loading effect is more than 5cm in an extreme case, while horizontal component is less than 5mm.However, thanks to improvement of GPS positioning accuracy, horizontal site displacement is detectable in some GPS stations.
Horizontal site displacement due to atmospheric loading is computed by convolving Green's function with global surface pressure values estimated by Japan Meteorological Agency. Computed horizontal displacement has correlation with horizontal gradient of surface pressure distribution; sites move toward high pressure. Comparison between theoretically computed horizontal site displacement and GPS results will be discussed.

AN ATTEMPT TO ASSESS DIGITAL TERRAIN MODELS – REPORT OF SSG 3.163

D. ARABELOS (Department of Geodesy and Surveying, Arisstotle University of Thessaloniki,Univ. Box 474, GR-540 06, email: arab@eng.auth.gr)

One of the main tasks of the SSG 3.163 was the assessment of the global digital terrain models. Apart of comparisons with high resolution data from national data-banks, an intercomparison of the 5' global DTMs ETOPO5, TBASE and JGP95E, showed considerable differences between them. The standard deviation of these differences globally is about 100 m with min. and max. values ranging from -3.8 to 4.7 km. An attempt was made to estimate the errors in the different types of topographic reductions due to the errors of the above mentioned DTMs. The results showed that the influence was smaller in the case of the RTM reductions. A plot of the standard deviation of the topography versus the standard deviation of the gravity computed from EGM96, showed that in different areas of the earth there are serious errors due to the low quality of the topography or/and of gravity.

FROM AIRBORNE GRAVIMETRY TO AIRBORNE GEOID MAPPING – REPORT OF SSG3.164

Wei MING

This paper summarizes some of the works done in the Special Study Group 3.164 "Airborne Gravimetry Instrumentation and Methods" over the last four years but it does not give a comprehensive overview of all activities. During the last four to five years, major advances in implementing airborne gravimetry as a production system have been made. The LaCoste & Romberg S-model gravimeter has been successfully used for airborne gravimetry by several groups. The inertial scalar gravimetry using inertial system in conjunction with DGPS has also reached a production level. The airborne gravity data over Greenland and parts of the Arctic and Antarctic has been used for determination of earth gravity model EGM96. The local geoid determination using airborne gravity data has achieved excellent results. All these progress shows that the roll of airborne gravimetry in geodesy, particularly in geoid determination, becomes more important.
After the review of the progress in airborne gravimetry, the paper discusses the different

techniques for airborne gravimetry. The concept and algorithm to determine geoid, especially the regional or local geoid, using the airborne gravity data combined with other gravity data are also described in the paper. This open a new subject - airborne geoid mapping, defined as determining geoid using airborne gravimetry data. Test results show that the local geoid determined by airborne gravity data has achieved an accuracy of 5 cm of the geoid undulation. Some critical issues in airborne gravimetry and airborne geoid mapping are also included as conclusions.

GLOBAL GRAVITY FIELD DETERMINATION AND EVALUATION – REPORT OF SSG3.165

Dr. Nikolaos K. PAVLIS (Phone: (301)-441-4121 Raytheon STX Corporation FAX: (301)-441-2432 7701 Greenbelt Road Suite 400 Greenbelt, MD 20770 e-mail: npavlis@geodesy2.gsfc.nasa.gov USA

This presentation will review some of the work performed by members of the Special Study Group (SSG 3.165), and by other interested colleagues, which addressed the goals identified in the SSG's program of activities. A major effort of SSG members and other interested parties involved the development and evaluation of contemporary global geo-potential models such as EGM96, TEG-3, and GRIM4-C4. The evaluation of EGM96 in particular was greatly enhanced through numerous tests that were performed by an international group of investigators, working under the auspices of IGeS. A significant effort was made to collect and systematically archive data and information that can be used to evaluate global geo-potential models. GPS-determined heights and levelling data constitute the bulk of this test database. The current status of this database will be reviewed, and the need for such independent test data in areas void of such information will be emphasised. The prospects of geo-potential mapping satellite missions such as CHAMP, GRACE and GOCE intensified the work related to the determination of the gravitational field and its temporal variations, from satellite-to-satellite tracking and satellite gradiometry approaches.

REGIONAL LAND AND MARINE GEOID MODELLING – REPORT OF SSG3.167

I.N. TZIAVOS (Department of Geodesy and Surveying, Aristotle Univ. of Thessaloniki, Univ. Box 440, 54006 Thessaloniki, Greece, Email: tziavos@eng.auth.gr)

This paper summarizes the activities and achievements of the IAG Special Study Group (SSG) 3.167: "Regional Land and Marine Geoid Modelling", which was established by the XXIth General Assembly of IAG held in Boulder, Colorado, USA, July 3-14, 1995. The objectives of the SSG3.167 reflects the duality between past and future and it consolidates what it has already been achieved, and works towards addressing open and new questions. The current state of knowledge in regional geoid modelling refers to: (a) theoretical models related to BVP (e.g., how to include terrain and non-linear effects); (b) data reductions and data preparations; (c) modelling procedures for land and marine geoids; (d) accurate regional-scale marine geoid solution and their contribution to sea surface topography and other related oceanographic studies; and (e) validation procedures regarding the quality of the geoid product. Looking to open issues we could mention: (a) new efficient ways of working with heterogeneous data; (b) the impact of GPS - heights not only to validation procedures but also to common adjustments with geoid heights; (c) the study of compatibility of neighbouring datums through geoid determination; (d) the contribution of oceanography to synthetic geoid modelling; and (e) new solutions of the global BVP, which can lead to better theoretical geoid models. In terms of applications, and in the frame of the above mentioned main tasks, considerable work has been carried out in regional land and marine geoid modelling applying successfully efficient spectral and stochastic algorithms, as well as several new alternatives, and using large amounts of terrestrial and airborne gravity data, satellite altimetry data from recent and most accurate missions, and new global reference models.

PROGRESS REPORT FOR IAG SSG3.177: SYNTHETIC MODELLING OF THE EARTH'S GRAVITY FIELD

W.E. FEATHERSTONE (School of Spatial Sciences, Curtin University of Technology, GPO Box U1987, Perth, WA, 6845, Australia, email: tfeather@cc.curtin.edu.au)

In 1997, the IAG created an out-of-cycle special study group concerning the construction of a synthetic model of the Earth's gravity field. This group aims to develop the theoretical basis and computational methods for the production of a synthetic, yet realistic, model of the Earth's gravity field. Such a model is not currently available to the physical geodetic community and geodetic researchers have to rely on analytical error estimates, often based on observed data. Importantly, many of the discrepancies between the various gravity field theories are at the limit prescribed by the current data availability. A synthetic gravity model will thus give an independent validation of the procedures used. This paper will give an overview of the aims and objectives of the Group, review what progress has been made in constructing a synthetic Earth gravity model, and summarise some of the current approaches being explored by the members of the Group. (The Group's web-page is located at http://www.cage.curtin.edu .au/~will/iagssg3177.html)

GRAVITY FIELD DETERMINATION 1

G3/W/39-A5 1100

THE 1999 GFZ PRE-CHAMP HIGH RESOLUTION GRAVITY MODEL

Th. GRUBER, Ch. Reigber, P. Schwintzer (GeoForschungsZentrum Potsdam / GFZ, Division 1, Telegrafenberg A17, D-14473 Potsdam, Germany, e-mail: gruber@gfz-potsdam.de)

In preparation of the CHAMP gravity and magentic field satellite mission, a completely new satellite-only gravity field solution named GRIM5 was recently computed by GFZ and GRGS. Based on the full variance-covariance matrix of this solution and terrestrial and altimetry derived surface gravity data, a new high resolution global gravity field model up to degree and order 359 was computed. The solution was calculated by a rigorous combination of full variance-covariance matrices from the satellite-only model and the land and ocean surface gravity data with block- diagonal structured variance-covariance matrices from the high resolution terrestrial and altimetric gravity information provided by the U.S National Imagery and Mapping Agency (NIMA). For this new solution the spherical harmonic degree and order for the full variance-covariance matrices was extended to 120, compared to degree 100 for previous GFZ solutions and degree 70 for the EGM96 model. It can be shown with this new model, that due to the extension of the full normal equation system the quality of the final model could be increased significantly for this frequency range. Quality parameters for such investigations were derived from the internal error parameters from the least squares solution and from comparisons with external independent gravity and geoid information. The new high resolution combination model represents a major improvement towards a series of new gravity models with unprecedented accuracy and resolution from the CHAMP and GRACE gravity field missions. With these missions long and medium wavelengths will be dominated by satellite data, while short wavelengths still will be determined solely from surface data. Therefore the presented combination technique can be extended also to the computation of high resolution CHAMP and GRACE based gravity models.

G3/W/42-A5 1120

THE REGIONAL GEOPOTENTIAL MODEL TO DEGREE AND ORDER 720 IN CHINA

Yang Lu H.T.Hsu F.Z.Jiang Institute of Geodesy and Geophysics, Chinese Academy of Sciences, email: luyang@asch.whigg.ac.cn

For the time being, the spherical harmonic expansion is a powerful method describing local and global gravity field in frequency domain yet. In principle, the resolution of gravity field and its precision expressed by spherical harmonic model are proportional to degree and order of model explaining. For this reason a higher degree geopotential model is advantageous for us. It is possible to develop a regional model to degree and order 720 although that seems more difficult for global model in terms of the precision and density of gravity data over global area. Following the tailored method, we have developed an ultra regional geopotential model to degree and order 720 suitable to China. The gravity anomalies from new model have a mean square error (6.4 mgal. The modeled geoid undulations have a mean square error (0.67m in China land, but both mean square errors of gravity anomaly and geoid undulation are the same as one from reference model EGM96 in global area without China.

G3/W/02-A5 1140

COMPARISON AND EVALUATION OF THE NEW RUSSIAN GLOBAL GEOPOTENTIAL MODEL TO 360 DEGREE

P. MEDVEDEV, (Geophysical Center, Russian Academy of Sciences, Molodezhnaya 3, 117296, Moscow, Russia, email: pmedv@wdcb.rssi.ru); G. Demianov (Central Research Institute of Geodesy, Air Surveying and Cartography, Federal Service of Geodesy and Cartography of Russia, 26, Onezhskaya, 125413 Moscow, Russia, e-mail: gleb@space.ru)

New Russian global geopotential model created with use the detailed gravity data, satellite tracking and altimetry data. The test data that we used for model evaluations include geoid undulations (or height anomalies) determinated from GPS positioning and levell observations, geoid undulations from EGG96 (Denker et al.), global geopotential models EGM96, GPM98A (Wenzel, 1998), global marine gravity field from russian GEOIK altimetry data and from GEOSAT, ERS-1, TOPEX (P.Medvedev et al., 1998; Sandwell et al. 1997; Andersen et al., 1998). Future problems geoid determinations discussed.

GRAVITY AND MACRO-MODEL TUNING FOR THE GEOSAT FOLLOW-ON SPACECRAFT

Frank G. LEMOINE (email: flemoine@olympus.gsfc.nasa.gov), David D. Rowlands, Gregory C. Marr (NASA Goddard Space Flight Center, Greenbelt, MD 20771 U.S.A.); Nikita P. Zelensky, Scott B. Luthcke, Christopher M. Cox (Raytheon ITSS, 7701 Greenbelt Rd., Greenbelt MD 20770 U.S.A.)

The US Navy's GEOSAT Follow-On spacecraft was launched on February 10, 1998 and the primary objective of the mission was to map the oceans using a radar altimeter. The spacecraft tracking complement consisted of GPS receivers, a laser retroreflector and Doppler beacons. Since the GPS receivers have not yet returned reliable data, the only means of providing high-quality precise orbits has been though satellite laser ranging (SLR). The spacecraft has been tracked by the international satellite laser ranging network since April 22, 1998, and an average of 7.4 passes per day have been obtained from US and participating foreign stations. Since the predicted radial orbit error due to the gravity field is two to three cm, the largest contributor to the high SLR residuals (7-10 cm RMS for five day arcs) is the mismodelling of the non-conservative forces, not withstanding the development of a three-dimensional eight-panel model and an analytical attitude model for the GFO spacecraft. The SLR residuals show a clear correlation with beta-prime (solar elevation) angle, peaking in mid-August 1998 when the beta-prime angle reached -80 to -90 degrees.
In this paper we discuss the tuning of the non-conservative force model, for GFO and report the subsequent addition of the GFO tracking data to the Earth gravity model solutions.

G3/L/22-A5 1220

THE NRL AIRBORNE GEOPHYSICS PROGRAM

John M. BROZENA, Vicki A. Childers, Naval Research Laboratory, Code 7420, 4555 Overlook Ave. SW, Washington DC, USA 20375-5350. Email: vicki@qur.nrl.navy.mil

In this talk we provide an overview of recent efforts under the Naval Research Laboratory (NRL) aerogeophysics program that includes large area gravity and magnetics surveying, noise reduction efforts in aerogravity, measurements of ocean surface and the geoid, and possibly gravity gradiometry. NRL, in conjunction with the University of Texas Institute for Geophysics and the University of Oslo, has been conducting a long-range, large-area aerogeophysical survey over the Arctic Ocean. The goal of this survey is to provide insight into the tectonic history of the region and to make continuous measurements of gravity, magnetics, and the geoid across the region. Over the course of five field seasons, aerogravity and magnetics were measured over a region that encompasses the southern Canada Basin, the Chukchi Plateau, the Alpha Ridge, and a portion of the Mendeleev Ridge out to the 180o meridian. Last summer, our survey extended to the Eurasian Basin, from east of the Alpha Ridge to the Svalbard continental slope, an area entirely contained within the ?hole? over the pole in the ERS-1/2 gravity data. This summer we return to Svalbard to extend the survey eastwards. There is the possibility that the Lockheed Martin gravity gradiometer will be installed in the aircraft for this mission, with our goal being to merge the long wavelength gravity information from the scalar measurements with the shorter wavelength gravity measurement from gradiometry to enhance the resolution of the aerogravity measurement.
Recently, our work has focused on developing new techniques for noise reduction in our aerogravity data. We have improved our determination of aircraft vertical positioning in several ways: GPS position solutions are corrected for jumps and spikes, are ?lever arm? corrected to translate the GPS antenna location to the gravimeter, and we now compute and compare accelerations determined from GPS, radar, and a combination of radar plus the acceleration of a gravimetrically derived geoid surface. We have enhanced the gravimeter measurement by improving the offlevel correction, averaging the two gravimeter measurements, and refining the lowpass filter for each particular survey. These developments have provided a substantial reduction in measurement error. Last summer…

GEOID MODELLING IN COASTAL REGIONS USING AIRBORNE AND SATELLITE DATA: CASE STUDY IN THE AZORES

M. J. FERNANDES (email: mjfernan@oa.fc.up.pt); L. Bastos (email: lcbastos@oa.fc.up.pt) Observatório Astronómico, Faculdade de Ciências, Universidade do Porto, Monte da Virgem, 4430 Vila Nova de Gaia, Portugal, R. Forsberg, (email: rf@kms.min.dk); A. Olesen (email: avo@kms.min.dk), National Survey and Cadastre, Rentemestervej 8, DK 2400, Copenhagen NV, Debmark F. Leite (Departamento de Matemática Aplicada, F. C. T. , Universidade de Coimbra, Apartado 3008, 3000 Coimbra, Portugal, email: cbl@mat.uc.pt)

Airborne altimetry and gravimetry can play an important role in regional geoid mapping, particularly in coastal zones where satellite altimetry shows limited accuracy. This study is concerned with the determination of a high resolution regional geoid in the area surrounding the Azores Islands, integrating multi-sensor airborne and marine observations with satellite and land data.
In the scope of the MAST III project AGMASCO several airborne gravimetry/altimetry campaigns have been performed. The usefulness of airborne measurements to complement satellite and marine data in coastal regions, bridging the gap between land areas and the open ocean, has been proved.
The airborne and marine data used in this study have been collected in one those campaigns, which took place in the Azores region, in October 1997. This area shows very high gradients in the sea bottom topography as well as in the islands altimetry, with corresponding large variations in the gravity field.
Airborne, marine and land gravimetry, together with altimeter derived gravity anomalies, have been merged in a combined geoid solution. In this computation an improved bathymetric and altimetric model has been used. The final geoid solution has been validated using airborne and satellite altimetry and tide gauge data.
Model accuracy and improvement over existing global and local models is accessed and presented.

G3/W/33-A5 1420

ASSESSMENT OF THE GLOBAL LAND ONE-KILOMETER BASE ELEVATION DEM

Allen M. HITTELMAN, David A. Hastings, Paula K. Dunbar (NOAA's National Geophysical Data Center, 325 Broadway, Boulder, CO 80303, USA, email: amh@ngdc.noaa.gov)

The Global Land One-kilometer Base Elevation (GLOBE) digital elevation model (DEM) is the most thoroughly designed, reviewed and documented global digital elevation dataset to date. GLOBE was developed by an international group of specialists, cooperating with the Committee on Earth Observation Satellites (CEOS) Working Group on Information Systems and Services (WGISS), International Geosphere-Biosphere Programme's Data and Information System (IGBP-DIS), and ISPRS Working Group IV/6.
GLOBE's initial objective was to populate a two-dimensional latitude-longitude 30 arc-second grid with the best available data that could be distributed with minimal restrictions. In addition, a completely unrestricted version of GLOBE was envisaged. The final DEM has been assembled using 11 original sources (raster and vector source data), some of which had more than one form of post-source processing. A total of 18 combinations of source/lineage were used in GLOBE.
The quality review of the GLOBE Version 1.0 DEM included (1) viewing source imagery with various color palettes in NGDC's GeoVu public domain browse and visualization utility and the GRASS GIS; (2) viewing slope, aspect, and shaded relief images of each source data set; (3) principal components analysis of all available sources for a given area; (4) histogram analysis for each source data set; and (5) statistical comparisons between sources.

G3/W/56-A5 1440

RECENT ADVANCES IN THE ACQUISITION AND USE OF TERRAIN DATA FOR GEOID MODELLING OVER THE UNITED STATES

Dr Dru SMITH

In recent years, the accuracy requirements for high resolution geoid models have reached the centimeter level. In order to attempt such accuracy, extremely detailed models of the terrain, free from systematic errors, must be used for computing the gravitational signal induced by topography. At the United States National Geodetic Survey, new efforts have been made to incorporate a 30 meter horizontal resolution digital elevation model (DEM, from the U.S. Geological Survey) into geoid computation procedures. This data, unlike previously available DEM's, has consistency in data collection, datum registration, and shows internal consistency with heights recorded at gravity measurement sites. Initial tests indicate that large systematic errors in previously used 3 arcsecond DEM data have induced geoid errors exceeding 10 cm, spread over 100 km or more. These systematic errors do not seem to exist in the new 30 meter data. The computer power needed to store and process the data is substantial: to completely describe the western half of the United States with this DEM requires 32 Gb. Acquisition of new data was only the first step. Recent investigations into methods for computing Helmert gravity anomalies indicate that the rigor with which the gravity signal induced by the terrain is computed must be increased. This new rigor removes many previous assumptions and replaces them with new techniques. This includes the use of spherical coordinates, sloped-tops for terrain prisms, attention to datum biases, and properly accounting for the terrain of the entire globe. While these new steps remove systematic errors that can exceed 10 mGals, there is a trade off for computational time that is being carefully weighed to find the most practical solution.

G3/W/11-A5 1500

GRAVITY FIELD AND GEOID FOR JAPAN

Yuki KUROISHI (Space Geodesy Laboratory, Geographical Survey Institute, 1 Kitasato, Tsukuba, Ibaraki 305-0811, Japan, email: yuki@gsi-mc.go.jp)

The Japanese islands are located in a trench and island arc region and the topography/bathymetry is very rugged. The gravity field and geoid, therefore, are complicatedly undulated.
A newer version of gravimetric geoid model, JGEOID98, was determined in a remove-restore manner by one-dimensional FFT realization of Stokes integration of residual Faye anomalies with reference to EGM96 global geopotential model. Gravity data were prepared only from surface gravity observation. Over the original geoid model, JGEOID93, several improvements of data quality were applied: replacement of reference model OSU91A by EGM96, removal of possible offset errors in network-adjusted ship gravity data, removal of Stokes kernel approximation (from 2-D FFT to 1-D FFT), and widening of ship gravity coverage.
When compared with nation-wide GPS/leveling geoidal undulations, JGEOID98 shows significant improvement of 30% in short wavelength over JGEOID93 after best-fit planes removed. Though the comparison was made only on land where both models share completely the same gravity data, improvement of data quality and coverage at sea yields the geoid improvement even on land.
Gravity data at sea seems to have some systematic errors in long wavelength. The adjustment method for ship data significantly improves inter-consistency, but has weakness in anchoring absolute values of gravity. In order to assess the data at sea, discussion will be developed with several models of gravity from satellite altimetry in this region.

G3/E/42-A5 1520

THE GWR DUAL SPHERE SUPERCONDUCTING GRAVIMETER C029 AT FRANKFURT A.M. AND WETTZELL - FIRST RESULTS AND CALIBRATION

Martina Harnisch, Guenter Harnisch, Ilona Nowak, Bernd RICHTER, Peter Wolf (Bundesamt fuer Kartographie und Geodaesie, Richard-Strauss-Allee 11, D-60598 Frankfurt am Main, Germany, email: richter@ifag.de)

The GWR dual spheres superconducting gravimeter enables enhanced reliability of the data and better drift monitoring to achieve a high resolution and reliability in monitoring temporal gravity variations. The dual sphere system is equivalent to two single instruments, but the technical expenditure and the costs are considerably reduced. By differencing the signals of both systems even micro steps can be detected. For test phase of 83 days the gravimeter C029 was installed in the basement of a BKG building in Frankfurt a.M. / Germany. Despite of unfavourable environmental conditions five small offsets between 0.1 and 1.5 microgal occured, which reliably were detected by the differential signal. The linear drift of both systems was in the order of + 30 and + 40 microgal/year with a small but significant exponential initial drift. At the end of October 1998 the C029 has been moved to Wettzell / Germany. Contrary to the results achieved in Frankfurt a.M., a very large initial drift occurred, different in sign and amplitude for the both systems. Whereas the upper system reached stability after about 2 weeks the decay process of the lower system is going on over more than 10 weeks. The noise of the gravity output (tide filter) is in the order of 0.1 microgal. No steps were observed in the first ten weeks of operation. - The scale factors of both systems of the C029 has been estimated by the acceleration method and by comparisons with absolute gravity measurements. The stability of the scale factors may be checked by comparison of the two gravity signal.

THE KMS99 GLOBAL ALTIMETRIC MARINE GRAVITY FIELD

O. Andersen, P. Knudsen, (both at National Survey and Cadastre, Copenhagen NV, Denmark, email: oa@kms.dk, pk@kms.dk)

The KMS99 altimetric derived global marine gravity field is the latest version of gravity fields derived from ERS-1 and GEOSAT geodetic mission. This presentations describes the new gravity field and the improvements over the older KMS global marine gravity fields as described by Andersen and Knudsen (JGR, 97, ERS special issue) . The present resolution of the KMS gravity field is 1/30 degree corresponding to 2 minutes or 4 km at the Equator. In order to improve the capability of the gravity field to map short spatial wavelength in the gravity field, it has been necessary to investigate if data with a higher along track sampling than the present 1Hz data can be used. For the KMS99 gravity field the possibility of using reinterpolated 2 Hz along track observations have been carried out. Some of the other improvements that have been introduced in the new version of the gravity field is the use of repeat track altimetry to improve the spatial resolution at high latitude. Similarly, investigation of a better screening of the raw data have been carried out to improved the gravity field in especially coastal regions.

RUSSIAN MODEL OF THE EARTH'S GRAVITY FIELD (GAO-98)

G.V. DEMIANOV, B.V. Brovar, A.V. Kryokova, A.N. Majorov, N.G. Nazarova, N.N. Pashina, V.A. Taranov (Central research institute of geodesy, air surveying and cartography, Federal Service of Geodesy and Cartography of Russia, 26, Onezhskaya, 125413 Moscow, Russia, e-mail: gleb@space.ru)

Through the research and operations executed, the global Earth gravity field model GAO-98 of ZNIIGAiK, Moscow, with the resolution level corresponding to the geopotential expansion into spherical harmonics up to 360th degree has been developed. The main parameters of the model developed are a set of mean anomalies for 30'*30' - blocks covering the whole surface of Earth and a set of spherical harmonics up to 360th degree resulted from the expansion of the geopotential. The said model is destined mainly for a highly accurate quasigeoidal heights determination which will significantly improve the efficiency of implementing GPS/GLONASS satellite equipment's unto the routine geodetic operations of the Federal Service of Geodesy and Cartography of Russia. Presentation of the EGF model GAO-98 in form of mean gravity anomalies for 30'x30' -blocks allows to make gravity data compatible with the global EGF parameters which contributes to detection and rejection of systematic errors of detailed gravity surveys.
The accuracy of absolute quasigeoidal heights by use of the model developed is for most

regions of Russia M =20-25 cm, and that for relative heights at the distance 200-300 km of m= 3-4 cm. These data of apriori accuracy estimation are confirmed by the results of precise GPS-measurements along the traverse Moscow-Sankt Petersburg on a high-precision levelling line.

THE 1998 TO 1999 GEOS-3 TRACKING CAMPAIGN: ANALYSIS AND RESULTS

F. G. LEMOINE (NASA Goddard Space Flight Center, Greenbelt, MD 20771 U.S.A, email: flemoine@olympus.gsfc.nasa.gov)

The GEOS-3 spacecraft was launched by NASA on April 23, 1975. The payload of the gravity-gradient stabilized spacecraft consisted of a radar altimeter, Doppler beacons, and a laser retroreflector. The GEOS-3 satellite-to-satellite tracking (SST) Doppler data and the satellite laser ranging (SLR) data have been an integral and valuable part of gravity model solutions developed at the Goddard Space Flight Center from GEM 9 through EGM96. GEOS-3 is located in an unique orbit at 850 km altitude and 115 degrees inclination. The data included in these solutions were acquired from 1975 through 1980. Since 1980, the SLR system precision has improved from 8 to 10 cm in 1980 to the subcm level for the best stations in the 1990's. The ILRS (International laser ranging service) initiated a new tracking campaign for this spacecraft in October 1998, and through January 1999, some 850 passes and 10,000 normal points were acquired. The quality of the "new" data obtained during this tracking campaign is assessed, and the impact of these "new" data on Earth gravity model solutions is evaluated.

NUMERICAL SIMULATION OF THE GRAVITY FIELD RESTITUTION WITH THE CHAMP MISSION

Sylvain LOYER, F. Perosanz, A. Balland, R Biancale (CNES/GRGS, Toulouse, France)

One of the main mission of the German satellite CHAMP that will be launched in December 1999 is the mapping of the global Earth gravity field as well as his temporal variations. The satellite will fly at a very low altitude (from 470 to 270 km) with a tracking system consisting of a GPS receiver (JPL-USA) and a Laser Retro Reflector. The non-gravitational accelerations will be measured by a very sensitive STAR accelerometer (ONERA/CNES-France). In order to assess the Earth gravity field recovery capability we have performed numerical simulations. One month of data of the three cited-above instruments including realistic noises and errors have been processed. We present the results of this numerical simulation in term of gravity field recovery as well as orbit precision and accelerometer calibration parameters restitution.

ESTIMATION AND EVALUATION TO THE DIFFERENCE BETWEEN THE NORMAL GRAVITY FIELDS FROM PHYSICAL GEODESY AND GEOPHYSICS

LI FEI and Chongbing Liu (both at Department of Geodesy, Wuhan Tech. Univ. of Surveying and Mapping,Wuhan, 430079, P.R.China, email: fli@dns.wtusm.edu.cn)

As we have known that the gravity anomaly used in physical geodesy means the difference between the observed gravity on the geoid and the normal(theoretical) gravity on the spheroid. Usually,the gravity anomaly is an important boundary value in determining the earth's figure and external gravity field.However,if the gravity anomaly is used to inverse the interior density anomaly relative to some theoretical density mode such as PREM from geophysics,there will exist two problems: one is caused by un-identity of the normal density, and the other by inconsistency of reference boundary surfaces and vertical deviation.Although such problems could be neglected in traditional gravity inversion,the errors covered by them are worth being taken into account in nowadays researches such as cm-order geoid and high resolution of gravity inversion.Therefore,the difference between the normal(theoretical) gravities corresponding respectively to normal spheroid and PREM mode is analyzed and compared from the original definition of the gravity anomaly. Then the errors in gravity anomaly caused by inconsistency of the reference boundary surfaces and vertical deviation are estimated. At last, the indetermination in inversion using gravity anomaly is summarized and evaluated,and a suggestion that gravity disturbance should be used directly is proposed.

Satellite Altimetry and Sea-level

THE KMS GRAVITY FIELD: ACCURACY ANALYSES AND IMPROVEMENTS

O. ANDERSEN, P. Knudsen (National Survey and Cadastre, Copenhagen NV, Denmark, email: oa@kms.dk, pk@kms.dk); R. V. Sailor, M.L. Driscoll, J.A. Shorter (Litton-TASC, Reading, MA, USA, email: rvsailor@tasc.com); D. Manning and R. Trimmer, (National Imagery and Mapping Agency, St Louis, USA, email: ManningD@nima.mil, TrimmerR@nima.mil)

The KMS global marine gravity field is based on 50 million 1 Hz radar altimetric observations from the ERS-1 and GEOSAT geodetic missions. The resolution of the KMS98 gravity field is 1/30 degree correspondingto 2 minutes (equivalent to 4 km at the Equator). Using 1 Hz altimetric data, the track to track distance (average 4 km) is shorter than the along track distance of 6-7 km between observations.
In an effort to improve the mapping of especially short wavelength gravity features, the 1 Hz along track spaced data was replaced with 2 or 3 Hz values computed from the raw 10 Hz observations. Averaging, least squares collocation, and the use of an equalizer function (inverse of the alpha-beta on board GEOSAT filter) have been tested.
Detailed investigations at NIMA and TASC, focused on the accuracy evaluation of the gravity field. Extensive comparisons with in-situ observations along with analyses of power spectral densities, and frequency content will be presented. One of the investigations has shown the existence of some discontinuities and outliers in the present KMS gravity field, especially close to the coast. Finally, recent improvements in the KMS global marine gravity field are presented. One of these being collocation interpolation of the geoid anomalies using a spatial varying covariance function that models local sea level variability.

SEA SURFACE TOPOGRAPHY ESTIMATION BY A GENERALISED MULTIPLE INPUT-OUTPUT METHOD

V.D. ANDRITSANOS (Department of Geodesy and Surveying, Aristotle University of Thessaloniki, 540 06 Thessaloniki, Greece, e-mail: bandrit@edessa.topo.auth.gr), M.G. Sideris (Department of Geomatics Engineering, The University of Calgary, 2500 University Drive N.W., Calgary, Alberta, T2N 1N4, Canada, e-mail: sideris@acs.ucalgary.ca) and I.N. Tziavos(Department of Geodesy and Surveying, Aristotle University of Thessaloniki, 540 06 Thessaloniki, Greece,
e-mail: tziavos@olimpia.topo.auth.gr)

The generalised theory of multiple input-output systems is briefly presented, with emphasis on the signal properties used. In addition, the theory of individual un-correlated systems is compared with the generalised form and the advantages and disadvantages of each technique are pointed out. The proper use of the data sets in each case is also discussed. The FFT application makes this method very efficient in combining large heterogeneous data sets. Additionally, data errors can be propagated into the results.
An application to the computation of Sea Surface Topography (SST) is presented using pure altimetric data derived from various satellite missions and shipborne gravity measurements. The assumptions related to the data noise are given, and comments are made on the noise spectrum determination. Finally, some comparisons with existing SST models are performed. Preliminary results have shown that the expected accuracy of this technique is at the level of a few to several centimetres.

DERIVED FROM THE 3RD GPS-CAMPAIGN 1997.4 OF THE BALTIC SEA LEVEL PROJECT

Alireza AZMOUDEH-ARDALAN and Erik W. Grafarend (Geodetic Institute, University of Stuttgart, Geschwister-Scholl Str. 24D, 70174 Stuttgart, Germany, Tel: +49 711 121 4086, Fax: +49 711 121 3285, email: ardalan@gis.uni-stuttgart.de)

An analysis of the Fundamental Geodetic Parameter based upon the 3rd GPS-Campaign 1997.4 of the Baltic Sea Level Project is performed. The computation is referred to the following method: (1) Cartesian co-ordinates of GPS positioned gauge stations are transformed into spheroidal co-ordinates. (2) The spherical harmonic expansion of the EGM 96 Geopotential Model (F.G. Lemoine et al, Nasa/TP-1998-206861, Goddard Space Flight Center, Greenbelt/Maryland 20771/1998) is transformed to the spheroidal harmonic expansion of the external gravity field of the Earth. (3) The orthometric heights of the GPS positioned gauge stations are used to obtain the spheroidal free-air reduction in order to convert the geopotential data at the GPS positioned gauge stations into potential values closest to Mean Sea Level. The best estimate in the Tide Free Reference System has been documented.

TIME VARIATIONS OF BASED ON THE GPS OBSERVATIONS OF BALTIC SEA LEVEL PROJECTS

ALIREZA AZMOUDEH-ARDALAN and Erik W. Grafarend (Geodetic Institute, University of Stuttgart, Geschwister-Scholl Str. 24D, 70174 Stuttgart, Germany, Tel : +49 711 121 4086, Fax: +49 711 121 3285, email: ardalan@gis.uni-stuttgart.de)

Based on GPS observations of the Baltic Sea Level Projects, First, Second, and Third Campaigns time variations of fundamental geodetic parameter is computed. The calculations are based on spheroidal eigenvalue eigenvector expansion of the external gravity potential field of the Earth. Cartesian GPS coordinates are first transformed into spheroidal coordinates. The spheroidal harmonic coefficients are supplied by conversion of geopotential model EGM96 into spheroidal harmonic coefficients using the numerical transformation method. Orthometric heights of the GPS stations are used to determine spheroidal free-air potential reduction for the calculated potential values at the GPS stations to reduce them into mean-sea-level or geoid's surface. Our best estimate for gauge value in tide free reference of geoid system corresponds to for the first campaign 1990.8, for the second campaign 1993.44, and for the third campaign 1997.4. The computations indicate a raise of in the value of .

IMPROVED TIDE MODEL FROM TOPEX/POSEIDON AND GEOSAT ALTIMETRY OVER SHALLOW SEAS

Xiaoli Deng and Dingbo Chao (School of Geo-science and Engineering, Surveying, Wuhan Technical University of Surveying and Mapping, 39 Luoyu, Road, Wuhan 430070, P. R. China, email: dxl@ultra2.wtusm.edu.cn)

TOPEX/POSEIDON (T/P) data and Geosat ERM data have been used to extract errors in major diurnal and semidiurnal tidal constituents of the CSR3.0 model over the Western Pacific. Due to spatial complexity of tides in shallow seas, the coarse bin technique, which is necessary to overcome tidal aliasing problems in altimetry, does not be simply performed to avoid considerable distortion of the tidal signal. Using the harmonic analysis, this has been done here from over 4.5 years of T/P data and Geosat ERM data, in which the T/P simulation is done along the ground track. Comparison of simulated tides with the CSR3.0 model shows that more accurate information about tides in shallow water can be obtained from along-track T/P data. The tides can be improved by combination of T/P and Geosat ERM data. They both contribute to the local region studied where resolution is more important than regular spacing.

IMPROVEMENT OF THE REGIONAL GRAVITY MODEL FOR CHINA AND ITS ADJACENT SEA BY COMBINING THE GRAVITY AND SATELLITE ALTIMETRY DATA

H.T.Hsu Yang Lu (Institute of Geodesy and Geophysics, Chinese Academy of Sciences, Wuhan 430077, P.R.China, Email: luyang@asch.whigg.ac.cn)

We study and develop the tailored method to improve the regional gravity model by using joint data of gravity and satellite altimetry, and obtain the improved local solution of the so-called altimetry-gravity fixed problem. By using the stack of four years (1992-1996) Topex/Poseidon and ERS-1 satellite altimetry data and the gravity anomalies (30'x30') of China land, we derive the geoid undulations of China and its adjacent sea. Then according to the tailored method mentioned above, we achieve a regional gravity model (IGG-LS) to degree and order 360 for China and its adjacent sea. To detect the actual external precision of the model, we compare geoid undulations and gravity anomalies computed from the model with their measurement values. The results obtained show: the gravity anomalies (30'x30') from model IGG-LS in China land (versus their actual measurement values) have a mean square error (8.7mgal, the model geoid undulations in China land (versus the GPS measurement results) have a mean square error (0.70m, the model geoid undulations of China-adjacent sea (versus the geoid undulations of satellite altimetry) have a mean square error (0.13m. As to the global model OSU91A, the corresponding mean square errors will be (23.7 mgal, (1.54m, (0.60m, respectively. In addition, for model IGG93, which is obtained from the tailored method with gravity data in China land only, the corresponding mean square errors are (8.8mgal, (0.71m, (0.58m, respectively. So IGG-LS model provides a considerably perfect representation of the gravity field feature in China and its adjacent sea. The regional gravity model can greatly improve the fitness of the global one in the local area. It can be computed from the different kinds of data and their combinations.

THE KMS99 GLOBAL HIGH RESOLUTION MEAN SEA SURFACE

P. KNUDSEN and O. Andersen (National Survey and Cadastre, Copenhagen NV, Denmark, email: pk@kms.dk, oa@kms.dk)

Satellite altimetry from the GEOSAT and the ERS-1 geodetic missions provide altimeter data with a very dense coverage. Hence, the heights of the sea surface may be recovered very detailed from these geodetic missions. On the other hand, satellite altimetry from the 35 days repeat cycle mission of the two ERS satellites and, especially, from the 10 days repeat cycle TOPEX/POSEIDON satellite mission provide repeated height observations, so that the mean sea surface heights along the ground tracks can be recovered very accurately. In this presentation a new and revised version of the KMS global high resolution mean sea surface (1/15 by 1/15 degree) is presented. The new KMS99 multi mission high resolution mean sea surface, has been derived from five different satellite missions using almost twice as many data as for the previous mean sea surface. Similarly, the resolution has been enhanced from 1/8 degree to 1/15 degree, and several steps in derivation of the mean sea surface has been improved.

COMPUTING MARINE GRAVITY ANOMALIES VIA LAPLACE'S EQUATIONS IN SPHERICAL COORDINATE FROM SATELLITE ALTIMETRY

Jiancheng Li; Dingbo Chao, (School of Geoscience and Surveying Engineering, Wuhan Technical University of Surveying and Mapping, 129 Luoyu Road, Wuhan 430079, China, email: jcli@wtusm.edu.cn, dbchao@wtusm.edu.cn)

Using Laplace's equation in planar coordinate, the gravity anomaly can be calculated from deflections of the vertical. In practice, the vertical deflection grids are formed in spherical coordinate. The errors will be caused due to transforming spherical coordinate into planar one in a local Cartesian coordinate system. To avoid this drawback, the formula for converting deflections of the vertical to gravity anomaly is derived based on the Laplace's equation in spherical coordinate. Its representation in frequency domain using FFT techniques is also given. With EGM96 model as the reference gravity field, the gravity anomalies over the China seas and their neighbours are implemented using deflections of the vertical derived from altimeter data according to this principle. The comparison of this procedure with that in planar coordinate is also discussed in this presentation.

AN INTEGRATED SATELLITE ALTIMETRY, GRAVITY AND GEODESY DATA BASE, DATA PROCESSING AND REGIONAL MARINE GRAVITY FIELD MODELLING

P. MEDVEDEV, D.Pleshacov, (Geophysical Center, Russian Academy of Sciences, Molodezhnaya 3, 117296, Moscow, Russia, email: pmedv@wdcb.rssi.ru); A. Bulychev, (Lomonosov MSU, Geology Faculty, Geophysical Department, Moscow, Russia)

The integrated database of satellite altimetry data and supplementary gravity and geodesy information which is necessary for geodesy, geophysics, geology and oceanography applications was created in Geophysical Center of RAS. The satellite altimetry data sets of the Russian GEOIK geodetic satellites and GEOSAT and TOPEX/POSEIDON data are used for marine gravity modelling North Atlantic region, Baltic and Okhotsk sea. The results of these investigations are presented. Comparisons with gravity measurements and resolution of satellite altimetry data are discussed. New approach to processing the altimetric measurements for closed seas and some unsolved problems are discussing also. The work was supported by Russian Basic Research Foundation.

HIGH-RESOLUTION GRAVITY ANOMALIES FROM ALTIMETRY IN COASTAL AREAS

Matthias RENTSCH, Michael Anzenhofer and Alexander Braun, (GeoForschungsZentrum Potsdam(GFZ), Division 1, Section 1.2, c/o DLR Oberpfaffenhofen, D-82234 Wessling, e-mail: rentsch@gfz-potsdam.de)

The generation of high-resolution marine gravity maps based on satellite altimetry is well known and was refined in the recent years by several groups. Although the processing can be improved and slightly better results can be expected, the main focus in the future should be on regional applications, also including airborne altimetry.
The standard altimeter geophysical data records are provided as 1-Hz measurements and are mainly flagged as 'invalid' in shallow water areas and near coastlines. The problem can be solved by using waveform data with a higher resolution, e.g. 20-Hz measurements for ERS-1 and ERS-2. Using retracking algorithms, these waveform data are processed individually and can be interpolated at different time stamps. However, new problems arise by using such data, e.g. a higher noise level and the absence of convenient corrections like ocean tide and wet troposheric path delay.
This presentation reflects the state-of-the-art of high-resolution marine gravity processing in coastal areas based on conventional altimeter data. Additionally, the new results using the retracked altimeter waveforms at different sampling rates demonstrate the gain in resolution and accuracy of satellite-derived gravity anomalies.

HIGH RESOLUTION MEAN SEA SURFACE HEIGHT AND MARINE GRAVITY ANOMALIES FROM SATELLITE ALTIMETER DATA

Y M WANG (Raytheon ITSS , Greenbelt, MD 20770, USA Email: wang@geodesy2.gsfc.nasa.gov)

The availability of high spatial resolution altimetry from the ERS-1 and Geosat missions in combination with the high-precision TOPEX/POSEIDON data has allowed significant advances to be made in computing marine-based geodetic quantities. We have computed the mean sea surface height and the gravity anomalies over the oceans on a 2' x 2' grid using satellite altimeter data from these three missions. In order to reduce the long and medium wavelength errors in the altimeter data (Geosat and ERS-1 data) a crossover adjustment is performed in a 2 degree latitude bands. The mean sea surface height is forced in the TOPEX reference frame by fitting the altimeter data to the 3-year TOPEX/POSEIDON mean tracks. The mean sea surface heights are computed on a 2' x 2' global grid using least squares collocation. Gravity anomalies are then computed using the mean sea surface height-implied geoid undulation in the inverse Stokes formula. A 1-dimensional FFT is used to speed up the evaluation of the global numerical integration. The accuracy of the mean sea surface and the marine gravity anomalies are provided at every 2' cell. The comparisons between the mean sea surface heights will be shown. Comparisons between ship gravity data and the gravity anomalies from the altimetry will also be presented.

ON THE ADVANCES OF MARINE GRAVITY ANOMALY MODELS DETERMINED FROM GEOSAT, ERS-1 AND TOPEX/POSEIDON SATELLITE RADAR ALTIMETRY

Yuchan YI (Department of Civil and Environmental Engineering and Geodetic Science, The Ohio State University, 470 Hitchcock Hall, 2070 Neil Avenue, Columbus, OH 43210-1275, USA, Email: yi.3@osu.edu); C.K. Shum and Hong-Zeng Tseng (both at The Ohio State University, USA); Michael Anzenhofer and Matthias Rentsch (both at GeoForschungsZentrum Potsdam, Germany); Cheinway Hwang (National Chiao Tung University, Taiwan)

Using an estimation procedure based on the gravity signal properties, the marine gravity field is determined from reprocessed satellite radar altimeter data in selected areas. These areas include the South China Sea region and regions off coast California. The specific improvements in these altimeter measurements include more accurate orbital, geophysical and media corrections for inferring sea surface heights, and studies on retracked altimeter measurements near coastal regions. The dense data of Geosat Geodetic Mission and ERS-1 Geodetic Phase are included as the sea surface height slopes along ground tracks. And the sparse but more accurate time-averaged sea surface height data from TOPEX/POSEIDON and ERS-1's 35-day repeat phase are combined to obtain the gravity anomaly predictions along with accuracy estimates. The accuracy of the resulting gravity anomaly model and other state-of-the-art models is assessed by the comparison with ship gravity profile data.

Airborne Gravimetry

SPECTRAL ANALYSIS AND POST-FILTERING OF AIRBORNE GRAVITY DATA

A.M. BRUTON, K.P. Schwarz, C.L. Glennie (Department of Geomatics Engineering, The University of Calgary, 2500 University Drive, N.W. Calgary, Alberta, Canada T2N 1N4)

A major challenge in airborne gravity is the task of simultaneously increasing the accuracy and resolution of airborne gravity data to meet the needs of geodetic and geophysical applications. This implies the need for a thorough understanding of the subsystem errors and a means of removing them. This paper will treat these problems using filtering methods in post-mission. In June of 1998 three flights were undertaken which tested a LCR gravimeter and a strapdown INS gravity side by side. Data from this test will be used in this paper because it provides a unique opportunity to study the responses of both the LCR gravimeter and strapdown INS systems to the same environmental conditions. Comparisons between systems and with shipborne gravity data will be used to do this characterization.
The paper has three objectives. The first is to characterize the errors currently coming from each of the component systems in the frequency domain. One way to remove these subsystem errors is by post-filtering the data.
The second objective is to use the common data set to compare and evaluate several methods of post-processing. These methods include filtering using an adaptive filter, a modified wave filter and the traditional method that uses a lowpass filter. The frequency response (phase and amplitude) of each of these is also studied and its importance made clear.
Finally, a proposal is made for ways to describe the quality of airborne gravity results. This includes discussions of both the spatial resolution and the accuracy that result from each of the filtering methods treated in this paper.

AIRBORNE GRAVITY SURVEY OF THE POLAR SEA NORTH OF GREENLAND

Rene FORSBERG, Arne V. Olesen, K. Keller (Geodynamics Dept., KMS, Rentemestervej 8, DK-2400 Copenhagen NV, Denmark, email: rf@kms.dk)

An airborne gravity survey was carried out north of Greenland i 1998, covering the Lincoln and Wandel Sea shelf areas of the Arctic Ocean. Measurements were done with a Twin-Otter, using a Lacoste and Romberg model S gravimeter, multiple GPS receivers, a laser altimeter and custom-made data logger and INS unit. Flight conditions were generally good and a high accuracy has been obtained in processing of the data, as indicated by 2 mgal r.m.s. cross-overs after bias adjustment, and independent comparisons to shipborne and ice surface gravity measurements. Our results show that with careful processing the need for cross-over adjustment of airborne gravity measurements can be virtually eliminated.
The paper will present the survey, processing methods and evaluation of results. Our measurements represent a contribution to the Arctic Gravity Project, an international effort to compile a grid of all available and releasable gravity data for the Arctic region, in support a.o. of the upcoming satetellite gravity field missions.

AIRBORNE VECTOR GRAVIMETRY USING INS/GPS – RESULTS

Christopher JEKELI, Jay Kwon (Department of Civil and Environmental Engineering and Geodetic Science, Ohio State University, 2070 Neil Ave., Columbus, OH 433210, USA, e-mail: jekeli.1@osu.edu); and Jin Wang (Center for Mapping, Ohio State University, Columbus, OH 43210, USA).

A number of recent airborne flights of an inertial navigation system (INS) integrated with the Global Positioning System (GPS) provided opportunities to test different algorithms for vector gravimetry, that is, the determination of the total gravity vector at aircraft altitude. The principle behind vector gravimetry is that INS senses only specific (action) forces, while the total trajectory, as determined from GPS, is due to both action and kinematic forces, where gravitation belongs to the latter. Therefore, the difference between accelerations derived from INS and GPS, in a generic sense, provides information about the gravitational field. Two algorithms were considered. The first compares positions determined from INS accelerations to GPS positions; the second compares accelerations determined from GPS positions to INS accelerations. Repeat tracks from one test flight showed internal consistency better than 8 mgal (rms) in the horizontal component not affected by high dynamics. For the second flight, a comparison to truth data, comprising ground deflections of the vertical, showed differences of about 5-6 mgal (rms). The vertical component was determined to an accuracy of about 4–5 mgal. The resolution for each component was about 10 km. The paper presents details of the algorithm comparisons and analyzes the significant sources of error.

GRAVITY MEASUREMENT USING A HELICOPTER-BORNE NEW GRAVIMETER

Jiro SEGAWA (School of Marine Science and Technology, Tokai University, 3-20 -1 Orido, Shimizu, Shizuoka 424-8610 Japan, email: jsegawa@scc.u-tokai.ac.jp); Hiroshi Hasegawa (Aero Asahi Corporation, 43rd Fl. Sunshine 60 Bldg., 1-1, Higashi-Ikebukuro 3-chome, Toshima-ku, Tokyo 170-0013 Japan); Takemi Ishihara (Geological Survey Japan, 1-3 Higashi 1-chome, Tsukuba-shi, Ibaraki-ken 305-0046 Japan); Sadaomi Sakuma (Tokimec Inc. 3-1 Takakuko, Nasumachi, Nasu-gun, Tochigi 325-0001 Japan)

Development of the airborne gravimeter started five years ago using a converted sea-gravimeter and a fixed-wing plane. Although this experiment taught us valuable things about the techniques and problems on airgravimetry, it proved to be a failure. In the course of the last study we changed the policy so that we use a helicopter as a gravimeter platform. The helicopter is able to adjust its speed in case of take-off and landing, and besides, when a detailed survey is necessary to enhance resolution, the helicopter can move as slowly as a motorcar while keeping a stable flight. As for the real time positioning, it has become possible to use the marine DGPS supporting stations maintained by Maritime Safety Agency Japan since last year. These stations are for ship's use, and enable the cruising ships to make positioning with the accuracy of 1 m in real time. We planned to utilize these stations, not from sea but from air. Our objective is to develop a helicopter-borne gravimetry system came from the necessity to fill in the gravity blanks in the land/sea bordered areas. We believe a deliberate operation of the helicopter gravimeter would be the only means by which the land-to-sea gravity gap could be filled. Our system is composed of a servo accelerometer sensor, a stabilized platform, an optical-fibre gyro to control the stabilized platform, a data processor and a controller, a GPS receiver and a receiver for the land-based DGPS supporting stations. The drift rate of the gravity sensor is a few mgal/month. The real time DGPS positioning was successful and we could get the positions of the helicopter within the error of two to three meters. For the exact correction for the effect of the helicopter motion an interferometric GPS positioning is necessary. This is done by post processings. We have made measurements from a heliport in the suburbs of Tokyo over to Ibaraki Prefecture and the neighboring seas. We will report the results from these measurements.

PLAN OF A G.I.S. TO ARCHIVE AND MANAGE PHYSICAL GEODESY DATA IN ANTARCTICA

Alessandro CAPRA and Stefano Gandolfi (DISTART Dept., University of Bologna, Viale Risorgimento 2, 40136 Bologna, Italy, email: alessandro.capra@mail.ing.unibo.it)

Within the activities of WGGGI (Working Group on Geodesy and Geographic Information) of SCAR (Scientific Committee on Antarctic Research)a "Physical Geodesy" project was planned for the period 1998-2000. Till today a geoid map of Antarctica was produced by AUSLIG (Australia)showing the geoid-ellipsoid separation between GRS80 and OSU89A. Researchers from different countries tried to compute new local and regional high-resolution geoid, but the goal of the project is the collection and the analysis of data useful to a development of a new high resolution geoid for the most part of Antarctica. A first phase of information and extensive data collection, related to geodesy, topography, bathymetry and gravity, was activated in collaboration with Institutions and Specialists Group (BEDMAP, ADGRAV, ADMAP, RAMP. The different set of data and their size need for a specific Data Base Management System: moreover the data representation in spatial and time ranges is important. A preliminary plan of a G.I.S. for a correct data archiving and management and for his utilisation for a successive geoid computation is presented.

A STUDY OF GROUNDWATER VARIATIONS BY MEANS OF MICOROGRAVITY MEASUREMENTS, ABSOLUTE GRAVITY MEASUREMENTS AND LEVELING SURVEYS IN BEPPU AREA, JAPAN

Yoichi Fukuda (Department of Geophysics, Graduate School of Science, Kyoto University, KitashirakawaOiwakecho, Sakyo-ku, Kyoto 606-8502, Japan, email: fukuda@kugi.kyoto-u.ac.jp) Hideo Mawatari, Yuki Yusa (both at Beppu Geothermal Research Laboratory Graduate School of Science, Kyoto University, Noguchibaru, Beppu 874- 0903, Japan
email: mawatari@bp.vgs.kyoto-u.ac.jp, yusa@ bp.vgs.kyoto-u.ac.jp), and Shuhei Okubo (Earthquake Research Institute, University of Tokyo, 1-1-1 Yayoi, Bunkyo-ku, Tokyo 113-0032, Japan, email: okubo@eri.u-tokyo.ac.jp)

It is obvious that the groundwater variations cause gravity changes at surface and gravity observations conversely give us important information about the hydrological characteristics in the area concerned. The groundwater level observations in the Beppu geothermal system, which is one of the largest geothermal systems in Japan, have been conducted over a long period to study the characteristics of the hot water flow or other purposes. It has already been known that the peak-to-peak amplitude of annual groundwater level variations are very large and it sometimes reaches more than 10 meters. In order to detect the gravity changes associate with the groundwater variations in Beppu area, we conducted repeat precise gravity measurements, absolute gravity measurements and leveling survey. Using a LaCoste & Romberg gravimeter (G-534), 40 microgravity surveys were made from February 1993 to January 1998, at 11 survey marks in the Beppu area. The absolute gravity measurements were conducted in June 1995 and in September 1997. The leveling surveys were conducted 7 times from June 1995 to January 1998 to monitor the vertical movements of the area concerned. The result of the gravity measurements shows that some tens micro gals of gravity changes were observed during the period, while no significant vertical displacement was observed by the leveling surveys. This means that all the gravity changes were due to the actual mass changes associated with the groundwater variations. To investigate the characteristics of the groundwater variations and/or the relation between the variations and the gravity changes, we employed Principal Component Analysis (PCA). The results of PCA shows that; (1) the 1st and the 2 nd components explain almost 90 % of the variations, (2) the 1 st component reflects the groundwater level of the shallow unconfined aquifer, the level to which the amount of rainfall directly relate, and (3) the spatial pattern of the 2nd component is possibly explained by the movements of the deeper groundwater.

COMPILING AND DOCUMENTING GRAVITY DATABASES

Allen M. HITTELMAN and David T. Dater (NOAA's National Geophysical Data Center, 325 Broadway, Boulder, CO 80303, USA, email: amh@ngdc.noaa.gov)

The 1999 2-volume edition of the Gravity CD from the National Geophysical Data Center (NGDC) has recently been released. This compilation contains a wealth of gravity measurements contributed by many national and international academic and government organizations, including: regional land and marine surveys, absolute measurements, regional and global gridded data sets, and correlative data (e.g., geoids and global relief). Approximately, 70 percent of the data are observed values; another 30 percent represent grids and other summary data sets.
Access software on the CD simplifies data and documentation extraction and browsing. To support end-user validation of the data: point distribution plots illustrate coverage (as .PCX and .GIF images); histogram distribution plots have been prepared for each parameter within each data set; and, a data dictionary presents standardized terminology to facilitate comparison of different data sets. The document contains HTML, Postscript, Word, and WordPerfect files that summarize source information, a printout of first ten records, and maximum and minimum values of each field. Instead of following the traditional approach of making all data sets fit into a fixed common format, NGDC employees a standard format description, preserving fields unique to a specific data collection and allowing access to the data without concern for formats.

BOUGUER ANOMALY MAP OF THE FENNOSCANDIAN SHIELD 1:4 MILL

Juha V. KORHONEN and Seppo Elo (Geological Survey of Finland, P.O.Box 96, FIN-02151 Espoo, Finland, Email: juha.korhonen@gsf.fi, seppo.elo@gsf.fi); Jussi K„„riainen (Finnish Geodetic Institute, Geodeetinrinne 2, 02430 Masala, Kirkkonummi, Finland, Email: jussi.kaariainen@fgi.fi), Sven Aaro (Geological Survey of Sweden, P.O.Box 670, 75128 Uppsala, Sweden, Email: sven.aaro@sgu.se), Lars ?ke Haller (Lantm„teriverket, 801 82 G„vle, Sweden), Jan Reidar Skilbrei (Norges geologiske unders›kelse, Postboks 3006 Lade, 7002 Trondheim, Email: jan.skilbrei@ngu.no), Dag Solheim (Statens kartverk, NO-3500 H›nefoss, Norway, Email: dagso@gdiv.statkart.no), Anatoli Tchepik (Northwest Regional Geological Centre, 24/1 Odoevsky Street, 199155 St Petersburg, Russia, Email: root@geol.spb.su), Anatoli Kulinich (Petersburg Geophysical Expedition, 195009 St Petersburg, Russia), Lioudmila Jdanova (State Company "Mineral", Veselnaya Street 6, 196106 StPetersburg, Russia, Email: frank@DF3136.spb.edu)

In 1998 the Geological Surveys of Finland, Norway and Sweden, the Petersburg Geophysical Expedition, the Finnish Geodetic Institute, the National Land Survey of Sweden and the Norwegian Mapping Authority started to compile a Bouguer anomaly map on a scale of 1:1 mill on a 2.5 km x 2.5 km grid to support compilation of a geological map of the Fennoscandian Shield. The participating countries provide the data of their territories as grids of Bouguer anomalies (Bouguer density 2670 kg/cum) in Gauss-Krueger projection (central meridian 21 deg E) and in WGS-84 datum. The reduction principles of the original data have been described, e.g. in the explanation of the Bouguer anomaly map of Finland 1:1 mill (K„„ri„inen, J., J. M„kinen, 1997. The 1979-1996 gravity survey and results of the gravity survey of Finland 1945-1996. Publ. Finn. Geod. Inst no. 125). A preliminary Bouguer anomaly map on a scale of 1:4 mill on a 5 km x 5 km grid, compiled in 1999, and examples of its geological correlation by petrophysics are represented.

PRECISE GRAVITY MEASUREMENTS IN AZORES ISLANDS

Clara LAZARO (Centro de Geodesia, Instituto de Investigacao Cientifica Tropical, Rua da Junqueira 534, 1300 Lisboa, Portugal, Email: cgeod@iict.pt J. Pereira Osorio (Observatorio Astronomico "Prof. Manuel de Barros", Faculdade de Ciencias, Universidade do Porto, Portugal); Luisa Bastos (Observatorio Astronomico "Prof. Manuel de Barros", Faculdade de Ciencias, Universidade do Porto, Portugal) Jaakko Makinen (Geodeettinen Laitos, Masala, Finland)
Gunter Hein (IfEN, University FAF Munich, Germany)

The Azores Archipelago is a region of well-known seismic and volcanic activity. It has been the object of scientific interest since it is located in the junction of three main tectonic plates: Eurasian, North American and African. Nine islands, two of them lying in the North American plate and the others in the so-called Azores microplate, form the archipelago.
The gravimetric surveys started in 1992 with the establishment of two absolute gravity stations, Flores and Faial, and relative measurements in all of the nine islands. These gravity measurements were intended to complement the GPS data obtained, since 1988, in the TANGO (TransAtlantic Network for Geodynamics and Oceanography) project. Therefore, the relative stations include all the GPS sites and other stations of geophysical, seismological and geodetic interest. Later, in 1994, a new absolute gravity station was established in S. Miguel Island and the Faial station was reobserved. The three absolute stations were reobserved in 1997. The absolute measurements have been made using the JILAg-5 gravimeter, belonging to the Finnish Geodetic Institute (FGI). A total of 114 relative gravity stations were measured by using LaCoste & Romberg gravimeters in three campaigns - 1992, 1994 and 1997.
In the paper, it is intended to present details of the three gravity surveys, the methods used for data processing and the results derived so far.

GRAVIMETRY IN SOUTH-WESTERN CHINA

H.LI, S.A.SUN, D.Z.Liu, C.F.Xing, G.Y.Fu, Y.J.Zhang, A.M.Xiang, X.E.Lei(Institute of Seismology, CSB)

As the part work of the Crustal Movement Observation Network of hina (CMONOC), gravity surveys in south-western China had been carried out during the September to December of 1998 by employing three LaCoste and Romberg gravimeters. The gravimetry connected 5 permanent stations and 14 base stations of CMONOC through about 80 connecting stations which comprised of absolute gravity stations, national gravity stations, local gravity stations, local GPS stations, high level levelling stations and some temporary stations. This paper will firstly introduce the network and the observations. Secondly, the adjustment of the measurements will be described.
At the last part, we will discuss the precision and its reliability.

GRAVITY CHANGES IN WEST YUNNAN OBSERVED BY RELATIVE GRAVIMETRY

H. LI, S.A.SUN, M.Y.JIA, C.F.Xing, A.M.Xiang (Institute of Seismology, CSB)

Since 1985, gravity surveys at the local gravity network in the Western Yunnan Earthquake Prediction Experiment Area(WYEPEA) have been carried out 2-3 times a year by the Institute of Seismology, Chinese Seismological Bureau(ISCSB), and the Yunnan Provincial Seismological Bureau (YPSB), employing LaCoste and Romberg (LCR) relative gravity meters. The network comprises several absolute gravity stations and more than 130 field gravity stations. Until now 32 observance campaigns were performed. This paper firstly introduced the network and the observations, which include absolute and relative gravimetry. Secondly, the adjustment of the measurements was described, and the gravity changes displayed by contour map were given. The results show that the precision of the network is estimated to 0.07-0.1ms-2*10-6(0.01ms-2*10-6=1gal*10-6). It means that the network can detect the gravity changes with the scale of about 02ms-2*10-6. At the last part, we discussed the relationship between the earthquake preparation especially for Lijiang earthquake(Ms7.0,1996) and gravity changes.

ADJUSTMENT OF SEA GRAVITY CRUISES USING ALTIMETRY DATA

SARRAILH Michel (BGI/CNES); Jiancheng Li (School of Geoscience and Surveying Engineering, Wuhan Technical University of Surveying and Mapping, 129 Luoyu Road, Wuhan 430079, China 430079 China)

Sea gravity often suffers, for the oldest ones, from biases and shifts, observed at crossovers. They can be adjusted between themselves, but the gravity information, derived from altimetric geodetic missions, can be used as a reference and offers an alternative way. Benefits and problems resulting from this last method are discussed.

PROPOSED GRAVITY BASE NETWORK OF IRAN

Mehdi NAJAFI-ALAMDARI (Surveying Eng. Dept., Faculty of Civil Eng., 1346 Valiasr Ave., Mirdamad intersection, Technical University of K.N. Toosi, E-mail: mnajalm@dpi.net.ir, Fax #: +9821 877 9476, Tehran, Iran); M. Mashhadi-Hossain-Ali, Y. Hatam-Chavari, F. Tavakkoli (National Cartographic Center (NCC) of Iran, Mearaadge Str., P.O. Box 13185- 1684, Fax #: +9821 600-1971, Tehran, Iran).

A gravity base network comprising of 19 points is proposed for Iran. For fast accessibility by relative instruments (gravimeters), the points will be located at airports. Absolute gravity will be measured at 9 of these points(absolute points). Six of these will make a calibration line, extending from extreme North-West to extreme South-East end of the country. The remaining 10 points, uniformly distributed throughout the country, will be connected to the absolute points by precise relative measurements.
Based on the 5 æGal accuracy of the Canadian gravimeter CG-3M and the assumed 3 æGal accuracy of a modern absolute gravimeter, pre-analysis of five different designs (networks)have been carried out. In the pre- analysis, the nine absolute points were considered known with limited observational weights and no correlations. The residual gravimeter drift was assumed linear in time within an interval no longer than 8 hours. Individual gravimeter readings were assumed uncorrelated, while mathematical correlations between reading differences (relative measurements) were assessed. Relative measurement accuracies were taken to be proportional to the time of measurement with the constant of proportionality to be determined by an adjustment.
Redundancy numbers and internal reliability at 90% probability level were evaluated for each design to study the robustness of each design against gross errors. Individual potential maximum undetectable gross errors were then displayed to show the potential maximum deformation of the networks. The optimum network design was chosen for which the achievable accuracy is the best, and redundancy numbers, all larger than 0.5, are uniformly distributed throughout the network. Even for the optimum design, gross errors up to 25 æGal may remain undetected, but the maximum potential distortion caused by this error would not exceed the sought accuracy of 5 æGal. In this design, unknown points are linked to at least three known points and every observational link is the line of flight, fore and back, with a relative gravity measurement.
Observations in the optimum network are to be carried out in two steps: 1) the relative measurements between absolute points are made to determine the scale factor and the accuracy of the gravimeter; 2) the relative observations between known unknown and unknown-unknown pairs of points are carried out. To test for outliers among the observational mis-closures, the estimated accuracy of the instrument is used.

UNIGRACE - A EUROPEAN PROJECT FOR THE UNIFICATION OF GRAVITY SYSTEMS IN CENTRAL AND EASTERN EUROPE

E. REINHART, B. Richter, H. Wilmes (Bundesamt fuer Kartographie und Geodaesie, Richard-Strauss-Allee 11, 60598 Frankfurt am Main, D, e-mail: reinhart@ifag.de) J. Sledzinski (WUT, Warsaw, Poland) I. Marson (DINMA, Univ. de Trieste, Italy) E. Erker (D. Ruess, BEV, Vienna, Austria) J. Makinen (Finn. Geod. Inst., Masala, Finland)

In the EC-funded project UNIGRACE, partner institutions from 12 countries in Central and Eastern Europe co-operate with the aim of unifying the gravity systems in the countries involved. Benefit is expected for metrology, mapping, surveying and navigation, height determination, sea level variation studies, geophysical research, geological exploration and mining. Five European groups from Austria, Finland, Germany, Italy and Poland carry out absolute gravity measurements on 17 reference stations at two epochs. They are supported by the partners in the hosting countries Bulgaria, Croatia, Czech Republic, Hungary, Romania, Slovakia and Slovenia who are responsible for the station selection and preparation and who determine the connections to the national gravity networks. This will build up a unified gravimetric reference in the countries involved and will enable to transform all gravity data available to the common reference. The first project phase 1998 was carried out with the reconnaissance and site preparation. The sites have been selected in each participating country emphasis to geological stability; in countries with access to the sea tide gauge sites have been added to the network in order to contribute to sea level variation studies. In the second half of 1998 absolute gravity measurements have been carried out at most of the selected sites including inter-comparisons at the reference sites Wettzell (Germany) and Josefoslaw (Poland) for all absolute gravimeters used in the project. In 1999 special emphasis is put on the relative gravity measurements on calibration lines an in the networks. In the year 2000 a second absolute gravity campaign will follow to verify the stability of stations and instrumentation.

GEODYNAMIC INTERPRETATIONS OF HEIGHT CHANGES (DERIVED BY PRECISE LEVELLING) BY GRAVIMETRIC METHODS

Diethard Ruess, Norbert HOEGGERL (Federal Office of Metrology and Surveying, Schiffamtsgasse 1-3, A-1025 Wien, Austria, email: diethard.ruess@univie.ac.at); Bruno Meurers (Institute of Meteorology and Geophysics, University of Vienna, Hohe Warte 38, A-1190 Wien, Austria, email: bruno.meurers@univie.ac.at); Ewald Brueckl (Institute of theoretical Geodesy and Geophysics, Technical University of Vienna, Gusshausstrasse 25-29, A-1040 Wien, Austria,
email: ebrueckl@luna.tuwien.ac.at)

Repeated precise levellings in Austria show recent height changes of the crust. The uplift of 1-2 mm/y may be an isostatic rebound effect but may also be caused by active tectonic movements. The periadriatic line in the south of Austria, a collision zone between the Eurasian and the African plate is of great interest for some more investigations about the recent seismicity in this area. Therefore several geodynamic GPS projects are running in the surrounding area. Furthermore a combination of repeated measurements in precise levelling and absolute gravity is an important method for analysing geodynamic processes. A common project founded by the Austrian Foundation of Scientific Research was started in 1995 to establish a network of precise levelling sites across the periadriatic line in the Karawanks combined with 4 absolute gravity stations. Short precise relative gravity profiles along the precise levelling lines near the absolute stations monitor their stability. The used absolute gravimeter JILAg-6 was upgraded to the technical standard of the FG5 absolute meters before the field observations were started. Absolute measurements at background stations and at international reference stations guarantee the results of the absolute gravity observations. Attention was directed to the precision of the instruments used and to the selection of the measuring points. An overview of the project, its tasks and first results of the observations that have been made so far are presented.

SEA SURFACE GRAVITY MEASUREMENTS WITH INTERFEROMETRY GPS POSITIONINGS

Mikio SATOMURA (Faculty of Sciense, Shizuoka University, Oya, Shizuoka 422-8529, Japan, E-mail: satomura@sci.shizuoka.ac.jp); Jiro Segawa (Faculty of Marine Science and Technology, Tokai University, Orido, Shimizu, Shizuoka 424-0902, Japan, E-mail: jsegawa@scc.u-tokai.ac.jp); Junji Tanimoto (Faculty of Sciense, Shizuoka University, Oya, Shizuoka 422-8529, Japan) Yuichi Imanishi, Chieko Kuramoto, Kin-ichiro Koizumi (Ocean Research Institute, University of Tokyo, Minamidai, Nakano-ku, Tokyo 164-0014, Japan)

One of the most serious error sources of gravity obtained on the sea surface is inaccurate estimation of the Eotvos corrections due to inaccurate positionings.
Gravity measurements were carried out by a NIPR-ORI gravimeter as well as interferometry GPS measurements with three antennas in the KH-96-1 cruise of Hakuho-maru on the Pacific Ocean, south off central Japan. Eotvos corrections for the gravity data obtained were performed by using four kinds of positioning data; 1) a single antenna position data of single positioning GPS, 2) a single antenna position data of interferometry GPS, 3) center of the three antennas of interferometry GPS, and 4) gravity sensor position from interferometry GPS. Velocities were calculated from their positions and a digital filter was applied to their EW component as well as gravity data.
Two gravity values at each cross point were compared each other in order to study the precision of gravity values obtained. As a result, gravity values based on interferometry GPS positionings were much more precise than those based on single positionings, while precisions of three kinds of gravity values based on a single antenna position, center of the three antennas and gravity sensor position were approximately equivalent.

ENVIRONMENTAL EFFECTS ON GRAVITY MEASUREMENTS IN THE CITY OF HANNOVER, GERMANY

Karin SCHMIDt (Institut fuer Erdmessung, Universitaet Hannover, Schneiderberg 50, 30167 Hannover, Germany, email: schmidt@ife.uni-hannover.de

For the interpretation of gravity observations to detect horizontal or vertical crustal movements, seismic activities or simply to define high precise gravity values in a gravity reference network, the measurements should have an accuracy of 0.01-0.1 µm/s_.
Since march 1998 the Institut fuer Erdmessung (IfE), University of Hannover, carries out a measurement project to analyse the variations of gravity which are caused by environmental effects with combination of relative and absolute measurements as well as earth tide recordings. Within the frame of the measurement project a micro gravity network consisting of 4 gravity stations was established. The gravity values of the 4 stations are monitored with weekly relative gravity observations between the stations with 2 or 3 LaCoste&Romberg modell-G gravimeters. The center of the network is located in a cellar of the IfE, since thirteen years the station was regularly occupied by the absolute gravimeter JILAG-3 of the IfE. During the measurement campaign absolut gravity determinations were carried out regularly in the cellar, also an earth tide registration was established. Additionally precipitation data, ground water data as well as global, regional and lokal air pressure data were collected. First results of the analysis concerning the correlation of precipitation, ground water an gravity values of the network will be presented.

G3/E/26-A5 Poster 1610-37

IS AN EVERY ABSOLUTE GRAVIMETER A PRIMARY STANDARD?

S. SVITLOV, G. Sidorenko, V. Bondarenko, Yu. Lokshin (State Scientific Industrial Association "Metrology", Ukraine, email: svet@online.kharkiv.com); A. Sas-Uhrynowski, A. Sas, L. Siporski, E. Zanymonski (Institute of Geodesy and Cartography, Warsaw, Poland, email: zgf@igik.edu.pl)

In this presentation some problems of legal metrology concerning gravimetry will be outlined. What is a primary gravity standard? To answer this question, an absolute gravimeter is considered any time at the head of the hierarchy scheme. But starting from the Sakuma-type device, every new generation absolute gravimeter discovers a systematic error of a previous one. At different gravity stations a difference between different type gravimeters (say, free-fall and rise-and-fall) can rea up to +/- 0.05 mGal that may be caused by unrecognized site-dependent systematic errors of the gravimeters. In this case we consider a gravity network adjusted using both various absolute and relative gravity determinations to be a primary group gravity standard. The New Polish Reference Gravity Network includes 10 absolute gravity stations which are occupied by the FG5-107 (USA), FG5-101 (Germany), JILAg-5 (Finland) and ZZG (Poland) absolute gravimeters. Relative connections are made with the La Coste & Romberg and Scintrex CG3 gravimeters. The combined adjustment of those stations is resulted in standard error of order 0.01 mGal. We have then 'calibrated' the Ukrainian (GP-05 type) and Polish (PBGM-97) transportable absolute gravimeters at the Polish Reference Gravity Network (Primary Standard). Standard error of an each gravimeter is estimated to be about 0.03 mGal that is a satisfactory value for a secondary standard. Hence, urthupgrading of a gravity system (creation of the 1st an 2nd order gravity networks) could be made using those secondary standards. Advantages to use an absolute gravimeter as a secondary standard and future plans to develop and unify Polish and Ukrainian gravity networks will be discussed.

G3/E/24-A5 Poster 1610-38

NEW ABSOLUTE GRAVITY DETERMINATIONS IN UKRAINE

S. SVITLOV (Kharkov State Research Institute of Metrology, Ukraine, email: svet@online.kharkiv.com)

Status of the Ukrainian absolute gravimetry will be outlined. Having get only few relative gravity stations of the former Soviet Union's gravity system, the modern Ukrainian gravity network lacks of absolute gravity sites. Furthermore, due to some reasons Ukraine did not join a current project called UNIGRACE (Unification of Gravity System in Central and Eastern Europe). Fortunately, in 1991-1993 it was performed a lot of repeated measurements at the gravity stations "Kharkov" (Ukraine) and "Borowa Gora" (Poland) with an Ukrainian rise-and-

fall absolute gravimeter, the GP-05. Later, in 1995-1997, this last station was re-visited by the FG5-101 (Germany), FG5-107 (USA), JILAg-5 (Finland) and ZZG (Poland) absolute gravimeters. Those results are scattered up to +/- 0.016 mGal about the FG5-101's value and give a possibility to compare the GP-05 gravimeter with others. Since the FG5-101 gravimeter is essentially involved in the international comparison campaigns as well as into the UNIGRACE project, we compare our GP-05 gravimeter just with the FG5-101 one. In such a way, a systematic error of the GP-05 gravimeter of order (+0.08 +/- 0.012) mGal was found. Being too large at first sight, this error is consistent with those shown by anotherise-and-fall gravimeters, the JAEGER/BIPM and GSI, during the ICAG94 comparison. Taking this systematic error into account, we have transferred the FG5-101's absolute gravity value from Borowa Gora to Kharkov. Hence, for the first time the new Ukrainian absolute gravity station connected with the international gravity network is established. Further we plan to develop the Ukrainian gravity network using the station "Kharkov" as a reference one. Comparing with older known gravity values obtained at Kharkov from adjusted relative determinations, the new one is lower up to 0.05 mGal. Possible interpretations of this difference will be given.

G3/E/25-A5 Poster **1610-39**

REDUCING EFFECT OF VIBRATIONS ON ABSOLUTE GRAVITY MEASUREMENTS

S. SVITLOV (Kharkov State Research Institute of Metrology, Ukraine, e-mail: svet@online.kharkiv.com)

Observed non-tidal gravity variations comprise various environmental effects (polar motion, re-distribution of atmospheric, hydrologic and oceanic masses, etc.) that are a matter of separate interests. Another disturbing effects occurring everywhere are external and internal vibrations. Ambient seismic noise reduces short-term resolution of gravity measurements. Being site-dependent, systematic errors due to gravimeter/floor recoil effect can considerably distort shallowspaced gravity results. That is why the modeled environmental effects must include influence of both ambient and internal vibrations on absolute gravity measurements. To solve these problems, theory of an absolute gravimeter analysis in the frequency domain is developed. Obtained exact and approximated frequency responses are useful tool to investigate gravimeters' errors caused by any vibrations. Firstly, the developed approach is used to design an anti-vibration system for an absolgravimeter basing on invariance principle. Vibration accelerations are independently detected by thehigh-sensitive piezo-electric accelerometer and then further transformed into correction following the frequency response of a rise-and-fall absolute gravimeter developed at Kharkov. As a result, standard uncertainty is reduced over 3 times. Secondly, frequency responses are applied to investigate a systematic error caused by coherent vibrations when the drop length and starting interval in an absolute gravimeter are varied. Assuming parameters of the FG5 absolute gravimeter in real measurement conditions, it is theoretically shown that unrecognised systematic errors order 0.01 mGal can be detected. It will also be shown that results of various related experiments could be easily explained using the proposed absolute gravimeter frequency response technique.

NEW GENERATION NAOM ABSOLUTE GRAVIMETER

T. TSUBOKAWA, H. Hanada and S. Tsuruta (National Astronomical Observatory, Mizusawa, Japan, email: tsubo@miz.nao.ac.jp); S. SVITLOV (Kharkov State Research Institute of Metrology, Ukraine, email: svet@online.kharkiv.com)

The National Astronomical Observatory, Mizusawa (NAOM), Japan, has developed a new generation transportable free-fall absolute gravimeter. The main features of the gravimeter are as follows: digital acquisition of a fringe signal, data processing algorithm based on a second difference method, simple dropping mechanism called "Silent Drop", automatic correction of the calculated gravity values using independent recording of ground vibration.A fringe signal is digitized with the high-speed waveform digitizer (digitization rate is 200 MHz) order to avoid possible errors due to analogue processing of the signal. A second difference method allows to calculate only the equally spaced in time fringe phases and then to reconstruct the falli distances intervals rather than to continuously process the signal. Performed theoretical uncertain analysis shows an achievable submicrogal resolution level in an absolute gravity value that is proven by simulation experiments when a stable function generator is used instead of real fringe signal. The "Silent Drop" uses three hybrid elements composed of a stacked piezo-translator and a mechanical expansion amplification system; this mechanism operates at high vacuum and produces as small as possible vibration disturbances. Ground vibrations during free fall are simultaneously recorded with a seismometer and than processed using a special algorithm in order to follow the frequency response of the absolute gravimeter. Developed gravimeter has to be used to monitor long-term absolute gravity variations at the NAOM and the Esashi gravity station.

MEASUREMENTS OF FREE FALL ACCELERATION AT SITE A OF THE GRAVITY MICRONETWORK OF THE BUREAU INTERNATIONAL DES POIDS ET MESURES (SEVRES)

Leonid F.VITUSHKIN and Jean-Marie Chartier (Bureau International des Poids et Mesures, Pavillon de Breteuil, 92312 Sèvres Cedex, France, email: lvitushkin@bipm.fr; jmchartier@bipm.fr)

The results of regular measurements of g made since 0october 1997 at site A at the Bureau International des Poids et Mesures are presented. Site A is used as a reference site for the International Comparisons of Absolute Gravimeters, which are held at the BIPM approximately every four years. The measurements were carried out using an absolute gravimeter FG5-108 belonging to the BIPM. They were generally performed on two days per week (usually during the weekends). Twenty-four sets of measurements were made on each day (one set per hour); each set comprised 150 or 200 drops with a time interval between drops of 10 s or 20 s. The data was processed using commercial software from "Micro-g Solutions, Inc.".

ADJUSTING OF SHIPBORN GRAVITY DATA WITHIN CANARY- BAHAMAS GEOTRANSECT (23-29 N) AND IN THE WESTERN RUSSIAN ARCTIC SHELF.

Andrew ZAYONCHEK (All Russian Research Institute for Geology and Mineral Resourses of the World Ocean, 1 Angliysky Pr., St. Petersburg, 190121, E-mail: andrew@vniio.nw.ru)

The adjustment procedure of shipborn gravity data was developed to create coherent gravity database. Results of recent high quality data were used as reference information for adjusting of historical observations of worse quality. Cross-over analysis of overlapped data sets obtained in the different cruises allows the systematic errors to be distinguished. This errors were divided for a few components connected both with incorrect definition of zero drift for single profiles and groups of profiles, and levelling problems. In order to identify and remove these errors, new software has been developed. It allows to adjust the data in interactive regime. This means that the individual solution could be found for each single profiles and cruise. As a results of processing, after removing of systematic errors, the final standard deviations of RMS of definition of gravity anomaly field within studied areas were reduced from previously estimated as 3,5 mGal to 1,2 -1,5 mGal. This allows to calculate more detailed 7x7 km grids and produce the accurate comprehensive free-air gravity anomaly maps with 5 mGal contour interval.

ON THE COMPENSATION OF SYSTEMATIC ERRORS IN MARINE GRAVITY MEASUREMENTS

GUAN ZHENG, Huang Motao, Zhai Guojun, Ouyang Yongzhong(all at Tianjin Institute of Hydrographic Surveying and Charting, Tianjin, 300061, China, email: nvsurvey@public.tjuc.com.cn)

Based on an analysis of the sources of errors in marine gravity measurements, an error model, firstly, is constructed mathematically which can characterise the change of the systematic errors and with which a new crossover adjustment model is presented in this paper. Then a new method of compensating the systematic errors is suggested, i. e. the self-calibrating adjustment. Some questions involved in solving the adjustment problem, such as the rank deficiency, the choice of error model, the weighting of additional parameters and the test of significance of compensation efficiency, etc., are discussed in detail. Finally, a practical survey data set is used as a case study to prove the efficiency and reliability of the compensation method.

AN INDEPENDENT GLOBAL ASSESSMENT OF THE QUALITY OF CURRENT GLOBAL DIGITAL ELEVATION MODELS

BERRY, P.A.M., Hoogerboord, J.E. & Pinnock, R.A. (Geomatics Unit, De Montfort University, Leicester LE1 9BH, UK)

Within the last few years, a number of Global Digital Elevation Models (GDEMs) have been created with a spatial resolution of five arc minutes or better. These GDEMs present global estimates of land orthometric heights derived from a compendium of ground truth datasets of varying and often unknown accuracy. Intercomparison of the various models in the public domain reveals differences in some regions, generally due to upgrading of the height data in particular regions as more precise information becomes available. However, to obtain an accuracy estimate of these models requires comparison with an independent dataset. The generation of a near global set of orthometric height data wholly derived from ERS-1 and ERS-2 radar altimetry has now enabled an assessment of the quality of public domain GDEMs. This paper presents the results from this comprehensive comparison with several GDEMs including GLOBE, TerrainBase and JGP95E, including the identification of common error 'signatures' where erroneous ground truth datasets have been incorporated into successive DEMs.

NATURAL LAND TARGETS FOR ALTIMETER SIGMA0 CALIBRATION.

BERRY, P.A.M., Pinnock, R.A. & Hoogerboord, J.E. (Geomatics Unit, De Montfort University, Leicester LE1 9BH, UK)

A global evaluation of the earth's land surface characteristics using ERS-1 and ERS-2 radar altimeter data has revealed several land sites where the surface characteristics and aridity permit accurate modelling of the spatial variation of sigma0 over areas of hundreds of square kilometers, by using an expert system to filter and interpret the individual altimeter waveform shapes. This paper presents results from ERS-1,ERS-2 and TOPEX data over these calibration sites, to provide an assessment of the precision to which sigma0 can be measured over land and hence illustrate the potential of land calibration. In addition, variations in TOPEX sigma0 measurements are quantified using those calibration sites for which TOPEX waveforms are available.

COMPARISON AND VALIDATION OF DTM'S IN THE SAME AREA

L. Biagi (Politecnico di Milano, IGeS, Facoltà di Ingegneria di Como, P.le Gerbetto 6, 22100, Como, Italy, Email: ludo@gemini.como.polimi.it) M. A. BROVELLI (Politecnico di Milano, DIIAR, P.zza Leonardo da Vinci 32, 20133, Milano, Email: maria@ipmtf4.topo.polimi.it), A. Monti Guarnieri (Politecnico di Milano, Facoltà di Ingegneria di Como, P.le Gerbetto 6, 22100, Como, Italy, Email: monti@elet.polimi.it)

In the scientific community there is a demand for very dense and accurate DTM's. This is true for geodetic (i.e. the RTC computation), for geophysical (inversion of the gravity field, determination of the seismic risk) and environmental (hydrological analyses) applications. At the same time there is today the availability of big amount of data provided by satellite techniques (i.e. SAR observations) which can be used to integrate the conventional DTM's. In this framework we can individuate two main aims. The first one consists in the statistical analysis, validation and classification of the available DTM's, in order to point out possible inconsistencies, blunders or outliers in the data. Secondly we present methods for consistently merging different data. In the present work some proposals in this direction are shown and are applied to significant examples belonging to Italian DTM's files.

AN EVALUATION OF TECHNIQUES FOR DIGITAL ELEVATION MODEL CORRECTION USING SATELLITE ALTIMETER DATA

DOWSON,M. ,Berry, P.A.M & Hoogerboord, J.E. (Geomatics Unit, De Montfort University, Leicester LE1 9BH. UK)

The identification of regional errors in Global Digital Elevation Models (GDEMs) using a near global set of orthometric heights derived from ERS-1 and ERS-2 altimetry data has confirmed that significant deficiencies currently exist in these models due to limitations in the source datasets. This paper presents initial results from a study exploring the use and limitations of altimeter data in quantifying and correcting these errors. Validation of the altimeter derived dataset by comparison with accurate regional DEMs has enabled a quality graded height set to be produced; the highest quality data have been used to examine the nature of the common error signatures detected in GDEMs and, where possible, to improve the data over these areas using a variety of techniques including crossover analysis, warping, and integration of ground truth and altimeter derived heights.

OPTIMUM POINT MODEL OF GRAVITY FIELD OF THE EARTH COMPILED ON THE BASIS OF ABSOLUTE VALUES OF GRAVITY

Stoyan AVDEV and Simeon Kostyanev (University of Mining & Geology,Sofia - 1100, Bulgaria, e-mail: skost@staff.mgu.bg)

An optimum point model of the global gravity field has been compiled on the basis of data for absolute values of gravity. It has been composed of point masses. Optimum parameters of the masses have been determined by the least squares method. This model is univalent and stable for the set of data used and provides the best description of the field with the least number of parameters of its sources. It approximates the used absolute values of the gravity with a mean squared error about 40 mGal, and only for data in the USA territory - 30 mGal. The field of the optimum point model is similar to the field of the rotary ellipsoid (the normal gravity field), and the other anomalies - to the free air anomalies.An advantage of the point model of the global field of the Earth in comparision to the ellipsoidal one is its flexibility and higher precision for information processing and its application in geophysics and geodesy.

ERROR COVARIANCE FUNCTIONS FOR MARINE GRAVITY DATA IN THE EUROPEAN SEAS

Dirk BEHREND (Institut d'Estudis Espacials de Catalunya, Edif. Nexus-204, Gran Capita 2-4, 08034 Barcelona, Spain, email: behrend@ieec.fcr.es)

Various tasks in gravity field modelling depend on the availability of suitable error information. A proper description of the error behaviour is provided by error (covariance) functions. These are employed e.g. in geoid determination when using spectral combination or collocation techniques. This presentation deals with the computation of error covariance functions of gridded gravity anomalies in different regions of the European Seas, being done by the author when he was with the Institut fuer Erdmessung, University of Hannover, Germany. To this end cross-over adjusted sea gravity data sets (cruises) were predicted cruisewise onto a common 1'x1.5' grid. As a certain number of grid cells is covered more than once, this "over determination" can be used to derive the looked-for error functions. The experimental functions thus obtained can be fitted to an exponential model, which show the following features: (1) The correlation length is almost identical for all functions (about 14 km). (2) The error standard deviations range between 2 mGal and 8 mGal.

DETERMING PARAMETERS OF A COVARIANCE FUNCTION BY ANALYTICAL RULES

Shaofeng BIAN (Institute of geodesy and geophysics, Chinese academy of sciences Xudong Road 54, 430077 Wuhan China)

Two analytic rules for determining the parameter of a covariance function are described in the paper. One is formulated from the analytic implication of collocation in the Hilbert space. Another is formulated from the equivalence between B-splines and Gaussian functions. Preliminary numerical examples are attached to illustrate the availability of the two rules. The investigation indicates that the two rules provide a good alternative for the usually adopted covariance function fitting in practice.

SELECTION OF THE DEGREE OF GEOPOTENTIAL MODEL AND INTEGRATION RADIUS FOR GRAVIMETRIC GEOID COMPUTATION

W.E. FEATHERSTONE (School of Spatial Sciences, Curtin University of Technology, GPO Box U1987, Perth, WA, 6845, Australia, email: tfeather@cc.curtin.edu.au); J.D. Evans (Department of Mathematics, The University of Wales, Aberystwyth, Ceredigion, SY23 3BZ, UK, email: joe@aber.ac.uk); P. Vanicek (Department of Geodesy and Geomatics Engineering, University of New Brunswick, PO Box 4400, Fredericton, NB, E3B 5A3, Canada, email: vanicek@unb.ca)

In regional gravimetric geoid determination, it has become customary to combine the complete expansion of a recent global geopotential model with terrestrial gravity anomalies via Stokesian integration over a region of arbitrary extent. This contribution derives a more objective means with which to select an optimal combination of the spherical harmonic degree of a global geopotential model and the integration area, which is taken to be a spherical cap. This approach is based upon the criterion that the error in the approximated geoid height is minimised. However, this approach ultimately depends upon the error degree variance of the global geopotential model and the degree and error degree variances of the terrestrial gravity data, which are not accurately known. Therefore, both published and postulated values of these quantities have been utilised in order to estimate the optimal combination of the degree of the global geopotential model and spherical cap radius. The optimal combination of these two variable parameters derived here broadly agrees with empirical results from gravimetric geoid computations made by other authors.

GEOLOGICAL REFINEMENT OF THE GEOID

Gottfried GERSTBACH (Inst.of Geodesy & Geophysics, TU Vienna, email: ggerstb@terra.tuwien.ac.at)

To get a centimetric geoid in alpine or tectonic areas, geology is a limiting factor. Several geoid projects show that usual terrain correction requires very narrow point spacing (1-2km gravimetry, 5km astro). Surface rock density data (2D) improve the geoid by 20%, subsurface data (3D) by 40-60%. This is demonstrated by examples in Austria (tectonic basin and Limestone Alps). For full 3D modelling of the geological subfloor a special program was developed, based on density regions and vertical prism gridding. A 2_D method (inclined layers) is used, if only rough geological data exist. Hence, aiming to a geoid of ±2cm/100km, astropoints of 10km spacing are sufficient. Together with the expected automation by CCD, this procedure is efficient even in very rugged terrain. At large networks the geoid error increases very slowly (±3cm/1000km).

USING A SYNTHETIC EARTH GRAVITY MODEL TO ASSESS THE PERFORMANCE OF MODIFIED KERNELS IN GRAVIMETRIC GEOID COMPUTATIONS

Simon HOLMES (School of Spatial Sciences, Curtin University of Technology, GPO Box U1987, Perth 6845, Australia. tel: +61 8 94873838, fax: +61 8 9266 2703, email: holmes@vesta.curtin.edu.au) Will Featherstone (tel: +61 8 9266 2734, fax: +61 8 9266 2703, email: Featherstone_WE@cc.curtin.edu.au)

A Synthetic Earth Gravity Model (SEGM), designed to generate matching sets of gravimetric and geometric quantities from first principles, can provide an independent means of testing the processing and interpretation of gravimetric data. In the current study, a preliminary SEGM based on spherical harmonics was used to assess the extent to which various modifications to the traditional Stokes kernel are able to reduce the truncation error in gravimetric geoid heights. This error results from the Stokesian integration of gravity anomalies over a spherical cap rather than over the entire Earth as the derivation of Stokes's integral requires. Some kernels also perform the auxiliary function of partially filtering low frequency errors from terrestrial gravity data. To test each kernel, self-consistent grids of synthetic gravity anomalies and geoid heights were computed from hypothetical geopotential coefficients used in a standard spherical harmonic series. Coefficients up to degree 1800 were sourced from the exiting geopotential model GPM98B. Model coefficients from degree 1800 were then scaled and 'recycled' as hypothetical coefficients for the higher degrees. FFT software was used to convolve the synthetic anomalies with various kernels using spherical caps of different sizes. The resulting grids of geoid heights were then compared with the 'control' grid generated from the synthetic model. The modified kernels were found to improve upon the traditional Stokes kernel.

APPLICATION OF ASTRONOMIC TIME-LATITUDE RESIDUALS IN GEOSCIENCE

Hu HUI, Wang Rui, Mao Jirong Yunnan (Observatory, Academia Sinica, Kunming, 650011 China)

Yunnan is a seismic active region. After the earthquake of Ms 6.1 occurred in Luquan County, Yunnan Province on April 18, 1985, we analysed in detail the relationship between the major earthquakes and the astronomical time-latitude residuals(ATLR) of Yunnan Observatory. It was found that there appear the anomalies of the ATLR before earthquakes which happened in and around Yunnan. Afterwards based on the studies the anomalous characters and laws of the ATLR of Yunnan Observatory were summarized before earthquake, and provided better warning information for a few major earthquakes. ATLR are the rest parts after drawing the Earth Orientation Parameters from the observations of time and latitude. They are quantities relating to the changes in the local geophysical field, including the plumb line variation(PLV). The PLV before the earthquakes due to the motion of the groundmass in a seismic region during the pregnancy of earthquakes may be the main reason of the anomaly. Recently the comparison analyse of the PLV at Yunnan has been made using the observations of the gravimetric network there and the ATLR of Yunnan Observatory by Li Zhengxin and Hu Hui et al.. The results of PLV at Yunnan from the two different techniques are in good accordance at interannual time scales, especially its south-north component. It once again confirms that the anomaly of ATLR is true. The anomaly reflects the PLV, instead of atmospheric refraction or meteorological effects. Therefore it is also used for monitoring the change in the gravity field around the Observatory.

TOPOGRAPHIC MASS MODELLING IN THE VIEW OF THE ONE CENTIMETER GEOID

Michael KUHN (Geodetic Institute, University of Karlsruhe Englerstrasse 7 D-76128 Karlsruhe Germany, Phone: ++49-721-6082723, Fax: ++49-721-694552 e-mail: kuhn@gik.uni-karlsruhe.de)

In the framework of determining the earth's gravity field the geoid as a particular equipotential surface plays a central role. In providing orthometric heights the geoid is the reference surface for this height system and therefore an exact knowledge is necessary for converting GPS-Heights in orthometric heights. But if we want an exact description of the geoid, with respect to a reference ellipsoid, we end up by the well known Stokes Problem and for the solution we need a sufficiently good knowledge of the topographic masses. Here a simple modelling of the topographic masses with a constant density is not sufficient for providing a geoid in the view of an one centimeter accuracy. This paper intends to give an insight in different possibilities to model the topographic and also the isostatic masses. Numerical results will be illustrated for theoretical examples and the area of Baden-Wuerttemberg in Germany.

G3/W/50-A5 Poster 1610-56

A STUDY OF NUMERICAL STABILITY AND ACCURACY OF BASIS FUNCTIONS IN THE EXPANSION OF GEOPOTENTIAL MODEL TO VERY HIGH DEGREE AND ORDER

JIANCHENG LI Dingbo Chao (School of Geoscience and Surveying Engineering, Wuhan Technical University of Surveying and Mapping, 129 Luoyu Road, Wuhan 430079, China, email: jcli@wtusm.edu.cn, dbchao@wtusm.edu.cn)

Some new geopotential models to higher degree and order more than 360 by spherical harmonic expansion increasingly improve the description of refined structure of Earth's gravity field, however their aliasing errors of geopotential coefficients still exist. The aliasing effects are caused by sampling of surface gravity data, methods of spherical harmonics expansion and accuracy of spherical harmonic functions etc.. The fact that the numerical instability of high degree associated Legendre functions is a main factor, which limited to their accuracy. This paper will concentrate on investigation of the numerical stability and accuracy as well as their behaviour of associated Legendre functions. An accurate algorithm for computing high degree associated Legendre functions are proposed. Some numerical results of spherical harmonic coefficients to higher degree have been compared between new accurate basis functions and those calculated by historic algorithm.

LOCAL GRAVIMETRIC SOLUTIONS FROM SATELLITE GRAVITY GRADIOMETRY DATA: A COMPARISON STUDY

ZHICAI LUO , Yongqi Chen (Department of Land Surveying and Geo-Informatics,The Hong Kong Polytechnic University,Hung Hum, Kowloon,Hong Kong. Email: lszcluo@polyu.edu.hk) and Jinsheng Ning (Wuhan Technical University of Surveying and Mapping,Luoyu Road 129,Wuhan 430079, P.R.China. Email: jsning@dns.wtusm.edu.cn)

For the determination of the earth's gravity field a large amount of gradiometry data is available from satellite gravity gradiometry in the near future. In local gravity field approximation three methods to deal with the downward continuation of gradiometry data are studied in the

paper,including least squares collocation in frequency domain,planar approximation method and spectral combination method with optimum integral kernel function.At first,the principles and corresponding mathematical models of above methods are discussed respectively,and then their advantages and disadvantages are analyzed theoretically. It's pointed out that some advanced numerical techniques and computational strategies should be considered carefully to overcome the spectral leakage and computational unstability. Finally, numerical simulation results are given to demonstrate the effectiveness of the methods proposed in the paper.These methods can be applied not only to process the downward continuation problem of satellite gravity gradiometry data,but also to refine the local gravity field by combining gradiometry data,terrestrial gravity anomaly,satellite altimetry data and etc..
Key Words satellite gravity gradiometry,downward continuation,least squares collocation in frequency domain,planar approximation method,spectral combination method.

A NEED TO CHANGE GRAVITY DATA REDUCTION PROCEDURE FOR TOPOGRAPHIC CORRECTION

D.V. SUBBA Rao (National Geophysical Research Institute, Hyderabad 500 007, India.)

In regional gravity studies, applying correction for topographic mass up to sea level and in prospecting, reducing data to local base have introduced additional anomaly in Bouguer gravity in form of negative bias in case of former and have changed nature of anomaly in case of later due to improper correction for topographic mass. This is based on the observation that gravity effect of local topography only is present while that of regional topography is represented by zero values in free air gravity

SPHERICAL EARTH TERRAIN CORRECTION MODELS

Douglas ROBERTSON (NOAA Table Mountain Gravity Observatory, 8600 North 39th Street, Longmont, CO 80503, USA, and CIRES, Campus Box 216, University of Colorado, Boulder, CO 80309, USA, e-mail: doug@tmgo.colorado.edu)

Analytic models that use terrain data to generate terrain corrections typically assume flat-topped rectangular Cartesian prisms on a flat-Earth model. To investigate the accuracy of such models, and to investigate more rigorous ways to implement Helmert's second method of condensation, we have developed a model that uses numerical quadrature techniques to calculate the gravitational attraction of topographic masses and condensed masses on a spherical Earth with non-Cartesian prisms and more realistic prism top shapes. One of the main problems with the numerical techniques involves the r=0 singularity in the region close to the observing station, which is dealt with using polynomial extrapolation. This model could be modified in a straightforward manner to make use of terrestrial density variation data if such data were available. Preliminary tests indicate that with a 30x30 arcsecond terrain grid the largest errors arise from the assumption of flat prism tops. In rough terrain, such as in the Rocky Mountains, these errors are of the order of tens of milligals. Most of this error is concentrated in the central prism and the next "ring" of 30x30 prisms. Errors arising from the flat-Earth assumption are much smaller. Comparison with 3x3 arcsecond data indicate that a bilinear-top prism model will produce agreement between the 3x3 and the 30x30 arcsecond grids at the level of better than one milligal.

GRAVITY SHIELDING: MYTH OR REALITY?

Lev SAVROV (Sternberg Astronomical Institute, Moscow University, Universitetsky av.13, 119899 Moscow, Russia, email: savrov@sai.msu.su)

M.Allais used the solid paraconic pendulum to detect the gravity effect during solar eclipses in 1954 and 1959. G.Jeverdan in 1961 and M.Denis in 1991 used the classic Foucault pendulum for the same aim. All of them observed the change of direction of the oscillation plane of pendulum during the phase of eclipse. These results are doubted mostly because the pendula were not isolated from the atmosphere. Author took part in international expeditions for total solar eclipses at Rostov(USSR,1961), Bielomorsk(USSR,1990), Mexico-City (Mexico,1991), Pato Branco(Brazil,1994), and tried to detect the gravity effects by paraconic pendula of his own constructions. All devices were placed in thermostatic vacuum chambers, and had remote control start-stop mechanisms, photoelectrical registration sensors, computing data acquisition systems. The increase of velocity of pendulum oscillation plane during solar eclipses was taken place in direction of Foucault effect with the value of order of Foucault effect. The analysis of data showed that all types of abnormal effects are inside of instrumental, measuring, and computational errors.

ON THE BEHAVIOUR OF THE ITERATIVE SOLUTION OF THE SCALAR FREE BOUNDARY VALUE PROBLEM ON A SPHERE AND AN ELLIPSOID

Kurt Seitz, Geodetic Institute, University of Karlsruhe, Englerstrasse 7, D-76128 Karlsruhe (Germany) Phone: ++49-721-608-6576, Fax: ++49-721-608-6808, e-mail: seitz@gik.uni-karlsruhe.de

One way to solve for the earth's gravity potential W in the mass-free space outside the boundary surface S is to formulate a boundary value problem. If we assume the horizontal position of all boundary points P to be known the vertical position of P and W remain as unknown funktions and we have to deal with the scalar free boundary value problem (bvp). In a first step the nonlinear boundary conditions are linearized with respect to suitably chosen approximations of the unknowns. In this context the normal potential w and the telluroid s is introduced. In the second step the linear reduced boundary conditions have to be (downward) continued from s to a reference surface which shows a rotational symmetry with respect to the earth's mean rotational axis. Here we consider a sphere and the surface of an ellipsoid of revolution. After the analytical continuation of the evaluation operator, the boundary condition can be split in two parts. The main component is covered by the isotropic term which corresponds to the Stokes-problem. The second part consists of the ellipsoidal and topographical components which are functionals of the disturbing potential which we solve for. Therefore an iterative solution strategy is appropriate. To model the ellipsoidal and topographical terms mostly ellipsoidal corrections in linear approximations are applied. In this paper we are dealing with ellipsoidal and topographical corrections in a second order approximation. In the third step the resulting isotropic problems have to be solved iteratively. The main topic of this contribution is to show the results of numerical studies, where the numerical behaviour of the iterative procedure is intensively studied. In case of the continuation onto the ellipsoid the procedure of the iterated harmonic analysis is convergent, but in case of the sphere divergence is observed.

A COMPARISON OF DOWNWARD CONTINUATION TECHNIQUES OF TERRESTRIAL GRAVITY ANOMALIES

Michael SIDERIS (Department of Geomatics Engineering, University of Calgary, Calgary, Alberta T2N 1N4, Canada, email: sideris@ucalgary.ca); Petr Vanicek and Jianliang Huang (both at Department of Geodesy and Geomatics Engineering, University of New Brunswick, Fredericton, N.B. E3B 5A3, Canada, email: vanicek@unb.ca)

There are two fundamental downward continuation techniques ofgravity for the determination of geoid used in geodetic practice:
(1) the discrete Poisson downward continuation which represents a discrete form of Fredholm's integral equation of the first kind; and
(2) the analytical downward continuation based on the Taylor expansion of the gravity anomaly In this paper, we compare these two methods numerically, using point and 5' by 5' mean values of Helmert gravity anomalies from the area of the Canadian Rocky Mountains.
The techniques are compared in terms of accuracy and computational efficiency and stability. Results are given both in the gravity and in the geoid space. For the downward continuation of point values, the "downward continuation correction" amounts to several tens of mGal (approximately between -25 and 65 mGal), with the mean and standard deviation of the order of 1 and 5 mGal, respectively. The corresponding values in the geoid space vary from -0.03 m to 0.80 m, with the mean of 0.43 m. For the downward continuation of mean anomalies, the values range from approximately -45 to 102 mGal, with a mean is 1 mGal and standard deviation of 8 mGal. The corresponding values in the geoid space are between -0.03 m and 0.93 m, with a mean of 0.48 m.

REGIONAL GRAVITATIONAL MODELS DERIVED BY MEANS OF THE SNAP METHOD

V.N. STRAKHOV (United Institute of Physics of the Earth, Russ. Acad. Of Sciences, Moscow, Russia); U. SCHAEFER (Bundesamt fuer Kartographie und Geodaesie, Aussenstelle Potsdam, Michendorfer Chaussee 23, 14473 Potsdam, Germany, email: ufer@potsdam.ifag.de); A.V. Strakhov (Computing Center of the Russ. Acad. of Sciences, Moscow, Russia)

A number of regional analytical models of the Earth's gravitational field for Central Europe has been developed on the basis of Strakhov's new analytical approximation (SNAP) method. The models are equivalent to spherical harmonic expansions of degree and order N=36,48,72,180,360,720 and 1080. These models have been derived as stable approximate solutions of strongly underdetermined systems of linear algebraic equations with up to about two million of unknowns using several thousands of original gravity data from the BGI gravity data base (i.e. point observations). The quality of the SNAP models has been evaluated by means of independent control data sets and by comparing them to other analytical models, as e.g. the EGM96. One of the outstanding results is that the SNAP models are nearly free of bias and provide a significant better RMS fit than the EGM96 not only in the original data set used to derive these SNAP models but also in the control data sets. The control points are randomly distributed over an test area of 700000 square kilometers, covering Germany and adjacent areas. Below is given -as an example- the mean deviation and the RMS for the SNAP#13 (N=360) model in the 4000 original and 424 control points: (-0.023 +/- 6.909) mgal; (+0.212 +/- 7.573) mgal and for the EGM96 (N=360) model: (-5.941 +/- 18.822) mgal; (-3.095 +/- 10.982) mgal, respectively.

EFFECT OF ANOMALOUS TOPOGRAPHICAL DENSITY ON HELMERT GRAVITY

Marc VERONNEAU (Geodetic Survey Division, Dept. of Natural Resources, 615 Booth Street, Ottawa, Ontario, Canada, K1A 0E9, email: marc@geod.nrcan.gc.ca)

For the computation of a gravimetric geoid model, it is customary to use an average topographical density of 2.67 g/cm3 when reducing the masses above the geoid. However, the lateral variations of density have to be taken into account for a high accuracy geoid model. Martinec (1993) demonstrated that anomalous density could contribute at the decimetre level in the Helmert approach. His work focused on the direct topographical effect and the primary indirect topographical effect, but he did not consider the implicit part of the density in the downward continuation. The anomalous density could contribute metres to the geoid model when the downward contribution is taken into consideration in the Helmert approach. However, the large effect of the anomalous density is not present in the current geoid models (with average crustal density) because the downward continuation and the condensed terrain effect have not been considered in the formulation. These two terms approximately cancel each other. A theoretical investigation of these effects is conducted on an earth model without atmosphere. The model omits the atmospheric effect, ellipsoidal corrections, the secondary indirect effects and the centrifugal force. This simplified model allows a better understanding of the behaviour of the topographical density without being cumbersome by a series of terms, which are negligible or not related to the topographical density. Therefore, a heterogeneous sphere, with topography on its surface, could represent the earth. In addition, the ellipsoidal earth model, which usually represents the normal field, is replaced by a homogeneous sphere, which has the same radius and mass as the earth without the atmosphere.

EXPLORING THE DETAILED STRUCTURE OF THE LOCAL EARTH'S GRAVITY FIELD USING FRACTAL AND FOURIER POWER SPECTRUM TECHNIQUES

Kefei ZHANG (IESSG, University of Nottingham, Nottingham, NG7 2RD, UK,
Email: kefei.zhang@nottingham.ac.uk); Will Featherstone (School of Spatial Sciences, Curtin University of Technology, GPO Box U1987, Perth, WA 6845, Australia,
Email: Featherstone_WE@cc.curtin.edu.au)

As one of the world's oldest continents, Australia has experienced a complicated geological history and thus has a distinctive landscape and an extensively weathered topography. As such, the gravity field of Australia behaves differently to that in other countries. This paper investigates the features of the Australian gravity field for both surfaces and profiles. The methods used are a simple statistical comparison, Fourier power spectrum analysis and the Hurst fractal technique. Fourier spectral analysis and the fractal geometry method offer a new paradigm for understanding detailed structure and features of the Earth's gravity field. Three test areas (the Hamersley Ranges, Central Australia and the Snowy Mountains), that represent extreme features of the Australian gravity field, have been selected. From these, it is shown that the gravity field of Australia is not always correlated with the terrain and the topography often contains longer wavelength features than the gravity anomalies. It is demonstrated that the simple statistical analysis and Fourier power spectral methods are the most informative tools for measuring the smoothness of the gravity field. Using these, it is then shown that none of the free-air, Bouguer or (Airy-Heiskannen) topographic-isostatic gravity anomalies is consistently the smoothest type in Australia. Sometimes, the Bouguer anomaly is more variable than the free-air anomaly and thus should not necessarily be used for gravity field gridding in Australia.

ASTROGEODETIC GEOID COMPUTATION FOR AUSTRIA USING SEISMIC MOHO DEPTHS

Hussein ABD-ELMOTAAL (Civil Engineering Department, Faculty of Engineering, Minia University, Minia 61111, Egypt, email: hamotaal@frcu.eun.eg); Norbert Kuehtreiber (Section of Physical Geodesy, Institute of Theoretical Geodesy, Graz University of Technology, Steyrergasse 30, A-8010 Graz, Austria, email: kueh@phgg.tu-graz.ac.at)

The depths of the Mohorovicic discontinuity (Moho depths) derived by seismic observations are available for this study for an area covering the central part of Europe. The computation of the terrain reduction is carried out using those pre-estimated seismic Moho depths. The TC-program (originally written by Forsberg, 1984) has been modified to compute the effect of the compensating masses on the gravity anomalies, geoid undulations and deflection components using the digital Moho models. Both fine (11.25" x 18.75") and coarse (90" x 150") digital height and seismic Moho models are available for this investigation. An astrogeodetic geoid for Austria has been computed using the seismic Moho depths, representing the compensating masses, by the least-squares collocation technique. For the sake of comparison, an another astrogeodetic geoid for Austria has been computed using the Airy-Heiskanen isostatic model for generating the compensating masses. A wide comparison between both geoids is carried out.

DENSIFYING GEOID INFORMATION IN VENEZUELA BY GPS DENSE POINTWEISE DETERMINATION OF GEOID UNDULATIONS IN VENEZUELA THROUGHT GPS

G. ACUÑA, M. Hoyer, E. Wildermann (Laboratorio de Geodesia Física y Satelital, Escuela de Ingeniería Geodésica, Universidad del Zulia, Maracaibo, Venezuela; email: mhoyer@luz.ve); J. Hernández (Servicio Autónomo de Geografía y Cartografía Nacional, Caracas, Venezuela)

The Zulia University (LUZ) and the National Cartographic Administration (DCN) planned and measured a GPS campaign in Venezuela (about one million Km2) with the aim to obtain dense geoid undulations in the country.
Venezuela, as most countries in South American, are working very intensive in their geoid determination. The information, for this target, obtained by a single observational procedure is not enough. Data from different sources have to be combined like gravimetric data, digital height information, GPS observations and geopotential models. As part of a national combined geoid project the GPS derived undulations in many stations of the country can help to increase the available information.
80 Bench Marks with mean separation of 50 Km were occupied in a 14 days observations campaign using 5 dual frequency receivers and the GPS permanent station (IGS-Maracaibo). In this first part of the GPS project was covered the half of the country, from its western limit to the central region. A second and last part of GPS observations is planned for the first half of 1999. The density of the points allows an uniform data concentration over the country with a high resolution for geoid calculations.
The specifications of the measurement campaign satisfied the high requirements of the height determination by GPS. The adopted procedure can be applied in similar projects. The processing by Bernese software tried to obtain highest quality for the results. The ± 1 cm rms. for the GPS derived ellipsoidal heights and the same level of precision in the orthometric heights of the Bench Marks used allowed to obtain the geoid undulations with equivalent quality. A later combination with different type of data by collocation is planned. Finally, the comparison with EGM 96 geopotential model showed discrepancies up to 2 m confirming the urgent need of a regional geoid determination in the country.

ASTROGEODETIC GEOID DETERMINATION IN TURKEY

Osman ALP (General Command of Mapping TR-06100, Ankara, Turkey, Tel : +90 312 3638550/2223 Fax : +90 312 3201495 Email: oalp@hgk.mil.tr)

Astrogeodetic deflections in ED50 at 200 astronomic points scattered throughout Turkey are utilized. The points at which astrogeodetic deflections are known are on the topographical surface, and the horizontal variation of the astrogeodetic deflections are nonlinear due to rough topography and large distances between the points. Hence, Helmert's astronomic leveling is extended to the astrogravimetric leveling considering both the gravimetric correction due to the non-linearity and the orthometric correction in order to project the astronomic point onto the geoid. In order to compute the gravimetric correction, gravimetric geoidal heights and gravimetric deflections of the vertical at points are interpolated using bicubic splines from 3'x 3' gridded file of Turkish Geoid-1991 (TG-91). To compute the orthometric correction, observed gravities and orthometric heights at points are used in the well-known orthometric correction formula. Two networks consisting of geoidal height differences resulted from Helmert's astronomic leveling and astrogravimetric leveling respectively are adjusted separately. The rms of (1.13 m for the difference between two geoids indicates the benefits of astrogravimetric leveling.

LAST DEVELOPMENTS IN ESTIMATING THE ITALIAN QUASI-GEOID AND FUTURE PERSPECTIVES

Riccardo BARZAGHI, Alessandra Borghi, Giovanna Sona, Vincenza Tornatore (DIIAR-Politecnico di Milano, Piazza Leonardo da Vinci 32, 20133 Milano, Italy)

New data and the last global geopotential model EGM96 made it possible to estimate an improved quasi-geoid for the Italian area. The remove-restore procedure was applied to get the final solution. The last geopotential model EGM96 was used to represent the low frequency component of the geopotential field. This improved the gravity residuals statistics with respect to OSU91A, especially in the are surrounding the Corsica island. A careful validation of the DTM used in the computation and density information led to a more refined RTC component, which is crucial in an area such as Italy. A windowed collocation solution was tuned and used to obtain the residual quasi-geoid component from gravity residuals. Comparisons of the new solution with GPS/leveling data were also computed and discussed. Finally, a new remove-restore procedure was proposed and tested in a small area in Central Italy.

G3/L/19-A5 Poster 1610-70

THE NEW IGES SOFTWARE FOR RTC

L. Biagi (Politecnico di Milano, IGeS, Facoltà di Ingegneria di Como, P.le Gerbetto 6, 22100, Como, Italy, Email: ludo@gemini.como.polimi.it), C. Sciarretta (Telespazio SpA, Space Geodesy Center, Matera, Italy, Email: cecilia@asi.it)

At present, very dense DTM's are available in some regions as well as information on surface density. It is well known that the software usually used in RTC computation goes by two alternative methods: numerical integration by prisms or FFT integration. The first approach involves long computation time, particularly for dense DTM's; the second one, faster, involves significant approximations in areas where topography is rough. In the framework of a cooperation between IGeS and ASI-CGS a new formulation for RTC has been studied and implemented; particularly, we have tried to develop a method based on approximations which are acceptable in the majority of cases and numerically fast. Besides, we are studying a possible approach for a correct modelling of surface density variations in RTC computation. In this work the proposed algorithms and the results
obtained are shown.

THE CONTINUOUS EFFORTS TOWARD A 10' RESOLUTION GEOID FOR SOUTH AMERICA

Denizar BLITZKOW (Sub-Commission for the Geoid in South America, Escola Politécnica da Universidade de São Paulo, Caixa postal 61548, - 05424-970 São Paulo - SP – Brazil, E-mail: dblitz@usp.br); Maria Cristina B. Lobianco (IBGE-DEGED, Av. Brasil, 15671, - 21241-051 Rio de Janeiro – RJ – Brazil, E-mail: lobianco@ibge.gov.br); J. Derek Fairhead (University of Leeds, Earth Science Department, Leeds UK, LS2 9JT, E-mail: jdf@getech.leeds.ac.uk)

In the last few years, as a result of the Sub-Commission for the Geoid in South America (SCGSA) establishment and due to the facilities offered by the GPS to derive geometric height, many efforts have been carried out in the different countries of South America, in order to improve the geoid (quasi-geoid) computations. A great validation process of the gravity data in many countries such as: Brazil, Uruguay, Argentina, Colombia and Chile has improved many of the gravity surveys. GPS observations carried out on bench marks of the geometric levelling have been facilitated by the SIRGAS (Geocentric Reference System for South America) project and are contributing for testing the gravimetric determination of the quasi-geoid. The Digital Terrain Model (DTM) has been improved considerably in Brazil and Argentina; Chile has been planing a big effort in the same direction as well. The objective is to generate a DTM grid of 3' resolution (DTM3) for the south-american continent. Gravity surveys carried out in the north of Brazil, in the Amazonas region, contributed for a better acknowledgement of the gravity field, at least along the rivers. Local and national geoid computations gained much more importance recently. The Second Geoid School, organized in Rio the Janeiro just after the IAG Scientific Assemby and supported by IGeS (International Geoid Service), has had a strong influence in the efforts for geoid computations in different countries. Numerical integration of the modified Stokes integral and the application of FFT are techniques much used up to now in South America with the objective of a 10' resolution quasi-geoid.

GRAVIMETRIC GEOID DETERMINATION. A CASE STUDY: ALGERIA

Mustapha BOUZIANE, Madani Aarizou (Laboratory of Geodesy, National Centre of Spatial Techniques, BP 13 Arzew 31200, Algeria)

Orthometric height differences obtained from a combination of global positioning system (GPS) ellipsoidal height differences and gravimetric geoid predictions have the potential of replacing costly and time-consuming spirit levelling, especially in remote unsurveyed areas like the south of Algeria. This paper provides numerical examples for the computation of the geoid heights by the solution of Stokes's Boundary Value Problem (e.g. using planar approximation, analytical kernel spectrum and rigorous one dimensional spherical evaluation). In order to obtain such a geoid, high resolution point or mean gravity field data and topographic information are needed as well as a good spherical harmonic reference model. A detailed geoid has been computed in the area covering Algeria $20° \le j \le 37°$, $-7° \le l \le 10°$ where j is the latitude and l is the longitude) using a gravity data file of 12000 gravity points, not homogeneously distributed. The gravimetric data used are on a grid with various spacing from 5 to 15 arc seconds and are predicted using collocation. The spherical harmonic coefficient set OSU91 completed to degree 360 was used for the calculation of the global solution. The Residual Terrain Model (RTM) method based on Bouguer plates was used. Involving a lkm Digital Terrain Model, the topographic effects were computed and subtracted from the free air anomalies in order to smooth the locally varying gravity field. The usual Remove-Restore method is used in order to smooth the gravity data which were used to compute the residual geoid using spherical Fast Fourier Transform.(Forsberg and Tscherning 1994). Numerical computations were done using FFT techniques, where 50% of zero padding was used. The largest changes between the quasi-geoid and geoid were notified in the north where the heights vary between 1000 and 3500 m. Differences are from few centimetres to few metres. The solution presented in the following is suffering from the lack of gravity data both in Algeria and the neighbouring countries.

G3/E/38-A5 Poster 1610-73

THE EFFECT OF HIGH BATHYMETRIC MODEL ON GEOID COMPUTATION

J.C. CATALAO (Faculdade de Ciencias de Lisboa, Escola Politecnica 58, 1250-102 Lisboa, Portugal email: mjoao@fc.ul.pt); M. J. Sevilla (Instituto de Astronomia y Geodesia, Universidad Complutense, 28040 Madrid, Spain email: maast01@sis.ucm.es)

The effect of a new detailed regional terrain model on geoid computation has been studied. A new detailed bathymetric model around Azores Islands has been constructed based on new ocean depth information obtained from echo soundings during ship surveys. These bathymetric data were merged with high precision height data on land producing a new terrain model (AZDTM98) with 1´x1´ resolution on sea and 20´´x20´´ on land. Global digital terrain models ETOPO5U and JPG-95E were compared with AZDTM98 model. Sea and land gravity data covering the area were merged with satellite derived gravity anomalies for geoid computation. Least squares collocation was used for geoid estimation according to the remove-restore technique using EGM96 geopotential model and RTM method. Three geoid solutions were obtained from AZDTM98, ETOPO5U and JPG-95E models and compared with 12 GPS stations on land and with ERS-1 and ERS-2 altimetric data on sea.

ANALYSIS OF GRAVITY MEASUREMENTS FOR NEW HEIGHT SYSTEM IN TAIWAN

Ruey-Gang CHANG (Department of Civil Engineering, Ming Hsing Institute of Technology, Hsingfong, Hsinchu 304, Taiwan, email: fukwo100@ms16.hinet.net); Chia-Chyang Chang (Department of Surveying and Mapping Engineering, Chung Cheng Institute of Technology, Tahsi, Taoyuan 335, Taiwan, email: ccchang@cc04.ccit.edu.tw)

The high precision absolute gravity measurements have been carried out by four times at selected sites in Taiwan area since 1991. These results have been analysed and investigated to realise the variations of the gravity values. It has been found that the absolute gravity values

are varied with the crustal vertical movement in this area. The sites measured by absolute gravimeter are assessed and to be selected as the base stations for a dense gravity network proposed for Taiwan area. This fundamental gravity network will be incorporated with the new national height system, consisting of the first-order levelling network and measured by precise levelling, GPS, and relative gravity. The measurements for the establishment of this new national height system will be carried on in 1999 and 2000, and expected to provide detailed information for all the geodetic and engineering applications.

GRAVIMETRY DATA VALIDATION IN ALGERIA

S. A. BENAHWD DAHO, S. Kahlouche, B. Chemaa (National Centre of Spatial Techniques Geodetic Laboratory - B.P 13 Arzew - 31200 - ALGERIA)

A Method for validation of gravity measurements is applied on a small zone in Algeria using the Least Squares Collocation (LSC) method and Gravsoft software of the Copenhagen University. The gravity data, provided by the Bureau Gravimétrique International (B.G.1)., and consisting of 12472 gravity measurements covering the region were analysed and validated. The validation has been applied systematically to predict free air gravity anomalies reduced from the effect of the spherical harmonic coefficient set OSU91A. The detected gross errors represents 1.1 8 % of the land data. This work shows the non homogeneity of data used and their insufficient accuracy.

G3/P/04-A5 Poster **1610-76**

THE NEW GRAVIMETRIC GEOID IN ALGERIA

S. A. BENAHMED DAHO, S. Kahlouche (National Centre of Spatial Techniques, Geodetic Laboratory - Po. Box 13 Arzew- 31200 - ALGERIA)

A new gravimetric determination of the geoid over Algeria has been made using the following data types :a) a global geopotential model, namely the OSU91A spherical harmonic coefficients set, b) a set of 12325 validated point free air gravity anomalies covering the region, and c) a 1000xlOOO meters digital terrain model for the north of Algeria and the ETOP05U for the rest of the area.
The method used for the computations is the remove-restore technique in connection with the Fast Collocation which allows to obtain the solution over the entire area in one step only. The input data were gridded gravity anomalies. The terrain correction was applied to the data and the corresponding indirect effect was taken into account.
The result final is a quasi geoid grid in $20° \leq j \leq 37°$, $-7° \leq l \leq 10°$ with a grid mesh of 5'x5'.
Unfortunately, the precise data type GPS/levelling is not available in Algeria. This will certainly help to make an independent verification of the precision of the geoid.

G3/P/02-A5 Poster **1610-77**

GEOPOTENTIAL MODELS COMPARISON IN THE REGION OF ALGERIA

S. A. BENAHMED DAHO, S. Kahlouche, B. Chemaa (National Centre of Spatial Techniques Geodetic Laboratory - B.P 13 Arzew- 31200 - ALGERIA)

The choice of the best geopotential model to reduce geodetic data is one of the critical step in computing the geoid. In this work, an analysis was carried out to define the geopotential model which fits best the gravity field in Algeria.
Global geopotential solutions which are used in the comparison are as follows: GPM2 and OSU91A. The test of the fit of these high order geopotential models to the gravity field in Algeria is based on using the point gravity data supplied by the Bureau Gravimétrique International (B.G.I.). The comparisons were made at all gravity points by calculation of the residual gravity anomalies (i. e. observed data minus model).
The result of this test comparison shows that the OSU91A model describes the geoid most closely in Algeria. The OSU91A model is able to recover gravity anomalies over 43% of the Algerian territory to within 5 mgal and over 71 % of the country to within I0 mgal.

GRAVIMETRIC GEOID DETERMINATION USING LAND AND SEA POINT GRAVITIES FOR DEFINING VERTICAL DATUM

E. ÖMÜR DEMIRKOL (General Command of Mapping, TR -06100, Ankara, Turkey Tel : 0 312 3638550/2210 Fax : 0 312 3201495, Email: odemirkol@hgk.mil.tr)

Determination of high accurate geoid has become an area of interest to many scientists and is attracting still more of them. Especially utilisation of space based techniques has significantly improved the importance of geoid which was once regarded as a pure theoretical topic. The practical use of satellite techniques such as GPS, SLR and VLBI necessitates a conversion from ellipsoidal height to orthometric height. The conversion is accounted by the difference between these heights which simply corresponds to geoidal height.
Among the techniques to determine geoid is the remove-restore which is also applied in this study. Gravity anomaly and geoidal height are split into three parts, corresponding respectively to long, medium and short wavelength effects of gravity field. In this study, 1762 land and 161 marine point gravities within the area with latitudes 36 - 37 and longitudes 30 - 31 are used. Long wavelength effects are calculated separately by geopotential models OSU91A and EGM96, while short wavelengths are obtained through RTM and isostatic gravity reductions utilising topography available at 15" x 20", 5' x 5' and 15' x 15' grid nodes. Least squares collocation and Fast Fourier Transform are applied for the computation of medium wavelength effect. Additionally, 4 GPS/levelling geoidal heights available for this area are utilised to increase the accuracy of geoid. Totally, 12 geoids are determined by combination of geopotential models, gravimetric reductions and prediction methods. The geoids differ from each other due to the differences in global models, gravimetric reductions and prediction methods. Inclusion of GPS/levelling geoidal heights has contributed significantly to obtain a more accurate geoid. Additionally, an attempt is carried out in order to define the vertical datum at Antalya tide gauge station, via using the GPS ellipsoidal height, geometric levelling height difference, tide gauge data and geoidal heights.

Johnston (Geodesy Section, Australian Surveying and Land Information Group, PO Box 2, Belconnen, ACT, 2616, Australia, email: GaryJohnston@auslig.gov.au) K.F. Zhang (IESSG, The University of Nottingham, Nottingham, NG7 2RD, UK, email: kefei.zhang@nottingham.ac.uk) R. Forsberg (Geodynamics Department, KMS, Rentemestervej 8, DK-2400 Copenhagen NV Denmark, email: rf@kms.dk) M.G. Sideris (Department of Geomatics Engineering, The University of Calgary, 2500 University Drive NW, Calgary, Alberta, T2N 1N4, Canada, email: sideris@acs.ucalgary.ca)

A new gravimetric determination of the Australian geoid has been made, based on a spectral implementation of the appropriate integrals in physical geodesy. This geoid solution has been termed AUSGeoid98 and is available free-of-charge from the Australian Surveying and Land Information Group (http://www.auslig.gov.au/geodesy/geoid.htm). AUSGeoid98 combines the EGM96 global geopotential model, the 1996 release of the Australian gravity data-base, a 250m resolution digital elevation model, and a set of marine gravity anomalies derived from several satellite altimeter missions combined with ship-track data via least squares collocation. The residual gravimetric geoid undulations were computed on a regular two-minute grid using the one-dimensional fast Fourier transform technique, which has been adapted to include a deterministically modified Stokes kernel over a spherical cap. This approach was necessary since the use of the whole Australian data area in conjunction with an unmodified Stokes kernel gives consi derably worse agreements with Global Positioning System (GPS) and Australian Height Datum (AHD) heights over the continent. This is most probably due to one or both of errors in the gravity data or systematic distortions in the AHD.

A PRELIMINARY GEOID MODEL FOR TIERRA DEL FUEGO (ARGENTINA)

Graciela FONT(Facultad de Ciencias Astronomicas y Geofisicas, Universidad Nacional de La Plata, Paseo del Bosque s/n, 1900 La Plata, email: graciela@fcaglp.fcaglp.unlp.edu.ar.); Claudia Tocho (Facultad de Ciencias Astronomicas y Geofisicas, Universidad Nacional de La Plata, Paseo del Bosque s/n, 1900 La Plata, Argentina, email: ctocho@fcaglp.fcaglp.unlp.edu.ar)

A preliminary geoid model has been computed for Tierra del Fuego province in the south of Argentina (52°30' S - 55°30'S; 64°30'W - 69°W). Since there are not orthometric heights in the island, orthometric heights were generated from ellipsoidal heights and the undulations of the Geopotential Model EGM96, in a tide - free system. Digital Terrain Model (3' x 3') from the University of Leeds was used to take into account the topography. Geoid undulations were determined using the remove - restore technique. The Gravimetric Network of the Tierra del Fuego Island, was established from a series of summer surveys by the Departamento de Gravimetria de la Facultad de Ciencias Astronomicas y Geofisicas. Gravity stations were determined on the existing Geodetic Network, additional stations, separated by 5 to 8 Km, were also measured in order to have a better coverage.The gravity values in the north of the island were referred to the pendular value of Rio Grande. It was determined by the Observatorio Astronomico de La Plata in 1940 using a pendulum instrument (Askania). The remainder values, at the south, were referred to the pendular value of Rio Grande and Ushuaia, both values are referred to the Pilar Fundamental de La Plata g = 979751.6 mgls. All gravity values have been adjusted to IGSN71. Disturbing and anomaly gravity maps are also presented showing the characteristics of the area. Both of them are referred to WGS - 84.

ASTROGEODETIC CCD MEASUREMENTS FOR CENTIMETRIC GEOID MONITORING

Gottfried GERSTBACH (Inst.of Geodesy & Geophysics, TU Vienna,
email: ggerstb@terra.tuwien.ac.at)

Geoid solutions of cm level need narrow point spacings of 5-10km (astro) or 1-3km (gravimetry). Because of high astrogeoid economy the effort is minimized by automatic measurement of vertical deflections with small CCD instruments. Geological data improve the geoid further by 50%. Hence, many countries may reach cm geoid accuracies within the next decade. Results of two CCD projects at the TU Vienna are shown. Transportable instruments yield accuracies of ±0.4" within _ hour of star observations:a) Servo-theodolites with CCD cameras; b) Prism astrolabe (Ni2) with CCD line or array; c) Zenith tubes (f~1m) with cooled CCD array. Presently the methods b, c are semiautomatic. Some problems concern CCD sensors, mounting stability and PC control.Automatic measurement will be possible in 2000, supported by dGPS navigation (±1m). Contrast tuning may enable daylight observations in 2005. Therefore CCD astrogeodesy fits the demand of precise GPS, terrestrial surveys and Integrated Geodesy on a cm-geoid level.

GPS/LEVELLING TRAVERSES FOR TESTING GRAVIMETRIC QUASIGEOID SOLUTIONS IN EASTERN ANDALUSIA (SPAIN)

Antonio J. GIL (Dept. Ing. Cartografica, Geodesica y Fotogrametria, Escuela Politecnica Superior, Universidad de Jaen, Virgen de la Cabeza, 2, 23071 Jaen, Spain, email: ajgil@ujaen.es) Gracia Rodriguez-Caderot and M.Clara de Lacy (Dept. Astronomia y Geodesia, Fac. CC. Matematicas, Universidad Complutense de Madrid, 28040 Madrid, Spain) L. Biagi (Facolta di Ingeg.di Como, Politecnico di Milano, Italy)

To test the accuracy of some gravimetric quasigeoid solutions computed in a test area located in the south of Spain two GPS traverses have been established with benchmarks belonging to the First Order Spanish Levelling Network in the east of Andalusia. The GPS constellation was tracked during 4 hours observed session windows over baselines ranging from 3 to 85 km. The equipment used consisted of 3 Leica SR399 and 1 Leica 9500 dual frequency carrier phase GPS receivers. Bernese 4.0 with precise ephemerides was used to process the GPS observations and NETGPS for the adjustment of the network. A statistical study of GPS results is presented. GPS/levelling geoid undulations have been compared with the values provided by Fast Fourier Transform and Fast Collocation methods. The mean values of the standard deviation of the discrepancies after a four parameter datum shift amount to 4 cm.

PRELIMINARY GEOID DETERMINATION IN THE CENTERAL PART OF THE ETHIOPIAN RIFT VALLEY

Addisu HUNEGNAW (Department of Geodesy and photogrammetry, Royal Institute of Technology, S-100 44 Stockholm, Sweden)

The central part of the Ethiopian Rift Valley is characterized by a complex near surface geology, and the existence of a number of different intrusive centers. The determination of the geoid may help further study of the geology and structural features in this area. Geoid solutions were carried out in the central part Ethiopian Rift Valley. These local geoid

predictions were based on terrestrial gravity data, height data, using as a reference the new EGM96 geopotential model. The irregularly distributed gravity data derived by land survey were gridded on 8' x11' geographical grid and in this form were used in the numerical tests. Combining the Stokes' kernel modification techniques and high degree reference gravity field techniques did the geoid computations. A total terrain correction directly on the geoid was applied following a new method by Sjöberg (1994, 1995 and 1996a, b). The atmospheric effect was also treated differently from the classical method adopted by the International Association of Geodesy (IAG) adopting a new method by Sjöberg (1998). The computed geoid heights were compared with 4 GPS/levelling stations within and above the rift valley an area charcterised by rough topography, along a trigonometric levelling line. The results show that the differences between control and predicted geoid heights have a standard error of 83cm. Using a regression model to the geoid predictions corresponding to the GPS/levelling values, we find an improvement from 83 cm to 74 cm.

DIFFERENT GRAVITY DATA SOURCES FOR LATVIA GEOID STUDIES

J.KAMINSKIS (State Land Service of Latvia, 11.Novembra krastmala 31, LV-1050 Riga, Latvia, email: kaminski@main.rsf.rtu.lv)

To follow up the growing need for accurate and common vertical reference network in our country the fitting of geoids has been made to find an effective technique that satisfies national needs for "quick" reference surface. As a starting point of using geoid for practical application the NKG89 should be mentioned. Later the Baltic`96 geoid has become available, too. Global European geoid solution EGG97 has been tested locally. The regional and irregularly distributed differences of the EGG97 to the local geoid are found. Basically our geoid solutions are evaluated using different gravity data sets by GRAVSOFT package. In 1998 the new gravity reference network is started to create in addition to our 12 000 gravity points originally from the 1960's. We would like to complete gravity reference network and continue gravity measurements to verify and improve Latvia gravity data base. For that purpose we are going to use our new gravimeter Scintrex CG-3.
For the maintenance of the Latvia geodetic reference system and needs of the surveying the local geoid has been authorised by national geodetic commune for the official use.

FOUR-COUNTRY ASTROGEODETIC GEOID IN CENTRAL EUROPE

Norbert KUEHTREIBER (Physical Geodesy, Technical University Graz, Steyrergasse 30, A-8010 Graz, Austria, email: kueh@phgg.tu-graz.ac.at); Bernhard Hofmann-Wellenhof (Positioning & Navigation, Technical University Graz, Steyrergasse 30, A-8010 Graz, Austria, email: howe@tu-graz.ac.at); Drazen Svehla and Kresimir Colic (Faculty of Geodesy, University of Zagreb, Kaciceva 26, HR-41000 Zagreb, Croatia, email: dsvehla@public.srce.hr and kcolic@public.srce.hr); Gyula Toth and Jozsef Adam (both at Department of Geodesy, Technical University of Budapest, Muegyetem rkp. 3.I.61, H-1111 Budapest, Hungary, email: gytoth@epito.bme.hu and jadam@epito.bme.hu)

In 1998, Austria has presented a recomputed Austrian astrogeodetic geoid at the "Second Continental Workshop on the Geoid in Europe" in Budapest. The impact for this recomputation was the input data set which has been improved not so much with respect to additional deflections of the vertical but more with respect to the refinement of the digital terrain model, additional orthometric heights and the inclusion of GPS points.
During the Budapest and further addressed at the Second International Symposium Geodynamics of the Alps-Adria Area at Dubrovnik, the idea evolved to extend the geoid computation over Hungary, Croatia, and Slovenia. From the theoretical point of view, the datum problem is most challenging since each of the four countries uses its own local datum. After unifying the input data in one common frame, the computation of the astrogeodetic geoid using either the collocation method or a free network adjustment is straightforward.

G3/E/34-A5 Poster 1610-86

AUSTRIAN GEOID2000 - MOST RECENT RESULTS

Norbert KUEHTREIBER (Physical Geodesy, Technical University Graz, Steyrergasse 30, A-8010 Graz, Austria, email: kueh@phgg.tu-graz.ac.at)

At the last General Assembly of the IUGG in Boulder the recomputation of the Austrian Geoid under the project title GEOID2000 was announced. The new computation of the Austrian geoid was initiated with the objective to obtain a relative accuracy of at least 0.5 ppm throughout the country. As far as Austria is concerned, the data input consists of a 50 x 50 m digital terrain model, some 30 000 gravity data, about 800 deflections of the vertical, and GPS-derived points. From the neighbouring countries, gravity and height information is available in different quality and density. Most recent results achieved by different approaches and data combination techniques (least squares collocation method, the integration method using Fast Fourier Transform) are presented.

G3/W/27-A5 Poster 1610-87

HIGH RESOLUTION REGIONAL GEOID DETERMINATION IN TARIM BASIN AND HAINAN ISLAND OF CHINA

JIANCHENG LI, Jinsheng Ning, Jingnan Liu, Dingbo Chao (School of Geoscience and Surveying Engineering, Wuhan Technical University of Surveying and Mapping, 129 Luoyu Road, Wuhan 430079, China, email: jcli@wtusm.edu.cn)

Two regional geoids with high resolution in Tarim Basin and Hainan Island, located in far west China and south China, respectively, have been determined. The geopotential models WDM94 and EGM96 are considered as the alternative reference field. The 2.'5¡ä2.'5 gridded free air gravity anomaly are formed using topographic-isostatic anomaly for alternative methods of smoothing and interpolating of the gravity field in computation of the geoid. The input data include 102,719 point gravity observations in Tarim Basin, and 1817 ones in Hainan Island, and a 0.'5¡ä0.'5 Digital Terrain Model for both geoid computations. The determination of geoid and quasi-geoid are based on a strict evaluation of both Stokes integral and Molodenskii series solution using Faye anomalies. The 1D convolution is commonly adopted for more effective evaluation of Stokes integral and Molodenskii series solution to determine the geoid and/or quasi-geoid. The geoid is then fitted to the one from GPS/Leveling data with 8 B order GPS points in Tarim and 87 C order ones in Hainan to yield a so called GPS-gravimetric geoid, and both a smoothed geoid and a smoothed quasi-geoid are finally determined in the two areas. The standard deviations of differences between the geoid height and height anomaly and the GPS/Leveling are ¡À0.63m and ¡À0.70m in Tarim and ¡À0.30m and ¡À0.29m in in Hainan. The standard deviations of residuals after fitting of geoid and quasi-geoid to GPS/Leveling points are better than ¡À0.33m and ¡À0.32m in Tarim and ¡À0.13m and ¡À0.14m in Hainan, respectively.

IMPROVEMENT OF THE QUASIGEOID MODEL IN POLAND BY GPS AND LEVELLING DATA

A.LYSZKOWICZ

The experience with comparison of the GPS/levelling data against high resolution quasigeoid model Quasi97b in Poland have shown discrepancies. This circumstance opens the possibility to develop an empirical corrector surface which relates the quasigeoid model to the reference system of GPS and levelling data. This paper presents the results of modelling such corrector surface.

THE FINAL SOLUTION OF THE SWISS GEOID CHGEO98

Urs MARTI (Federal Office of Topography, Seftigenstr. 264, CH-3084 Wabern, Switzerland, email: urs.marti@lt.admin.ch)

In the last few years the geoid and quasigeoid of Switzerland was developed in a joint project of the Federal Institute of Technology (ETH Zurich) and the Federal Office of Topography (L+T, SWISSTOPO). In summer 1998 the final solution CHGEO98 was calculated and was declared as the official geoid for Switzerland in October 1998. The geoid is now available to the public and can be interpolated on-line via our www-Site (www.swisstopo.ch). It forms the reference surface of the new orthometric national height system of Switzerland (LHN95).
The method used for the determination of the geoid and quasigeoid was a least squares collocation. As input about 600 deflections of the vertical and about 80 GPS/levelling stations could be included. The gravity data were used only for the downward continuation to sea level of the other observations. The remove/restore process was performed with a 25 meter DTM, a 5 km model of the Moho-depth and some other density information. The accuracy of CHGEO98 is in the order of 3 cm in the flatter areas and about 5 cm in the Alps over the whole country. This could be verified by a comparison with the European quasigeoid EGG97 and with the comparison of GPS/levelling measurements which were not included in the adjustment process.
The poster shows the final solution of the geoid, the comparison with GPS/levelling measurements, the comparison with the solutions of neighbouring countries and presents the software as now available to the public.

TOWARDS A PRECISE QUASI-GEOID MODEL FOR SOUTHERN AFRICA

Charles MERRY (Department of Geomatics, University of Cape Town, Private Bag, Rondebosch, 7701, South Africa; e-mail: cmerry@engfac.uct.ac.za)

The quasi-geoid plays a crucial role in transforming GPS-derived heights to normal heights. This paper describes a pilot study to determine quasi-geoidal heights from gravity data, for southern Africa. The global EGM96 model is used to define the long-wavelength components, and the convolution approach is used for the detailed quasi-geoid structure, for a selected test area. The result is compared to a quasi-geoid determined from a combination of GPS and precise levelling, yielding an RMS agreement of 6cm. Proposals are made for the extension of this technique to the rest of southern Africa.

COMPARISON BETWEEN GEOIDAL MODELS IN ARGENTINA

María Cristina PACINO (IFIR – UNR, Av. Pellegrini 250, 2000, Rosario, Argentina,
E-mail: mpacino@fceia.unr.edu.ar); Claudia Tocho and Graciela Font (both at FCAGLP, Paseo del Bosque s/n, 1900, La Plata, Argentina, E-mail: graciela@fcaglp.fcaglp.unlp.edu.ar); Denizar Blitzkow (EPUSP, Sao Paulo, Brazil, E-mail: dblitzko@usp.br); New geoid models were calculated for Argentina under the umbrella of the SCGSA (Sub Commission for the Geoid in South America).

Preliminary models have been computed performing the numerical integration of the modified Stoke's formula with several resolutions (30'x30',20'x20', 10'x10'). Recently, a new geoidal model was developed using FFT methods on a 10'x10' grid. All the models use the same local gravity data, topographic information and the EGM-96 geopotential model for the global field. Comparisons between all the calculated models and with GPS/levelling
measurements are described in the paper.

G3/W/46-A5 Poster 1610-92

THE IMPROVEMENT OF THE GEOID MODEL OF LITHUANIA

Eimuntas PARSELIUNAS (Department of Geodesy and Cadastre, Vilnius Gediminas Technical University, Sauletekio al. 11, 2040 Vilnius, Lithuania, email: eimis@ap.vtu.lt); Rene Forsberg (National Survey and Cadastre, Rentemestervej 8, Copenhagen, Denmark, email: rf@dk)

The geoid model for Lithuania territory was calculated by the Geoid Determination Working Group of the Nordic Countries Geodetic Commission three times: in 1994, 1996 and 1998. The main efforts were directed for collecting the gravity data and for determination of the most reliable benchmarks set. Gravity data of the terrain, Baltic Sea and Kursiu lagoon, totally about 12000 points, and DTM with agrid of 1 km have been prepared. The average density of the gravity data is 1 point per 5 sq km. The sources of the gravity data were the gravimetric maps at the scale of 1:200000 and catalogues of the gravity points. The gravity data used are of the period of 1954-1974. Also the some data from the surrounding areas were involved, totally about 3000 points.
The accuracy of ellipsoidal heights ensures the Lithuanian GPS Network, which consists of zero, first and second order stations, totally 1078 points. The Zero Order GPS Network covering the territories of Estonia, Latvia and Lithuania was established in 1992, during the international EUREF BAL'92 GPS campaign. The First Order GPS Network was designed and observed in 1992-1993 by the Geodetic Institute, Vilnius Technical University. The Second Order GPS Network was measured and adjusted in 1994-1996 by Geodetic Institute as well. Density of Lithuanian National GPS Network is 1 station per 60 sq km. According to the software for the adjustment of the GPS networks the accuracy of the ellipsoidal heights of the stations of the state GPS network is 2-5 mm. But these parameters do not reflect the real co-ordinating accuracy. More realistic accuracy was calculated from the differences of the double co-ordinating. In this case the 20 mm accuracy of the ellipsoidal heights was determined.The GPS network was a base for the positioning the benchmarks of the first and second order levelling lines. Totally it was co-ordinated 120 benchmarks, from which 70 most reliable were chosen for the geoid fitting. The GRAVSOFT software package was used for calculations. The geoid model of Lithuania fit at the 3 cm level was obtained.

A PRELIMINARY RESULTS OF WEST JAVA AND ITS SURROUNDINGS AREA GEOID DETERMINATION BASED ON GETECH'S GRAVITY DATABASE

Kosasih PRIJATNA and J. Kahar (Department of Geodetic Engineering, Institute of Technology Bandung, Jl. Ganesa 10, Bandung, Indonesia, email : prijatna@gd.itb.ac.id)

The need of a detailed geoid in Indonesian region is mainly related to the increase of GPS heighting application. An existing formal gravimetric geoid of this region was derived in 1981 with a precision of about 4 meters. In this case, the subject of gravimetric geoid determination as derived earlier needs to be reconsidered.
Now a days, the gravity data covering Indonesian archipelago and its surroundings are available. Based on the so called South East Asia Gravity Project, GETECH (University of Leeds) processed and compiled all types of gravity data in the region into a unified data set. The GETECH's derived gravity product is in the form of 5'x5' grid of free-air, Bouguer, and isostatic anomalies. Recently, there is also new geopotential model available, i.e. EGM96.
This paper will present preliminary results of detailed gravimetric geoid determination in the Indonesian region by combining gravity data and geopotential model. In this case, the use of Molodenski's approach will be studied. Here, the area of West Java and its surroundings will be used as case study area. Several conclusions and recommendations will be made for future work.

A PRECISE GEOIDAL MODEL FOR SANTA FE (ARGENTINA)

Rubén RODRÍGUEZ (Geomática Argentina S.A., Julio A. Roca 584, 1067 Buenos Aires, Argentina, E-mail: geomatic@server1.startel.com.ar); María Cristina Pacino (IFIR – UNR, Av. Pellegrini 250, 2000, Rosario, Argentina, E-mail: mpacino@fceia.unr.edu.ar)

Santa Fe province (Argentina) is located westwards the Paraná river, between 28° and 34° South latitudes and between 59° and 63° West longitudes. It has an area of 133.000 Km2 and the altitudes range between 10 and 125 meters. Marcovich, Lebedinsky & Asociados, by contact with the Servicio de Catastro e Información Territorial (Cadastral office of Santa Fe Province) measured a precise geodetic net with 120 stations, 100 of which had orthometric heights values. With this data and the ellipsoidal height, we obtained the N value and then a geoidal chart was constructed for the province. The chart was compared with values from OSU 91A and EGM 96 geopotential models up to different grades. It was also compared with the 20'x20' geoidal model for Argentina and a –0,4 meters average deviation was obtained. Undulations differences (DN) were also calculated with respect to a fixed data point. The average deviation with respect to the referred models reach a few centimeters.

TOWARDS A BETTER GEOID MODEL FOR COLOMBIA

Laura Sanchez, William MARTINEZ and Juan Florez. (Instituto Geografico Agustin Codazzi, Carrera 30 No. 48 51, Santafe de Bogota, Colombia. E-mail: lsanchez@igac.gov.co)

A new high-resolution geoid, GEOCOL99, has been computed for Colombia and its adjacent marine areas. The EGM96 geopotential model was combined with 10 x 10 mean gravity anomalies and 5 x 5 topographic grids. The remove-restore technique was used for the computation of terrain effects by Helmerts condensation reduction. The contribution of the local gravity data to the geoid was computed by using the FFT method.
Satellite altimetry derived geoid heights and marine gravity anomalies have been combined to determine a detailed gravity field over marine areas using spectral analysis.
The relative precision of the new Colombian geoid was also evaluated through error propagation analysis by FFT. Its values show that the new geoid achieves better agreement than GEOCOL98 with the GPS/leveling data.

DIFFERENT APPROACHES TO PRECISE QUASIGEOID MODELLING – CASE STUDY FOR THE CZECH REPUBLIC

Jaroslav SIMEK (Research Institute of Geodesy, Topography and Cartography - Geodetic Observatory Pecny, 251 65 Ondrejov 244,CZ, email: gope@asu.cas.cz) Ivan Pesek (Czech Technical University, Faculty of Civil Engineering, Department of Advanced Geodesy, Thakurova 7, 160 00 Praha 6,CZ, email: pesek@fsv.cvut.cz)

After a detailed evaluation of terrestrial gravity anomalies coming from different sources, high resolution gravimetric quasigeoids (1'x1.5') are modelled on parts of EGM96 and EGG97 global/regional models for the territory of the Czech Republic using 1D spherical FFT. The results are further stepwise evaluated by other data types (GPS/levelling, vertical deflections) and after that these data are incorporated into least squares processing to produce a combined model based on heterogeneous data. In addition, the combined solution is compared with the model based on point masses.

GRAVIMETRIC GEOID FOR ARGENTINA USING FFT

Claudia Tocho (Facultad de Ciencias Astronomicas y Geofisicas,UNLP, Argentina, email: ctocho@fcaglp.fcag lp.unlp.edu.ar); Graciela Font (Facultad de Ciencias Astronomicas y Geofisicas, UNLP, Argentina, email: graciela@fcaglp.fcaglp.unlp.edu.ar); Maria Cristina Pacino (Instituto de Fisica de Rosario, UNR, Argentina, email: mpacino@fceia.unr.edu.ar); Denizar Blitzkow (Escola Politecnica da Universidade de Sao Paulo, Brazil, email: dblitzko@usp.br)

A new gravimetric geoid has been computed for the whole Argentina,between the limits 22ºS to about 55ºS for latitudes and 55ºW to 76ºW for longitudes. The geoid was generated combining the EGM96 global geopotential model with a 10'x10' mean gravity anomaly grid and a 3'x 3' Digital Terrain Model for South America. Geoid undulations have been determined using the classical remove - restore technique. The contribution of the reduced gravity data to the geoid was computed by the spherical 1D - FFT technique, which allows the evaluation of the discrete spherical Stokes integral without any approximation, parallel to parallel. To demostrate the performance of the gravimetric geoid, comparison between the undulations derived from gravimetric information and GPS points established on the geometric leveling network are presented.

IMPROVING OF REGIONAL GEOID MODELLING IN TAIWAN

GWO-CHYANG TSUEI (Department of Civil Engineering, National I-LAN Institute of Technology, No. 1, Shen Lung Road, I-LAN 260, Taiwan, email: gctsuei@mail.ilantech.edu.tw)

With the rapid expansion applications of GPS positioning and the improvement of positioning accuracy, there is a demanding need for an unified gravimetric geoid of high accuracy. We have seen in the past the necessity of a geoid with metre accuracy changed to a geoid in the cm level accuracy. Especially in the case of determining orthometric heights from GPS-derived ellipsoidal heights.
A new 3' X 3' high resolutions geoid model has been computed for the Taiwan area, using remove-restore technique by 1D Fast Fourier Transform method. The computations was carried out by using EGM96 geopotential model, 3' X 3' terrestrial gravity data, and 0.5' X 0.5' terrain model of Taiwan. The terrain effects on the geoid computation due to the second method of Helmert's condensation and residual terrain model were studied. And the effect of different topographic representations is investigated. Using the mass prism topographic model and the mass line topographic model. The differences between GPS/Levelling and gravimetrical geoid undulations in Mean, RMS, Min. and Max. values are 4, 8, -12, 19 cm for Helmert geoid, and 7, 11, -12, 19 cm for RTM geoid. By fitting four parameter model to the geoid prediction, yield geoid fits of about 4 cm for both Helmert and RTM geoids. The relative accuracy achieved was of the order of 0.4 to 0.8 ppm for a mean baseline of 100 km.

BIASES AND ACCURACY OF, AND AN ALTERNATIVE TO DISCRETE NONLINEAR FILTERS

Peiliang XU (Disaster Prevention Research Institute, Kyoto University at Uji, Kyoto 611-0011, Japan, email: pxu@rcep.dpri.kyoto-u.ac.jp)

The purposes of this paper are to discuss the biases and accuracy of the extended Kalman filter (EKF) and a second order nonlinear filter (SONF) from the point of view of a frequentist, which are, otherwise, often derived by applying the relevant conditional quantities to the linear Kalman algorithm under the Bayesian framework. The EKF and the SONF are biased, though the SONF has been derived with hope to improve first order filters. Unfortunately, the biases of the SONF may be magnified further, because the second order terms of the relevant Bayesian conditional quantities have never been properly used to derive the SONF from the frequentist point of view. The variance-covariance matrix of the SONF given in the literature is proven to be incorrect up to the second order approximation, and the correct one is derived in this paper. Finally, also from the point of view of a frequentist, an alternative, almost unbiased SONF is proposed, if the randomness of partials is neglected.

G4/E/10-A3 **1105**

A WAVELET APPROACH TO NON-STATIONARY COLLOCATION

Wolfgang KELLER (Geodetic Institute, University Stuttgart, Geschwister-Scholl-Str. 24/D, 70174 Stuttgart, GERMANY, email: wolfgang.keller@gis.uni-stuttgart.de)

Collocation is based on the assumption of stationarity. Typical data types, as for instance gravity data, are not stationary: Due to the regionally varying measurement techniques the variance of the data is also regionally varying. The paper extends collocation to the non-staionary case. The resulting Wiener-Kolmogorov equations are not longer of convolution type. Since the data-noise variance is regionwise constant, the covariance functions can be modeled by wavelets. This leads to wavelet-Galerkin equations for the solution of the non-stationary Wiener-Kolmogorov equations. These equations can efficiently be solved by a preconditioning using the sparse structure of the Galerkin matrix.

G4/W/06-A3 **1125**

CONVOLUTION OPERATORS IN GEODESY COMPUTED BY WAVELET TRANSFORM

Battista BENCIOLINI, Paolo Zatelli (Dpt. Ingegneria Civile e Ambientale, Università degli Studi di Trento Via Mesiano, 77, 38050 Trento, Italy, email: battista.benciolini@ing.unitn.it, paolo.zatelli@ing.unitn.it)

Several convolution operators, including Stokes and terrain correction, are siutable for the application of numerical methods based on multiresoltion techniques, namely the wavelet transform. This is related to the behaviour of the implied kernels that are smooth far from the origin (in fact the traditional partition into "inner zone effect" computed with a fine data grid and "far zone effect" computed with a coarse data grid is an ante-litteram multiresolution technique). We investigate both the implementation problem and the general performance of the evaluation of the operators, taking into account the special structure of the wavelet transform of convolution kernels.

G4/W/11-A3 1145

A GENERAL LEAST-SQUARES SOLUTION OF THE GEODETIC BOUNDARY VALUE PROBLEM

Martin VAN GELDEREN (Delft Institute for Earth-Oriented Space Research, Delft University of Technology, Thijsseweg 11, 2929 JA, Delft, The Netherlands, email: gelderen@geo.tudelft.nl); Reiner Rummel (Institut fuer Astronomische und Physikalische Geodaesie, Technische Universitaet Muenchen, Arcisstrasse 21, D-80333 Muenchen, Germany,
email: rummel@iapg.step.verm.tu-muenchen.de)

The geodetic boundary value problem in the spherical, constant radius approximation can be easily formulated as a least-squares adjustment problem. Assuming a continuous and homogeneous data coverage closed expressions for the solution can be found for many combinations of observation types; all integral operators of Stokes' type. Under some restrictions, a general solution for arbitrary data types can be found. Specialisations to many common gbvps are also given with their solution both in the frequency and in the space domain. Weighting of the observations is possible as long as the weights are uniform in the entire domain.

G4/W/03-A3 1205

A THEOREM OF INSENSITIVITY OF THE COLLOCATION SOLUTION TO VARIATIONS OF THE METRIC OF THE INTERPOLATION SPACE

F. Sansó (DIIAR, Politecnico di Milano, Facolta' di Como, p.le Gerbetto 6, 22100 Como, email: fsanso@ipmtf4.topo.polimi.it); C.C.Tcherning (Dep. of geophisics; University of Copenhagen, Julian Meries vej 30, Copenhagen, email: cct@gfy.ku.dk); G. VENUTI (DIIAR, Politecnico di Milano, Facolta' di Como, p.le Gerbetto 6, 22100 Como, email: giove@ipmtf4.topo.polimi.it)

The collocation approach to the estimation of a field from observed functionals, is known, by examples and simulations, to display a not very strong dependence from the choise of the specific reproducing kernel-covariance function. In fact the situation is similar to the case of the dependance of least square parameters on the weight of observations. The paper, after recalling the basic theory according to the deterministic and stochastic interpretation, shows that the variation of the sought solution is infinitesimal with both, the variation of the metric of the interpolation space, going to zero, and the quantity of information carried by the observations on the specific functional of the field that we want to predict, going to 100%. The combined effect of the two gives an infinitesimal of the second order, namely a theorem of "insensitivity" of the solution to the metric of the interpolation space. Different simulations show the action of this particular effect.

G4/W/20-A3 1225

BOUNDARY VALUE PROBLEMS FOR AN ELLIPSOIDAL BOUNDARY

HECK Bernard (Geodetic Institute, University of Karlsruhe, Germany)

Boundary value problems for ellipsoidal surfaces result quite naturally from various set-ups of the Geodetic Boundary Value Problem (GBVP) by neglecting the topographic terms in the boundary conditions or by having continued the boundary data analytically from the earth's topographical surface to the chosen earth ellipsoid. The boundary operators resulting in this way from the fixed, scalar free and vectorial free versions of the GBVP are compared with other forms of the boundary conditions published in literature. Further alternatives of boundary conditions for ellipsoidal boundary value problems result from choosing different curvilinear coordinate systems. Thus, another comparison of boundary conditions refers to the choice of elliptical, geodetic and polar co-ordinates. The respective forms are derived up to second order terms in the flattening, presupposing a normal field of Somigliana-Pizzetti type. Finally, closed analytical solutions for first order approximations of the boundary conditions are developed, based on an ellipsoidal boundary.

G4/W/17-A3 1400

VERTICAL DEFLECTIONS, THE HORIZONTAL BOUNDARY VALUE PROBLEM AND THE COMPLETION OF THE MEISSL DIAGRAM

Erik W. GRAFAREND (Geodetic Institute, Stuttgart University Geschwister-Scholl-Str. 24D, D-70174 Stuttgart, Germany, email: grafarend@gis.uni-stuttgart.de)

If vertical deflections are given on a geodetic reference figure, e.g. a sphere of reference , then as a linear horizontal operator (LHO) they define a special horizontal boundary value problem (hor BVP). The external hor BVP is solved in the space of vector-valued spherical harmonics. Special reference is made to G.G. Stokes (Transactions of the Cambridge Philosophical Society 8 (1849) 163-164, formulae (40), (41)). The solution of the external hor BVP completes the vertical Meissl diagram by its horizontal constituents. In particular, it can be used to relate vertical deflections in the space outside the geodetic reference figure, e.g. or (the level ellipsoid of revolution of Somigliana-Pizetti type), with those vertical deflections on the geodetic reference figure. As an inverse first linear integral equation it solves by regularization the downward continuation of vertical deflections.

G4/W/12-A3 1420

A COMBINED PANEL CLUSTERING AND FAST MULTIPOLE METHOD FOR THE SOLUTION OF THE SCALAR MOLODENSKY PROBLEM

Martin VAN GELDEREN, Roland Klees (Delft Institute for Earth-Oriented Space Research, Faculty of Civil Engineering and Geosciences, Delft University of Technology, Thijsseweg 11, 2629 JA Delft, The Netherlands, e-mail: klees@geo.tudelft.nl)

When standard boundary element methods are used in order to solve the scalar Molodensky problem we have to deal with large dense linear systems of equations. We propose a combination of panel clustering and fast multi-pole method, which allow to set up and solve the linear system of equations in a number of operations that grows almost proportional to the number of unknowns. The method is based on an approximation of the kernel function of the integral operator by a degenerate kernel in the farfield, which is provided by a multipole expansion of the kernel function. We present numerical results for the scalar Molodensky problem, which is the basis of today's global gravity field solutions. Moreover, we compare the solution with classical boundary element methods, which proves the superiority of our approach.

G4/E/16-A3 1440

NUMERICAL REALIZATION OF THE NEW ITERATION PROCEDURE FOR RECOVERING THE POTENTIAL SPHERICAL HARMONIC COEFFICIENTS

Margarita PETROVSKAYA and Andrey Vershkov (both at Main Astronomical Observatory of Russian Academy of Sciences, Pulkovskoe Shosse 65, Pulkovo, St. Petersburg, 196140, Russia, email: petrovsk@gao.spb.ru) Nikolaos K. Pavlis (Raytheon STX Corporation, 7701 Greenbelt Road Suite 400, Greenbelt, MD 20770, USA, email: npavlis@geodesy2.gsfc.nasa.gov)

The application of the standard iteration procedure for recovering the spherical harmonic coefficients Cnm of the earth's potential (used in particular by Pellinen, Rapp and Cruz, Petrovskaya) reveals the "exotic" behavior of the found Cnm, as a consequence of the unbounded increment of the iteration coefficients with increasing the degree n. The new iteration procedure recently proposed by Petrovskaya is more appropriate for evaluating high degree potential coefficients. In the present paper this procedure is numerically realized for recovering Cnm on the base of the global gravity data which were used for constructing EGM96 geopotential model. The results of computations of the potential coefficients by means of both the old and new iteration procedures are presented in figures and tables. Their comparative characteristics and the asymptotic behavior of Cnm with growing n are studied.

ON THE DETERMINATION OF SCALE EXPONENTS IN ENERGY SPECTRA AND STRUCTURE FUNCTIONS WITH WAVELETS AND THEIR APPLICATION TO CCD-CAMERA DATA

Stefan BETH, Willi Freeden (Geomathematics Group, University of Kaiserslautern, P.O. Box 3049, D-67653 Kaiserslautern, GER, email: beth@mathematik.uni-kl.de); Norbert Casott, Dierk Deussen, Bertold Witte (Geodetic Institute, University of Bonn, Nussallee 17, D-53115 Bonn, GER)

Wavelets are selfsimilar functions, more explicitly, the dilated and translated versions look similar to corresponding mother wavelet. Hence they can be used to characterise the fractal and multifractal properties of functions in terms of scaling exponents in structure functions and energy spectra. In general, the determination of scaling exponents requires a sufficient number of realizations of an experiment under the same conditions. Often this is not possible such that stationarity and ergodicity are assumed. Stationarity allows the time series analysis of single points and ergodicity causes independence of the direction and place. Under these conditions the energy spectra of a time series is easily constructed by the Fourier transform, which in general does not lead to a smooth result, but to a mean variation around the expected scaling behaviour. Therefore filter techniques are applied to smooth the characteristic regions of the spectra. In recent years it could be shown that the same effect can be gained by a wavelet based energy spectra. In particular, the computation can be summarized to one working step. In the same way it was proven that wavelet based structure functions of positive order behave like structure functions of positive order as usually defined via differences. Moreover, the wavelet based structure functions can also be defined for negative orders, which supplements the multifractal theory. For both methods a good coincidence is proven for the application on wind velocity data and in addition the problem of the evaluation of CCD--Camera data concerning refraction effects in the surface layer.

HARMONIC SPHERICAL SPLINES WITH LOCALLY SUPPORTED KERNELS

Guilhem MOREAUX (University of Copenhagen, Department of Geophysics, Juliane Maries Vej 30, 2100 Copenhagen O, Denmark, email: gm@gfy.ku.dk)

Harmonic spherical spline is a very flexible method in gravity field modelling, which permits the use of data of different kinds and with different noise-characteristics. The method has however the drawback that one needs to solve a symmetric positive definite (SPD) system which (1) involves as many equations as the number of data and parameters (2) is full due to the harmonicity of the reproducing kernels. Therefore, for large data sets, both direct and iterative methods give heavy computation burden. Meanwhile, because for a great number of harmonnic kernels there exists angles of separation beyond which the kernel values, i.e. the matrix entries, are negligible small, Moreaux and al. (1998) proposed three techniques to approximate any harmonic kernel on the sphere by locally supported strictly positive definite functions in order to get sparse SPD approximations of the full SPD matrices.
In this talk, we apply the first technique developped in Moreaux and al. (1998) to gravity field modelling in both cases of differentiation (gravity gradients from gravity) and integration (geoid and gravity from gravity gradients) and compare the results with the ones obtained by the full kernels. After that, some numerical results about the use of these sparse matrices as pre-conditioners of the full systems for the conjugate gradient method are given.

IMPROVED ANALYTICAL APPROXIMATIONS OF THE EARTH'S POTENTIAL FIELDS

V.N. Strakhov (United Institute of Physics of the Earth, Russ. Acad. of Sciences, Moscow, Russia); U. SCHAEFER (Bundesamt fuer Kartographie und Geodaesie, Aussenstelle Potsdam, Michendorfer Chaussee 23, 14473 Potsdam, Germany, email: ufer@potsdam.ifag.de); A.V. Strakhov (Computing Center of the Russ. Acad. of Sciences, Moscow, Russia)

One of the burning problems in gravimetry and magnetics is to derive linear analytical models of the Earth's potential anomaly fields with high spatial resolution that are consistent with the observations of various potential field elements at the Earth's surface and in outer space. For modelling the anomalous potential on a global, regional or local scale it is meaningful to apply linear approximations since they allow to find other field elements (e.g. higher derivatives) by means of elementary operations. From a methodological point of view it is essential to make direct use of observations at the physical surface of the Earth and/or from outer space without any reductions to a certain reference surface. In that case the problem to find out linear analytical approximations may be reduced to the problem of solving huge systems of linear algebraic equations. The matrix of the respective equation system is full and the number of unknowns may reach the order of 10^5 to 10^6. These equation systems can be generated by means of three main approaches: 1) simply equating the analytical approximations with the observed data; 2) using the least square method (in the frame of given base functions, e.g. spherical or spheroidal functions); 3) using linear integral representations and variational principles (generalized Backus-Gilbert method). In the first approach one normally get systems with rectangular matrices with N>M for global and N<M for regional and local approximations (N equations; M unknowns). For the second and third approach one obtains systems with symmetric positive semi-definite matrices. We present main constructional ideas ensuring to receive stable solutions of the problem. One of them is perfectly new in numerical linear algebra: to reduce huge systems to 1 equation with 1 unknown.

THE IMPACT OF UNCERTAINTIES OF THE STOCHASTIC MODEL ON THE RESULTS OF LEAST SQUARES ADJUSTMENTS

Hansjoerg KUTTERER (Geodetic Institute, University of Karlsruhe, Germany)

In common adjustment problems both the functional and the stochastic model are considered to be free of errors. If the adjustment results have to be interpreted in a wider context, the development of a proper perturbation theory for the mathematical model and the quantities derived by means of least squares adjustments is indispensable. The paper studies the impact of uncertainties of the stochastic model on some characteristic results of least squares adjustments like the estimated values of the parameters and their variance-covariance matrix. Linearizations are used regarding rigorous error bound. To efficiently treat the uncertainty aspect, interval mathematics proves to be a useful tool.

OPTIMAL DESIGN OF THE REFERENCE AND OBSERVATIONS WEIGHTS IN GEODETIC NETWORKS FROM CRITERION MATRIX

Jose Luis VACAFLOR (Instituto de Geodesia. Facultad de Ciencias Exactas y Tecnologia. Universidad Nacional de Tucuman. Avenida Independencia 1800. (4000) San Miguel de Tucuman. Argentina. email: vacaflor@arnet.com.ar)

An efficient strategy based in the least square solution (LESS) of the Gauss-Markov model (GMM), is developed in order to find the optimal Datum definition - by means of an appropriate set of constraints - of a geodetic network, in such way that: any improvement in the weights of the observations will produce a Dispersion Matrix of the estimated parameters close to the given Criterion Matrix. Finally, a geodetic network is processed in detail as a numerical example.

G4/E/09-A3 Poster 1620-03

THE EFFICIENCY OF OPTIMIZED WEIGHTS FROM CRITERION MATRICES

Nardo Geronimo Lopez Fernetti, Jose Luis VACAFLOR (both at Instituto de Geodesia. Facultad de Ciencias Exactas y Tecnologia. Universidad Nacional de Tucuman. Avenida Independencia 1800. (4000) San Miguel de Tucuman. Argentina. email: geosupe@herrera.unt.edu.ar , vacaflor@arnet.com.ar)

Once the Datum, the configuration of the geodetic net together with its criterion matrix is decided, then: taking into account the characteristics of the avalaible instruments for measurements and the alternative ways for conformation of a stochastic model, we endeavor to obtain a real solution which matches as closely as possible to the previous one, proving the potentiality of the notion of "sensitivity". The theoretical concepts and the designed methodology are shown in detail on a geodetic network.

SEPARABILITY OF LINEAR MODELS AND ITS APPLICATIONS IN GEODESY

Jinling WANG (School of Spatial Sciences, Curtin University of Technology, GPO Box, U1987, Perth, WA 6845, Australia, email: Wang@vesta.curtin.edu.au)

Geodesists, like other scientists, are sometimes confronted with the problem of selecting one best model from two or more competing linear models. For example, in GPS and GLONASS carrier phase integer ambiguity resolution, the identification of the most likely integer ambiguity combination from numerous potential combinations can be considered as a process of model selection. In practice, the model selection is commonly performed using a search criterion based on the minimisation of the quadratic form of the least squares residuals. Intuitively, the best model is associated with the minimum quadratic form. Before the best model is employed in data processing, however, it is important to test whether or not the best model is statistically better than the second best model as defined by the second minimum quadratic form of the residuals. To this end, rigorous statistical tests have recently been developed, called model discrimination tests.
Like other statistical tests, the power of the model discrimination tests depends on the significance level used in the tests, the stochastic model of observations and the geometry of compared models. Following Baarda's reliability theory, separability of compared linear models is introduced. Applications of the concept of separability in GPS/GLONASS ambiguity resolution and the outlier detection and identification will be presented.to determine a derived flood frequency curve.

ROBUST ESTIMATORS FOR NETWORK ADJUSTMENT

Entela KANANI, Alessandro CAROSIO (both at Institute of Geodesy and Photogrammetry, Swiss Federal Institute of Technology, CH-8093 Zurich, Switzerland, email: kanani@geod.ethz.ch); FridolinWicki (Vermessungsamt der Kanton Aargau, Frey-Herosestrasse 12, CH-5000 Aarau, Switzerland, email: fridolin.wicki@ag.ch)

Most parameters in geodesy are determined by statistical estimator procedures. The method most commonly employed is that of Least Squares - an optimal estimator for normal distributed measurements. In practical evaluation, however, there often occur many observations which do not conform to the expected normal distribution. The classical compensation method of Least Squares is extremely sensitive and quickly leads to unusable results when significant deviations from the normal distribution are present. Robust estimators are currently of considerable interest therefore, and our research is directed at establishing and developing new procedures based on robust estimators for geodetic applications such as: compensation of geodetic networks and linear geodetic transformations. An optimal estimator which bounds the influence of standardised residuals has been developed for the evaluation of geodetic networks. The chosen estimator is a Maximum Likelihood-estimator of Schweppe-type and has an objective function similar to the Least Square Method. When no outliers are present (normal distributed measurements) this estimator gives the same results as the method of Least Squares, when this is not the case, the algorithm limits the influence of the standardised residuals (instead of the residuals as in P. Huber estimator, for example). This has the effect of providing an upper limit to the influence of a spurious observation (e.g. an gross error) on the unknown parameters also in cases of small redundancy (leverage points). The limiting value is determined by the standard deviation of a residual multiplying a constant c. Furthermore, our attention has been directed towards high breakdown estimators and their implementation for the determination of unknown parameters in the linear geodetic transformations. Although this group of estimators is generally associated with a large amount of calculation time, their implementation for the analysis of deformation measurements can be of considerable value. The number of parameters to be estimated in a linear transformation is limited (4, 6, 7 and so on), which restricts the calculation time to manageable proportions. A high breakdown estimator (Least Median of Squares) has been investigated further. The results have shown that inserting a robust estimator…

THE LP ESTIMATION OF THE SCALE PARAMETER AND THE ACCURACY EVALUATION

Shinjian ZHOU (Dept. of Surveying Engineering, East China Institute of Geology, Linchuan City, Jiangxi Province, China, email: zsj@ecgi.jx.cn)

Abstract not available at time of going to press.

G4/P/05-A3 Poster 1620-07

THE UNIQUNES AND UNBIASEDNESS OF THE LP ESTIMATION

Shijian ZHOU, Deyan Zang (Dept. of Surveying Enginerring, East China Institute of Geology, Linchuan City, Jiangxi Province, P.R. of China, email: zsj@ecgi.jx.cn); Yongqi Chen and Conrad Tang (Dept. of Land Surveying and Geo- Informatics, The Hong Kong Polytechnic University, Hong Kong, email: yqchen@polyu.edu.hk)

It is well known that the LP estimation can be applied in the processing of the observational data with the outliers distributed, but the statistical properties of the Lp have less discussed, thus it's not convenient to employ for us. This paper aimed at this problem, the uniqueness of the Lp estimation has first obtained when p>1 and the error distribution is symmetrical population. Basing on a symmetrical and the objective function is an even function, the robust estimation is an unbiased estimation that has first been proved if it is calculated by iterative weight Least Squares with an antisymmetrical estimation as starting points, so that the Least absolute Sum has also unbiasedness as a special case of the robust estimation. The results ensure that the Lp estimation has the optimal statistical properties also and can be employed widely.

BIASED ESTIMATION FOR PAPAMETER ADJUSTMENT WITH CONSTRAINTS

Gui QINGMING, Zhang Jianjun (both at Zhengzhou Institute of Surveying and Mapping, No.66 Longhai Road, Zhengzhou 450052, Henan, P.R. China)

The parameter estimation problem in parameter adjustment model with constraints is considered when some multicollinearities occur among the columns of the design matrix. We propose a class of restricted biased estimators by grafting the unrestricted biased estimation philosophy into the restricted least squares (RLS) estimator, and establish some important statistical properties. Many well known unrestricted biased estimators (e.g. shrinkage least squares estimator, ridge estimator, principal component estimator etc.) are extended to parameter adjustment model with constraints. A numerical example is presented to illustrate that these restricted biased estimators are superior to the RLS estimator in sense of the reduced MSE.

RELIABILITY OF GPS OBSERVATIONS USING A WEIGHTED IONOSPHERE

Kees DE JONG (Delft University of Technology, Department of Mathematical Geodesy and Positioning, Thijsseweg 11, 2629 JA Delft, The Netherlands, e-mail: k.dejong@geo.tudelft.nl)

The theory and application of statistical quality control is well-established in surveying and geodesy. Internal reliability, as represented by the Minimal Detectable Bias (MDB), describes the size of biases (model errors) that can just be detected using appropriate test statistics. For GPS these biases are assumed to consist of outliers in the pseudo range and (integer) cycle slips in the carrier observations. The MDBs can be computed without actual data. Therefore, MDBs provide an important design tool when setting up a GPS measurement scenario. Recently, analytic expressions for the MDBs of GPS pseudo range and carrier single-difference observations were derived and published. These expressions, however, apply to short baselines only, i.e., baselines for which the ionospheric effects at both ends are fully correlated. For longer baselines, residual ionospheric effects should be taken into account. In the research described here general analytic expressions have been derived using an ionospheric variance matrix, which allow for a weighting of the ionosphere. The presented expressions differ depending on the observation scenario considered (static receivers, one static and one moving receiver, both receivers moving).

A COMBINED ADJUSTMENT OF ASTRO-GEODETIC NETWORK AND GPS GEODETIC NETWORK IN CHINA

Ziqing WEI (Xian Research Institute of Surveying and Mapping, 1 Yanta mid-road, Xian, Shaanxi 710054, P.R.China, email: ziqingw@public.xa.sn.cn)

A combined adjustment of the whole astro-geodetic network and the nation-wide first-order GPS geodetic network was carried out in China in recent years, which embraces 48,519 astro-geodetic points and 40 first-order GPS points evenly distributed over the entire country and involves 311,986 directions, 467 taped or EDM distances and extension sides, 1,693 traverse sides, and 942 Laplace azimuths. The adjustment was undertaken on the reference ellipsoid in the geocentric datum, whose origin, orientation and scale are totally defined by three-dimensional coordinates of GPS points referred to the ITRF91. The results show that, on the average, the standard errors for the length and bearings are 4.0 ppm and 0.59" respectively for 10-20 km sides, and 1.48 ppm and 0.31" respectively for 21-35 km sides. The absolute accuracy of horizontal coordinates of a point relative to the defined datum is at the submetre level. Hence, as a consequence of adjustment, the accuracy and homogeneity of the astro-geodetic network has been significantly improved; the regional geocentric coordinate system has been established with 1m accuracy.

RESEARCH ON THE COMBINATION OF LOCAL GPS AND TERRESTRIAL OBSERVATIONS

Zha MING, Ouyang Guichong (Xi'an Technical Division of Surveying and Mapping, 36 Xiyinglu,Xi'an, Shaanxi 710054, P.R.China)

With the development of GPS and traditional surveying techniques, the combined use of GPS and traditional surveying techniques might be the optimal choice in many cases. Because GPS surveying yields three-dimensional vectors, the three-dimensional geodetic model is the most natural model to be used. This paper proposes the method of combined three-dimensional adjustment of local GPS and terrestrial observations. Deflection components of the vertical are used to make up for the lack of astronomic latitudes and longitudes, the first-order atmospheric vertical refraction effect is deleted by using the vertical angles at each end of the line. It is preferable that the coordinates of GPS stations are introduced into the adjustment as weighted parameters reflecting the accuracy of the GPS geodetic network. Based on the model, the three-dimensional adjustment software CPSTGD has been developed. According to combined adjustment results of several local GPS and terrestrial networks, it has been shown that the method is theoretically perfect and practically effective.

ON THE LOCATION OF ABNORMAL DATA IN MARINE SURVEYING

Huang Motao, Zhai Guojun, Wang Rui Ouyang Yongzhong, Guan ZHENG (all at Tianjin Institute of Hydrographic Surveying and Charting, Tianjin, 300061, China, email: nvsurvey@public.tjuc.com.cn)

Based on an analysis of the characteristic of marine surveying, two robust methods for detecting the abnormal data in marine measurements are proposed in this paper. One is called the statistical hypothesis test based on sample quantile. The other is called the interpolation comparison test based on robust M-estimation by iterative weight determination. Some questions involved in the implement of the suggested methods are discussed in detail. Compared to the existing methods, the two new methods have more strong capacity of locating abnormal data. A synthetic study and an actual numerical example for multibeam soundings are given to test the performance of the methods. The results have illustrated the effectiveness of the methods in the detection and identification of multiple blunders. The use of the new methods will play an important role in improving the quality and reliability of marine measurements in our country.

REGIONAL GRAVITY FIELD RECOVERY FROM FUTURE SATELLITE MISSIONS USING MULTI-SCALE APPROXIMATION

Juergen KUSCHE, Stephan Rudolph (Institute of Theoretical Geodesy, University of Bonn, Nussallee 17, 53115 Bonn, Germany, email: kusche@uni-bonn.de)

The task of the envisaged SST/SGG-missions like CHAMP, SAGE, GRACE, and GOCE is the computation of a global gravitational field with high resolution and precision and - if possible - with repetition in time. Global approaches are aimed at the recovery of spherical harmonic coefficients. The spherical harmonics provide a "natural" multiresolution of the field, but they do not possess any localising properties in space. Therefore it is not possible to focuse the analysis of satellite mission data to regions of special interest, i.e. for the study of time-dependent phenomena. On the other hand, regional approaches have been developed to recover gravity anomalies or point masses. They provide good space-localization, but lack in scale decomposition properties. This means, phenomena on different length scales are not clearly separable. To overcome these difficulties, wavelet and filtering techniques have been proposed recently. In our study, wavelet and filtered copies of base functions are combined to form a multi-scale version of the classical approximation in a Hilbert space. A rigorous theoretical analysis is performed. Special emphasis is laid on the topic of regularisation, which is always a crucial point in regional approaches. Next, parameter choice strategies for "designing" a suitable base function system are considered. Finally a two-scale approximation scheme is constructed suitable to a low-low SST gravity field mission and a simulation experiment using GRACE mission parameters is performed. First results are encouraging.

THE USE OF WAVELETS FOR THE ANALYSIS AND DE-NOISING OF KINEMATIC GEODETIC MEASUREMENTS

A.M. BRUTON, J. Skaloud, K.P. Schwarz (Department of Geomatics Engineering, The University of Calgary, 2500 University Drive, N.W. Calgary, Alberta, Canada T2N 1N4)

The objective of this paper is to discuss and demonstrate the use of wavelets for improving the performance of geodetic measurement systems. More specifically, wavelets are used as a tool for analyzing and de-noising the errors that are inherent in such systems. Because the Wavelet Transform provides a time-scale representation of a signal, it offers the ability to both analyse the error characteristics of a system at different resolutions and to localize them in time. These features are the key components used for analysing and de-noising the measurements in kinematic geodetic systems.
Examples are drawn from research projects being carried out at the University of Calgary. These use real data and include discussions of GPS and INS measurement systems. Issues such as practical implementation, observed error characteristics (under varying vehicle dynamics) and accuracy improvements are treated. First results indicate that these tools can be used to significantly improve the performance of a navigation grade INS. In this case, it is observed that the noise is self-similar over several decades of frequencies (i.e. has the same characteristics in more than one frequency band). A model for the noise is developed using a frequency band in which vehicle dynamics are not present and then used to de-noise the bands that do contain dynamics. This results in an improvement of 20% over traditional techniques.

WAVELET ANALYSIS OF SSH DERIVED FROM ERS-2 ALTIMETER DATA NEAR CHINA SEA

Hanjiang WEN, H.Suenkel (Institute of Theoretical Geodesy, Steyrergasse 30, TU-Graz, A-8010 Graz, Austria)

A small area near China sea was used to study the sea surface height derived from ERS-2 altimeter data. Firstly, continuous wavelet transform was used to get the scalogram of SSH along satellite ground tracks about 4000km in length, from which one can see that the energy of SSH is mainly concentrated on the wavelength between 1000km and 1200km. Secondly, the orthogonal discrete wavelet transfrom was applied to get the multiresolution analysis of SSH, from which, the information contained in SSH was divided into different parts with respect to different scales, variations of the information between successive scales can be seen. We also got the wavelet variances at different scales of the SSH.

THE WAVELET ARITHMETICS OF THE G1 -TERM IN MOLODENSKY'S BOUNDARY VALUE PROBLEM

Yu JINHAI, Peng Fuqing (both in Institute of Zhengzhou Measuring and Mapping, 450052, Zhengzhou, Henan, P.R. China)

Molodensky's boundary value problem cannot be directly used in actual works because of the complexity in computing singular integrals, although Molodensky, Brovar, Moritz, Holota and many other scholars have made great contributions to it. In this paper, following the Brovar's series solution, we strictly prove the existence of strongly singular integral G1 -term in the sense of Chauchy principal value at first, and then discuss its arithmetics with help of wavelet method where a compact scaling function is chosen. The obtained results illustrate that the key step lies in resolutions of the kernel function, which are independent on the terrains and the gravity anomaly and can be computed in advance. The computation results in an area of 20km x 20km with step length 200m also illustrate that the wavelet arithmetics are much superior to FFT which only fits to convolution integral. Particularly, the obtained wavelet arithmetics satisfy the requirements in large scale computation of singular integrals in physical geodesy.

APPLICATION OF THE WAVELET TRANSFORM FOR CLOCK BREAKS DETECTION IN THE VLBI OBSERVATIONS

TAIBI H., Ghezali B., Kahlouche S. (Geodetic Laboratory, National Centre of Spatial Techniques, BP 13 ARZEW, 31200, Algeria)

The method of clock breaks detection developed in the National Centre of Spatial Techniques is based on the concept of multi-resolutions (time - frequency) using wavelet analysis. The object of this method is to identify the clock breaks which are translated into great coefficients with high frequency of the associated wavelet. The used observations in the processing are constituted by an IRIS-A program session including 518 observations and comprising three primary stations and a secondary (mobile) station.
In the processing of the VLBI data, the behaviour of each clock is a linear model, consequently the residues after adjustment of parameters have to be randomly distributed around a straight line. The deviations between the clocks can be detemined only if one of the clocks (the most stable) is chosen as a reference. The signal to analyse is represented by a cloud of points constituting the residues of VLBI observation as a function of time.
The detection criterion of the clock breaks rests on the analysis of the residues regularity : the clock break, which is a systematisme, is translated by the presence of a very great coefficient with high frequency of the associated wavelet. In the regions where the signal is very regular, the coefficients of the associated wavelet of high frequencies are very small while an abrupt discontinuity of the signal makes "explode" the coefficient of the associated wavelet.
The results obtained with this method are identical to these obtained by the manual method.

THE GEOID TAKING THE FLATTENING OF THE ELLIPSOID INTO ACCOUNT

Z.L. Fei, M.G. SIDERIS (Department of Geomatics Engineering, University of Calgary, 2500 University Drive NW, Calgary, Alberta, Canada, T2N 1N4, email: sideris@ucalgary.ca)

Geoid undulations are typically being computed by Stokes's formula. They can be called spherical undulations because the flattening of the ellipsoid is neglected in the computation. We are proposing a new method for computing the ellipsoidal geoid, which consists of two parts: the Stokes solution No (spherical geoid undulation) and the ellipsoidal correction N1. The ellipsoidal correction N1 is expressed as a sum of two closed integral formulas, integrating gravity anomaly data ?g and spherical geoidal undulation data No. The kernel functions have the same degree of singularity at the origin as the original Stokes function. The relative geoidal undulation error is O(e4), which can be neglected for most practical purposes.
This method is especially suited for the computation of ellipsoidal corrections in areas where spherical geoid undulations are available. It avoids some of the approximations employed in other methods available in the geodetic literature and it also uses simpler integration kernels. In this paper, besides the theoretical equations, we give a numerical computation of N1 in some areas in Canada where we have both gravity anomaly data ?g and spherical geoidal undulation data No.

SIMPLIFICATION OF TRANSFORMATIONS BETWEEN THE ELLIPSOIDAL AND SPHERICAL SPECTRA OF THE GEOPOTENTIAL

Margarita PETROVSKAYA (Main Astronomical Observatory of Russian Academy of Sciences, Pulkovskoe Shosse 65, Pulkovo, St. Petersburg, 196140, Russia, email: petrovsk@gao.spb.ru)

When constructing the geopotential models OSU91 and EGM96 Jekeli's ellipsoidal harmonic approach was successfully applied for recovering the spherical harmonic potential coefficients Csnm from the surface gravity anomaly. In the present paper the transformation formulas between Csnm and the ellipsoidal harmonic potential coefficients Cenm, derived from gravity data at the ellipsoid surface, are modified. The original relations between them contain hypergeometric series which converge very slowly for large values of n and m. Now such a series is transformed to a product of simple binomial factors, depending on the ellipsoid eccentricity, and a very quickly convergent hypergeometric series. As a result, the numerical procedures for evaluating the coefficients Csnm from Cenm will be essentially simplified while constructing the earth's potential models. The above transformations are also used for deriving a boundary relation which connects Cenm, expressed in terms of Csnm, and the gravity anomaly at the ellipsoid surface. It will allow to apply the least squares collocation procedure in a simultaneous treatment of satellite and gravity data at the ellipsoidal harmonic approach.

FUZZY SET THEORY AND GEOSPATIAL DATA MANAGEMENT: A FOCUS ON BOUNDARY VALUE PROBLEM

E.A. SHYLLON, J.B. Olaleye, V.O.S. Olunloyo (Geoinformatics Laboratory, Faculty of Engineering, University of Lagos, Lagos, Nigeria)

To deal with unmanageable complexity of Geospatial data at all levels, Geospatial data Managers resorted to the use of statistical averages and probability theory. In spite of its wide

usage, the probability theory is not capable of capturing uncertainty in boundary values (data element "which is" or "which is not" within).
Fuzzy set theory exploits the tolerance for uncertainty, imprecision and partial truth of various types to achieve tractability, low solution cost and better rapport with reality. It provides a strict mathematical environment in which vague conceptual phenomena are rigorously studied. The membership grade functions of the fuzzy subsets are constructed to define the boundary values. This is an interval between [0,1]. It is easy to formulate for soft computing. The primary aim of this paper is to explain and develop computational methods that produce acceptable solution to boundary value problem.

SPECTRAL DECOMPOSITION OF THE GRAVITY ACCELERATION VECTOR AND GRAVITY GRADIENT TENSOR

Gilles METRIS (CERGA, Observatoire de la Côte d'Azur, Av. N. Copernic, 06130 Grasse, France, email: metris@obs-azur.fr)

In satellite geodesy, many measurements (e.g. satellite altitude, radial velocity, components of the gradient of acceleration) have more simple expressions in the satellite orbital frame. This has motivated a large effort in the last years to (1) derive the expressions of the variations of position, velocity, acceleration, gradient of acceleration due to the gravity potential, in that frame, and (2) to compute their spectral decomposition using simplified theories of satellite motion. This is used to efficiently analyze the expected performances of satellite to satellite tracking or satellite gravity gradiometry missions.
We propose an alternative method to obtain the spectral decomposition, in the orbital frame, of the gravity acceleration vector and gravity gradient tensor components. We use the relation between spherical harmonics and rectangular coordinates to directly (i.e. without derivatives with respect to spherical coordinates) express the successive derivatives of the gravity potential with respect to body fixed rectangular coordinates. Then, the classical rules of tensor transformation by rotations are applied to convert the components into the orbital frame. Finally, we use a Kaula like development to express these components as functions of orbital elements. They are decomposed in sums of periodic functions using a linear theory of the satellite motion. We have used this new method in the study of the French space mission MICROSCOPE, which aims at testing the equivalence principle by means of accelerometric measurements.

THE SENSITIVITY OF THE REDUCED DYNAMICS TO THE EARTH'S GRAVITY MODEL IN THE ORBITOGRAPHY OF LEO SATELLITES WITH GPS: THE POSAT - 1 CASE STUDY

Isabel OSÓRIO, J. Pereira Osório (both at Faculty of Sciences, University of Porto, Monte da Virgem, 4430 Vila Nova de Gaia, Portugal, email: iposorio@oa.fc.up.pt, posorio@oa.fc.up.pt); J.M. Rebordão (INETI / LAER - Aerospace Laboratory, Estrada do Paço do Lumiar, 1699 Lisboa Codex, Portugal, email: jmr@laer.ineti.pt)

Codephases and Doppler measurements from a TRIMBLE TANS II receiver are available on board of the Portuguese micro-satellite PoSAT - 1. Due to the big amount of geometrical information contained in the GPS measurements and, also, due to the cadency of these observations (0.5s) a reduced dynamical model is used as the satellite orbit propagator in a Kalman filter, where the observations are the codephases smoothed by Doppler measurements.
As PoSAT -1 is a polar LEO satellite, at an altitude of 710 km, the effect on its orbit of the nonspherical gravity field has a meaningful value. There are not any specific gravity field model advised for this satellite. So, in this work, different Earth gravity models were used and the differences in the positions were plotted. The state variables used to describe the satellite motion are modified Poincaré variables. Indeed these variables are a quasi-canonical set of variables and, by this reason, a semi-analytical process for the orbit propagation was used. In this paper the algorithms developed are described and the results are presented.

AERODYNAMIC FORCE ENHANCEMENTS FOR THE ERS SATELLITES

P. MOORE, S. Carnochan, R.J. Walmsley (Aston Geodesy Group, Division of Civil Engineering, Aston University, Birmingham, B4 7ET, UK, email: moorep@aston.ac.uk)

Accuracy of orbit determinations for altimetric satellites such as ERS-1 are now approaching that achieved for the higher satellite TOPEX/Poseidon. Much of this improvement is due to gravity field enhancement specific to the ERS orbit. For example ERS-1 crossover rms residuals of 8.9cm, 8.4cm and 7.6cm have been obtained for the first multidisciplinary, geodetic and second multidisciplinary phases respectively. These are close to the 7cm obtained with TOPEX. However, the ERS-1 residuals reflect the decrease in solar activity from 1993-6 and thus reveal imperfections in the underlying thermospheric model. In this study we propose a methodology for enhancing the DTM94 thermospheric model through ERS-1 along track accelerations. Comparisons of the original and enhanced models will be presented.

ANATOMIZING THE GRAVITATIONAL LOAD LOVE NUMBERS

Ming FANG, Bradford H. Hager (Dept. Earth Atmospheric & Planetary Sci., MIT, Cambridge, MA 02139, USA, email: fang@chandler.mit.edu)

Recent estimates (Wahr, 1998) indicates that the gravitational signals of post-glacial rebound and contemporary surface mass redistribution will be prominent in the high precision data to be collected by the Gravity Recovery And Climate Experiment (GRACE) mission. Contributions of the solid Earth to these signals are traditionally modelled by calculating the surface response as a function of rheological parameters within the mantle. This approach fails to provide a clear picture of how the surface responses relates to the perturbations in the interior. In this paper, we present an integral relation which directly links the gravitational load Love number, kn, to the displacement field in the core, lower, and upper mantle. For a laterally homogeneous Earth, this relation can be reduced to a simple radial integral allowing us to infer ("anatomize") the contributions of each individual layer to kn. We demonstrate by numerical modelling the application of our new method to the interpretation of the rate of change of gravity at a variety of spatial frequencies.

GLOBAL TREND OF THE EARTH'S PRINCIPAL AXES AND MOMENTS OF INERTIA: CANONICAL FORM OF SOLUTION

Alexander N. MARCHENKO, Oleg A. Abrikosov (both at Faculty of Geodesy, State University 'Lviv Polytechnic', S. Bandera St. 12, 290646 Lviv, Ukraine, email: march@polynet.lviv.ua)

Evolution of the Earth's dynamical figure was formulated as the time-dependent eigenvalues-eigenvectors problem in the canonical form and based on the special standardisation of the time-dependent quadratic form of the 2nd degree gravity potential U(t). A remarkable separation of the 2nd degree harmonic coefficients was applied: 1) second degree variance of these coefficients, representing the invariant quantitative characteristic of U(t); 2) standardized harmonic coefficients of the 2nd degree, describing the qualitative characteristics of U(t) of this quadrupole's potential. As a result, the non-linear functional dependencies between the standardised harmonic coefficients were found.
The non-linear hyperbolic model for harmonic coefficients was constructed especially for avoiding infinite values of U(t) when time t tends to infinity. This model restores the properties of the well known linear model exactly at the neighbourhood of an adopted reference epoch and provides the limited potential U(t) at the ends of infinite time interval. So, the linear model is nothing else but the boundary case of the hyperbolic one. The trigonometric form of the hyperbolic model leads to the consideration of the potential U(t) as U(w) (w corresponds one-to-one to t) within the closed finite interval for w. These theoretical investigations and temporal variations of 5 harmonic coefficients according to EGM96 gravity model and special additional conditions lead to the evaluation of the global trend of the Earth's principal axes, moments of inertia and global density distribution within the whole infinite time interval that becomes possible in contrast to the standard linear model.

THE DIFFERENCE BETWEEN COMPRESSIBLE WAVE AND DILATABLE WAVE AND THE MODIFIED BRANDT'S ELASTIC THEORY

Xu LIU, Zhu Yanqing(Both at Shanghai Seismological Bureau, Shanghai 200062, China, email: xliu@sbsn.net)

Based on the discontinuity, a model of mass bi-spring is suggested. The model together with some experiments approve that there can be a great difference of wave velocity between compressible wave and dilatable wave. Within 1/4 of wavelength, the pure compressible or dilatable wave can be tested. A new concept, elastic cementing coefficient ECC , is put forwarded. ECC can comparatively represent the degree of cementation. When the geotechnical relations between primary wave velocity and engineering parameters are studied, primary wave should be thought of as compression or dilatation respectively. The Brandt's elastic theory for porous granular media is modified by a term in that its volume modulus is identical to that of Biot-Geertsma's theory. A new way to calculate the skeleton elastic wave velocity is suggested. Some effect of physical parameters on elastic wave velocity are discussed. Key wards: Elastic wave, geotechnical engineering, the skeleton of soils.

DEFORMATIONS OF A NUMERICAL EARTH MODEL (NEM) DUE TO A) SURFACE LOADS, B) INTERNAL DISLOCATIONS

M. ABOLGHASEM, J. Engels, E.W Graferand (Geodetic Institute, University of Stuttgart, Germany)

This is the result of an attempt to compute the displacement field of a Numerical Earth Model (NEM) under the application of a deformation source. A NEM, compared to the present analytical models, is more flexible to account for:
(1) lateral, in addition to radial, heterogeneity, which is not expected to be negligible in the near-field displacements of a dislocation source
(2) internal discontinuities
(3) input of geodetically observed displacements as boundary conditions.
The paper presents the deformations of a NEM under a)surface loads, b)internal dislocation source, and concludes with a comparison of the results with those obtained from analytical models.

CONTEMPORARY KINEMATICS OF THE PHYSICAL SURFACE OF THE EARTH: SURFACE STRAIN AND SURFACE VORTICITY DEDUCED FROM VLBI DATA

B. VOOSOGHI, E. W. Grafarend (Geodetic Institute, University of Stuttgart, Stuttgart, Germany)

The Global patterns of surface strain and surface vorticity (surface rotation) are derived from a data set of VLBI velocities. In contrast to a strain and surface-vorticity analysis with respect to a reference surface of the earth, here focus is on surface strain and surface vorticity with respect to the physical surface of the Earth (topographic surface) via a finite element triangulation.

G4/E/03-A3 Poster **1620-29**

A GLOBAL TOPOGRAPHIC-ISOSTATIC GEOID BASED ON A LOADING THEORY

Wenke SUN, Lars E. Sjoberg (both at Royal Institute of Technology, Department of Geodesy and Photogrammetry, S-10044 Stockhom, Sweden, e-mail: sunw@geomatics.kth.se)

This new global topographic-isostatic model originates from a completely new idea - the geoid undulation is the response of an elastic earth to the topographic mass load. Assuming the topography as a condensed surface mass load, expressions are derived for calculating the vertical displacement, potential and equipotential surface changes, based on the load theory proposed in Sun and Sjoberg (1998). The modeled geoid is composed of three parts: loading potential, surface displacement and mass redistribution. The surface displacement and mass redistribution of the earth compensate to some extent the topography. In practical calculations the Getech's Global Digital Terrain Model (DTM5) is adopted. Using the load Love numbers and Green's functions obtained from the PREM earth model, the vertical displacements and equipotential surface changes are calculated and discussed for the following depths: earth's surface, d=36 km and the core-mantle boundary. Numerical results show that the displacements at depth 36 km and the earth's surface have the same distribution pattern and magnitude, while the vertical movement of the core-mantle boundary appears much smoother and smaller. The modeled geoid undulations at the earth's surface caused by the topographic mass load vary between -352 and +555 m. Comparing the modeled and observed geoid undulations shows that there are strong positive correlations between them, but a compensation only by elastic deformations is not sufficient to explain the observed undulations because of the big difference in magnitude between the two geoids. More geodynamic effects should be considered to better explain the long-wavelength geoid features.

INVERSE PROBLEMS IN ISOSTASY: THE CASE OF VENING MEINESZ

Hussein ABD-ELMOTAAL (Civil Engineering Department, Faculty of Engineering, Minia University, Minia 61111, Egypt, email: hamotaal@frcu.eun.eg)

Inverse problems in isostasy will consist in making the isostatic anomalies to be zero under a certain isostatic hypothesis. In case of the Vening Meinesz isostatic hypothesis, the density contrast is constant, while the Moho depth (depth of the Mohorovicic discontinuity) is variable. Hence, the inverse Vening Meinesz isostatic problem aims to determine a suitable variable Moho depth for a prescribed constant density contrast. The main idea is easy but the theoretical analysis is somewhat difficult. Moreover, the practical determination of the variable Moho depths based on the inverse Vening Meinesz problem is a laborious and time consuming task. The formulas used for computing the inverse Vening Meinesz Moho depths are derived. The computational tricks essentially needed for computing the inverse Vening Meinesz Moho depths are described. The Moho depths for a test area are computed based on the inverse Vening Meinesz isostatic problem. The resulted inverse Vening Meinesz Moho depths are compared with Moho depths obtained from seismic profiles. The comparison shows a good agreement between both sets of Moho depths.

GEOID AND CRUSTAL STRUCTURE IN ARGENTINA

María Cristina PACINO (IFIR - UNR, Av. Pellegrini 250, 2000, Rosario, Argentina, email: mpacino@fceia.unr.edu.ar)

Land uplift, according to isostatic concept, is a process through which the uppermost zone of the Earth deforms towards equilibrium. Isostatic theories (Airy's, Pratt's, Vening-Minesz's) have been very helpful in interpreting the Earth's gravity field since any land uplift causes changes in the gravity field due to mass redistribution inside the Earth. Besides gravity change, the geoid rises together with the Earth' surface. The Argentina geoidal chart - computed using the Stoke´s integral algorithm- as well as several geopotential models (JGM-3, OSU-91A, EGM-96) show geoid undulations which softly remains the topography reaching almost 50 meters beneath the Central Andes. A geophysical interpretation of this geoidal undulations is presented here. It will be shown that geoidal heights may be only partially justified at crustal levels.

ON COSMOLOGICAL ORIGIN OF CERTAIN GEODETIC FEATURES OF THE EARTH

A.O. ADEKUGBE-JOSEPH (Center for Fundamental Study, P.O.Box 22415 University of Ibadan P.O., Ibadan, Oyo State, Nigeria, email: nigeria@netbox.com)

The angle 66.5 degrees of inclination to the ecliptic of earth's rotational axis (rotational slanting of the earth), has been predicted accurately, and the ratio of polar diameter to equatorial diameter,(polar flattening of the earth), of 0.997 has been recalculated exactly, within a new cosmological model.
An instantaneous rate of increase of earth's radius of 0.108cm/yr, as well as instantaneous relative drift rate of 0.108y cm/yr. of two points with longitudinal separation of y degrees along the equator, have been calculated as consequences of the expansion of the earth with the universe in the new model. A remarkable agreement of the predicted rate of increase of earth's radius of 0.108cm/yr, earth's rotational slanting of 66.5 degrees and earth's polar flattening of 0.997 is shown.
The slight westward deflection in the north and eastward deflection in the south of continental plates have also been explained as local consequence of the new cosmological model. These numbers as well as the westward deflection in the north and eastward deflection in the south of continental plates are increasing, but discernible changes occur in time scales of between 10 million and billion years only.

DEGREE-ONE ELASTIC DEFORMATION OF THE EARTH

GREFF-LEFFTZ Marianne (Institut de Physique du Globe de Paris, 4 place Jussieu, 75005 Paris, France) Legros Hilaire (E.O.S.T., 5 rue R. Descartes, 67084 Strasbourg, France)

The degree one deformations of the Earth, in a reference frame related to the centre of mass of the planet, are computed using a theoretical approach (Love numbers formalism) at short time-scale, where the Earth has an elastic behavior. The translations at each interface of the incompressible layers of the Earth's model (especially at the surface, at the Core-Mantle boundary (CMB) and at the Inner Core boundary (ICB)) are computed when the excitation source is the atmospheric pressure or a magnetic pressure acting at the CMB and at the ICB. The effects of external and internal tangential tractions are also investigated. The total force, resulting from the excitation sources, in a geographic frame (centred at the centre of mass) has to be equal to zero,in order to conserve the centre of mass of the Earth. This involves a relation between the different forcing mechanisms; we obtain a Consistency Relation, i.e., a special condition that the degree-one valid solutions have to obey (Farrell, 1972). As geophysical application, we have computed the degree-one deformation induced by atmospheric loading. To conclude, we note that in using the degree one Love numbers, it is necessary to be carefully about the definition of the Love numbers and the chosen reference frame, especially its origin, that is whether it is related to the mass centre of the deformed Earth or theundeformed Earth and whether it is related to the centre of figure or the surface of the planet (for geodetic measurements, the stations are located at the Earth's surface).

OCEAN LOADING TIDES IN GPS AND RAPID VARIATIONS OF THE FRAME ORIGIN

H-G. SCHERNECK, J.M. Johansson (both at Chalmers, Onsala Space Observatory, SE-43992 Onsala, Sweden, e-mail: hgs@oso.chalmers.se); F.H. Webb (Jet Propulsion Laboratory, Pasadena, CA 91190, e-mail fhw@dunsinane.jpl.nasa.gov)

Increasing precision and long record lengths from observations of GPS satellites in precise point-positioning mode make possible the retrieval of sub-mm oscillations in the three spatial components. We determine co-tidal oscillations at a number of stations operating for the IGS. Due to limitations in the orbit ephemerides and the daily processing scheme we are at present able to only retrieve tides due to principal lunar terms. Using extremely continental stations like Irkoutsk (Siberia), we can clearly demonstrate that geocentre tides (movements of the centre of the solid earth counterbalancing the mass centre of the ocean tide) are not contained in the range between the satellite and the station, most probably because they were not included in the generation of the orbit data. We conclude that the physical geocentre is only weakly constraining the translation components of the orbit alternatively the frame origin, and that models for geocentre tides are not needed at present. We end by suggesting to SLR groups to attempt a similar project in order to resolve whether this technique has a higher sensitivity.

ABOUT TIDAL ANGULAR MOMENTUM BUDGET OF THE OCEAN

DE VIRON O, Dehant V, Van Hoolst T,

The effect of the ocean on the Earth's rotation in the diurnal time scale is mostly related with the oceanic tides. This effect can be computed by using the angular momentum budget equation of the ocean-Earth system: the tidal angular momentum change of the ocean is equal to the angular momentum change of the Earth related to the tidal forcing. This effect can also be evaluated by computing the interaction torque between the Earth and the ocean. The two methods, as presently developed, give quite different results due to a non-equivalence that can be shown analytically. This problem will be investigated.

GEODYNAMICS FROM MEAN ORBITAL MOTION OF GEODETIC SATELLITES: LAGEOS, LAGEOS-2, AND STARLETTE

Pierre EXERTIER, S. Bruinsma, G. Métris, Y. Boudon and F. Barlier, (Observatoire de la Côte d'Azur - CERGA - GRGS, avenue Copernic, F-06130 Grasse, France)

The secular and long periodic perturbing forces acting on the orbit of an artificial satellite have been modelled and included in a semi-analytical theory of the mean orbital motion. Gravitational and non-gravitational forces have been averaged using analytical transformations and numerical quadratures, respectively. As non-gravitational modelling is the first source of problems arising in the determination of geodynamical parameters, special attention has been given on this question. Resulting averaged equations of motion are integrated numerically allowing to exhibit long periodic signals in the classical mean orbital elements. Observed mean orbital elements of Lageos (18 years), Lageos-2 (6 years) and Starlette (14 years) have been carefully computed from Satellite Laser Ranging (SLR) measurements which have been first reduced by classical orbit fits on short arcs. The results of our long arc solutions using the three orbits exhibit geodynamical coefficients at different frequencies ranging from seasonal (6 months, 1 year) effects to long period and secular ones. Values of coefficients are compared to geophysical processes like atmosphere mass redistribution, ocean and solid tides, anelasticity and post-glacial rebond. Finally, inputs are proposed in order to homogenize satellite orbit contributions which actually use different processes and units and provide geodynamical parameters that are not directly comparable.

LOW DEGREE GRAVITATIONAL CHANGES FROM EARTH ROTATIONAL VARIATIONS

J.L CHEN, C.R.Wilson, B.D. Tapley, and R.J Eanes, (Center for Space Research, University of Texas at Austin, Dept of Geological Sciences, University of Texas at NASA Headquaters, Washington D.C Email: chen@csr.utexas.edu)

We estimate the 2 degree gravitational variations (C21, S21, C20) using Earth rotational changes, caused mass redistribution and movement within the Earth system. These rotation changes are accurately measured by space geodetic techniques. Wind and oceanic current effects are removed from the earth rotation series using atmospheric and oceanic circulation data-assimilating models. The results are compared with Lageos satellite laser ranging (SLR) determinations, and also with geophysical contributions estimated from the atmospheric surface pressure, continental water storage, and non-steric sea level change. Our conjecture is that using Earth rotational changes to infer long wavelength gravitational variations has the potential to be more accurate than satellite-based techniques in some case. Consistent with this we find that C21 and S21 variations from this study are in better agreement with geophysical observations than Lageos SLR determinations of C21 and S21, especially at intraseasonal scales.. however , the earth rotation-derived estimate of C20 variation is probably less accurate than the Lageos-derived result, due to the large atmospheric wind contribution to LOD variation which must be removed , and the natural sensitivity of Lageos to C20 changes, via precession of the satellite node.

OCEAN LOADING TIDES IN VLBI AND PERTURBATIONS OF EARTH ORIENTATION PARAMETERS

R. HAAS, H-G. Scherneck (both at Chalmers, Onsala Space Observatory, SE-439 92 Onsala, Sweden, e-mail: haas@oso.chalmers.se)

A greater fraction of geodetic VLBI stations are located suffiently close to the coast for being significantly affected by ocean tide loading. We show the impact of horizontal displacements particularly on the estimation of earth orientation parameters in sparse global networks. We can show that local problems like differences between models of the tides in the Gulf of Maine

cause effects exceeding 0.2 mas in for instance the CORE project devised for monitoring earth rotation during the coming years. In order to test and improve existing ocean tide loading models we use the VLBI network to estimate amplitude and phase parameters of loading tides for a variety of stations and tide constitutents in the diurnal and semidiurnal bands for both vertical and horizontal displacement components. The estimation succeeds with typical standard deviations of 0.2 to 0.5 mm.

MODULATION OF WAVES OF ATMOSPHERE TIDES

Tadeusz CHOJNICKI (Space Research Centre, Polish Academy of Sciences, Bartycka 18A, 00-716 Warsaw, Poland, email: tch@cbk.waw.pl)

Seasonal modulation of Earth tide waves has now been investigated for several years, however, the origin of this modulation is unclear. Much indirect evidence points to Earth atmosphere as the source generating modulation of Earth tide waves. Therefore our Warsaw research group undertook a study of atmosphere tides, based on previous 10-year air pressure observations conducted at over a dozen of stations throughout Poland s territory. In this work we present the results concerning one aspect of the observations, namely the seasonal modulation of waves of atmosphere tides. The methods used were similar with those used previously for calculation of the seasonal modulation of Earth tides: for analysis the observations were collected in groups embracing the same months from different years. The results for greater waves are given, and conclusions and suggestions are made concerning the relationship between modulation of Earth tides and the Earth atmosphere.

ATMOSPHERIC TIDES AND THEY DISTRIBUTION IN THE AREA OF POLAND

Janusz BOGUSZ (Institute of Geodesy and Geodetic Astronomy, Warsaw University of Technology, 00-661 Warszawa, POLAND, e-mail: jb@gik.pw.edu.pl)

Growing accuracy of tidal measurements (actually below 0.1 ?Gal) makes us to consider many of environmental parameters which affect these observations. The biggest of them is the ocean indirect effect, nowadays very well known and many times presented. This papers deals with the distribution of the tides of the atmosphere in time and space and their influence to the gravimetric tidal measurements. The ocean tides, observed by rise and fall of the water twice a day on most open ocean coast have been known from time immemorial. Obviously atmospheric tides cannot be measured in this way, as atmosphere does not have such a boundary layer. We assumed that the changes showed by barometer indication system are accompanied by daily changes of mass distribution of the air. So the analysis was done upon 10-years of observations of the pressure changes on several Polish stations of the Institute of Meteorology and Water Management. Paper presents the results of such computing: dimension of the tidal parameters (amplitude and phase shift) for particular tidal components, investigation of seasonal properties of considered phenomenon and distribution of the atmospheric tides in the area of Poland. Additionally the size of atmospheric indirect effect is exhibits.

DIURNAL AND SEMIDIURNAL LOAD GREEN FUNCTIONS TO A POINT LOAD

Shuhei OKUBO, Daijiro Tsuji, and Masato Furuya (Earthquake Research Institute, University of Tokyo, Yayoi 1-1-1, Bunkyo-ku, Tokyo 113-0032, Japan, email: okubo@eri.u-tokyo.ac.jp)

Load Green functions (gravity/tilt/strain etc) were first presented by Farrell (1972) assuming quasi-static response of the earth. They are now routinely used to correct for the effects of oceanic loading on continuous measurements of gravity, tilt, strains and so on.
Recalling that the oceanic loading has specific periods and that the load Love numbers are dependent on the loading frequency, the Green functions themselves must have frequency dependence. We will present representative Green function for diurnal and semidiurnal frequency for the PREM earth model. We also include the effect of anelasticity when computing the Green functions. These functions will serve for the better correction of oceanic tide against the earth tide registration.

THE ELASTIC CHARACTERISTIC PARAMETER OF EARTH TIDE AND ITS ABNORMAL VARIATION

Yanbin ZHANG, Jun Jiang, and Shengle Li (Institute of Seismology, China Seismological Bureau, Wuhan, 430071, China)

According to the definition of Love number in tidal theory, Love Number can be used to describe the earth's deformation and it is also a parameter indicated the elasticity. The change of Love Number will be caused by an elastic variation of the earth medium. In this paper, Love Number that is a tidal parameter is regarded as a characteristic parameter in the kinds of tidal precursory observation. Based on tidal theory, we discuss the uniform and synthetic method for tidal data processing and Love Number inversion using actual tidal data included tidal linear strain, plane strain, volumetric strain, tilt, gravity and water level, etc.. The anomalous evolution of Love Number is studied by the physical and deformational properties of Love Number.
This paper intends to analyze synthetically a physical property of the crust using tidal observations. We regarded Love Number that can describe both micro deformation and elasticity of the crust in tidal observation as a physical and mechanical parameter. Research a seismic mechanical process and its precursory abnormality of a region based on the variation of Love Number. In this paper, a feasible way and method to synthetically calculate the second-step Love Number on the earth's surface is discussed and determined by tidal theory. Love Number h2 in the boundary region of Sichuan and Yunnan province is practically calculated using tidal observations, and the precursory anomalous variation of Lijiang earthquake (Ms=7.0, Feb. 9, 1996) is analyzed. The result shows that large-scale Love Number anomaly in the Sichuan-Yunnan region began from 1994. The anomaly moves from south to southeast, north and northwest in the region, and the epicenter is an anomalous empty. Finally, the anomalous area was concentrated to Lijiang and Yongsheng located northwestern Sichuan-Yunnan region on December 1995, and the epicenter area in future is drawn out clearly.

EFFECT OF ROTATION AND ELLIPTICITY ON EARTH TIDES AND FORCED NUTATIONS

Vladimir GORBUNOV (Vavilov State Optical Institute, Birzhevaya 12,St.-Petersburg, 199034, Russia, E-mail: gorbunov@neva.spb.ru); Polina Serebryanaya (SPbF IZMIRAN, Muchnoi per.2, St.Petersburg, 191023, Russia, Email: gorbunov@neva.spb.ru)

We present the results of numerical computations of the frequencies of normal modes, body tides and forced nutations of rotating, elliptical and oceanless earth model. Our numerical procedure is direct integration of linearized equations of motion by using expansions in vector spherical harmonics. This approach that has been already used by numerous authors (M.Smith, J.Wahr, V.Dehant,...) allows a simultaneous computation of the Earth's deformational and rotational tidal response which systematically includes the effects of rotation and elliptical material stratification. The motivation for the present work is the hope that more accurate implementation of this method can remove some discrepancies in modelling earth tides, nutations and near diurnal free wobble. The scheme we use to convert vector equations with boundary conditions into an equivalent set of ordinary differential equations over radius is considerably modified. Among other things it does not require the ellipticity to be small.
Rotation and ellipticity can be modeled either together or separately. It is interesting to note the existence of nutational normal mode with a period slightly larger than 1 day duration in the case of rotating but spherically symmetric Earth. This mode involves the rotation of the solid inner core with respect to the outer core and mantle and it is caused by coupling between them due to only elastogravitational deformation. We have found that the spectrum of internal oscillations in a stably stratified fluid core (modified PREM) radically contrasts with that of core without rotation. Eigenperiods of core low-degree modes with increasing undertone
numbers accumulate towards a limiting value. Work on numerical solutions
for the forced motion is currently underway.

FREE OSCILLATION OF THE EARTH'S INNER CORE IN THE EARTH'S NONEQUILIBRIUM COVER FIELD

Sergey Pasynok, Sternberg Astronomical Institute, Moscow State University, Universitetskii prospect 13, 119899, Moscow, Russia. Email: pasynok@sai.msu.su

This paper has paid special attention to nonequilibrium Earth cover influence on the free oscilation of the Earth's inner core. Oscilations are considered in any direction which may be not polar. The additional mass tensor for this task was obtained. Earth's nonequilibrium cover field corrections in the periods are proportional to Earth's rotation corrections. Periods have spliting at the nonequilibrium Earth's cover field and it (and it's amplitudes) are very like as spliting periods which were obtained by D.E.Smylie[14]. Therefore new Smylie's spliting periods interpretation as the spliting periods in the nonequilibrium Earth's cover field is proposed.

ROTATION OF THE EARTH'S INNER CORE IN THE EARTH'S NONEQUILIBRIUM COVER FIELD

Sergey Pasynok, Sternberg Astronomical Institute, Moscow State University, Universitetskii prospect 13, 119899, Moscow, Russia. Email: pasynok@sai.msu.su

This paper has paid special attention to non-equilibrium Earth cover influence on the Earth's inner core rotation. Part of the mutual gravitational potential function of the Earth's non-equilibrium cover and Earth's inner cover which depends on Earth's inner core Euler angles have been obtained. The Earth's inner core rotation parameters were calculated for Earth's external core absence case. It was showed that non-equilibrium Earth's cover field could be dissymetrical velocity field source. It is important result for geomagnetic field generation problems. It was shown that non-equilibrium Earth's field has to take in to account rotation theories, which include ellipticity as the first power. One can use this potential function which was obtained in this paper.

LUNAR INTERIOR AND FREE CORE NUTATION OF THE MOON

Natasha PETROVA, Alexander Gusev, Viktor Bashkov (Dpt. of Astronomy and GRG, Kazan University, Kremljevskaja Str., 18, Kazan, 420008, Russia, E-mail: petrova@astro.ksu.ras.ru)

The interdisciplinary approach to lunar investigations: traditional astronomical observations, laser and seismic ranging, spacecraft experiments (Apollo 1969, Galileo 1989-1991, Clementine 1994, Lunar Prospector 1997) - gives an essential progress in our knowledge about deep lunar interior. Many modern observational data, such as the noticeable free librations in the presence of great dissipation, involve the appropriate consideration of active lunar internal stratigraphy, including elliptical liquid core (of 220 to 500~km) and rigid or viscose mantle. Certain discovery of free lunar librations and large rotational dissipation from LLR analyses propose the existence of a small lunar core. The instable thermodynamical processes at lunar CMB, arising under differential core-mantle rotation, lead to lower dissipation factor $Q=26.5$ of the Moon. The presence of fluid core with a turbulent or convective layer at CMB appears to be the plausible source not only for great dissipations, but also for exciting and supporting of free librations. The dissipative energy at CMB, converted in heat, creates instable thermal layer leading of the upwelling mantle plumes. Top of the plumes in early Moon were conserved in form of mascons in the lunar continental crust (up to 100~km). Then the specific surface characteristics should be observed. These are such phenomena as the pluto-like bodies ("mascons"), as specific fluctuations of thermal, gravitational fields, as the Moho uplifts and as topographic features --- such as the plume at the thick Russian plate of the Earth is manifestated itself. The plume trace on the surface should be manifested in the form of "warm spot" and of arched lineament chain, if the crust moved through the top of plume. In the frame of the two-layer model of the Moon (rigid mantle and elliptical liquid core) Chandler mode with period $P_{CW}=74.06~yr$ and Free Core Nutation $P_{FCN}=6.782~yr$ are calculated. It is calculated that prograde super-rotation of lunar core relative the mantle is roughly to $2.4^{o}/yr$.

VARIATION OF THE EARTH ROTATION DERIVED FROM TIMED OBSERVATIONS OF ECLIPSES IN ANCIENT CHINA

HAN Yan-Ben (Beijing Astronomical Observatory, Chinese Academy of Sciences, Beijing 100012, P.R. China, email: hyb@class1.bao.ac.cn); Zhang Pei-yu (Purple Mountain Astronomical Observatory, Chinese Academy of Sciences, Nanjing 210008, P.R. China)

Some ancient observations, such as the observations and records of solar and lunar eclipses in ancient times, are useful to the study of secular variation of the Earth's rotation in recent about 30 centuries. The relationship between the variation of the rotation and ancient observations is set up through the use of different time scale. In China, the history of observations and records of ancient solar and lunar eclipses is very long and the rich observations are preserved in ancient books. The authors made the textual research again for Chinese ancient timed observations of over 80 solar and lunar eclipses are analyzed in the

study. A ΔT series, which can describe the secular variation of the Earth's rotation, is derived from the ancient observations of the eclipses. The variation of the length of the day is about 1.5 millisecond per century according to the result.

POSSIBLE CONTRIBUTION OF JAPANESE TIMED RECORDS OF SYZYGY IN HISTORY FOR STUDY OF THE EARTH'S ROTATION VARIATION

HAN Yan-Ben (Beijing Astronomical Observatory, Chinese Academy of Sciences, Beijing 100012, P.R. China, email: hyb@class1.bao.ac.cn)

Records of observed time of some ancient astronomical phenomena in local time scale, such as the local apparent solar time of eclipses and syzygy, can be used in the study of the variation of the Earth's rotation. There are some records of syzygy in Japan in the period of 19th-20th century. In this paper, the observations of syzygy and the possibility that the data are used in the study is investigated. The initial result showed that the observations will be significant for the study of the variation of the Earth's rotation in the period.

LENGTH OF DAYLIGHT

Tarzadin ULAANBAATAR (Department of Earth Sciences, National University of Mongolia, email: numelect@magicnet.mn)

For the study of time-dependent phenomena a best way of controlling opportunities of motions in the Earth's system is that mathematical understanding of the nature of length of daylight by daily and yearly motions of the Earth themselves. Otherwise, to describe more realistic and detailed simulations of the length of daylight we must not drived to the astronomical calculations, but it needs only for comparison.
Length of day is a whole hierarchy of complexity. However, if we can know it by step to step this hierarchy will clear in front of us, i. e. after final calculations the remains or biases between the model result and observation of the length of daylight indicate the irregular time change connecting the impacts of external objects and Earth's interior or man-made. Without this manner we can not select the self-supporting and impacting phenomena on the length of day, as well as study of time-dependent phenomena is very difficult.
In this matter the equation of length of daylight model including three simple parameters: number of day from winter solstice, measuring time in hour, minute, second, and geographical latitude as well model results, daily and yearly changes of sun's altitude, times of sunrise and sunset, directions of sun's location in space are described.
Utilization of the model in space-time study of time-dependent phenomena, and climate is presented.

ESTIMATION OF REAL ACCURACY OF EOP PREDICTION

Zinovy MALKIN (Institute of Applied Astronomy RAS, nab. Kutuzova 10,St.Petersburg 191187, Russia, e-mail: malkin@quasar.ipa.nw.ru)

Many authors propose various methods for improvement accuracy of prediction of EOP. For comparison of various methods they compute rms residuals between predicted and observed values of EOP using preceded several years IERS series. However, such estimation of accuracy of prediction doesn't reflect real errors of predicted values of EOP because they depend not only on method used for prediction but also on initial EOP series used as fiducial for the computation of predicted values.
Real EOP prediction needed for practice have being made using operative EOP values with accuracy worse than accuracy of final EOP series that usually used for test investigations of accuracy of prediction. To estimate real accuracy of prediction by various methods used in practice of EOP services special tests have been performed.
The first test is intended to estimate real accuracy of EOP prediction on preliminary testing stage. For this purpose fiducial EOP series used for computation of prediction and further comparison of predicted and observed EOP values was artificially disturbed in such a way that it could imitate real errors of operative EOP as compared with final ones. Results of this test show that error of predicted value may be several time large than inputted error for some methods of prediction.
For estimation of real accuracy of prediction all predictions made by IERS Subbureau for Rapid Service and Prediction and in the IAA EOP Service beginning from March 1998 were analyzed. Results show that errors of prediction are practically the same for both centers but differ substantially from published values.
Supplement criteria was used for estimation accuracy of prediction. Usually rms residuals used as only criteria. However it seems interesting to know also maximum error of prediction to allow user to have "guaranteed" accuracy which may be useful for practical needs. So, these maximum errors was obtained for predictions computed in the IERS and IAA and was found that they are about 2-3 times large than rms errors.

REPORT OF THE WG ON NON-RIGID EARTH NUTATION THEORY DEHANT V. ET AL., (ROYAL OBSERVATORY OF BELGIUM, BRUXELLES)

The WG on 'Non-rigid Earth nutation theory' has been created 6 years ago and is at the end of its term. We present here the report of the activities of this WG. These activities are mainly meetings and email exchanges with discussions over particular points of interest for nutations of a non-rigid Earth. We have worked on 6 levels: (1) seismic models used, (2) Earth's transfer function, (3) nutations for a rigid Earth, (4) convolution between the Earth's transfer function and the nutations for a rigid Earth, (5) atmospheric and oceanic effects on nutations, (6) comparison of the theoretical nutations with the observations.

FUNDAMENTAL CONSTANTS

REPORT OF SC 3 ON FUNDAMENTAL CONSTANTS

Erwin Groten (IPG, Darmstadt Institute of Technology, Darmstadt D-64287, Germany, email: groten@ipgs.ipg.verm.tu- darmstadt.de)

The report summarises the activities of Special Commission 3 during the interval 1995-1999. Current best values as well as official values of Fundamental Constants are reviewed and considered in detail. Research on the related topics is reflected for the interval 1995 to 1999. The values were reconciled with those which are to be published in the forthcoming IERS conventions 1999. Changes of related parameters with time are also taken into account. The results represent those values which found general agreement of members of Special Commissions 3 and the international scientific community.

REFRACTIVE INDICES OF LIGHT, INFRARED AND RADIO WAVES IN THE ATMOSPHERE

JEAN M. RüEGER (School of Geomatic Engineering, University of New South Wales, Sydney NSW 2052, Australia, email: J.Rueger@unsw.edu.au); Philip E. Ciddor (National Measurement Laboratory, CSIRO, P.O. Box 218, Lindfield NSW 2070, Australia, e-mail: pec@dap.csiro.au); Michael G. Cotton (Institute of Telecommunication Sciences, NTIA/ITS.S3, 325 Broadway, Boulder CO 80303, USA, e-mail: mcotton&ntia.its.bldrdoc.gov); Yuri S. Galkin, Ecological Laboratory, Dept of Physics, Moscow State University of Forestry MGUL, Mytischy-1, Moscow Region 141001, Russia, e-mail: galkin@mgul.ac.ru); Reginald J. Hill (R/E/ET6, NOAA, US Department of Commerce, 325 Broadway, Boulder Colorado 80303, USA, e-mail: rhill@etl.noaa.gov); Hirokazu Matsumoto, Quantum Metrology Division, National Research Laboratory of Metrology (NRLM), 1-4, Umezono I-Chome, Tsukuba Ibaraki 305, Japan, e-mail: hiro&nrlm.go.jp); Ruben A. Tatevian, Dept of Metrology and Standardisation, General Research Institute of Geodesy, Air-Survey and Cartography, Onezskaya 26, Moscow 125413, Russia)

This ad-hoc working group of the IAG Special Commission (SC3) has carefully reviewed the progress in the measurement and modelling of the refractive index of air. For light and near infrared waves, a closed simple formula is proposed for electronic distance measurement (EDM) to 1 ppm precision or worse. For EDM of higher precision, a computer routine is proposed that uses the full Lorentz-Lorenz relationship, the new temperature scale of 1990, the BIPM density equations and the recently revised water vapour refractivity. The group notes that the perceived accuracy of any continuum formula is invalidated by anomalous refractivity near absorption lines. Further work on the effect of absorption lines on the phase and group refractive indices of air is strongly recommended as are new absolute measurements of the refractivity of the constituent gases of the atmosphere (incl. water vapour) at non-laboratory conditions.

GEODYNAMICS OF S.E. ASIA: RESULTS OF THE SULAWESI 1998 GPS CAMPAIGN

W.J.F. SIMONS, D. van Loon, B.A.C. Ambrosius (DEOS, TU Delft, The Netherlands); J. Kahar, H.Z. Abidin, D.A. Sarsito (ITB, Bandung, Indonesia); S. Haji Abu (DSMM, Kuala Lumpur, Malaysia); P. Morgan (University of Canberra, Australia)

In November 1998, concurrently with the third GPS campaign of the international GEODYSSEA (GEODYnamics of South and South-East Asia) project, a dense geodetic network in Sulawesi, Indonesia was re-measured with GPS. The network is situated in a tectonic complex region near the triple junction of the Eurasian, the Philippine and the Indo-Australian tectonic plates. The GPS campaign included second and third repeat measurements for densification sites of the GEODYSSEA network in this region, and also a re-measurement of a Palu-Koro fault transect in Sulawesi. The acquired data, together with data from IGS stations in the same region, have been processed at DEOS, using the JPL GIPSY-II software, while the DEOS 3D-Motion software was used for the network deformation analysis. The station coordinates were analyzed together with those of the previous Sulawesi campaigns and the GEODYSSEA campaigns of 1994 and 1996. Our kinematic model for the present motions was further validated and improved, and contains both steady state velocity and non-linear displacements. The tectonic block and fault motions are compared with previous results and are geophysically interpreted, and provide detailed new information for this region.

BACKARC SPREADING OF THE MARIANA TROUGH AS OBSERVED BY GPS OBSERVATIONS

T. KATO, S. Nakao, Y. Kotake, H. Takiguchi (Earthquake Research Institute, University of Tokyo, 1-1 Yayoi 1, Bunkyo-ku, Tokyo 113-0032, Japan, email: teru@eri.u-tokyo.ac.jp); A. Kurashima (Faculty of Science, Ibaraki University, 2-1-1 Bunkyo-cho, Mito, Ibaraki 310-0056, Japan); T. Matsushima (Shimabara Earthquake and Volcano Observatory, Kyushu University, 2-5643-29, Shinzan, Shimabara, Nagasaki 855-0843, Japan); J. Beavan (Institute of Geological and Nuclear Sciences, P O Box30-368, Lower Hutt, New Zealand); J. T. Camacho (Emergency Management Office, Saipan, CNMI)

The Mariana trough is one of rapidly spreading backarcs in the world. The magnetic lineation data at spreading center suggests about 30mm/yr spreading in the recent geological age. In order to estimate its instantaneous spreading rates, we have conducted GPS observations in the Northern Mariana Islands. The first observation was done in 1992 and 1994. Succeeding to these first occupations, the second observation was conducted in January to February 1998. The sites that we reoccupied are Guam (AAFB), Saipan(MPLC and SPNA), Anatahan, Guguan, Pagan, and Agrihan islands from south to north. We used 1994 and 1998 data to estimate backarc spreading rates, except Agrihan where no observation data was available in 1994. For baseline analysis, first, we estimated the motion of the Philippine Sea plate relative to Eurasia based on otherwise obtained GPS data. Then the displacement of Guam(GUAM) IGS site relative to the Philippine Sea plate was estimated. The results suggest of about 57.8mm/yr eastward motion relative to the Philippine Sea plate. Then, the rates of displacements of the Northern Mariana Islands; Saipan, Anatahan, Guguan, Pagan; were estimated assuming that AAFB site has the same velocity as GUAM IGS site. The results show that the displacement rates are, from south to north, 46.5mm/yr in Saipan, 40.5mm/yr in Anatahan, 28.9mm/yr in Guguan, and 27.7mm/yr in Pagan. The average of five islands is 40.3mm/yr, which is more than 30% larger than the geological rates from magnetic lineation data. This might suggest that the spreading has accelerated in the recent years, or, the spreading rate is not uniform between the Mariana trench and the Mariana trough. Moreover, the rate is decreasing from south to north and the direction of motion is not uniform but has component of north-south spreading. The Euler pole of the Mariana block is located nearly the northern end of the block. The third observations that will be done in February 1999 may provide us with more accurate results as well as new results in Agrihan.

This paper describes and reviews the progress of a European Commission FP4 (Climate and Natural Hazards) funded project entitled GPS Seismic Hazard in Greece (SING), in which a major international interdisciplinary consortium is investigating and comparing strain derived using both geodetic and seismic methods. The specific objectives of SING are to assess strain accumulation throughout Greece, to identify areas of high seismic hazard, to develop new and more efficient operational and computational methods for GPS, and to improve our understanding of the relationships between geodetic strain, seismic catalogues and geological data. New GPS networks have been installed in regions of significant hazard and some initial computations have been carried out. To date a primary result of SING is the integration of 33 historical geodetic data sets to provide a national strain map. This gives the first full picture of geodetic strain in Greece and provides the basis for the setting up of the new geodetic networks.

THE AFRICA-EURASIA PLATE BOUNDARY

USING GPS OBSERVATIONS FOR STUDYING THE DYNAMICS OF THE AZORES-GIBRALTAR REGION

Luisa Bastos, Jose Osorio and Paulo Baptista (Astronomical Observatory, University of Porto, Portugal); Gunter Hein (IfEN, University FAF Munich, Germany); Ron Noomen (DEOS, TU Delft, The Netherlands); Rui FERNANDES (DMI, University of Beira Interior, Portugal, email: rmanuel@noe.ubi.pt)

The western part of the Eurasian/African plate boundary meet the Mid Atlantic Ridge at the Azores triple junction. Different models for the structure and behaviour of this section of that plate boundary have been proposed but a definite solution has not yet been found. We have used GPS observations, from stations located in three different plates, acquired during several campaigns realised since 1988, and combined them with data from the IGS stations, in order to obtain a velocity field for our stations in a global reference frame (ITRF96). From this velocity field, we have derived strain parameters. We compare the results obtained for the motion of our stations with the results proposed in global and regional tectonic models (based on geophysical and geological data). We show that, for the most part of the stations, the magnitude and direction of the displacements is in good agreement with some of those models. We also interpret the computed strain parameters for some of the sub-networks under analysis, in the frame of the proposed geodynamic models for those regions.

GROUND DEFORMATION MONITORING IN THE CENTRAL SECTOR OF BETIC CORDILLERA (SPAIN) FROM GEODETIC TECHNIQUES: STATUS REPORT

Antonio J. GIL, A.M. Ruiz, E. Mata, M. J. Borque, M.A. Caro (Dept. Ing. Cartografica, Geodesica y Fotogrametria, E.P.S. de Jaen, Universidad de Jaen, Virgen de la Cabeza, 2, 23071 Jaen, Spain. e-mail: ajgil@ujaen.es); Gracia Rodriguez-Caderot, M. Clara de Lacy (Dpto. Astronomia y Geodesia, Fac. C.C. Matematicas, Universidad Complutense, 28040 Madrid, Spain); Mario Ruiz (I.G.N., Divina Pastora, 7, 18012 Granada, Spain); Mattia Crespi (Universita di Roma La Sapienza, via Eudossiana 18, 00184 Roma, Italy)

The aim of this research is the application of geodetic techniques to the central sector of Betic Cordillera, the most important region in Iberian Peninsula from Active Tectonics point of view, to detect microdisplacements to be correlated with the seismicity in the area. Seismicity in this area is tied to a regional comprehensive strain in NW-SE direction along the convergence zone between African and EuroAsian plates. None the less numerous faults in all directions present normal vertical movements, which are not congruent with that compression.Ground movements related to geophysical phenomena are generally subdividied into horizontal and vertical deformations. In order to find the former in the area, a local triangulation and trilateration network measured by means of high-precision geodetic instrument has been established. With the purpose to detect vertical movements, a series of high-precision levelling profiles have been observed. A regional network observed by GPS has been measured so as to find both of them.This paper describes the status of this research project, which started in October 1998, to determine ground deformations in the central sector of Betic Cordillera.

DISPLACEMENT FIELD OF THE CENTRAL MEDITERRANEAN AREA: RESULTS AFTER EIGHT YEARS OF THE TYRGEONET PROJECT

Marco ANZIDEI, Giuseppe Casula, Federica Riguzzi (Istituto Nazionale di Geofisica, via di Vigna Murata 605, 00143 Roma, Italy, email: riguzzi@ing750.ingrm.it); Paolo Baldi (Dipartimento di Fisica, Universita` di Bologna, viale B. Pichat 8, 40100 Bologna, Italy, email: baldi@ibogfs.df.unibo.it); Alessandro Galvani, Arianna Pesci (Italian Space Agency Fellowships at Istituto Nazionale di Geofisica, via di Vigna Murata 605, 00143 Roma, Italy, email: galvani@ing750.ingrm.it); Antonio Zanutta (DISTART, Universita` di Bologna, p.le Risorgimento 2, 40100 Bologna, Italy)

The TYRGEONET (TYRrhenian GEOdetic NETwork) project started to work in 1991 with the aim to study the crustal deformations of the Italian and surrounding regions by analyzing repeated non-permanent GPS surveys. At present, we dispose of GPS data coming from six large campaigns performed in 1991, 1994, 1995, 1996, 1997 and 1998, involving each time more than 15 sites of the TYRGEONET. Each campaign lasted more than six DOYS to achieve a good redundancy of observations. GPS data processing was performed by the Bernese v. 4.0 software obtaining one network solution per DOY. All the baselines and the covariance matrices pertaining to each campaign were jointly adjusted obtaining one network solution (coordinates and error ellipsoids) per year into the ITFR96 reference system. The significance of the coordinate differences of each sites were evaluated by computing the 2D displacement vectors and the corresponding error ellipses on the local tangent plane. The displacement pattern of the analyzed area displays interesting features both for the sites whose trends were previously known and for those not yet investigated by GPS.

GEODYNAMICAL STUDY OF THE NORTH OF ALGERIA BY GPS : THE ALGERIAN GEODYNAMICAL NETWORK (ALGEONET)

S. KAHLOUCHE, S. Touam, B. Gourine, B. Ghezali, H.Taibi (Geodetic Laboratory, National Centre of Spatial Techniques, BP 13 ARZEW- 31200 - ALGERIA); H. Mouzaia, A.Khalfoun (National Institute of Cartography, BP 430 Hussein Dey, ALGIERS, ALGERIA); A. Abtout (Research Centre in Astronomy, Astrophysics and Geophysics, BP 15-16 Bouzareah, Algiers, Algeria).

The western Mediterranean, particularly the north African region, is characterised by an important geodynamical activity due essentially to the collision between the Eurasian and African plates and gave place to some earthquakes of strong intensities (El Asnam 1980).
Since 1998, the National Centre of Spatial Techniques (CNTS), with the collaboration of the National Institute of Cartography (INC) and the Research Centre in Astronomy, Astrophysics and Geophysics (CRAAG) have set up the ALGEONET (Algerian Geodynamical Network) project with the aim of a geodynamical surveillance of the Northern Algerian Country. The network, composed of eight stations selected for their situation on stable blocks with a geodynamical criteria, is located in the Tellian Atlas, the Saharian Atlas and Northern Sahara. As two stations of the network (Arzew and Algiers) are included in the TYRGEONET (Tyrrhenian Geodetic Network) project since 1995, both ALGEONET and TYRGEONET GPS observations campaigns were performed during the simultaneous period (June 1998) using the Ashtech Z-12 receivers.
The processing of the data collected during 6 days were performed with the Bernese 4.0 Software. The final solution was obtained by the adjustment of the daily GPS baselines with regard to the fixed station Arzew. In the north of Algeria, for determining the slow geodynamical movements (5mm/year), as provided by global models, observations have to be performed over a long period.

G5/E/27-A4 Poster **1230-05**

GRAVIMETRIC STUDY OF THE ALGIERS SEISMIC ZONE

A. ABTOUT, A.K. Yelles Chaouche and S. bourouis (Both at C.R.A.A.G., Algerian Research Center of Astronomy, Astrophysics and Geophysics, B.P. 63, Bouzareah, Algiers,Algeria, e-mail: geoph@cerist.ist.dz)

During the last centuries, the Algiers region (northcentral part of Algeria) has experienced several major earthquakes (02/01/1365 ; 10/03/1673 ; 03/02/1716 ; 02/01/1867, 29/01/1989 ;04/09/1996) causing huge damages to the capital and other important towns of the Mitidja basin. Until now, a little is known about the active faults which generate this strong activity. In the Algiers region, gravimetric data collected are issue from: the Lagrula's measurements, the gravimetric survey on the Algiers massif, 171 stations of the Chenoua's massif survey and the BGI data blank.
The Bouguer's anomaly map displays near the cost E-W positive anomalies which reach values of 90 mgals due to effect of the oceanic nature. Towards the south, the Bouguer anomalies decrease (5 mgal/km) and become negative with a value of -40 mgal. Data analysis display two major tectonic features: one corresponding to the Sahel anticline which has previously triggered several major earthquakes. The second tectonic feature with an orientation NNW-SSW crosccut the Mitidja basin in two parts. This later major fault was never revealed by geological investigations. Orientation of the faults agree with the compression NNW-SSE stress regime which characterizes the northern region of Algeria.

MONITORING RECENT CRUSTAL MOVEMENTS IN SINAI, GULF OF AQABA AND GULF OF SUEZ, EGYPT

S.MAHMOUD, H.Khalil and T.Kebeasy (National Research Institute of Astronomy and Geophysics, Helwan, Cairo, Egypt, email: salahmm@frcu.eun.eg); H.Koivula, (Finnish Geodetic Institute, Masala, Finland)

Recent seismic activity has been observed in regions of Sinai, Gulf of Aqaba and Gulf of Suez. For Monitoring the recent crustal movements in Sinai and around the Gulf of Suez a regional GPS network consists of 11 geodetic points was established early 1994.
The initial geodetic measurements were performed in 1994 and repeated in 1995, 1996, 1997 and 1998 using Trimble 4000 SSE/SSI receivers. A Co-Seismic displacements of 16 cm was determined 20 km southwest the epicenter of the 22, November 1995 earthquake in the Aqaba Gulf using GPS observation. This study is initiated for more better understanding of the seismotectonics in and around these regions. The analysis of these measurements together with the frequency and intensity of seismic activity may leads for more understanding the earthquake activities and geodynamics of these regions.

GPS MEASUREMENTS AROUND NASSER LAKE FOR MONITORING CRUSTAL DEFORMATION, ASWAN, EGYPT.

A.Tealeb, K. SAKR, H.Khalil, S..Mahmoud, A.S.Mohamed.(National Research Institute of Astronomy and Geophysics,Helwan,Cairo,Egypt. e-mail: kamalmos@frcu.eun.eg)

A program for monitoring recent crustal movements has been started as far as early 1983 after the occurrence of an earthquake in 1981 with magnitude 5.6. This earthquake occurred 70 km south of the Aswan High Dam which consider the main project in Egypt. The epicenter of the earthquake located on the active zone of Kalabsha fault. Local geodetic networks were established to cover the area of active faults at northwestern part of Nasser Lake. For monitoring regional crustal movements for Nasser Lake area, GPS network from 11 stations was established around the northern part of the Lake in 1997 with baseline lengths from 12 to 87 km.. This network was measured three times with Trimble Receivers 4000SSE and 4000SSI. Analysis of GPS data shows that, the range of displacement of geodetic points for horizontal component between o.o3 - 15mm.

SEISMIC HAZARD ASSESSMENT IN THE MARMARA SEA REGION

Namk Yaln, Semih ERGINTAV, Mustafa Aktar (T_B TAK, MRC, ESRI, Istanbul, Turkey, email: Semih@Mam.Gov.Tr); Emin Ayhan, Onur Lenk (General Command Of Mapping, Ankara,

Turkey); Aykut Barka, Haluk Eyido (Istanbul Technical University, Istanbul, Turkey); Cemil Gorbuz, Onur Gorkan (Bo Azi‡I University, Koeri, Istanbul, Turkey); Robert Reilinger, Nafi Toksoz (Massachusetts Institute Of Technology, Erl, USA)

The Marmara Sea region which accommodates 30% of Turkey's population, including the Istanbul area, and 40% of all national industrial activity is bisected by three major strands of the North Anatolian Fault (NAF). During the historical period, the North Anatolian Fault Zone (NAFZ) has been responsible for creating number of large earthquakes. Recent GPS studies indicate that ~20 mm/yr slip is accommodated by the NAF system in this region which is significantly higher than the rates obtained from the previous geological and seismological studies. For this reason, a multidisciplinary project has been initiated with contributions from different organizations and universities. The main goal of the project is to monitor strain accumulation and release along the strands of the NAF in the Marmara Sea region. To achieve this goal, 10 continuous GPS stations have been installed around the Marmara Sea. Using the GAMIT/GLOBK software and precise IGS orbits, we automatically process the daily observations from this continuous network and publishing the results immediately on the World Wide Web. Periodically, a denser network of approximately 40 GPS sites is occupied by mobile GPS receivers. This combined continuous and survey style GPS study provides the dense temporal and spatial resolution necessary for estimating interseismic strain accumulation, coseismic slip and postseismic relaxation. Additional studies (e.g. detailed mapping of active faults, monitoring earthquakes with denser seismic network and detailed bathymetric survey), have also been undertaken. We will present an overview of the project and discuss the preliminary results.

MONITORING OF THE FAULT ZONE BETWEEN THE AFRICAN AND THE EURASIAN PLATE (PERIADRIATIC LINEAMENT) IN THE SOUTHERN REGION OF AUSTRIA

Norbert HOEGGERL, Diethard Ruess (both at Federal Office of Metrology and Surveying, Schiffamtsgasse 1-3, A-1025 Wien, Austria, email: diethard.ruess@univie.ac.at)

The Periadriatic lineament from the Seisa Zone (Italy) to the Pannonic Lowland (Hungary) is one part of the collision zone between the African tectonic plate and the Eurasian tectonic plate. The activity of this lineament is documented by different earthquakes during the last centuries (Villach/Austria 1348, Friaul/Italy 1976, Bovec/Slovenia 1998, a.o.). To monitor possible displacements of the earth's surface along the Peradriatic lineament, different control networks were established in this part of southern Austria: control points measured by GPS-technology were tied to a network of different levelling lines. These different networks contain control points situated north and south of the fault zone. The control points are spread over an area of about 20x50km. In addition to the geodetic control network, 4 absolute gravity points were established. The local stability of these absolute gravity points will be monitored by micro-gravimetric measurements and precise levellings. The combination of the geodetic and the gravimetric networks offers the possibility to investigate and jointly interpret changes of the earth's surface and of the earth's interior. Results derived from the comparison of repeated levelling measurements (periods 1952, 1964, 1976,1987 and 1997) across the Periadriatic lineament show significant height changes. The correlation of these height changes with the earthquakes 1976 and 1998 will be presented.

ON THE RECENT VERTICAL CRUSTAL MOTIONS IN UZBEKISTAN

A.R.YARMUKHAMEDOV, D.A.Tashkhojaev, L.P.Yun (Institute of Seismology, Khurshid str.3, 700128 Tashkent, Uzbekistan, email: root@seismo.tashkent.su)

A new map of the recent vertical motions (RVCM) of the territory of Uzbekistan (scale-1:2500000) was constructed in 1997 on the basis of new geodetic data (to 1994 inclusive). Analysis of this map and large-scale map of some test-grounds and cities shows that RVCM include platform and orogenous areas of Uzdekistan. Adout 70% of the territory of Uzdekistan are involved in the rise. Distinct geostructural differentiation of RVCM is outlined in some structures. The most part of the geological structures in the platform areas is involved in the rise and intensity of their vertical motions increases from east to west and north-west. Intensive ascending motions (from 6 to 10 mm/year) include both the positive and negative (under 6 mm/year) geostructures. Tectonic activity is typical for the structures adjacent to the Aral Sea (10-14 mm/year). The connection between RVCM and seismicity indicates the sign-alternating motion of tectonic nature. One of the main features of RVCM is their differentiation caused by engagement of the border parts of the blocks. Destruction of the engagement zones leads to the stress drop in some regions but does not change the regional motions. It follows from the above stated that slow and quick (seismic) motions are intercommunicated manifestation of the continuous processes of stress accumulation and discharging in the earth's crust. Three main directions for the zones of the high-gradient motion change are outlined. Intersections of the zones are connected with earthquake sources, cracked zones and engineering-geological processes.

THE GEOPHYSICAL AND GEOLOGO-GEODETIC STUDIES OF THE RECENT CRUSTAL MOTIONS ON THE TAVAKSAI TEST-GROUNDS IN UZBEKISTAN

K.N.ABDULLABEKOV, A.R.Yarmukhamedov, S.Kh.Maksudov (Institute of seismology, Khurshid str.3, 700128 Tashkent, Uzbekistan, email: root@seismo.tashkent.su)

The geomagnetic, geologo-geodetic and radiometric studies have been carried out on the gedynamic test-grounds of Uzdekistan and in particular on the Tashkent test-grounds sice 1968 to determine strong earthquake precursors and their spatial and temporal features. In geologo-tectonic respect the region under investigation is located in the zone of the regional Karzhantau and Tavaksai faults intersection. The north side of the Karzhantau fault is a rise of the same name, the south one is Chirchik depression. In 1992-1995 10 cycles of the high-precise repeated levelling, length measurement between special triangulations (20 sides) and 8 cycles of geomagnetic and radiometric observations were being carried out. The results obtained show that there are some anomalous changes of the geomagnetic field (T), recent vertical (h) and horizontal (L) crustal motion, gamma-activity in the geological structures of the Tavaksai test-grounds. Spatial and tempral variations of the T and h values have the following tendencies: anomalous changes of the geomagnetic field (T) of small amplitude (1-5 nTl) on the right side of the Tavaksai fault do not correlate with the geodetic data; considerable changes of the T value (10-15 nTl) which are in a good agreement with the geodetic data are registred directly in the Tavaksai fault zone; anomalous trend of the recent crustal motions (direction, intensity) and geophysical parameters forestalling seismic event becomes apparent in different geotectonic structures of the fault.

CORRELATION BETWEEN RECENT STRUCTURES AND RECENT GPS MOTIONS WITHIN THE CENTRAL TIEN SHAN (KYRGYZSTAN AND KAZAKHSTAN)

Yuriy Trapeznikov, Alexander Zubovich, Vitaly Bragin and Alexander MIKOLAICHUK (International Research Center - Geodynamic Proving Ground in Bishkek, 720049, Bishkek-49, Kyrghyzstan, email: mav@laurel.gdirc.ru)

East-west trending ranges alternating with subparallel sedimentary basins are the main structural units of the Central Tien Shan. The ranges are characterized by block and fold deformation of pre-Paleogenic erosion surfaces which are uplifted to elevations of 5-7 km. In the sedimentary depressions this structural surface is lowered to 3-4.5 km below sea level. The maximum thickness of Cenozoic deposits reaches 5-5.5 km. Within this region a GPS network was installed, presently including 240 sites. Regular measurements have been conducted for six years. The whole system of ranges and depressions shortens in the sublatitude direction relatively to the Kazakh platform. The velocity of motion decreases to the north, varying from 11 - 12 mm/yr at the Kokshaal range to 0 - 1 mm/yr at the Zaili range. At the meridional section, the Tien Shan ranges bound depressions by right and left-striking reverse-slip faults. The observed horizontal motion gradient field does not comply with these major faults. The structure of vertical motion modern field also does not comply with major morphostructural units of the Central Tien Shan.

CRUSTAL DEFORMATION MONITORING OF VOLCANOES IN JAPAN USING L-BAND SAR INTERFEROMETRY

Makoto MURAKAMI, Satoshi Fujiwara, Shinzaburo Ozawa, Hiroyuki Nakagawa And Mikio Tobita (Geographical Survey Institute, Kitasato-1, Tsukuba-Shi, Ibaraki-Ken, 305 Japan, Tel : +81-298-64-6925, Fax: +81-298-64-2955, E-mail: mccopy@gsi-mc.go.jp)

Since 1994 we have been conducting studies to apply interferometric L-band SAR (InSAR) for the detection of crustal deformations. L-band InSAR is particularly useful for monitoring of crustal deformations associated with volcanic activities. We observed crustal deformations caused by inflation of magma source of Mt. Mihara of Izu-Oshima Island as well as subsidence of the volcano's caldera. The pattern of crustal deformation is in good agreement with predicted by an inflation model. We also detected the volcanic crustal deformation of Mt. Iwate which has been active since March 1998. The spatial pattern of the detected deformation by InSAR strongly suggests an existence of an inflation source about 8 km below the ground surface. Our experiences show that in some applications the InSAR data plays a key role to understand physical process of volcanic activities. We also carried out a repeatablity study over Izu-peninsula where coverage of JERS-1 data is fine and crustal deformations are persistent. We processed many scenes and compared them. We found to model water vapor distribution is difficult without additional information. Water vapor effects sometimes show a correlation with topography but it is not always consistent. A pragmatic way to eliminate this effect is to perform temporal averaging for multiple interferograms obtained at different epochs. After this averaging the precision of measurement of crustal deformation using JERS-1 SAR is estimated better than 1 cm. In this paper we will review our experiences using L-band InSAR for volcanic studies and discuss advantages and limitations of the technology. Although JERS-1 ceased to operate on October 12, 1998, there are enormous amount of existing data taken by JERS-1 available and we can detect unknown crustal deformations from them. Another good news is a next generation L-band SAR sensor onboard ALOS is to be launched in 2002.

ABSOLUTE CALIBRATION OF SUPERCONDUCTING GRAVIMETERS - A COMPRISON OF METHODS

Bernd RICHTER, Ilona Nowak, Herbert Wilmes (all (Bundesamt fuer Kartographie und Geodaesie, Frankfurt a.M., Germany, email: richter@ifag.de)

Stationary superconducting gravimeters can be calibrated by parallel observations with other gravimeter types during phases of relatively strong (tidal) gravity changes or by applying known artificially induced accelerations to the gravimeter sensor. Repeated parallel observation with an absolute gravimeter have two advantages: (1) the improved determination and verification of the gravity factor and (2) the survey of drift behaviour respectively the determination of drift factors. Artificial accelerations can be applied to the superconducting gravimeter by the Frankfurt calibration system. Periodic vertical movements of the gravimeters with varying period lengths and amplitudes exert known accelerations which are used to determine the calibration factors and instrument cha racteristics of the superconducting gravimeter. New developments have been made to increase the vertical basis and to improve the precision of the interactive feedback and registration system.
The results of the different methods will be compared and analysed in relation to systematic effects.

SIMPLIFIED SUPERCONDUCTING GRAVIMETERS FOR OPERATION AT REMOTE LOCATION

Bernd RICHTER (Bundesamt fuer Kartographie und Geodaesie, Frankfurt a.M., Germany, email: richter@ifag.de); Eric W. Brinton, Richard C. Reineman, R. J. Warburton (all GWR Instruments, Inc., 6264 Ferris Square, Suite D, San Diego, CA, USA, email: (warburton @gwrinstruments.com)

Except for two dense clusters of Superconducting Gravimeters (SGs) in Europe and Japan, the worldwide distribution remains sparse. This is both due to the difficulty and expense associated with supplying liquid helium needed for cooling the gravimeter, and by the need for highly trained technicians to operate the gravimeter. In this paper, we report progress toward a SG system that is easy to deploy and operate at remote sites, requires no helium replenishing, and which can be operated remotely via modem. In recent work, we describe the development of an ultra long holdtime dewar where all boiled off helium gas from the dewar is

re-condensed. Developments have been started for a system that uses only 2 kW of power and methods will be discussed to avoid helium loss during power failures. This system is designed to be serviced and maintained by local personnel. Setting up, initializing, and operating a SG requires a technician with specialized skills which currently are learned over a period of several years working with SGs. Progress is made to simplifying these procedures so they can be performed via computer modem by either users or GWR personnel operating from their home base. These improvements and simplified operation will enable users to operate SGs at many new sites of geophysical interest.

GRAVITY OBSERVATIONS AT THE GEODYNAMIC OBSERVATORY MOXA, GERMANY

Corinna KRONER and Thomas Jahr (both at Institute for Geosciences, FSU Jena, Burgweg 11, 07749 Jena, Germany, e-mail: kroner@geo.uni-jena.de)

In the scope of the expansion of the seismological observatory Moxa (Thuringia, Germany) into a geodynamic broadband-observatory the continuous monitoring of temporal gravity changes started last year.
In order to determine first tidal parameters for Moxa station and to get to know the station noise in the period range from a couple of minutes up to several days, a LCR earth tide and a LCR-D gravity meter recorded simultaneously for some months. These recordings were basically done in preparation of the monitoring with a superconducting gravimeter at the observatory starting in 1999. Results obtained from these first gravity observations esp. with regard to station noise and environmental influences are presented.

HIGH PRECISION TIDAL MODELLING AT THE GRAVIMETRIC STATION OF BRASIMONE (ITALY).

Giuseppe CASULA (Istituto Nazionale di Geofisica, Roma, c/o Department of Physics - Sector Geophysics Univ. Of Bologna, V.le C.B. Pichat n.8 40137 Bologna, Italy, E-Mail: casula@ibogfs.df.unibo.it); Paolo Baldi (Department of Physics Univ. Of Bologna, V.le C.B. Pichat n.8 40137 Bologna, Italy, E-Mail: baldi@ibogfs.df.unibo.it).

A superconducting gravimeter GWR number T015 was installed in the ENEA research center of Brasimone, in the Italian Apennines between Bologna and Florence (44° 07' N 11° 07' E 890m H). The Instrument was involved in the Global Geodynamics Project in July 1996 and is actually recording continuously the local acceleration of gravity.
The gravimeter is continuosly calibrated by means of a moving mass system with a precision of 0.3% or better; the calibration factors computed with the mass experiments were verified by means of an intercomparison campaign with the absolute gravimeter FG5-205 of IPG of Strasbourg, in October 1997. The results of the two calibration methods are in good agreement and the calibration constant of the SG gravimeter has been improved by a factor 2 by means of absolute gravimetry.
Several months of data records were collected and sent to the ICET (International Center of Earth Tides), the data were elaborated with the aid of Eterna-Preterna Softwares to compute amplitudes, gravimetric factors and phases of the Tamura 1987 tidal catalogue.The effect of the barometric pressure on gravity was computed and the resulting barometric pressure admittance, about -0.32 microgal/mbar, is in agreement with the physical models, and was used to eliminate barometric pressure noise from data.

OBSERVATIONS OF THE EARTH TIDE VARIATIONS IN SOUTH KOREA

Uk HAN (Dept. of Environmental Sciences, Korea Military Academy, Seoul, 139-799, Korea, email jigugong@chollian.net); Jung Hwan Park (Dept. of Earth Sciences & Engineering, AIMST, Seoul, 139-799, Korea)

Earth tide observations were taken at KMA observatory in South Korea by LaCoste-Romberg ET gravimeter for determining the gravimetric factor (d) and analysing the tidal components from September 2 to 16, 1997. Meter drifts were corrected by regression and then denoised by threshholding wavelet, a data processing tool. The mean value of d is 1.2 and the mean phase lag of k(M2, S2) and AK(K1, 01) is 0.07 ± 0.03° and 0.08 ± 0.07° by analysing the observed earth tides. For yielding measurements of gravity accurate to about 0.01 mgal, the Earth tide observations are required by ET meter. The tidal variations are due to the planet's distance and zenith angle. With the exception of Earth-Moon and Earth-Sun mechanism, the possible causes of tidal variations are tectonical, meteorological and hydrological perturbations. The long period and broad observations are required for determining the state of gravimetric factor and tidal constituents in Korea.

DEVELOPMENTS OF MULTICOMPONENT LASER STRAINMETER SYSTEMS AND THEIR USE IN SEISMOLOGY AND GEODYNAMICS

Mstislav N. DUBROV and Rostislav F. Matveev (both at Institute of adioengineering and electronics, Russian Academy of Sciences, ac. Vvedensky sq., 1, Fryazino, Moscow region, 141120 Russia, email: mnd139@ire216.msk.su)

Our recent progress in laser interferometry developments brings forward the new approach to instrumental geophysics and terrestrial observations. The number of tensor components which characterise the deforming earth surface can be obtained by means of the novel laser strainmeters. The original scheme of multicomponent laser instrument with spatially distanced arms has been analysed. We obtained the forms of seismic wave responses for arbitrary laser strainmeter length and orientation. Seismic and strain signals have been investigated by two separately located laser strainmeters at Moscow region. The distance between the instruments is about of 100 km, the analysed frequency band is 10**(-6)...120 Hz. The analogue and digital records and the results of their spectral analysis have been obtained. The comparison of seismic waves parameters has been done for simultaneous records by pendulum seismometers and 2-component laser strainmeter. The experimental prototype of jamproof laser strainmeter has been tasted. and its resolution of 1 nm has been proved on the basis up to 150 m. The quantitative relation between atmospheric pressure variations and earth strain oscillations has been investigated in the wide frequency range. We have obtained the values of strain/pressure ratios for the laser strainmeters. Specific features of the strain-pressure interactions have been revealed. The problems of laser strainmeter's practical application in the global geodynamic reference frame are analysed.

THE LONG WATER TUBE TIDAL INSRIUMENT IN KSIAZ GEOPYSICAL STATION

Marek KACZOROWSKI Space Research Centre, (Polish Academy of Sciences, Bartycka 18A, 00-716 Warsaw, Poland, email: marekk@cbk.waw.pl)

In 1997 Commity of Scientific Investigations accepted to realisation project Installation of the long water tube tidal instrument in Ksiaz geophysical station". Since April 1997 initial works were made. Natural geological and morphological conditions are very suitable there to carry out tidal observations. During 25 years the tidal observations are permanently realised in Ksiaz station by use of the quartz horizontal pendulums. Relationship between old tidal observations gather in Ksiaz station and recent one obtained with use long water tube make a good change to initial new investigations of earlier series of tidal observations. In case of the long water tube we have in practise instrument without drift. Comparison of the observations of two different instruments allowed us to determine drift of quartz horizontal pendulums. We can expect that long water tube instrument help use to improved accuracy of determination the long period and systematic variations of vertical line as well as yearly and half yearly modulations of daily and half daily tidal waves. Absent of drift in water tube instrument make a special occasion to initialisation new investigations like investigations of secular variations of the world gravity field, modern crust movement and tectonic of the Sudet mountain. Transitionally, a new instrument will heave monitoring process occurred in global ocean which caused generation of the long period and systematic variations of vertical and tidal waves modulation. The mention variations in the ocean are generated by global hothouse effect being fundamental ecological problem. The installation works of long water tube are leading parallel in underground of Ksiaz station as well as in optic laboratory of Space Research Centre of Polish Academy of Sciences.

THE SEA SURFACE OF THE BALTIC =96 A RESULT FROM THE BALTIC SEA LEVEL PROJECT (IAG SSC 8.1)

Markku POUTANEN and Juhani Kakkuri (Finnish Geodetic Institute, Geodeetinrinne 2, FIN-02430 Masala, Finland email: Markku.Poutanen@fgi.fi)

We describe the final results of the Baltic Sea Level (BSL) 97 GPS campaign and the combination of three successive BSL campaigns. Because the last campaign was made simultaneously with the EUVN (European Vertical Reference Network) GPS campaign, we were able to obtain a well-defined connection between the two networks.
Moreover, combining tide gauge data and gravimetric precise geoid NKG96, we recomputed the sea surface topography (SST) of the Baltic Sea with a greater accuracy than before. We compare this with the more detailed SST obtained from the satellite altimetry. In satellite altimetry we use a Gradient method which we describe in the paper. We also discuss the future of the Baltic Sea Level project.

PRELIMINARY STUDY OF BLOCK ROTATION MODEL IN NORTH CHINA AREA BY USING GPS MEASUREMENTS

Caijun XU ,Jingnan Liu, Dingbo Chao,and Ting Chen (School of Geo-science and Surveying Engineering, Wuhan Technical University of Surveying and Mapping, 129 Luoyu Road,Wuhan, 430079, China, email: cjxu@hpb1.wtusm.edu.cn); Jusheng Xu (Institute of Seismology, State Seismological Bureau, Xiaohongshan, Wuhan, 430071,China)

North China as a lithospheric dynamics subregion is located in the middle part of eastern China. It is characterized by more intense activity of lithospheric dynamics in comparison with Northeast China and South China. Two parts of North China region separated by Taihang Mts. The eastern part is basin, it may be further divided into Jizhong block, Jilu block, and Luliao block from west to east, and their boundaries are Changdong fault and Yilu fault respectively. The western part may be divided into two blocks by Ordos's fault; they are Ordos block and Taihang block.
Repeated GPS surveys in North China provide a direct measurement of current crustal motions. GPS surveys have been carried out in the region in1992,1995,and 1996 respectively, the GPS velocity field are estimated and they are used to estimate that North China sub-plate and intra-block rotation motions. The rotation rate of North China sub-plate by GPS measurements is good fitting the ratio of fault slip to fault spacing from Neogene in this area. The current rotation pattern of Ordos block,Taihang block and North China Plain block indicate decreasing actions toward western boundary of Ordos block from south to north by Qinghai-Tibet plateau uplifting and extending. It is also associated with the collision of India, Pacific with Eurasia.

A REVIEW OF PLATE TECTONIC MOTIONS IN SOUTHEAST ASIA

Sobar SUTISNA and Parluhutan Manurung (both at Center for Basicdata Survey, National Coordination Agency for Surveying and Mapping, P.O.Box 46/CBI, Cibinong 16911, INDONESIA, email: sobar@cbn.net.id)

This paper is aimed at reviewing and discussing the major tectonic activities of the current plate motions existing in the Southeast Asia. The study based on literature of various publication of research activities, of which mostly are carried out by geophysicists. Publications of regional studies with geodetic measurements are also discussed based on GPS observation started from the past ten years ago.
This review concluded that in terms geodynamics, Southeast Asia is considered as a young region, active and very complicated where continental collision, subduction, continental-island arc collision and junction of four plates are occur. This region accounts for a substantial number of earthquakes and also severe and catastrophic in where 500 million people are living. This area are indeed an excellent field laboratory for studying plate tectonic motions. Some GPS geodynamic monitoring results in the region from some years ago are also highlighted and discussed.

SPATIAL AND TEMPORAL VARIATIONS OF CRUSTAL STRAIN IN THE TAIWAN AREA

Shui-Beih YU, Long-Chen Kuo and Chin-Hsiang Yen (Institute of Earth Sciences, Academia Sinica, P.O. Box 1-55, Nankang, Taipei, Taiwan, R.O.C., e-mail: eayusb@ccvax.sinica.edu.tw)

The "Taiwan GPS Network" is composed of 131 annually surveyed mobile stations and 9 continuously recording permanent stations. The mobile stations have been surveyed 7-8 times from 1990 to 1997, while the permanent stations have been in operation since November 1991. The changes of baseline length are utilized to study the spatial and temporal variations of crustal strain in the Taiwan area. The entire network is divided into 78 subnets. Then the average strain rates and their annual variations for each of the subnets are estimated. Dramatic compressive strain rates are observed in the Longitudinal Valley of eastern Taiwan and near the Chukou fault of southwestern Taiwan. The extremely high strain rates in the Longitudinal Valley area are mainly caused by the aseismic slip on the Longitudinal Valley fault. In contrast, the crustal strain is likely to be accumulating in the vicinity of Chukou fault and gives rise to a possibility of generating major earthquakes. The western Coastal Plain and central Taiwan show slight to moderate contractions, while the southern Central Range, northern Taiwan and Ilan Plain reveal significant extensional deformation. Except the strain rates of very few subnets have been disturbed by the occurrence of the nearby moderate earthquakes, the temporal variations of crustal strain are generally quite uniform during the past few years.

TIME SERIES OF INTERPLATE COUPLING IN THE TOKAI REGION, CENTRAL JAPAN, DEDUCED FROM EDM RANGING AND LEVELING DATA IN 1978-1997.

Fumiaki KIMATA (School of Science, Nagoya University, Nagoya, 464-8602 JPN, email: kimata@seis.nagoya-u.ac.jp). Kazuro Hiragara (Graduate School of Science, Nagoya University, Nagoya, 464-8602 JPN, email: hirahara@eps.nagoya-u.ac.jp); Naoyuki Fujii (School of Science, Nagoya University, Nagoya, 464-8602 JPN, email: fujii@seis. nagoya-u.ac.jp).

To clear the time series of interplate coupling of the Eurasian Plate and the Philippine Sea Plate under the Tokai region, southwest Japan, authors discuss the EDM and leveling data observed seasonally or yearly in the period 1978-1997. Discussing the EDM rangings on two baselines clear that contraction of line lengths are repeated acceleration and reduction of the contraction with a frequency of four to five years. For example, contractions show 5.4 x 10-7/yr and 4.2 x 10-7/yr in 1983-1987 and deduced to 0.9 x 10-7/yr and 0.0 x 10-7/yr in the next period of 1987-1991. Episodic vertical movements are also deduced from the yearly leveling by Geographical Survey Institute. When the contractions of line lengths are accelerated, the subsidence on the west coast of Suruga Bay is extended to the westward in this region. Contrary subsidences are observed only in the eastern part of the west coast in the period of deduced contraction. The inversion analysis based on baseline length changes and vertical movements shows back slip vectors of 3-4 cm /yr toward northwest under the Tokai region throughout the observation period, and vectors of 10 cm/yr in 1983-1987, which is the period of acceleration of contraction and tilting. It is suggested that interplate coupling is episodic with time in the Tokai region.

INVESTIGATING THE EFFECT OF MW 6.2 EARTHQUAKE IN TAIWAN WITH GPS OBSERVATIONS

Jenn-Taur LEE (Department of Surveying and Mapping Engineering, Chung Cheng Institute of Technology, Tahsi, Taoyuan, Taiwan 33509, email: jtlee@ccit.edu.tw)

The biggest earthquake for last thirty-four years occurred on July of 1998 in the southern portion of Taiwan. In 1906, there was a MW 7.1 earthquake appeared around the same area. Since Taiwan is located at the collision belt between Eurasia plate and Philippine sea plate, the collision and oppression happened frequently between these two plates. The conducted stress does obviously move towards the western parts of Taiwan and the energy may release at the active fault along the western coast of Taiwan.
A set of GPS observations was obtained from the Taiwan's GPS network project to study the effect of the MW 6.2 earthquake in Taiwan. The GPS raw data measured with TurboRogue SNR-8000 come from five GPS continuous stations in the Taiwan GPS network, FLNM, KDNM, PKGM, TMAM, and YMSM. These GPS measurements were linearly combined to the ionosphere free form and the double-differencing technique associated with the relaxing satellite orbit was used to do the estimation task. Moreover, the phase ambiguity resolved with the wide-lane approach. Since the PKGM station is not far away from the origin of earthquake, the position variation of PKGM is about 2, 3, and 20 cm along the north, east, and upper directions, respectively. The length between PKGM and the others are shorten about 5 cm which is similar to the average normal field velocity per year of Taiwan island. In addition, the movement direction of each baseline is approximately to the PKGM station in which may explain the outcome from the oppression of the collision belt.

PREDICTION OF MODERN CRUCTAL MOVEMENTS IN THE AREAS OF NUCLEAR POWER PLANT

V.N. Morozov, V.N. Tatarinov, A.A. Lopanthuk (Geophysical Center, Russian Academy of Sciences, Molodezhnaya, 3, Moscow, II 7296, Russia)

It is well known that the deformations features of geological environment can serve as precursors of seismic events. Complex geophysical and geodetic monitoring allows us to estimate speeds and directions of modern geodinamic horizontal movements, to connect them with periods of preparation of possible seismic events, and to make conclusions about conditions of geological environment in zones of abnormal deformations in the areas where ecologically dangerous nuclear-fuel cycle objects are located,
In 1995-96 three series of GPS-observations were conducted on geodynamic sites in the area of Kalinin and Novovoronezh Power Plant. As a result of this work, the technique of GPS-observations was elaborated, initial coordinates and lengths of basic vectors between reference points were obtained and preliminary data on features of modern geodynamic movements in the areas were nuclear power plants are located where received.
The data were correlated with data obtained by regional observation stations located on the East-European platform, thus allowing us to obtain the relative error of basic vectors length definition equal - 1 .10-6.

INVERSE ANALYSIS OF GPS MONITORING DATA IN SUZHOU, CHINA

Jicang WU, Dajie Liu, and Congwei Hu (Surveying Department, Tongji University, Shanghai, 200092, China, email: jcwu@celiang.tongji.edu.cn)

In this paper, four campaigns of GPS monitoring data (distance changes, and hight changes) since 1996 have been used to determine the local crust defomation model by Bayesian inversion method. The geological investigation data, and seismic activities of the main geological faults in this area have been used as the prior informaiton in the inverse analysis. According to the GPS monitoring data, this area has suffered the significant subsidence caused by extracting underground water. Our inversion results show that the gound subsidence cused by human has a significant affect on the movements of the main geological faults in this area.

THE ESTIMATION OF CRUSTAL DEFORMATION IN SHANXI AREA, CHINA, FROM THE 1995 AND 1996 GPS OBSERVATIONS

Q.W. LIU and Y.Q. Chen (both at Department of Land Surveying & Geo-Informatics, The Hong Kong Polytechnic University, Hunghom, Kowloon, Hong Kong, email: lsqwliu@polyu.edu.hk); Y.X. Li (The First Crustal Deformation Monitoring Center, State Seismological Bureau of China, Yihaoqiao, Hedong District, Tianjin 300180, China, email: dzjl@shell.tjvan.net.cn)

Two years of GPS data is analysed to detect crustal deformation in the Shanxi area, one of the most seismological active area in China. A rigorous statistical iterative approach based on the classical F (Fisher) test is applied to solve the datum problem. The multi-epoch simultaneous estimation model, is employed to construct a regional displacement rate field. Furthermore, the displacement-strain relationship with some special modelling considerations is used to build the regional strain field. Although more substantial geophysical conclusions require more detailed observations, the estimated displacement pattern and strain pattern are generally coherent with the features of the main tectonic structures identified for this area. Some important regional deformation information has been found in this study.

DIFFERENCES BETWEEN VERTICAL DATUMS, POSTGLACIAL REBOUND EFFECT AND HORIZONTAL MOVEMENTS IN THE SOUTHERN PART OF BALTIC REGION DETERMINED FROM BSL GPS CAMPAIGNS PERFORMED IN 1993 AND 1997

Ryszard ZDUNEK, Janusz B. Zieliński (Space Research Centre of the Polish Academy of Sciences, ul. Bartycka 18A, 00-716 Warszawa, Poland)

In a frame of Baltic Sea Level Project three GPS Campaigns were performed up till now. The first campaign in 1990 was organized rather for testing purposes. The second one was made in 1993 and the third (from May 21 to May 29, 1997) coincided with the European Vertical GPS Reference Network (EUVN). This paper presents some results obtained from these measurements. For studies of main goals of the project (e.g. unification of vertical datums and their time variability for the countries around the Baltic Sea, determination of mean sea level and sea surface topography of the Baltic Sea, study of the effect of sea floor topography and monitoring the postglacial rebound of Fennoscandia) 29 stations were selected from the whole network which were identical in last two GPS BSL campaigns. Coordinates of these stations were computed using Bernese Software ver. 4 with vector constructions which minimalized known systematic effects like e.g. mixing different types of antennas and receivers. Taking into account obtained accuracy of station coordinates (ab. 1mm in horizontal and 3mm in heigh component) and the additional data from precise levelling and tide gauge readings collected during GPS campaigns in 1993 and 1997 we determined the differencies between national vertical datums existing in Baltic countries and postglacial rebound effect as well as horizontal movements of stations especially in southern part of Baltic region.

GEODYNAMICS OF THE EAST SUDETEN (BORDER AREA OF THE CZECH REPUBLIC AND POLAND)

Vladimír SCHENK, Zdeòka Schenková and Pavel Kottnauer (all at Institute of Rock Structure and Mechanics, Academy of Sciences, CZ-182 09 Praha 8, The Czech Republic, email: schenk@ irsm.cas.cz); Stefan Cacoñ, Bernard Kontny and Jaros_aw Bosy (all at Department of Geodesy and Photogrammetry, Agricultural University, PL-50-357 Wroclaw, Poland, email: cacon@kgf.ar.wroc.pl)

The structural geological block Sudeten builds the north-east part of the Bohemian Massif. Occurrences of earthquakes, neovolcanic intrusions, CO2 mineral water sources, monitoring of geodetic deformations give evidences on an existence of the recent mobility on its tectonic elements. In 1997 the existing Polish and Czech regional GPS geodynamic networks joined into one SUDETEN network. Its length is approximately 150 km in the NW-SE direction and approximately 80 km in the perpendicular direction. The GPS points, in a form of concrete blocks with a base of 40x40 cm and height between 40 and 120 cm, were built on places of hard rock outcrops and/or very stable structures. Moreover, in the area of the SUDETEN network three permanent and three local seismic stations with start-stop registrations and one local seismic array operate. In 1997 and 1998 two simultaneous GPS campaigns on Czech and Polish points were performed. The main goal of the present geodynamic investigations of the Sudeten area, realised under the Polish and Czech research projects, is an identification of recent mobile active zones, a motion potential classification of particular geological blocks and a verification of a possible mobile activity of significant equatorial faults. Applied methodology allowed the accuracy in GPS points determination to be increased. RMS errors calculated for individual points were obtained lower than 2 millimetres. The results of this investigations and preliminary interpretation of the GPS monitoring verified by seismic observations are presented in the paper.

ON MONITORING THE FINNISH PERMANENT GPS NETWORK -FINNREF

Hannu KOIVULA and Markku Poutanen (Finnish Geodetic Institute, P.O.Box 15, FIN-02431 Masala, Finland email: Hannu.Koivula@fgi.fi)

The Finnish GPS network FinnRef has been operating since 1994. The full deployment of 12 stations was reached in October, 1996. All stations are equipped with Ashtech Z-12 receivers with Dorne Margolin antennas (except Mets=E4hovi, which is equipped with a Turbo Rogue). The network is used as reference when the GPS network has been densified. Data are processed using Bernese 4.0 Software. From daily solutions the normal equations are saved

and used later to produce weekly and monthly solutions and their time series. We will show the latest status and the performance of the network and show three years time series, the effect of the Finnish winter on them, and how they are and will be used for studying and monitoring the post-glacial rebound.

ACHIEVEMENTS OF THE LONG TERM COOPERATION IN GEODESY AND GEODYNAMICS OF SIXTEEN CEI (CENTRAL EUROPEAN INITIATIVE) COUNTRIES. FUTURE PLANS

Janusz SLEDZINSKI (Warsaw University of Technology, Institute of Geodesy and Geodetic Astronomy, 00-661 Warsaw, Poland, Pl. Politechniki 1, e-mail: sledzinski@gik.pw.edu.pl Chairman and International Coordinator of the CEI WGST Section C "Geodesy" Chairman of the IAG Subcommission "Geodetic and Geodynamic Programmes of the CEI")

The paper includes concise information on some recent geodetic and geodynamic projects that are realised in international co-operation of the Central European countries in the frame of the scientific programme of the CEI WGST Section C "Geodesy". The main achievements of the first phase of the international European geodynamic project CERGOP (Central Europe Regional Geodynamics Project) are outlined. The general objectives of another CEI project UNIGRACE (Unification of Gravity Systems in Central and Eastern Europe) and the results of the 1998 campaign of absolute gravity measurements are pointed out. The programmes of activities of the Section C Working Group on Satellite Navigation Systems and actions realised by the Working Group on University Education Standards are summarized. Some cooperation links between CEI WGST Section C and European Geophysical Society (EGS) and International Association of Geodesy (IAG) are mentioned.

VERTICAL MOVEMENT AT SLR STATIONS

R. KOLENKIEWICZ and D. E. Smith (Laboratory for Terrestrial Physics, NASA GSFC Code 920, Greenbelt, MD 20771, USA e-mail: ronk@ltpmail.gsfc.nasa.gov); P. J. Dunn and M. H. Torrence (Raytheon Corp., 7701 Greenbelt Rd., Greenbelt, MD 20770, USA)

The twenty year record of vertical position at SLR stations tracking the LAGEOS I satellite contains signals with periods between hours and years, as well as the long-term effects of crustal movements or post-glacial rebound. Improved temporal sampling from the second satellite in the LAGEOS constellation enables us to separate geophysical from instrumental effects better than was possible with LAGEOS I data alone, as well as to eliminate the effect of orbit error. A growing number of SLR instruments of constantly improving accuracy have been tracking a number of lower geodetic satellite, in particular, Starlette, and these observations also reveal a variety of features in station position motion. Crustal movements which affect vertical control at a station include the Earth's tidal response to the sun and the moon, and strong sensitivity to this variation enables the SLR network to define accurate global parameters, as well as to indicate any geographical dependence. We also find that atmospheric pressure loading produces millimeter level displacements with a signal which depends on the regional pressure, and the effects of ocean tidal loading also appear at some stations. This facilitates the use of the Global Laser Tracking Network's geocentric reference frame to connect regional and local positioning networks monitoring sea level change.

INTERANNUAL VARIATIONS OF THE VERTICAL AND THEIR POSSIBLE INTERPRETATION

Zheng-xin LI (Shanghai Observatory, Chinese Academy of Sciences, 80 Nandan Road, Shanghai, 200030, China, email: lzx@center.shao.ac.cn)

Base on the results of plumb line variation (PLV) measured by the gravimetry and astrometry techniques at two different locations (Jozefoslaw of Poland and the Yunnan province of China), the studies of the interannual variations of the plumb line (vertical) is concluded in the paper. It is clear now that other than the tidal variations of the plumb line, which have already been corrected now in the studies, there are also detectable non-tidai PLV in these two regions, of which the interannual component is in the order of 0.01"-0.02", and one can use either of the two techniques to measure it in practice. Base on the discoveries of the correlationship between the interannual PLV, detected at a certain regions over the world, and the other geodynamical quantities, some possible interpretation is also given in the paper.

DYNAMICAL STUDY OF CRUSTAL DEFORMATIONS

GRAVIMETRIC AND TOPOGRAPHIC FEATURES ACROSS SUBDUCTION ZONES

P. HARABAGLIA,(Universit' della Basiticata, Centro di Geodinamica, via Anzio s.n, Potenza 85100 Italy Tel no. 39971-474-413 Email: hp245sci@unibas.it); C. Ciorciari, C. Doglioni

We derive the average gravimetric and topographic features of world-wide subductions by stacking of profiles across subduction zones, after an appropriate multiple cross-correlation. The averaged profiles we obtain for each subduction can be grouped in two different categories depending on the orientation of the subduction. In the first there are subductions dipping W-ward or NW-ward; in the second there are those E-ward, NE-ward or NNE-ward. In a hot-spot reference frame, the lithosphere has an average delay of about 2 cm/yr with respect to the underlying upper mantle; this in turn can be as a relative eastward mantle flow. The first group of subductions would contrast this flow, while the second would be oriented flow-ward.

PLUMB LINE VARIATION CALCULATED FROM RELATIVE GRAVIMETRY

H. LI, G.Y.Fu (Institute of Seismology, CSB), Z.X.Li(Shanghai Obervatory, Chinese Academy of Science)

32 and 46 campaigns of gravity surveys at the local gravity networks in the Western Yunnan Earthquake Prediction Experiment Area (since 1985) and the north China(since 1987) have been performed by using LaCoste and Romberg relative gravity meters, respectively. This paper firstly gave the gravity changes displayed by contour map. Then the plumb line variations were derived from the gravity changes with the Vening-Meinesz formula for Xiaguan and Beijing point which located at the central part of the network, respectively. The results displayed the long term changes and some periodic changes with the scale of about several 0.01". Spectrum analyses show that the amplitudes of interannual changes are about 0.02". These results are consistent with the that derived from the astronomical observance, especially for the that of Xiaguan derived from the gravimetry to that of Kunming derived from the astronomical observance.

INTERANNUAL VARIATIONS OF THE VERTICAL AT YUNNAN BY ASTROMETRY AND GRAVIMETRY TECHNIQUES

Zheng-xin LI (Shanghai Observatory, Chinese Academy of Sciences, 80 Nandan Road, Shanghai, 200030, China, email: lzx@center.shao.ac.cn); Hui Li and Guang-yu Fu (Institute of Seismology, SSB, Xiao Hongshan, Wuhan, 430071, China, email: lihuidz@public.wh.hb.cn); Hui Hu (Yunnan Observatory, Chinese Academy of Sciences, Kunming, 65011, China, email: huhui@public.km.yn.cn)

A determination of the plumb line variation (PLV) during 1985-1997 at the Yunnan province of China has been made recently in using the observations of the gravimetric network there. The purpose of this study is to compare the PLV results, obtained from gravimetry technique, with the time and latitude residuals at the same period derived from the observations of photoelectric astrolab at Yunnan Observatory. The interannual variation of the PLV obtained from the gravimetric technique are in a good accordance with the correspondent component in the time and latitude residuals derived from the astrometric observations. This fact shows once again the evidence with which one may recognize the reality of the interannual variations of the plumb line(vertical) at Yunnan, of which the amplitudes are in the order of 0.02", and also the ability of the two techniques in measuring them in practice.

THREE DIMENSIONAL ISOSTATIC STUDY OF TAGUS ABYSSAL PLAIN AND AMPERE SEAMOUNT

Alexandra CARVALHO (Centro de GeofÃsica da Universidade de Lisboa, R. Escola PolitÃ©cnica, 58, 1250 Lisboa, Portugal, email: adias@fc.ul.pt); J.M. Miranda (Centro de GeofÃsica da Universidade de Lisboa e Departamento de FÃsica da Faculdade de CiÃªncias da Universidade de Lisboa, R. Escola PolitÃ©cnica, 58, 1250 Lisboa, Portugal, email: jmiranda@fc.ul.pt)

The isostatic equilibrium of the Western Iberian Margin has been already analysed from ship gravity compilation and Seasat gravity data. However, no clear results was obtain, even in what concerns the main geological features of the area. Being so, a new gravity compilation over the West Iberian Margin was performed and together with TOPEX-ERS-1data we study the Isostatic compensation of Tagus Abyssal Plain and Ampere Seamount, in North Atlantic Ocean, on a spectral domain, in a 3D approach. Results were compared with studies made by seismology.
We conclude that Tagus Abyssal Plain shows evidence for a local compensation scheme with a crystal thickness of 105 km and that Ampere Seamount is not isostatically compensated.
