Summary Listing

The Summary Listing gives an overview of all Symposia and Workshops the Associations are organising and/or are involved in. It also indicates the duration of each Symposia and Workshop. There is no indication of morning (AM) or afternoon (PM) when the Symposium lasts a full day. Please note that Inter Association Symposia and Workshops are listed as part of the Inter - Association programme and are repeated under the leading and sponsoring Associations.

UNION LECTURES

UNION SYMPOSIA

INTER-ASSOCIATION SYMPOSIA AND WORKSHOPS

IAVCEI - International Association of Volcanology and Chemistry of the Earth's Interior

IASPEI - International Assocaiation of Seismology and Physics of the Earth's Interior

JSV36 UNDERSTANDING VOLCANOES BY GEODESY, SEISMOLOGY, ELECTROMAGNETICS AND GEOCHEMISTRY B.93

JSM41 THE CONTRIBUTION OF SATELLITE OBSERVATIONS TO GLOBAL CLIMATE, OCEAN, AND TERRESTRIAL MONITORING B.117

IAPSO - International Association for the Physical Sciences of the Ocean)

IAMAS - International Association of Meteorological and Atmospheric Sciences

IAHS (International Association of Hydrological Sciences)

IAGA (International Association of Geomagnetism and Aeronomy)

IAG (International Association of Geodesy)

Contents – abstracts week A

Please Note:
Abstracts are divided into the equivalent of two published volumes for weeks A & B

Key for Abstract Book

1. Symposia and Workshops are listed according to organising or leading Association, where:
UNION = U
INTER-ASSOCIATION = IA (IAVCEI, IASPEI, IAPSO, IAMAS, IAHS, IAGA and IAG)
IAVCEI = V
IASPEI = S
IAPSO = P
IAMAS = M
IAHS = H
IAGA = A
IAG = G

2. This Assembly has a much larger Inter-Association programme then usual. In the Abstract Books, these have only been listed as part of the Inter-Association programme and have not been repeated under the leading and sponsoring Associations, as has been done for the Programme Book.

3. Oral Presentations are listed according to time of presentation.

4. Poster presentations are listed:
- as part of the oral presentations if the convenor allocated a short presentation time or a scheduled viewing time
- at the end of the symposium if the convenor specified a particular half day for poster viewing, concurrently held to an oral session.
- at the end of the symposium if the convenor did not allocate a specific time for poster viewing; the posters are scheduled concurrently to the first half day of that symposia/workshop.

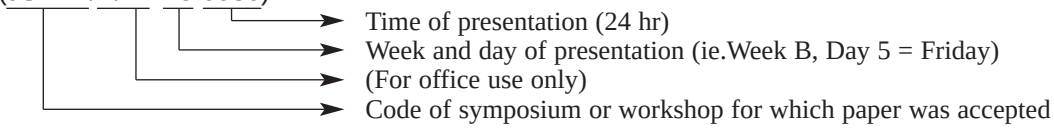
The organisers endeavour to leave posters up for the duration of the symposium or workshop they belong too. Please check the POSTER SCHEDULE, placed at the entrance of each lecture theatre and poster room, for final information.

Convenors and Chairs, who have not already done so, are encouraged to specify at the beginning of their symposium or workshop a time when poster presenters are expected to be at their posters. Alternatively, poster presenters can make use of the 'I will be at my poster….' Messages available in each poster room.

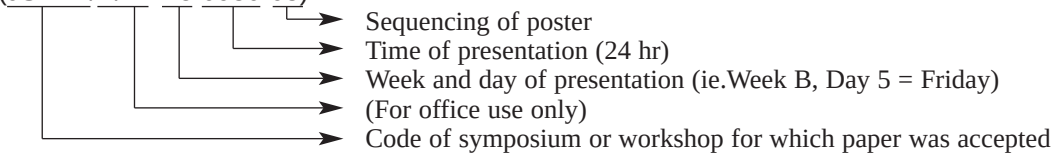
Key to Index

Authors are listed alphabetically, followed by the code of their abstract and indication of week, day and time of presentation, where:

SMITH, P (JSM24/E/14-B5 0930)



SMITH, P (JSM24/E/14-B5 0930-08)



N.B: IUGG cannot accept any responsibility for textual errors to the content of the submissions. Due to regional differences in software, some specific symbols may have been automatically substituted by the publishers native version.

IUGG apologise for any confusion that these errors may cause.

UNION LECTURE 1 — Tuesday 20 July

Location: Great Hall **0830**

MARS AND THE SEARCH FOR LIFE ELSEWHERE

EDWARD C. STONE, Jet Propulsion Laboratory, 4800 Oak Grove Drive, M/S 180-904, Pasadena, California 91109, USA, email: edward.c.stone@jpl.nasa.gov

Life thrives on Earth wherever there is water. As a result, the search for life elsewhere focuses on the search for water and the molecular building blocks of life. Mars once had flowing water, Jupiter's moon Europa may have water beneath its icy crust, and the surfaces of comets, Pluto, and Saturn's moon Titan are rich in the organic building blocks of life. Over the next twelve years we will explore each of these and bring back samples from several of them. We will also look for Earth-like planets orbiting nearby stars as we extend our search for life beyond the Solar System.

UNION LECTURE 2 — Thursday 22 July

Location: Great Hall **0830**

THE STATE OF THE MANTLE - RECONCILING STRUCTURE AND PROCESSES

B.L.N Kennett (Research School of Earth Sciences, Australian National University, Canberra ACT 0200, Australia, email: Brian.Kennett@anu.edu.au)

Over the last decade the rapid development of seismic tomography has provided a wealth of information on seismic wavespeed structure on a wide range of scales - from the local to the global. Increasingly information from P and S wave information is being combined to provide insight into the nature of the three-dimensional heterogeneity revealed in the tomographic images. Such seismic information provides a snapshot of Earth structure, whilst such major features such as subducting plates at depth reflect past environments. Geochemical probes can provide both a time component and considerable subtlety of insight into some aspects of the process which lead to the observed heterogeneity in surface samples.
The zones of strongest heterogeneity occur near the major boundaries, at the surface and the core-mantle boundary but there are other zones of significant variation, not just at the 660 km discontinuity which is commonly taken as the boundary between the upper and lower mantles. The newer views of the mantle are indeed more complex than the simple pictures drawn from radial reference models but offer greater concordance between geophysical and geochemical viewpoints.

THE EARTH SYSTEM AND GLOBAL CHANGE

U2/L/01-A2 **0930**

THE EARTH SYSTEM: WHAT DO INTERMEDIATE COMPLEXITY MODELS TELL US?

Martin Claussen and Andrey GANOPOLSKI (both at Potsdam Institute for Climate Impact Research, PO Box 60 12 03, D-14412, Potsdam, Germany, Email: andrey@pik-potsdam.de)

Due to the large computational cost of the state-of-the art models of different components of the climate system and biosphere, the development of integrated models of the Earth system up to now has been based on the so-called models of intermediate complexity. The main idea behind such models is to achieve a fast turnaround time by a reducing the resolution and complexity in the description of the individual processes, and at the same time retain a sufficient degree of realism ("as simple as possible but as complex as necessary"). This class of models allows us to perform many long-term simulations that advances our understanding of the Earth system. In particularly, these models has been used for studying the role of different feedback and synergism between components of the Earth system. These models contribute to a better understanding of the stability of the climate and the mechanisms of abrupt climatic changes which took place in the past and may happen in the future. Finally, the models of intermediate complexity allow us to assess a very broad spectrum of scenarios of future climatic changes and to study the role of uncertainties in forcing scenarios and in the description of individual processes.
CLIMBER-2 model, developed at Potsdam Institute for Climate Impact Research, is an example of an Earth system model of intermediate complexity. This is a coarse resolution 2.5-dimensional geographically explicit model designed for long-term (up to a million years) simulations. The results from the model illustrate a potential of models of intermediate complexity for the study of the Earth system dynamics on different time scales, in particularly the role of climate-biosphere feedback and the stability of thermohaline ocean circulation. The model has been used for paleoreconstructions and simulations of future climate change scenarios.

U2/E/09-A2 **0950**

THE IGBP GLOBAL CARBON PROJECT: UNDERSTANDING THE BREATHING OF THE PLANET

W. Steffen, International Geosphere-Biosphere Programme, Royal Swedish academy of Sciences, Box 50005, S-10405 Stockholm, Sweden E-mail will@igbp.kva.se

The post-Kyoto world has put the planet's biogeochemical cycling into the forefront of international political and economic concerns, and has posed a considerable challenge to the international global change research programmes. The International Geosphere-Biosphere Programme (IGBP), in collaboration with its partner programmes the World Climate Research Programme (WCRP) and the International Human Dimensions Programme on Global Environmental Change (IHDP), is rising to this challenge by launching a major international research effort on the science of the global carbon cycle. The twin objectives of the IGBP Global Carbon Project are: (i) to produce a synthesis of our current understanding of the global carbon cycle, including a fast-track scientific overview in time for inclusion in the IPCC special report on land-use change and forestry; and (ii) to develop an international framework for collaborative research on the carbon cycle; involving appropriate elements from IGBP, WCRP and IHDP, and to co-ordinate an international research effort under such a framework. This talk will focus on the current status of the IGBP synthesis effort on carbon, and will briefly outline the emerging framework for ongoing collaborative international research on the carbon cycle under the three international programmes. Critical aspects of the carbon cycle to be dealt with in the IGBP Global Carbon Project include palaeo-carbon studies, observational and process studies of oceanic carbon fluxes, coastal biogeochemical budgets, measurement of terrestrial carbon fluxes, reliability of the terrestrial carbon sink into the future (i.e., 'sink saturation'), effects of land-use/cover change on the carbon fluxes, and integrated modelling of the global carbon cycle.

U2/E/10-A2 **1010**

ABRUPT CLIMATE CHANGE: UNDERSTANDING THE DYNAMICS OF THE EARTH SYSTEM

F. Oldfield, PAGES Core Project Office, Barenplatz 2, CH-3011 Berne, Switzerland
E-mail: oldfield@pageigbp.unibe.ch

It is only within the last few years that overwhelming evidence has accumulated pointing to the capacity of the climate system to undergo major changes on time-scales of less than a century, in some cases, less than a decade. The paper will outline four types of abrupt change and consider their possible future implications. On 'Milankovitch' timescales (tens to thousands of millennia), where external forcing through astronomically controlled changes in solar irradiance drives the rhythm of Earth System response, smooth changes in forcing across critical thresholds, trigger abrupt global responses, as may be seen at both the onset and termination of glacial periods. On sub-Milankovitch timescales – millennial and shorter – the best known and most dramatic changes are those that were first detected in the Greenland ice core record from the period of the last glacial (Marine Isotope Stages 2,3 and 4). These 'Dansgaard-Oeschger' oscillations appear to have involved changes in temperature over much of the Greenland ice cap of well over half the amplitude of the full range of temperature shift between full-glacial and Holocene optimum conditions. They were also marked by synchronous climate changes over much of the earth's surface. Their onset and termination appears to have taken place on decadal timescales in most cases. The best known and most fully understood of the major oscillations also includes the transition from glacial (Younger Dryas) to Holocene conditions and there is a growing body of evidence regarding the dynamical basis of the transition which took place over two or three decades at most.
The issue of abrupt changes during the Holocene (the last 11.5 kyrs) is a rather more controversial topic. A dominantly polar-centric view of variability has tended to foster the notion that the Holocene was a period of much reduced variability. This perspective is demonstrably false as soon as we turn to lower latitudes and consider hydrological, in addition to temperature, variability. During the first half of the Holocene, smooth changes in solar irradiance were accompanied by many kinds of earth system readjustment in the wake of the last glacial termination – the mssive reduction in the extent of polar ice, especially in the Northern Hemisphere, a global rise in sea-level and dramatic changes in terrestrial…

GLOBAL OCEAN CIRCULATION

Harry L. Bryden Southampton Oceanography Centre, Southampton, SO14 3ZH UK
E-mail: Harry.L.Bryden@soc.soton.ac.uk

In the past few years schematic diagrams of the global ocean circulation have become very popular. Rather than taking such sketches to be blueprints for the real ocean circulation, we should use them to help identify the key unknown elements of ocean circulation. In contrast to the simple sketches, measurements during the World Ocean Circulation Experiment reveal the complexity of the actual ocean circulation: maps of global sea surface height from satellite altimetry, basin-scale distributions of tracer fields in the interior ocean, and subsurface drifter trajectories demonstrate the richness of variability at a multitude of temporal and spatial scales. Simultaneously, numerical simulations of ocean circulation have been increasingly successful at representing present-day ocean circulation. Yet there remain fundamental questions as to what controls the strength of the ocean circulation, both the wind-driven basin-scale circulations and the global thermohaline circulation. Answering these questions is the key to understanding how the ocean circulation will evolve under changing climate conditions.

U2/E/12-A2 **1120**

EVOLUTION OF THE 1997-98 EL NINO/LA NINA CYCLE

Michael J. McPhaden, NOAA/Pacific Marine Environmental Laboratory, Seattle, Washington 98115, USA. E-mail: mcphaden@pmel.noaa.gov

The 1997-98 El Nino, the strongest on record by some measures, has been called "The Climate Event of the Century". The event unfolded rapidly in the tropical Pacific beginning in early 1997, and by June 1997 sea surface temperatures in the eastern Pacific reached historic highs. By December 1997, 28-29˚C surface water filled the equatorial basin. Then, in May-June 1998, SST dramatically plunged 8˚C in 30 days along the equator in the eastern Pacific. The El Nino ended as suddenly as it began. began, replaced by La Nina conditions characterised by below normal sea surface temperatures and stronger than normal trade winds.
This presentation reviews the observations and forecasts of the 1997-98 El Nino/La Nina cycle in the tropical Pacific. A major contributor to recent progress in El Nino studies has been the development of an ocean observing system comprised of complementary satellite and in situ measurements.
The data from this observing system were used to initialise and validate model forecasts of the 1997-98 event, and to provide high definition monitoring of the event in real-time. The observations also provided new insights into the dynamics of coupled ocean-atmosphere interactions in the tropical Pacific, and highlighted issues concerning the relationship of El Nino to both shorter time scales associated with the intraseasonal Madden-Julian Oscillation, and longer time scales associated with interdecadal variability and global warming. Thus, while the 1997-98 El Nino/La Nina serves to emphasise fundamental advances made in seasonal-to-interannual climate research in the past 10-15 years, it also raises new challenging research questions for the future.

U2/E/07-A2 1140

INTERANNUAL VARIABILITY OF THE OCEAN-ATMOSPHERE SYSTEM THROUGH GLOBAL GENERAL CIRCULATION MODEL RESULTS: THE TROPICAL PACIFIC OCEAN

STEPHANE RAYNAUD, Sabrina Speich (both at Laboratoire de physique des Océans, Université de Bretagne Occidentale, UFR Sciences, 6 avenue Le Gorgeu - BP 809, 29285 BREST CEDEX - FRANCE) and Gurvan Madec (Laboratoire d'Océanographie DYnamique et de Climatologie, UPMC T26e4, boite 100, 4 place Jussieu, 75252 PARIS CEDEX 05).

A global coupled General Circulation Model is used to study the interannual variability of the ocean-atmosphere system in the Pacific region. Two 40 years simulations are analysed in order investigate the impact of the lateral diffusion of the ocean tracers (T & S) onto the climate variability in two different configurations: horizontal versus isopycnal diffusion.
The El Niño-Southern Oscillation (ENSO) phenomenom is clearly present but shows significantly different caracteristics between the two runs, concerning the amplitude and the spectral properties. It can be attributed to a different mean state or to the direct effect of the isopycnal diffusion.
In this study, ENSO is regarded as combination of linear quasiperiodic modes pertubed by weak non-linearities, that we can identify with the Multichannel Singular Spectrum Analysis (MSSA). Applied to various fields, MSSA allows to find a qualitative and quantitative physical coherence in the cycle of each mode. Diagnostics of the tendency terms responsible for the sea surface temperature evolution are useful to evaluates the role of advection, air-sea fluxes and diffusion in the persistence of anomalies. Explanations are then purposed for the differencies in the ENSO behavior of these two simulations.

U2/E/08-A2 1200

ROLES OF BIOGEOCHEMICAL PRODUCTIVITY IN THE CARBON CYCLE USING A SIMPLE GLOBAL OCEAN MODEL

MASAHIKO FUJII, Motoyoshi Ikeda and Yasuhiro Yamanaka (Graduate School of Enrironmental Earth Science, Hokkaido University, Sapporo 060-0810, Japan, email: fujii@ees.hokudai.ac.jp, mikeda@ees.hokudai.ac.jp and galapen@ees.hokudai.ac.jp)

A simple physical and biogeochemical ocean model is constructed. Horizontally, the global ocean is divided into four regions; i.e., the Pacific/Indian Ocean (PI), the Atlantic Ocean (AT), the Southern Ocean (SO) and the Greenland/Iceland/Norwegian Sea (GIN). The PI and AT are vertically continuous, while the SO and GIN are divided into two, the surface layers (50m thick) and the lower layers. This model is used to estimate the oceanic carbon cycle contributed by physical and biogeochemical processes. The physical parameters are chosen to represent the air-sea CO2 flux, the thermohaline circulation, and vertical and horizontal diffusions. The biological productivity is controlled only by phosphate in the surface layers. The geochemical process is parametrized by a calcite productivity in the surface layers. The products are remineralized in the lower layers. The observed distributions of radiocarbon, phosphate and alkalinity are used as tracers to optimize the parameters. The total carbonate concentration is then calculated, and the vertical carbon flux is quantitatively estimated. A major feature is a clear contrast between the PI and AT; i.e., the total carbonate is richer in the PI than the AT, along with the other biogeochemical components. As the anthropogenic sources increase the CO2 concentration in the atmosphere, the effects appear significantly in the AT, while a signal is extremely weak in the PI.

THE CRYOSPHERE AND ATMOSPHERE

U2/E/13-A2 1400

ASSESSMENT OF MASS BALANCE OF THE NOVAYA ZEMLA ICE SHEET BASED ON TWO CLIMATIC SCENARIOS

Natalia Davidovich and Maria Ananicheva Institute of Geography, Russian Academy of Sciences, Staromonetny 29 Moscow 109017, Russia. E-mail: Maria@glacinfo.msk.ru

Fluctuations of the global thermal regime, recorded during the instrumental observation period of the last hundred years are better pronounced during the cold than warm period of the year; they are especially pronounced in high latitudes as e.g. the Atlantic sector of the Arctic. These changes are connected mainly with the atmospheric circulation and precipitation regime. Novaya Zemlya Archipelago is situated in a region of high oceanity and climatic fluctuations; it was subjected to significant variations in its glaciation regime. During the first half of the 20th century the type of ice sheet nourishment changed there at least twice. According to our calculations anomalies of winter precipitation of various signs and melting rates varying by 20-30% may lead to entirely different types of ice formations and therefore to significant changes in mass balance during one so two decades. Taking this into account, we tried to find out how a possible warming may affect the type of nourishment, mass balance and glacier runoff in the main glaciological zones of the Novaya Zemlya ice sheet.
We compare the results with the 1932-1962 sheet geometries for which detailed balance calculations are available. The GFDL model for the climate development, if the hydro-glaciological conditions are based on a change in winter temperature of 9.5oC; this is quite realistic for the whole Novaya Zemlya region. However the rise of the summer temperature cannot be the same everywhere. Due to the negative feed back of the melting processes at the glacial surface, the warming over the ice sheet should be less than over ice-free land. Changes in precipitation on Novaya Zemlya predicted by the GFDL model led us to assume an increase of 25%.
The growth of the carbon dioxide and other greenhouse gases in the atmosphere during the epochs of global warming were most intense in the Cenozoic and took place 3-4 million years ago in the Young-Middle Pliocene, with a doubled CO2-concentration as compared to today. The mean temperature of the Northern hemisphere was about 5oC higher than it is now, and in the Arctic there was no polar ice. Palaeoclimatic maps for this epoch which…

U2/E/14-A2 1420

INDICATIONS OF THE EXTENT AND CAUSE OF GLOBAL TROPOSPHERIC OZONE POLLUTION

PENKETT, Stuart(1) Reeves, Claire(1) Bauguitte, Stéphane(1) Green, Tim(1) Carpenter, Lucy(1) Law, Kathy(2) Evans, Mathew(2) Methven, John(3) Schmitgen, Sandra(4) Richer, Hannah(5) Dewey, Ken(5) Kent, Joss(5)Kaye, Andrew(6) Zanis, Prodromos(7), Schüpbach, Evi(7)& Monks, Paul(8)
(1)University of East Anglia, Norwich (UK); (2)University of Cambridge, (UK); (3)University of Reading, (UK); (4)KFA Jülich, (Germany); (5)MRF, Farnborough (UK); (6)NERC Scientific Services, Swindon (UK); (7)University of Berne, (Switzerland); (8)University of Leicester (UK)

Our understanding of the behaviour of ozone in the troposphere has been increased significantly in the last few years by experiments carried out on the ground and from aircraft, and by indications of its global distribution from satellites. A number of factors are involved, including the development of instruments capable of studying the free radical chemistry associated with in-situ ozone production and destruction in real time, and the realisation that long-range intercontinental transport of ozone and other pollutants is occurring in both hemispheres on a large scale. This survey will show results collected in the atmosphere with increasing degrees of contamination from the marine boundary layer of the southern hemisphere to polluted air in the free troposphere over the Atlantic and the Alps, and to the more polluted boundary layer over the USA and Europe. The survey will also contrast the importance of transport as shown by trajectory analysis, with in situ production as a source of free tropospheric ozone. IGAC has played a major role in these developments, particularly in the background atmosphere; IGAC's role has been supplemented by information from satellites, from commercial aircraft and from national programmes designed to study air pollution.

U2/E/15-A2 1440

PRECIPITATION FLUCTUATIONS OVER EASTERN EUROPE AS A REFLECTION OF GLOBAL ATMOSPHERIC CHANGES

Valeria Popova Institute of geography, Russian academy of sciences, 29 Staromonetny per, Moscow 109017, RF, E-mail: climat@ipcom.ru

In order to determine statistical correlation between multyear precipitation fluctuation on the eastern Europe (Russian Plain) and atmospheric circulation processes the annual and seasonal data of spatial averaged precipitation on 30 regions of the Russian Plain for 1890-1985 so well as different kinds of indicator of circulation changes have been used. Data on circulation changes indicators include: archive of large-scale circulation processes in the extratropical zone on Northern hemisphere types by B.L.Dzerdzeevsky, which covers each day of the 20th century, the meridianality index by A.L. Katz estimated since 1950 and the anomalies of location variation of Iceland low pressure since 1890. It has been obtained patterns of correlation coefficient between precipitation fluctuation and each of circulation changes indicator. These patterns coincide to each other and show that the correlation is spatial distributed. It allowed to conclude that intensification of meridianal atmospheric large scale processes cause the increase of precipitation on the east and south-west of Russian Plain and increase of precipitation on the northern-west is associated with intensification of zonal circulation. Peculiarities of distribution of the correlation coefficients between precipitation and circulation processes coincide with obtained earlier data on spatial structure of multyear precipitation fluctuation on the Russian Plain. These results explain the climatic cause of Caspian sea level fluctuations during 20th century because the main part of river Volga basin is located on the East of Russian Plain. It has been shown that present rise of Caspian Sea level is associated with the intensification of meridianal atmospheric processes.

U2/L/02-A2 1500

RECENT STRATOSPHERIC TRENDS

Marie-Lise CHANIN (Service d'Aéronomie du CNRS, BP 3 Verrières-le-Buisson, France, email: chanin@aerov.jussieu.fr)

The stratosphere has shown the most spectacular anthropogenic changes of any atmospheric region. But even though the discovery of the Antarctic ozone hole, in 1985, triggered a strong interest in monitoring ozone all over the globe, changes in the vertical distribution of ozone are still poorly known, particularly around the tropopause, region where ozone changes have the strongest effect on climate. The stratosphere is shown to have cooled in the last decades, mostly as a consequence of ozone depletion. Both ozone and temperature trends have been updated recently as an initiative of the SPARC Project and the results, which are part of the recent WMO-UNEP Ozone Assessment, will be presented.
The radiative effect of water vapour makes it the most important of the greenhouse gases, and its concentration might be expected to change through the increase and subsequent oxidation of methane, as well as from changes in the atmospheric thermal structure. However the dataset available are scarse and too short to lead to concluding results.Where we stand on this issue will be discussed. During the last decade, the stratosphere has also experienced changes as a consequence of various naturally occurring effects. The impact of aerosols deposited in the stratosphere by the eruption of Pinatubo has been measured accurately and globally for the first time in surface temperature, in addition to its direct effect at other altitudes and its indirect effect through affecting stratospheric chemistry. It should be noted that the monitoring of any long term trend in background aerosol is difficult due to the long residence time of volcanic aerosol reaching the stratosphere (~5 years).
In addition to the rather direct radiative effects and the indirect chemical effects, there is also the possibility of more complicated changes occurring through changes in atmospheric dynamics. It is known that small changes in radiative forcing can have large effects on the dynamics of the winter stratosphere. Preliminary results on the activity of planetary waves, zonal mean wind and the occurrence of stratospheric warmings in the last decades will be presented.

HUMAN INFLUENCES AND THE FUTURE

U2/E/17-A2 1600

LAND COVER DYNAMICS IN AFRICA - OBSERVATIONS BY REMOTE SENSING AND SPATIAL MODELLING

Eric Lambin, Department of Geography, University of Louvain, place Louis Pasteur, 3 B-1348 Louvain-la-Neuve, Belgium. E-mail: lambin@geog.ucl.ac.be

Quantitative data on where, when and why land-cover changes take place are still incomplete. Remote sensing techniques allow a systematic collection of data on land-cover changes at a range of spatial scales. Spatial modelling techniques, based on geographic information systems, can support a better understanding of the major determinants of land-cover change processes.
First, a continental-scale analysis of Africa was conducted, based on ten years of AVHRR remote sensing data, to detect land-cover change « hot spots ». Processes such as drought and fire impacts on vegetation, and forest clearings were identified at a broad scale. The results highlight the dynamic character of African ecosystems. Few areas in Africa are affected by continuous, unidirectional change processes.
Second, fine scale remote sensing data were used for validation and to better understand the land-cover change processes. A sample of fifteen intensive study sites, well-distributed across Africa, was selected. Time series of remote sensing data and long-term field data have been assembled to identify generic trajectories and processes of change.
Third, spatial statistical models of land-cover change were developed for each site. The approach consists in analysing the location of different categories of land-cover changes in relation to natural and cultural landscape attributes. One output is a projection of areas at risk of being affected by land-cover conversion in the future and the simulation of possible impacts.

U2/E/05-A2 1620

CLIMATE CHANGE OVER MOZAMBIQUE AND SOME IMPACTS ON AGRICULTURE

ADAO HENRIQUE MATONSE (Faculty of Natural Sciences & Mathematics, Pedagogical University, C.P. 4040, Maputo-6, Mozambique. Email: misa@zebra.uem.mz)

According to IPCC, global temperatures have increased by over 0.5 oC since the nineteenth century, and may increase between 1.5 and 4.5 degrees by the doubling of CO2 concentrations. Different GCMs are applied to produce climate change scenarios for the region of Mozambique. The results for the annual mean values, given by the models, indicate a sensitivity between 1.8 and 3.1 degrees, and a change in precipitation ranging from - 9 % to +11 %. The economy of Mozambique is based on agriculture which accounts for nearly half of the country's GDP, and 70 % of the foreign exchange earnings. The most important traditional food crops are maize, cassava, groundnut, rice, sorghum and millet. The absence of irrigation in Mozambique (less than 2 % of the cultivated area is under irrigation) increases the sensitivity of crop yields to climatic variations. Possible impacts on agriculture are projected in terms of the productivity of maize, with the use of CERES- Maize model.

U2/E/16-A2 1640

GLOBAL ENVIRONMENTAL CHANGE: THE HUMAN DIMENSIONS CHALLENGE

Jill Jaeger International Human Dimensions Programme Secretariat, University of Bonn, Nussallee 15a, D-53115 Bonn, Germany. E-mail: ihdp@umi-bonn.de

The realisation that human activities cause global environmental change, that individuals and societies can be affected by it and that they will develop responses has brought home forcefully the fact that studies of global environmental change must be broadly interdisciplinary, incorporating the social and natural sciences, and international. The range of social science disciplines involved in research related to global environmental change is large. The paper looks at the research challenges arising in studies of the causes, consequences and responses to environmental change, in understanding human attitudes and behaviour with respect to the environment, in dealing with questions of scale and with harmonising and integrating social science data. In the last 10 years interest has also focused on "sustainable development", for which there is a need for truly integrative assessments that combine various streams of knowledge from the social and natural sciences as well as the accumulation of experience in the implementation of local Agenda 21 and present it in a way that it can be useful in the decision-making process.

INSIGHTS FROM HIGH-SPATIAL RESOLUTION MODELING OF THE THERMOSPHERE-IONOSPHERE T.

L. KILLEEN (Space Physics Research Laboratory, Department of Atmospheric, Oceanic, and Space Sciences, University of Michigan, 2455 Hayward Street Ann Arbor, MI 48109-214, USA, Email: tkilleen@umich.edu), W. Wang and A. G. Burns (both at Space Physics Research Laboratory, Department of Atmospheric, Oceanic, and Space Sciences, University of Michigan, 2455 Hayward Street Ann Arbor, MI 48109-2143, USA, Email: wenbin@engin.umich.edu, aburns@umich.edu

Many important phenomena in the thermosphere/ionosphere system manifest themselves over mesoscales (10's to 100's of km) rather than over global scales (1000km). Features associated with such phenomena often remain unresolved by thermosphere-ionosphere models of conventional spatial resolution (standard grid spacings of 5degx5deg or 2.5degx15deg). High-latitude electrical dissipation (Joule heating) is a good example of a globally significant process that can and does vary considerably over scales of tens to hundreds of kilometers. In principle, mesoscale phenomena can be modeled using General Circulation Models (GCMs), but this requires increasing the resolution of the models greatly. The consequent increase in array size and running time can be prohibitive in terms of the computer resources required. The analogous problem is solved in the lower atmosphere by using local area models, when interaction with larger scale features is not important, and nested or adaptive grid models, when such interaction is important. Over the past 5 years, a nested grid model of the thermosphere and ionosphere (TING) has been developed and deployed to study mesoscale processes in the thermosphere-ionosphere. The TING model is based on the NCAR series of highly-developed thermosphere-ionosphere codes and has been parallelized for real-time use in a predictive mode. Results from the high-spatial-resolution (1.5x1.5deg grid) TING model calculations are presented and compared with their equivalent low-resolution counterpart calculations using identical inputs. Calculated Joule heat rates are significantly greater when the high resolution grid is used. Many other mesoscale features (low latitude troughs, electron temperature enhancements, tongues of ionization, etc.) are modeled at the higher resolution and can be investigated in detail using post-processor diagnostic codes. The paper will present an overview of insights derived from the use of high spatial resolution for coupled models of the thermosphere-ionosphere.

COUPLED CHEMICAL-DYNAMICAL MODELLING OF THE MIDDLE ATMOSPHERE

T.G. SHEPHERD (Department of Physics, University of Toronto, Toronto, Ontario M5S 1A7 Canada, email: tgs@atmosp.physics.utoronto.ca)

The "middle atmosphere" is the name given to the stratosphere and mesosphere; it lies between the troposphere below and the thermosphere above. In the middle atmosphere, chemical and radiative-dynamical processes all play equal roles in determining the atmospheric state, and coupled chemical-(radiative-)dynamical phenomena abound. The Antarctic ozone hole is but one example. The nature of chemical-dynamical coupling in the middle atmosphere presents many challenges for climate system modelling, because of space and time scale mismatches. In addition, because of the strong radiative-dynamical driving from the troposphere, comprehensive modelling of the middle atmosphere always includes the troposphere. This introduces a chemical interface (the chemical tropopause), separating the strongly layered stratosphere from the relatively well-mixed troposphere.
This talk will describe some of the key aspects of chemical-dynamical coupling in the middle atmosphere, together with their implications for climate system modelling. Particular attention will be focused on those aspects affecting ozone and climate change. The points will be illustrated using observations as well as results from a comprehensive chemical-radiative-dynamical general circulation model of the troposphere-stratosphere-mesosphere system (the Canadian Middle Atmosphere Model).

U3/E/07-A3 Invited 1000

MODELLING CHEMISTRY-CLIMATE FEEDBACKS

KATHY LAW (Centre for Atmospheric Science, University of Cambridge, Cambridge, CB2 1EW, U.K., Email: kathy@atm.ch.cam.ac.uk)

Atmospheric chemistry models of the troposphere and stratosphere have been developed to further our understanding about a wide range of important issues related to past, present and future changes in radiatively active trace gases, such as ozone and methane, and also, aerosols. Examples will be used to illustrate our current modelling capability. To date, chemistry transport models have been used to study particular feedbacks between chemical, dynamical and radiative processes. For example, the impact of ozone depletion on the stratospheric circulation. Other examples will be discussed.
Current developments are focusing on the inclusion of atmospheric chemistry in global climate models in order to study the impact of changing trace gas and aerosol concentrations on the climate system and vice versa. Models are also being developed which link the atmosphere to the biosphere through interactive emissions of source gases (e.g. wetland emissions of methane).

THE NCAR CLIMATE SYSTEM MODEL

Byron A. Boville (National Center for Atmospheric Research, Box 3000, Boulder CO 80307 USA, email: boville@ucar.edu)

The NCAR Climate System Model (CSM) is a physical climate model containing component models for the atmosphere, land surface, ocean, and sea ice, communicating through a coupler. The CSM produces stable solutions for present (or pre-industrial) climate on multi-century time scales, without the need for flux corrections. Although the surface climate was stable, the initial version of the CSM had substantial deep ocean trends. Recent improvements in the model have significantly reduced the deep ocean trends. These improvements will be summarized and results from pre-industrial control simulations and from transient greenhouse gas forcing experiments will be discussed.

U3/W/07-A3 Invited 1130

CAN WE ASSESS THE ROLE OF LAND-SURFACES ON CLIMATE CHANGE ?

Nathalie de Noblet (Laboratoire des Sciences du Climat et de l'Environnement, Unite mixte de Recherche CEA-CNRS, Bat. 709 / Orme des Merisiers , 91191 Gif-sur-Yvette, FRANCE,
email: noblet@lsce.saclay.cea.fr)

Sensitivity experiments, using models of different complexity, have demonstrated the importance of biosphere/atmosphere interactions for climate studies. In addition there is evidence, from paleoecological data, that the global distribution of biomes has strongly varied through time. Therefore a full treatment of climate change, past or future, requires the use of integrated biosphere models. Coupled AGCM-Biome models have then been developed. Static biome models were first used, requiring as input an equilibrium state of the atmosphere. Such coupled models were applied to simulations of present-day climate, to test whether the AGCM was in equilibrium with the present-day land-surface conditions. Applications were also carried out for past climates : - accounting for feedbacks from vegetation redistribution during the last glacial inception (115000 years ago) may have contributed to the build up of continental ice-sheet; - during mid-Holocene (6000 years ago), the orbitally-induced increase in African monsoon was enhanced by the subsequent growth of vegetation in the southern border of the Sahara. Some simulations of future climate change have recently been re-run accounting for the physiological response of plants to changes in the atmospheric CO2 concentration. An additional warming of the whole globe has been found, the vegetation-induced response being larger in the tropics than in the mid to high latitudes. If we want to go a step further and evaluate the potential response of global ecological processes to anthropogenic perturbations, and its feedbacks to climate, the time behaviour of the biosphere must be examined. Coupled models such as those introduced above are therefore not applicable. Models that include the parameterization of vegetation dynamics are therefore being developed in several groups and will be briefly discussed.

U3/W/16-A3 Invited 1200

A DYNAMICAL STABILIZING MECHANISM IN THE CLIMATE SYSTEM: RESULTS FROM A SIMPLE MODEL AND A GCM

J. R. BATES and V.A. Alexeev (Danish Center for Earth System Science, University of Copenhagen, Juliane Maries Vej 30, DK-2100 Copenhagen O, Denmark. email: jrb@gfy.ku.dk)

A fundamental problem in climate research is that of explaining how the Earth's climate remains stable on very long timescales. Positive feedback mechanisms such as the ice-albedo feedback and the lower tropospheric water vapour/infrared radiative (WVIR) feedback are known to exist which could, in principle, drive the climate system far from its observed mean state even in the absence of any external forcings. Extreme scenarios that have been envisaged are a completely ice-covered Earth and a runaway greenhouse such as seems to have occurred on Venus.
There is at present no generally accepted explanation for the stability of the Earth's climate, though a number of stabilizing mechanisms (based mainly on the radiative effects of clouds or upper tropospheric water vapour) have been proposed. Recently, a new stabilizing mechanism based on the linkage between the global atmospheric angular momentum (AM) cycle and the surface winds and evaporation has been proposed (Bates, 1999, Tellus in press). An empirical relationship found between the poleward AM transport across 30° and the difference between the mean height of the 500hPa surface in the tropics and extratropics has allowed a simple climate model to be constructed in which the surface fluxes of energy from the ocean surface are calculated explicitly. An analytical solution for perturbations about the model's equilibrium

climate has been obtained. This provides criteria for the stability of the model's equilibrium climate. The tendency towards instability resulting from the WVIR feedback is found to be overcome by the stabilizing influence of the evaporative heat loss determined by the atmospheric AM transport. Supporting evidence for the validity of the stabilizing mechanism is provided by experiments with a GCM in which the sea surface temperature is perturbed.

CLIMATE SYSTEM INTERACTIONS IN EL NINO/SOUTHERN OSCILLATION.

David Neelin, University of California, Los Angeles, USA, email: neelin@ucla.edu

The El Nino/Southern Oscillation (ENSO) phenomenon provides a prime example of a complex suite of interactions among climate system components. These include ocean-atmosphere interaction, interaction of convective ensembles with large-scale atmospheric flow, cloud-radiative interaction, the interactions involved in teleconnections, interaction of ENSO with Earth's seasonal cycle, and interaction of the slow components of the ocean-atmosphere system with weather. A combination of review and current work is presented, focusing on how to make a distiction among different degrees of coupling between subcomponents of the climate system within a phenomenon. ENSO may be said to be "strongly coupled" in the following sense: neither the time scale nor the spatial structure are characteristic of either the atmospheric or oceanic subsystem considered alone. While the ocean provides the memory of the system, it does so subject to the spatial structure of the wind stress. The atmosphere's adjustment by fast internal waves tends to set large spatial scales, but the specific structure depends on the interaction with the ocean. The characteristic timescale and spatial structure of ENSO may thus be considered fundamentally the product of coupling. On the other hand, while interactions of the ENSO phenomenon with both the seasonal cycle and weather are important, meaningful separations can be made. For instance, weather can be approximated as a noise product independent of ENSO in a climate model, and ENSO predictability in presence or absence of weather noise can be evaluated. The interaction between deep moist convection and large-scale atmospheric flow, as occurs in ENSO and other tropical phenomena is another example of strong coupling. Cloud-radiative interaction can play an significant role in ENSO teleconnections within the tropics, but it appears to be a modifying role rather than a fundamental one.

U3/W/12-A3 Invited **1430**

LOW FREQUENCY CLIMATE VARIABILITY AND ITS LINK TO THE OCEAN'S THERMOHALINE CIRCULATION

Andrew J. WEAVER (School of Earth and Ocean Sciences, University of Victoria, PO Box 3055, Victoria, BC, CANADA, Email: weaver@uvic.ca)

Climate records during the Holocene and the last glaciation have revealed substantial variability on decadal-millennial timescales. Both coupled atmosphere-ocean and uncoupled ocean-only models have also suggested mechanisms for this observed variability. Recent model results are presented to elucidate these mechanisms with special attention given to the role of the North Atlantic thermohaline circulation.
Initially, modelling evidence is given to suggest that the North Atlantic interdecadal variability, found in the GFDL coupled model, is a mode of the full coupled atmosphere-ocean-sea ice climate system. A follow-up analysis using the UVic coupled model suggests that interactions between the North Atlantic thermohaline circulation and Arctic sea-ice and freshwater export may play a crucial role in understanding this variability.
Recent numerical results from both coupled and uncoupled models are also presented to examine mechanisms for centennial-millennial timescale North Atlantic climate variability. Particular attention is given to understanding the observed millennial timescale Dansgaard-Oeschger variability during the last glaciation, its packaging into Bond Cycles and its association with Heinrich events.

U3/L/01-A3 Invited **1500**

MODELLING CRYOSPHERE-CLIMATE INTERACTIONS DURING THE LAST GLACIAL CYCLE

Paul J Valdes and Robin Glover (Department of Meteorology, University of Reading, Whiteknights, PO Box 243, Reading. RG6 6BB UK, email: P.J.Valdes@reading.ac.uk)

The last glacial-interglacial cycle presents a particularly challenging test of Earth System Models, and especially the coupling between the atmosphere-ocean system and the cryosphere-lithosphere system. General circulation models (GCM) have had particular problems in simulating the glacial inception period without having to invoke further feedbacks from vegetation. We will review this work and show new results from a cryosphere model forced by snapshot climate simulations from the UGAMP GCM. The work helps explain the problem of simulating glacial inception.
In addition, we will apply the same technique to the last glacial maximum and the subsequent deglaciation.

U3/E/01-A3 Invited **1600**

THE LATE PLEISTOCENE ICE-AGE CYCLE: AN ASTRONOMICALLY FORCED NONLINEAR OSCILLATION IN THE CLIMATE SYSTEM

Richard Peltier(Department of Physics, University of Toronto, Toronto, Ontario, M5S-1A7, Canada, email peltier@atmsop.physics.utoronto.ca)

The 100 kyr quasi-periodic oscillation of continental ice volume that has dominated climate variability since med-Pleistocene time is entirely explicable as a nonlinear response of the system to orbital insolation forcing. A successful model of the phenomenon appears to require explicit treatment of atmospheric, cryospheric and solid-earth processes as well as an accounting for the amplification of the direct influence of insolation forcing due to the varying concentration of atmospheric carbon dioxide. I will describe a sequence of experiments with a model based upon this minimal mix of ingredients which explicitly predicts both the geographical regions that are subject to glaciation and deglaciation as well as the magnitude of the sea level depression that is observed to have attended ice-sheet growth.

U3/W/04-A3 Invited **1630**

THE COUPLED SYSTEM OF MANTLE CONVECTION AND LITHOSPHERIC PLATE TECTONICS: TOWARDS A SELF- CONSISTENT MODEL

Paul J. Tackley (Earth and Space Sciences Department, University of California, Los Angeles, CA 90095, USA, email: ptackley@ess.ucla.edu)

Lithospheric plate tectonics and mantle convection are different aspects of the same, coupled system, yet mantle convection simulations do not exhibit plate tectonic behavior unless it is imposed by the modeler, largely because 'realistic' temperature-dependent viscosity results in a stiff, immobile, rigid lid. Traditional methods of coupling 'plates' into mantle convection simulations involve the specification of plate boundaries as 'weak zones' or faults, or the specification of plates themselves as a velocity boundary condition. While such approaches have facilitated some important research, it is ultimately necessary to identify the correct 'self-consistent' description of plate tectonics and mantle convection, in which both components arise naturally out of a unified material description of rock deformation as a function of temperature, pressure, and stress. Field observations and materials science suggest that lithospheric strength may be dominated by ductile, semi-brittle deformation processes in the middle lithosphere, with brittle failure (faults) being important in the upper ~15 km, and viscous creep in the deep lithosphere and mantle. Thus, ductile shear localization in the mid-lithosphere may be the key process in the formation of weak plate boundaries. Possible localization mechanisms can be described using time-dependent evolution equations, allowing evolving lithospheric strength heterogeneity with long-term memory. Such descriptions are used to demonstrate the formation of weak transform boundaries in a 2-D model, and convergent, divergent and strike-slip boundaries in 3-D models. The role of elastic and brittle behaviors will also be discussed, as will future directions and philosophical issues.

U3/W/02-A3 Invited **1700**

NUMERICAL MODELLING OF THE GEODYNAMO AND CORE-MANTLE COUPLING

Jeremy BLOXHAM (Department of Earth & Planetary Sciences, Harvard University, Cambridge, MA 02138, USA. Email: Jeremy_Bloxham@harvard.edu)

Of the various components of the Earth system, the most remote is the geodynamo operating in the Earth's core. The concomitant scarcity of observations is exacerbated not only by the complexity of the physics of the geodynamo but also by the inaccessibility of the dynamical regime of the core to direct numerical investigation. The almost vanishingly small role played by viscosity and the almost equally small, but nonetheless important, role played by inertia renders the system one that presents a great challenge to numerical studies.
Nonetheless, significant progress has been made over the last few years in the development of numerical models of the geodynamo, though none of the models is free of approximations, some of which are, unfortunately, introduced more for numerical expediency than for sound geophysical reasons. Here we review this progress and comment on the effect of these approximations on the solutions.
An additional complicating factor is that the geodynamo cannot be considered in isolation from the rest of the Earth system. The transport of heat from the core - which drives the geodynamo – is controlled by the mantle, and the pattern of mantle convection imposes lateral variations in the heat flux from the core. We show that this thermal core-mantle coupling influences the pattern of magnetic field at the core-mantle boundary, and that the pattern of mantle convection inferred from seismic tomography gives rise to a certain observed features in the magnetic field.

THE REDUNDANCY IN NUMERICAL MODELS OF COMPLEX GEOPHYSICAL SYSTEMS

IRINA P. CHUBARENKO (P.P. Shirshov's Institute of Oceanology of Russian Academy of Sciences, Atlantic Branch, Prospect Mira, 1, 236000, Kaliningrad, Russia, E-mail: irina@ioran.kern.ru)

The majority of predicting models for complex geophysical systems (for example, for seaside lagoon)are based nowadays on the numerical solution of differential equations of movement, state or balancefor some values. In doing so, some restrictions such as additional conditions and various approximations are applied because of the complexity of accurate decision. So, the numerical solutions obtained are not precise because of both restrictions of the problem statement (it is impossible to put down all the equations, managing the system), and its numerical realization (variety of approaches of the discretization of governing equations and time-space domain approximation). Besides, model solutions are always labour-consuming because of difficult procedure of calibration and verification, especially in the case of non-linear relationships using. The alternative approach to complex system model creation is to use modern philosophy of the processes hierarchy, scaling, fructal properties of natural processes and systems together with ideas of the redundancy within the model. In the work presented the ideas of redundancy are discussed in application to inter-disciplinary complex model creation. As for this case the redundancy of the model means the possibility to calculate some parameters of a system or process in different ways simultaneously. This approach has required research of peculiar problems: analysis and transmission of the information obtained in to the models complex between various space and temporary scales, between different submodels of the process; advisable degree of redundancy; criteria for choosing of the simulated system development version.

GROUND-ATMOSPHERE-IONOSPHERE-MAGNETOSPHERE COUPLING CONCEPTION INCLUDING SEISMIC ACTIVITY

PULINETS S. A. , Boyarchuk K.A., Hegai V.V., Shklyar D.R. (IZMIRAN, Troitsk, Moscow Region, 142092, Russia, E-mail: pulse@izmiran.rssi.ru)

During last 10 years the model of atmosphere-ionosphere coupling based on the quasi-electrostatic vertical atmosphere electric field penetration into the ionosphere was developed at IZMIRAN. The model consist of three parts: 1-electric field generation model, 2-electric field penetration at thermosphere-ionosphere heights, and 3-effects of electric field in the thermosphere- ionosphere. In the first part a model of ion kinetics in a near-ground layer of troposphere is considered. It explains the appearance of strong vertical electric field up to several kV/m near the ground surface. Second part with the help of existing model of atmosphere conductivity vertical distribution makes calculations of penetrated electric field at the heights from 90 up to 1000 km. It explains the transverse to geomagnetic field lines electric field ~ 1 mV/m at the ionospheric heights as a result of original vertical electric field ~ 1 kV/m at the ground surface. The third part demonstrates the effects of electron concentration modification over the vertical electric field source. Self-consistence of the model is substantiated by correspondence of the calculated parameters to the measured experimentally. Recently the model was supplemented by effects in magnetosphere (ion composition changes, VLF noises amplification), as well as by near-ground calculations (underwater effects, near-ground generation of ELF-VLF emissions). In present state the complete set of works could be regarded as complete conception of Ground- Atmosphere-Ionosphere-Magnetosphere Coupling based on the quasi-electrostatic vertical electric field effect.

CONCERNING SOME ASPECTS OF THE EARTH SYSTEM

RASULOV D.Kh., Lange Institute of Hydogeology and Engineering Geology Tashkent, Uzbekistan, e-mail: root@ariel.tashkent.su

The work gives in details a new piezoelectric model of terrestrial magnetism which permits all the main features of geomagnetic field to be explained from the unified positions (see abstracts in GA1.01 and JSA37). In accordance with the model, owing to semi-diurnal rising tides, in the liquid Earth's core a torroidal flow in equatorial region which is normal to the geographic axis is to exist. Geomagnetic field inversion occurs when changing relatively mantle the direction of the core rotation angular velosity to the reverse one. The model permits some phenomena of the nature to be explained quite simply whose physics was not ascertained finely. One of this phenomenon is a fact of the constant presence of electric charge on the terrestrial surface. Today, in accordance with the model, negative charge will constantly flow to the surface of the Earth in the regions located at the low and middle latitudes. Again, positive electric charge stored at the rotation axis of the core. Owing to vertical atmospheric currents, an electric charge stored at the surface decreases, but because of rotation of the liquid core in the magnetic field it restores again.

FERTILIZER FEEDBACKS ON CLIMATE

ROBERT DICKINSON, PAS Rm 480, P.O. Box 210081, University of Arizona, Tucson AZ, 85721, USA

Evapotranspiration is a key control on climate. Much of the transfer of water from soil to atmosphere passes through leaves where stomates control the rate. Recent formulations of leaf stomatal functioning implemented in climate models have followed a framework for photosynthesis first formulated by Farquhar, and have related stomatal controls on evapotranspiration to leaf carbon assimilation. However, the maximum photosynthetic capacity parameter of such formulations depends on the numbers of enzymes in the leaves that catalyze the leaf uptake of CO2. These enzymes, the most important of which is Rubisco, require substantial amounts of nitrogen for their construction. A model has been developed for coupled cycles of carbon and nitrogen integrated in a GCM climate model that illustrates the dynamics of such a system. Both soil plant exchanges and atmospheric sources and sinks are treated. This system has been built on BATS/CCM3 heritage code but is largely independent of that framework. The presentation title derives from the assumption that agricultural systems have a larger external source of nitrogen than do natural ones from which they are differentiated by their increased productivity and accompanying evapotranspiration. The presentation will address one of the more interesting physiological details that are treated, aspects that are still somewhat speculative, and comparison of the CCM3 15 year simulation with controls not including these interactions. An initial framework for the carbon aspects of seasonally varying leaf growth has been published in Dickinson et al., 1998, J. Climate.

ATMOSPHERIC OXYGEN RISE AT ABOUT 1.9 GA: REE (CE ANOMALY) EVIDENCE FROM CARBONATE SEDIMENTS

QIU Yu-zhuo and Fan Wen-ling (Institute of Geochemistry, Chinese Academy of Sciences, Guiyang 550002, CHINA)

More REE analyses of Chinese, South African and Australian Precambrian carbonate sediments confirmed and refined the preliminary idea suggested by Qiu (1987), which mainly based on rather limited samples of Chinese formations analyzed at Prof. Haskin's INAA lab. This result supports the traditional model of atmospheric oxygen evolution, i.e. the gradual increasing model, and is also in agreement with constraints indicated by other studies on temporal developments of BIFs, red beds, stratiform Cu deposits and Au-U conglomerates as well as the carbon isotope excursions all over the world.It may be more reasonable to consider an equilibrium state between atmosphere and upper hydrosphere (shallow sea water), in which most carbonates precipitated. As to the BIF, the formation condition should be more complicated. Therefore, unreliable is the model that argued Archean atmosphere to be in high oxygen level on the basis of negative Ce anomalies discovered in BIF ores. An oxygen fugacity vs pH value diagram has been constructed by means of thermodynamic calculation. Preliminary estimation for atmospheric oxygen level at about 1.9 Ga, when Ce(III) was oxidized to Ce(IV) in seawater or weathering surface, has been made for varied atmospheric CO2 levels and pH values.

UNITED TIME SYSTEM OF EARTH SYSTEM MODEL

Tarzadin ULAANBAATAR (Department of Earth Sciences, National University of Mongolia, email: numelect@magicnet.mn)

In Earth System Model must incorporate Earth's basic support system: air, water, ocean and land, geophysical system: gravity, geoelectromagnetism, heliogeothermosphere, seismology and physics of Earth's interior, as well as biogeochemistry, climate system and society. For instance, the success of developing complete Earth System Model depends on the fundamental assumption, according to which all the sub-components of the Earth are necessary, at first, to be described by uppermost elementary parameters, at second, to be governed under a united time system based on the daily and yearly motions of the Earth in geographical coordinate system.
In this paper some laws and principles in hierarchy complexity in the thermal regimes on and near the Earth's surface, climate oscillation and daylight for reconstruction, estimation and predictability in different time interval of global, regional and local scales are described brand-newly by time of calculation, date, geographical latitude, terrain height and albedo.
Furthermore, their results and some proposed ideas for developing Earth System Model are shown. Among above mentioned systems the basic support system, heliogeothermosphere, climate system, biogeochemistry, gravity and their wide use in the service of humankind, as well as application in planetology, planetary-scale explorations of organic resources in earth's crust and so on are described.

ON THE SOUNDS OF THE CLIMATE SYSTEM'S DYNAMICAL STATUS AND EVOLUTION

Peter CARL (Climate Dynamics Project, c/o Forschungsverbund Berlin, Hausvogteiplatz 5-7, D -10117 B Berlin, Germany, email: pcarl@ spclim5. wias-berlin.de)

One of the intriguing questions in climate dynamics is concerned with low-dimensional contributions in the system's motion and predictability. Self-restriction in dimensionality is bound to synchronisation - which offers a conceptual key when trying to indentify the status and evolution of the Earth system. "Dynamic control" by the annual forcing constitutes the topological nature of its seasonal cycle. As studies with a conceptual GCM of about 4.000 d.o.f. have shown, the very existence of today's intraseasonal monsoon dynamics may indicate presence of a "route to chaos" via successive Hopf bifurcations in the atmosphere-land system. The resulting toroidal 'geometry of behaviour' in boreal summer provides a useful conceptual view on climate scales and phenomena across the annual forcing.
If the model does correctly exhibit monsoon onset as a 'hard', subcritical transition into a chaotic July regime, onset dates define natural Poincare sections that offer hints to the topology behind interannual climate dynamics, too. Reading this century's score of monsoon onsets from the southern tip of peninsular India by time-frequency methods comes up with that expectation. Moreover, the challenging methane anomaly of the early 90th presents itself as a phase coincidence across the annual forcing scale, announced in the monsoon series. Full modal structures unveil frequency relationships that point to organised yet highly complex, nonstationary dynamics.

GEOMAGNETIC CHARACTERISTICS OF THE DOJRAN LAKE AREA

Todor Delipetrov (Faculty of Mining and Geology, University "Kiril and Metodij" Skopje, Stip. MK, email: todor@rgf.ukim.edu.mk); Krsto Blazev (Faculty of Mining and Geology, University "Kiril and Metodij" Skopje, Stip, MK, email: krsto@rgf.ukim.edu.mk) Deljo Karakasev (Faculty of Mining and Geology, University "Kiril and Metodij" Skopje, Stip, MK, email:karak@rgf.ukim.edu.mk)

Terrestrial measurements of the total vector of magnetic field were carried out in the 'area o the Dojran Lake. Study of data made possible to compile a map of the anomalies of total vector of magnetic field DT. The application of method of polynomial regression analysis as filter separated the regional DTR from local DT anomalies.
The map of local anomalies separates the eastern from the northern contour faults along which relative dip of the depression took place with relation to surrounding blocks of uplift.
The map of regional anomalies of the total vector of magnetic field DTR indicates that the field is fairly quiet or the gradient of the field above the lake is very low. Greater changes can be found in the northeast and southeast parts of the Dojran depression.

A MODEL FOR FLUID PORE PRESSURE AND ITS AFFECTION ON THE SEISMICITY IN THE SYSTEM

Li LI and Guomin Zhang (Center for Analysis and Prediction, China Seismological Bureau, P.O. Box 166, Beijing 100036, China, email: zgm@cap.ac.cn); Yaolin Shi (Graduate School, University of Science and Technology in China,

A dynamic network is used to simulate the transportation and the diffusion of pore fluid in a seismogenous system and the triggering effects of the variation in pore pressure on the temporal, spatial and magnitude distribution of earthquakes in the system are analysed in detail. The model contains 10 pre-existed seismic belts and there are 15 potential seismic sources in each belt. The whole system is a 2D netlike model that comprises of 150 Maxwell bodies, which will produce artificial catalogues with some definite boundary condition. Another Maxwell body is laid between every two neighboring sources in different belts, which is used as a coupled seismic source that will never break and as a passage for the stress and fluid between the potential sources in neighboring belts. Assumed that the pore fluid spreads in the system following the diffusion equation, i.e., , where S is the temporal propagating coefficient of pore pressure, P is the pore pressure, Kx and Ky are the spatial propagating coefficient along x axis and y axis respectively, and A is for fluid source. The equation is dispersed according to the model used in this paper and solved in an implicit way. Based on the interpretation by Brace and Byerlee in 1996 (Brace, W.R and Byerlee, J.D., 1996) that the mechanism of the shallow shocks is the unstable stick slips and the experimental results by Ziqiang Guo et al in 1989, we assumed that there are no fluid sources in the system and the pore pressure within the broken seismic source decreases about 1/n of its strength immediately after the shock, while the pore pressures in its neighboring sources increase 1/4n of their strengths respectively, in spite of how many potential sources are around the broken one. The coefficient of n is the pore pressure response parameter of the system, which shows the influence intensity of the pore pressure on the strength of the seismic sources. The larger the n is, the smaller is the influence. The G-R relations, the $\sum N$ - t and M-t curves of the artificial shocks are compared in this paper for the wet system in which the influence of the pore pressure is considered and for the dry system in which on fluid is transported. The result shows that the pore fluid and the derived pore pressure have triggered many shocks in the wet system. Under the pore pressure, the number of the shocks in the wet system is larger than that in the dry system and the maximum magnitude of the shocks is higher. The fluid in the system influences the seismicity in the 2D system totally, in temporal and spatial distribution and in the magnitudes and makes it more difficult to forecast the shocks in the system.

DEVELOPING EARTH SYSTEM MODEL THROUGH CHAOTIC DYNAMICS

H.N. SRIVASTAVA (India Meteorological Department, New Delhi- 110003, India, e-mail: snb@imd.emet.in)

Earth atmosphere system has been investigated by integrating different observations derived from chaotic dynamics extending from earth's core to the outer atmosphere. Deeper insight has been provided through our results to distinguish earthquake dynamics on different type of plate boundaries. The atmospheric dynamics could be discussed through the strange attractor dimension of about 6 in respect of atmospheric pressure, maximum and minimum temperatures and monsoon rainfall. In the middle atmosphere, same order of predictability was found from ozone observations. However, ionospheric magnetospheric system had a low dimension of about 2 to 3. Using the concepts of compound chaos predictability of monsoon rainfall over India can be studied for Lorenz and Rossler Systems using any two parameters like ENSO and minimum temperature. However, since, this method can not be extended to more than two parameters, the question of earth system predictability appears to remain unresolved using this dynamical approach.

A NEW EARTH SYSTEM MODEL FOR THE LONG-TERM COEVOLUTION OF GEOSPHERE AND BIOSPHERE

Siegfried Franck, Arthur Block, Werner von Bloh, Christine Bounama, Hans-Joachim Schellnhuber, Yuri Svirezhev (all at Potsdam Institute for Climate Impact Research, PF 601203, D-14412 Potsdam, Germany, email: franck@pik-potsdam.de)

We present a qualitative geosphere-biosphere model to analyse the evolution of the Earth system on a global scale from the geological past to the planetary future in 1.5 billion years. Our Earth system model consists of the components solid Earth, hydrosphere, atmosphere,

and biosphere. It evolves under the external influence of increasing solar luminosity.
The model is based on a quasi-equilibrium formulation of the large-scale global carbon balance between the main sources and the main sinks as modified by the biosphere. To calculate the weathering rate we take into account the growth of continental area over geological time scales and extrapolate the present continental growth rate to the future. We determine the "terrestrial life corridor" for the existance of a photosynthesis-based biosphere in the dependence on the state parameters of the Earth system. In the case of the stady-state approximation without continental growth we reproduce the results of Caldeira and Kasting (1992) about the life-span of the biosphere. The consideration of continental growth in the new model gives a higher atmospheric carbon content for the past but a much stronger decrease for the future. This leads to a reduction of the life-span of the biosphere of up to some hundred million years. We calculate the habitable zone for the past, the present, and the planetary future. From this results we derive the optimum position for an Earth-like planet and calculate -the maximum life-span of any photosynthesis-based biosphere.

THE GLOBAL MODEL OF THE EATH'S ANOMAL STRUCTURE FROM THE MODERN SEISMIC, PETROLOGICAL AND GRAVITY DATA

Susanna A. Kazaryan (Sternberg State Astronomical Institute, Universitetskij pr.13, Moscow, e-mail: kazaryan@sai.msu.ru), Nadejda A. Chujkova and Tatiana G. Maximiva (both at Sternberg State Astronomical Institute, Universitetskij pr.13, Moscow, e-mail: chujkova@sai.msu.ru)

The Earth's equivalent rock topography and depths of Moho discontinuity are represented as the spherical function expansion up to degree 30. The gravity field of the crust is calculated and substracted from the Earth's global gravity field. The interpretation of the remainding anomalies sources is carried out. The coordinates of sources are determined from the map of the remainding gravity anomalies. The masses and depths are determined from the decision of the inverse problem. The obtained results show, that global gravity anomalies near Antarctica (negative) and Australia (positive) can be caused by the anomalies of the outer core boundary; positive anomaly near Caspian sea can be caused by the shift of the Earth's inner core; negative anomaly in Indian ocean corresponds to upper mantle' anomaly; positive anomaly in South Atlantic ocean corresponds to crust' anomaly.

DYNAMICS AND CHEMISTRY OF ATMOSPHERE AND OCEANS IN AN EARTH SYSTEM MODEL

Carlos R. MECHOSO, J. D. Farrara, L. A. Drummond, R. P. Turco, M. Gupta, and J.A. Spahr (all at Department of Atmospheric Sciences, University of California, Los Angeles, CA 90095-1565, email: mechoso@atmos.ucla.edu); Y. Chao (Earth and Space Science Division, JPL, California Institute of Technology, Pasadena, CA 91109, email: yc@comp.jpl.nasa.gov) J. Demmel, H. B. Robinson, and K. Sklower (all at Department of Computer Sciences, University of California, Berkeley, CA 94720-1776, e-mail: demmel@cs.berkeley.edu)

This paper describes the methodology for design, code performance and preliminary results of an Earth System Model (ESM) developed by a team of Earth and computer scientists. The model is used for ensembles of climate simulations in high-end computing environments.
The ESM has three modules: 1) "Models", 2) Distributed Data Broker (DDB), and 3) Verification, Analysis and Control System (VACS). Currently, "Models" includes an atmospheric general circulation model (UCLA AGCM), oceanic general circulation model (Parallel Ocean Program, POP), and atmospheric chemistry model (UCLA ACM). It will soon incorporate an oceanic chemistry model. DDB performs data exchanges and synchronizations between model subdomains based on a consumer-producer paradigm. VACS uses a Data Base Management System (DBMS) and a specialized data schema called "BigSur" to verify and analyze the model output, and has a web-based user interface to control model execution. Some of the model codes, particularly the AGCM, have been highly optimized with emphasis on algorithm improvement and load balancing. The AGCM (2.5 lon x 2 lat x 29 levels) with tracers CFC-11 and CFC-12, coupled to an Atlantic version of POP (1/6 lon x 1/6 lat x 37 levels) requires 47 s to simulate one day of climate on 756 processors of a CRAY T3E-600 (~40 GFLOPS). Selected model results will be presented at the Conference.

EURASIA MORPHOTECTONICS AND RELIEF OF THE GEOID AND THE CORE-MANTLE BOUNDARY

Gennady F. UFIMTSEV. Institute of the Earth's Crust, Lermontov str. 128, 664033 Irkutsk, Russia.
E-mail: ufim@gpg.crust.irkutsk.ru

1. In relief of geoid and the core-mantle boundary two associations of forms escape and their combinations are circumscribed by different groups of symmetry. In a sector the West Pacific ocean, Indian ocean and Asia forms of relief of both surfaces are antisymmetric each other. In a sector of Atlantic region, Africa and America bilateral symmetry takes place. These sectors are divided by the Ural-Oman-Madagascar lineament ("axis") being in relief of both surfaces. This "axis" together with the East Asian lineament is the largest boundary in the post-gondwanian (Late Mesozoic and Cenosoic) Earth structure.
2. In the geoid relief the Urals-Oman-Madagascar "axis" is a slope of a geopotential surface. The meridional sutural block orogen of the Urals adjoins to its upper lip, but the extensive escarpment on the right-side of the Yenisei dividing young West Siberian and ancient Siberian platforms adjoins to its bottom. This escarpment is similar to the great escarpments of margins of the gonwanian continents.
3. The Ural-Oman-Madagascar axis divides Eurasia into two parts with mirror similar dislocation of main forms of tectonic relief: uplifted plains and plateau of the Siberian and Russian platforms, their marginal escarpments of the north-western Scandinavia coast and the northern slope of the Putoran plateau; young mobile belts of low base and mediterranean seas (Alpine belt and Mediterranean region, Indo-China and Zondian region); orogenic belts of high base (Iran and Asia Minor, Tibet-Himalayas); gondwanian subcontinents and their coastal great escarpments adjoined to Eurasia (Arabia and Hindustan). Rejuvenated orogenic belts spread on the east of Eurasia only and adjoin to the "cold" cap in a form of the largest depression of geoid surface.
4. The Pamirs-Punjabian and Assamian syntaxes are situated in the Ural-Oman-Madagascar and East-Asian slopes of a geopotential surface limits correspondingly which restrict the depression of geoid surface. This depression is divided into two steps. Plunging anticlines of the geoid's surface being connected with the Alpine-Himalayan mobile megabelt are disposed between them. The Himalayan front faced southward connects with steep scarp of the geopotential's surface.

THE PREDICTION OF THE REGIONAL NCEP ETA MODEL WITH DIFFERENT LAND SURFACE SCHEMES

YONGKANG XUE, Y. Ji(both at Department of Geography, University of Maryland, College Park, MD 20742,USA Tel: 301-405-4050; fax: 301-314-9299, email:yxue@geog.umd.edu); E. Roger, T. Black, Z. Janjic and K. Mitchell (all at Development Division, NCEP, NOAA, Camp Springs, MD, USA)

Previous studies show that a coupled Eta/SSiB model is able to realistically simulate different climate scenarios. In these experiments, the model is only integrated for 48 hours. The forecast for June 1988 and July 1993 are averaged, respectively, to obtain the regional climate. However, because the model is initialized every 24 hours in these studies, the prediction for some hydrological variables, such as runoff, is mainly determined by the initial conditions.
To understand the regional climate predictability, we have developed the Eta/SiB model for long term prediction studies. Long term numerical integrations are carried out for June and July 1998, June and July 1993, and June 1988 to investigate the time scale of the predictability for the Eta model. Both the 1993 and 1998 spring season have strong ENSO events, The summer of 1988 is extremely dry.
The Eta/SSiB has reasonably good simulations for 1998 and 1988. The results from the Eta/SSiB are compared with the current Eta model simulations (with different land surface scheme).
The preliminary results show that adequate simulations of large scale circulation, i,e, the low level jet and 200mb wind fields, are the key in successful North American regional climate prediction. The results also show that land

A TYPE OF COMPUTATIONAL CLIMATE DRIFT OF THE LARGEST SCALES MOTIONS IN BAROCLINIC PRIMITIVE EQUATIONS

Qing ZHONG, Institute of Atmospheric Physics, Chinese Academy of Sciences , Beijing 100029, China, Email: zhongq@sgi50s.iap.ac.cn

A type of computational climate drift of the largest scales motions in baroclinic primitive equations system is newly revealed in this work. The origin of this computational drift is analyzed, and its unfavorable sequence in relation with predictability of numerical models for weather and climate is also discussed. Moreover, a new successful numerical technique to eliminate this kind of computational systematical error sources/sinks thereby largely reduce the total characteristic model errors in relation with the largest scales motions of atmosphere is discovered, formulated as well as numerically tested. In addition, some applications of this technique is also discussed as a new way to eliminate a corresponding type of computational systematic error source/sink in any Earth System Models , based on currently-used traditional type numerical techniques, with more sophisticated sub-components and thereby make further progress on the fundamental problem of Earth System predictability.

DEVELOPMENT OF SEISMIC RAPID REPORTING AND EARLY WARNING SYSTEM IN TAIWAN

Yih-Min Wu(1), Jen-Kuang Chung(1), Tzay-Chyn Shin(1), Yi-Ben Tsai(2), and William H.K. Lee(3)
1. Central Weather Bureau, 64 Kung Yuan Road, Taipei, Taiwan, 2. Institute of Geophysics, National Central University, Chung-li, Taiwan, 3. 862 Richardson Court, Palo Alto, CA 94303, USA

In 1994, two prototype seismic early warning systems have been implemented in Taiwan: (1) a rapid reporting system using a telemetered network of digital accelerographs spread over the entire island, and (2) an alert system exploring the use of modern technology for the highly seismic area of Hualien. After four-years operation, the rapid reporting system was successfully operated in the seismic monitoring system of the Central Weather Bureau (CWB) for felt earthquake observation (Taiwan Rapid Earthquake Information Release System, TREIRS). It has achieved in the determined of precise earthquake location and magnitude computation about in one minute after the earthquake origin times. On the other hand, the Healien alert system was phase-out in 1998 due to large uncertainty of source parameters determination caused by small station coverage, unsuitable automatic phase picker, and only using P waves in determining the magnitude, although it performed a very well reporting time. Recently, the Hualien alert system stations were equipped with the digital accelerograph and combined to the TREIRS system. By adding the Hualien alert system stations to the TREIRS system, we have obtained a good precision for source parameter determination and a well reporting time for Hualien area earthquake monitoring. During the experiment in the past several years, we benefited from these two prototype seismic early warning systems and optimized the TREIRS system. We are encouraged forwards in the development of seismic early warning system based on the successful experience.

BASIC EARTH SCIENCES AND HAZARDS IN MEGACITIES

Vladimir Keilis-Borok (International Institute of Earthquake Prediction Theory and Mathematical Geophysics, Russian Academy of Sciences, Warshavskoye shosse 79 kor.2, Moscow 113556, Russia, email: vkborok@mitp.ru)

The paper outlines the methodological background of the R&D aimed at containment of the hazards threatening the megacities. While each megacity is unique, this background is partly common for all of them. Three groups of problems are considered: 1) Geotechnical instability of a megacity. 2) Evaluation of possible damage to population, economy and ecology, the worldwide ripple effect included. 3) Disasters' prediction, preparedness, and (in some cases) control. New yet untapped possibilities for R&D in these problems come from integration of: 1) Modeling of "universal" scenarios of critical transitions, common for diverse chaotic systems, not necessary Earth - specific. 2). Modeling of Earth -specific scenarios, intervened with universal ones. 3) Joint phenomenological analysis of the relevant observed fields. 4) Probabilistic risk analysis. Important immediate promise comes from a proper choice of scaling.

VOLCANOES AND MEGACITIES

Grant HEIKEN and Greg Valentine (Earth and Environmental Sciences Division, Los Alamos National Laboratory, Los Alamos, NM 87545, email: heiken@lanl.gov and gav@lanl.gov); Giovanni Orsi (Osservatorio Vesuviano, viale Gramsci, 17b, 80122 Napoli, Italy, e-mail: orsi@ischi.osve.unina.it)

Cities will continue to grow in the 21st Century as the living environment for most of humanity and as foci for the global economy. A volcanic eruption near a large city can have serious regional or global effects. Globally, there are 59 cities near potentially active volcanoes, including 2 megacities; the combined population at risk is over 50 million. As a result, more volcanologists are moving "into the city." There is a growing focus toward the integration of volcanic hazard studies with data-based models of urban infrastructure (e.g., transportation, energy, telecommunications, water distribution, and public health), and with the social and political framework. To prevent large-scale disasters in cities located on or near volcanoes, we must go well beyond the traditional hazard mapping and monitoring and involve the community in extensive education and public awareness campaigns. Risk evaluation must rely heavily on modeling and visualization of physical processes and their effects in a fashion that can be easily grasped by emergency planners, the insurance industry, policy makers, and the public. But it is not enough to focus individual disciplines such as volcanology on urban issues. We must take major steps toward integrating all the geophysical, atmospheric, hydrologic, and geological sciences for interdisciplinary approaches to solving the urban problems of vulnerability and sustainability. An additional but essential step is the integration of these physical sciences with the biological sciences and with infrastructure engineering and planning. IAVCEI therefore proposes to the IUGG that the years 2000-2010 be the "International Decade of Geosciences in the Cities," and that each nation select a "Decade City" for focused interdisciplinary study.

HYDROLOGICAL HAZARDS AND SUSTAINABILITY

Erich J. PLATE (Universität Karlsruhe(TH), Kaiserstr.12, Tel. ++49-721-608-3814, Fax: ++49-721-661329, e-mail: erich.plate@bau-verm.uni-karlsruhe.de)

Cities and their environments strongly interact, what happens in the city affects the social and natural structure of its surroundings, and the surroundings influence the course of development of the city. The larger the city, the more far reaching is this interaction. Rural surroundings and city form a fairly rigid system of complicated interdependencies which is in a precarious balance and quite vulnerable to sudden changes, for example when a major natural disaster, such as a flood, strikes. The vulnerability is enhanced if large parts of the population are unable to cope with natural disasters. In particular the large megacities of the world in developing countries, have drawn very large numbers of poor people who settle in areas which are susceptible to floods and landslides.
There exists a direct link between natural disasters in large cities, and sustainability. An important criterium of sustainability of a society is its stability, which implies that a population is able to adjust to changes without social disruptions. The larger a city is relative to the total population of a country, the more does its stability determine the ability of the country for a sustainable development. The strong link of megacity stability and sustainable development has been emphasised by the InternationaL Decade of Natural Disaster Reduction (IDNDR).

U4/E/04-A4 1145

GEOPHYSICAL STUDIES FOR THE EARTHQUAKE HAZARD MITIGATION IN BEIJING

Yun-tai CHEN (Institute of Geophysics, China Seismological Bureau, Beijing 100081, People's Republic of China, email: chenyt@public.bta.net.cn)

The city of Beijing has a population of 12 million. It is among the megacities that historically and recently have been struck by destructive earthquakes occurred in its surrounding areas. With rapid development in economy during the past two decades, Beijing is vulnerable to earthquake. In order to mitigate earthquake hazard in Beijing, seismic activity monitoring in Beijing, especially in the earthquake-prone Yanqing-Huailai basin, 60km NW of Beijing is intensified. The potential seismic risk in the Yanqing-Huailai basin is estimated using the historical documents, tectonic stress field data, velocity structure of crust-upper mantle from deep seismic reflection and other geophysical measurements as well as the data of recent seismicity. It is inferred that an earthquake with magnitude 6.0 is likely to occur in the Yangqing-Huailai basin. We also carry out studies on the seismic ground motion in the Yanqing-Huailai basin. The results obtained indicate that the source spectrum of the earthquakes occurred in the Yanqing-Huailai basin can be described by a simple omega-squared model and that the quality factor, ranging from 140 to 360, for the SH waves in the Yanqing-Huailai basin are very low. Based on the geological and geophysical data, the shallow velocity structure model of the Beijing area is constructed and the characteristics of seismic ground motion in the Beijing area are modeled. It is found that the thick Tertiary sedimentary basin in the city of Beijing plays an important role in causing amplification of seismic signals. The peak ground acceleration and the total energy of ground motion in the Tertiary depression areas are much greater than that in the other area.

U4/W/05-A4 1215

SAN SALVADOR, EL SALVADOR, A HIGH RISK, MULTIPLE HAZARD MEGACITY

D J SOFIELD, J W Vallance, and W I Rose (Geological Engineering and Sciences, Michigan Technological University, Houghton, MI, 49931, email:djsofiel@mtu.edu)

Volcanism and earthquakes are the most dire geological hazards that threaten San Salvador, El Salvador's largest city (population, 1.7 million), with a rapidly growing population, and few plans or resources for hazard mitigation.
Financial, transportation, and governmental centers of El Salvador all reside within San Salvador. The city lies on a plain within severe hazard zones of two active volcanoes (San Salvador to the W and Ilopango to the E) and also lies in a zone of major subduction earthquakes. In the past 60 Ka, a caldera 12 km E of the city now occupied by Lake Ilopango erupted at least four significant pyroclastic deposits, each of which blanketed the valley that San Salvador now occupies. The last of these eruptions devastated all El Salvador in AD 260 and drove pre-Classic Mayan civilization northward into the jungles. A dome eruption in 1880 and small seismic swarms beneath the lake indicate continuing unrest.
Neither San Salvador volcano nor its numerous flank vents has erupted atastrophically since European colonization, however numerous explosive eruptions occurred prior to that. San Salvador volcano erupted ash-rich tephra and pyroclastic flows 800 years ago and caused mudslides that would likely kill many thousands today. Because of the frequency of earthquakes, the people of San Salvador are much more aware of seismic risk than volcanic risk. The city has had to rebuild 7 times after earthquakes since 1712. The most recent devastating earthquake in 1986, killed 1500, injured 10,000 and left 100,000 homeless. Thick unconsolidated pyroclastic and tephra deposits amplify the effects of shallow-focus, moderate magnitude earthquakes beneath the city. Timely international involvement could provide the impetus that San Salvador needs to begin effective hazard-assessment, monitoring, and educational programs. A significant part of this work will be to make the population of a volcanic country more aware of its vulnerability to volcanic hazards. The recent occurrence of hurricane Mitch offers an opportunity to advance all hazard work in Central America.

CRITICAL CONTRIBUTIONS OF GEOPHYSICS TO THE IDNDR

Bruce A. BOLT (Department of Geology and Geophysics, University of California, Berkeley, CA, 94720, USA, email: boltuc@socrates.berkeley.edu)

The application of recent scientific and technological expertise in geophysics, geology, and geodesy has led to decisive steps forward during the IDNDR, particularly, basic research in physical modelling, surveillance instrumentation, including GPS satellite links, accessible computer networks and data bases, and user friendly software. The World Wide Web has proved a remarkable adjunct. Seismic intensity data are now accessible during and immediately after a strong earthquake through commercial technology, as used in California, Iceland, Taiwan, Mexico, Japan, and elsewhere. The advantages of digital recording for near real-time warning of and response to earthquakes, volcanic eruptions and tsunamis has become clear.
Advances in forecasting of the various hazards have been uneven, but issues have been clarified. Although prediction of eruption initiation has been advanced, that of earthquakes has not. Successful earthquake prediction is now seen as estimating realistic strong ground motions for engineering design and other risk mitigation. There are two main gaps:representative data bases and more relevant professional education. Liability from error is a problem. In all geophysical research germane to risk reduction and recovery response, there remains a need for precise definition of estimation procedures, and standardization of hazard parameters. Theoretical modelling of magna movements and tsunami and seismic waves in three-dimensional structures awaits acceptance as a reliable predictive tool in hazard mapping and in engineering. Widespread transfer to mitigation programs and public knowledge is still a challenge.

U5/W/22-A4 1600

ATMOSPHERIC AND CLIMATIC HAZARDS

Neville Nicholls, Bureau of Meteorology Research Centre,PO Box 1289K, Melbourne 3001, Australia

The last few years have seen enormous damage and loss of life from climate and weather phenomena. The most damaging have included the 1997/98 El Nino (with its near-global impacts), Hurricane Mitch, and floods in China in mid-1998. What have we learnt regarding the causes, variability, and predictability, of these phenomena? Do we understand how and why the frequency and intensity of such extreme climate and weather events varies from year-to-year and from decade-to-decade? Can we predict the occurrence of these extremes, and can we assist decision-makers to mitigate their damage? I will review what we have learnt in the last decade or so regarding the predictability of these cliamte and weather extremes. I will also discuss the impediments to the effective use of forecasts of these extremes to mitigate damage and loss of life.

U5/L/02-A4 1700

HYDROLOGICAL HAZARDS AND RISKS

Robert J. MOORE, Institute of Hydrology, Wallingford, Oxon, OX10 8BB, UK
email: R.J.Moore@mail.nwl.ac.uk)

Floods and droughts are hydrological hazards that result from extremes of meteorological conditions interacting with the terrestrial environment. Hydrological hazards in turn lead to hazards to man and the environment, including ecological systems involving the survival of plants and animals. The risk to the environment posed by hydrological hazards is reviewed from a perspective of scientific understanding, estimation, modelling, forecasting and management. Advances in the understanding of hydrological hazards and the development of improved methods to estimate the rarity of extremes and to mitigate their effects - through catchment planning, structural measures and forecasting-warming-control systems - are outlined. Future scientific challenges concerning hydrological hazards and risks that remain at the close of the IDNDR and the start of the new millenium are identified.

MESOSPHERE MEAN STRUCTURE, PLANETARY WAVES, TIDES, AND WAVE-WAVE INTERACTIONS SIMULATED BY A MIDDLE ATMOSPHERE GCM

W. NORTON (AOPP, University of Oxford, UK, email: wan@atm.ox.ac.uk) J. Thuburn (Dept. of Meteorology, University of Reading, UK)

A global circulation model which extends from the surface to approximately 128 km has been used to examine the dynamics of the mesosphere. It is found that changes to the strength of parameterized gravity wave breaking has a strong influence on the mean structure of the mesosphere, for example, the temperature of the summer mesopause. Associated changes in the vertical shear of the summer mesospheric jet change the amplitude of the two-day wave which is generated through baroclinic instability.
It is shown that large two-day wave activity reduces the amplitude of the diurnal tide around the solstice. The interaction of the tides with the two-day wave produces other waves including a wave-number 4, 16 hour wave.

JSM01/W/20-A1 **0900**

EXCITATION MECHANISMS OF NORMAL MODE ROSSBY WAVES

T. HIROOKA, T. Yonemitsu and Y. Miyoshi (all at Department of Earth and Planetary Sciences, Kyushu University, 6-10-1, Hakozaki, Fukuoka 812-8581, Japan, email hirook@geo.kyushu-u.ac.jp)

Normal mode Rossby waves are planetary-scale free or resonant oscillations of the atmosphere. Prominent among the waves are the three gravest modes of zonal wavenumber 1, which are called 5-day, 10-day and 16-day waves. As for the geopotential field, the 5-day and 16-day waves have symmetric structures with respect to the equator, while the 10-day wave has antisymmetric one. Although these waves frequently appear in the middle atmosphere, their excitation mechanisms have not been well understood. In this paper, the excitation mechanisms are investigated by a series of general circulation model experiments with different boundary conditions and physical processes. Results indicate that heating process due to the moist convection is essential for the excitation. Moreover, some different conditions are necessary for the excitation of individual modes, corresponding to each horizontal structure and travelling period.

JSM01/W/103-A1 **0920**

SIMULATION OF KELVIN WAVES IN THE MIDDLE ATMOSPHERE USING A GLOBAL MODEL OF PLANETARY WAVES

A.I. POGORELTSEV (Institute of the Ionosphere, Ministry-Academy of Science of the Republic of Kazakstan, Almaty, 480068, Kazakstan; e-mail: pogor@ionos.alma-ata.su)

A 2D linearized numerical model of the global structure of planetary waves is used to simulate the propagation of Kelvin waves with zonal wave number one and period 4-, 8-, and 16-days (ultrafast, fast, and slow modes, respectively). The dependence of the vertical structure of Kelvin waves over the equator on the zonal mean wind is investigated through the comparison between the results of simulation for the windless atmosphere, and with taking into account the background wind distribution for solstice and equinox conditions. It has been shown that ultrafast mode is insensitive to zonal mean wind and propagates from the lower into the upper atmosphere without substantial attenuation. The propagation conditions of the slow and fast Kelvin waves are strongly dependent on the background wind and its vertical gradients, and these modes dissipate at the altitudes of the stratosphere and mesopsphere. Eliassen-Palm flux divergence is used as a diagnostics of wave-mean flow interaction. It is found that zonal mean forcing due to dissipation of the slow and fast Kelvin waves does not exceed 1 m/s/day in the stratosphere and mesosphere. Ultrafast mode propagates into the lower thermosphere and provides substantial (about 10 m/s/day) eastward acceleration of the mean flow at the low latitudes in this region.

JSM01/E/39-A1 **0940**

OBSERVATIONAL VARIABILITY IN SIMULTANEOUS MEASUREMENTS OF MESOSPHERIC WINDS BY RADAR AND OPTICAL METHODS

G J FRASER(1), S M Marsh(1), W J Baggaley(1), R G T Bennett(1), K A Deutsch(2), G Hernandez(2), B N Lawrence(1), M Plagmann(1), G E Plank(1) and R W Smith(3) (1) Dept. Physics and Astronomy, University of Canterbury, New Zealand (2) Graduate Program in Geophysics, University of Washington, Seattle, USA (3) Geophysical Institute, University of Alaska, Fairbanks, Alaska, USA

Observed differences between mesospheric wind measuring techniques may arise from a variety of sources including atmospheric variability, the physics of the technique being used, diurnal variations in sampling rate, the scale of the sampling volume and the duration of one observation. The nature and significance of differences will be illustrated by comparing measurements of the semidiurnal tide from 70 - 105km using an MF radar, a meteor wind radar (able to measure only the meridional component) and a Fabry Perot spectrometer. The two radar systems are at the same site near Christchurch, New Zealand, while the Fabry Perot spectrometer is situated 170km to the west of the radars. Results from this network, including meteor wind measurements near-coincident in time but at points up to 300km apart horizontally, will be presented to investigate any significant differences in the observed tide as the observation interval is increased from one day to one month.

JSM01/E/47-A1 **1000**

STUDIES OF STRATOSPHERIC DYNAMICS USING THE ALOMAR DOPPLER WIND AND TEMPERATURE SYSTEM

DAVID REES (CASS, Utah State Univ. Utah State University, Logan, UT 84322-4405, USA) E-Mail: walnut1@easynet.co.uk, Gerd Baumgarten, PIBU, Germany, and Nick Lloyd, ISAS, Saskatchewan, CA.

Since early 1997, series of measurements of winds in the lower and middle stratosphere have been made using the Doppler Wind and Temperature System of the ALOMAR Facility in Northern Norway (69oN). These wind observations have been intercompared with nearby MST radar, radiosone and rocket measurements, validating the wind lidar technique and analysis procedures. The wind measurements are being used to describe the stratospheric transport appropriate to local measurements and studies of stratospheric ozone above Northern Scandinavia during the winter and spring periods in 1997 and 1998.

JSM01/E/33-A1 **1050**

PLANETARY WAVES STRUCTURE IN THE MIDDLE ATMOSPHERE IN 1991-1992 ON BASE OF DATA ANALYSIS AND MODELLING

Alexei KRIVOLUTSKY, Tatyana Vyushkova (both Central Aerological Obs., Pervomayskaya Str.3, Dolgoprudny 141700, Moscow Region, Russia,email: alkriv@mycomp.netclub.ru) Dora Pancheva (Geophysical Institute, Sofia, Bulgaria) Pavel Vargin and Adolf Ebel (University of Cologne, Germany,email: pv@eurad.uni-koeln.de

Global temperature (UKMO assimilated and UARS - ISAMS instrument), geopot. heights (UKMO), ozone content (UARS - MLS instrument), radio absorption and meteor radar data has been used for 1991-1992 interval to study motions structure in the middle atmosphere in this period. 2-D special statistical procedure was used for transient wave analysis using global UKMO data in the vertical range 0-50 km.Because of rather short temporal interval based on the observations from UARS MEM spectral teknique was used also. Meteor radar data(at 95 km level over Bulgaria were analysed using wavelet analysis to study temporal evolution of short-period waves in the meteor region. The results of such complex data base has revealed the presence of transient waves with periods: 2-3, 3-5 and 8-12 days. It should be mentioned that short period waves has a good manifestation in the mesosphere and lower thermosphere, but it is rather difficult to find these waves at lower levels. 2-D and 3-D model simulations has been used to support data analysis results.

JSM01/W/67-A1 **1110**

QUASI 16-DAY OSCILLATIONS IN THE MESOSPHERE AND LOWER THERMOSPHERE: MULTI-YEAR/MF RADAR OBSERVATIONS FROM THE ARCTIC TO SUBTROPICS, AND GSWM MODELING-RESULTS

Y.LUO, A.H.Manson, C.E.Meek (Institute of Space and Atmospheric Studies, University of Saskatchewan, Saskatoon, Canada, email: luo@dansas.usask.ca); C.K.Meyer (HAO, National Center for Atmospheric Research, Boulder, USA); J.M.Forbes (Dept. of Aerospace Engineering Sciences, University of Colorado, Boulder, USA); C.M.Hall (Dept. of Physics, University of Tromso, 9037 Tromso, Norway); W.K.Hocking, J.MacDougall (Physics Dept., University of Western Ontario, London, Canada); D.C.Fritts, D.Riggin (Colorado Research Associates, Boulder, USA); G.Fraser (Physics Dept., University of Canterbury, Christchurch, New Zealand)

The daily mean winds observed by MF radars, located between the Arctic and the Subtropics (one is in southern hemisphere) are used to investigate the quasi "16-day" oscillations in the mesosphere and lower thermosphere. In Saskatoon (52N), the 16-day wave occurs there mostly in winter with maxima at 60~65 km and covers a large range of altitudes; in summer, however, it is much weaker and confined to ~85 km. The vertical wavelength in winter tends to be very long but in summer is a little shorter. The inter-annual variations of the 16-day imply certain associations with the equatorial QBO. Data from the other radar locations (Tromso, 70N; London, 43N; Hawaii, 21N and Christchurch, 45S) are used for similar analysis of annual variations. The winter 16-day wave activity is very weak over Tromso comparing to those over other sites; and the Hawaii shows relatively strong activity. The Global Scale Wave Model has been run to get the annual 16-day wave simulations from the ground to 200 km and for all latitudes of the globe. The comparison with the observation at Saskatoon indicates good agreement. Generally similar seasonal trends are seen by the other MFRs and GSWM, but differences in latitudinal and hemispheric responses are highlighted.

JSM01/W/99-A1 **1130**

NONLINEAR COUPLING OF PLANETARY WAVES AND TIDES OBSERVED BY METEOR RADAR IN THE LOWER THERMOSPHERE ABOVE BULGARIA

Dora PANCHEVA (Geophysical Institute, Bulg. Acad. Sci., "Acad. G. Bonchev" str., bl.3, 1113 Sofia, BULGARIA; Email: dpanchev@geophys.bas.bg) Plamen Mukhtarov (Geophysical Institute, Bulg. Acad. Sci., "Acad. G. Bonchev" str., bl.3, 1113 Sofia, BULGARIA)

The variability of the atmospheric tides observed by meteor radar in the mesosphere/lower thermosphere region above Bulgaria during January , 1991 - June, 1992 demonstrates a complicated temporal behaviour. Waves with different dominant frequencies may occur at different time intervals. To investigate the localised variations of power within a time series of diurnal and semidiurnal tidal amplitudes, as well as of neutral wind, a Morlet wavelet transform is applied. The main periods observed in the variations of the tidal amplitudes and neutral wind are: about 2, 4-6, 8-10 and 14-18 days. The most regular oscillation presented in the neutral wind and in both tidal amplitudes is the well known "16-day wave". A process of a periodic frequency modulation of the 16-day wave with a modulating period of 2-3 monrhs is visible. The nonlinear interaction between tides and planetary waves is studied by bispectral analysis. The results of this analysis indicate that the nonlinear interactions between semidiurnal tide and planetary waves with period in the range 2-20 days are stronger than those of the diurnal tide and planetary waves.

JSM01/W/69-A1 **1150**

SPATIAL STRUCTURE OF QUASI-2-DAY WIND VELOCITY VARIATIONS IN THE MESOPAUSE - LOWER THERMOSPHERE REGION

B.L. Kashcheyev, A.N. Oleynikov, V.N. Oleynikov (Kharkov State Technical University of Radioelectronics, Ukraine, email:ort@khture.kharkov.ua) CH. JACOBI (Institute for Meteorology, University of Leipzig, Germany, email: jacobi@rz.uni-leipzig.de) Yu.I. Portnyagin, E.M. Merzlyakov, T.V. Solovjova (Institute for Experimental Meteorology, Obninsk, Russia, email: portnyagin@iem.obninsk.ru)

Quasi-2-day wind variations in the mesopause - lower thermosphere region were first detected by radio meteor investigations carried out by the Soviet equatorial expedition in Somalia (2 N, 45 E) from August 1968 to 1970. The period of these variations can differ from 48 hours for several hours. The origin of the quasi 2-day variations is not yet fully established, leading to continuous interest to this phenomenon. It is conjectured that the moment of quasi-2-day variations appearance is connected with the interplanetary magnetic field sign changes. The analysis of measurement results obtained at different sites (Kharkov, Mogadishu, Khabarovsk, Molodezhnaya, Collm etc.) showed that the disturbances with the quasi-2-day cycle exhibit the global nature of a westward propagating wave. Simultaneous measurements carried out in Kharkov and Khabarovsk in July-September, 1973 revealed a zonal wave number of 4.5 - 5, which is contrary to many observations revealing a zonal wavenumber of 3 - 4. In this paper the structure of quasi 2-day waves at different altitudes measured during radio meteor location

at Kharkov (1987-1988, 1998) and Mogadishu (1968-1970) is discussed. The higher intensity of the quasi-2-day variations in middle latitudes is observed in summer in July and manifests itself both in the zonal and meridional components. The second, smaller maximum of the quasi-2-day variations activity is sometimes observed in winter, namely in January. The amplitude changes from month to month can be described by the sum of mean annual, annual and semi-annual components.

JSM01/E/05-A1 1210

THE SOUTHERN HEMISPHERE 2-DAY WAVE OF JANUARY 1998

G.O.L. JONES (British Antarctic Survey, Cambridge, UK) D. M. Riggin and D. C. Fritts (both at Colorado Research Associates, Boulder, CO80301, USA)

A quasi 2-day wave in the dynamics of the mesosphere is a common summertime occurrence. The phenomenon has been found to be particularly strong and stable in the southern hemisphere. We report on a 2-day wave which was clearly seen in the southern hemisphere during January, 1998.
Radar observations were made from several ground-based sites around the edge of the Antarctic continent providing information on both temporal and spatial variations. The wave was a significant feature of the mesospheric wind pattern for a 3-week interval. The relationship between the vertical structure of the wave's amplitude and the background wind and tides will be discussed. Possible links with other esospheric phenomena such as the summertime zonal jet will also be considered.

PLANETARY WAVE VARIABILITY IN THE MLT: AN OBSERVATIONAL PERSPECTIVE

R. A. VINCENT, S. Kovalam, and I. M. Reid (Department of Physics and Maths Physics, University of Adelaide, Adelaide 5005, Australia, email rvincent@physics.adelaide.edu.au) D. C. Fritts and D. Riggin (Colorado Research Associates, Boulder, CO 80301, USA, email dave@colorado-research.com)
T. Tsuda and T. Nakamura (Radio Atmospheric Science Center, Kyoto University, Kyoto, Japan, email tsuda@kurasc.kyoto_u.ac.jp)

Transient planetary waves, such as the quasi-2- day wave and the 6.5-day wave, are prominent features of the mesosphere and lower thermosphere. Ground-based radar observations in the Asia/Pacific region are used to describe the spatial and temporal variability of global-scale waves with periods from hours to days and their possible interactions with other atmospheric waves.

JSM01/W/07-A1 1430

MODELLING THE DYNAMICS OF THE 2-DAY WAVE

Maisa ROJAS and Warwick Norton, Atmospheric, Oceanic and Planetary Physics Department, University. of Oxford.

Traveling planetary waves in the stratosphere and mesosphere in the Extended UGAMP GCM (EUGCM) have been analyzed. The frequency and wavenumber spectra for two years of the model run have been compared with meteor radar data from Aberystwyth. There is good agreement in periods of strong wave activity. Both data show a strong 2-day wave present during the summer months.
To understand the forcing mechanisms of this 2-day wave a linear instability calculation using zonal background fields from the EUGCM was performed. This used a two dimensional linearization of the primitive equations on the sphere. This showed for July a fastest growing mode of wavenumber 3 or 4 with period around 37 hours with a structure that peaks in the northern hemisphere at 60 degrees and 70 km height.
To examine the nonlinear evolution of the waves, the same zonally symmetric state, as used in the instability calculation, was used to initialize a Mechanistic model. This showed the growth to finite amplitude of the waves, including vortex merger, and decay; a 'baroclinic lifecycle' in the middle atmosphere. In the Mechanistic model one can observe the development of two independent waves with e-folding time of 4 days and 9 days and periods of 35 and 40 hours respectively.
The first one corresponds to the fastest growing mode of the instability calculation, even though this mode growth fastest it reaches finite amplitude and the dies, whereas the second persists for much longer reaching larger amplitude and has a more global structure, comparable to the 2-day wave in the EUGCM.
Analysis will be presented as to how these unstable modes relate to the Rossby-Gravity modes in the model.

JSM01/W/100-A1 1450

ANNUAL VARIABILITY OF PLANETARY WAVES AS MODELED BY THE GLOBAL SCALE WAVE MODEL: EFFECTS OF MEAN WINDS, FORCING AND GRAVITY WAVES

Christian MEYER (High Altitude Observatory - National Center for Atmospheric Research, P.O.Box 3000, Boulder, CO, 80307, USA, email: meyerc@hao.ucar.edu)

Annual variations in the quasi 16-day and quasi 2-day wave are investigated using a 2-dimesional, steady-state, linearized, perturbation model. The effects of mean winds, location of forcing and the influence of internal gravity waves are explored. Background atmospheres based upon empirical models (HWM-93, MSIS) and satellite observations (UARS: HRDI) are utilized. Simple profiles of eddy diffusion, and those based upon a gravity wave parameterization are employed. When mesospheric wave signatures are significant, the interaction between the planetary wave and gravity wave are also examined.
It is seen that the mean winds have a significant effect on the month-to-month realization of the waves, and that the model predictions vary substantially as a function of background atmosphere that is used. By varying the location of the forcing it is possible to isolate what deltas in the mean wind fields are responsible for the majority of differences. The model predictions are compared to ground and space-based observations of the planetary waves.

JSM01/W/107-A1 Invited 1510

TIDI - A TIMED DOPPLER INTERFEROMETER DESIGNED TO STUDY THE DYNAMICS AND THERMODYNAMICS OF THE MESOSPHERE AND LOWER THERMOSPHERE

T. L. KILLEEN, (Space Physics Research Laboratory, Department of Atmospheric, Oceanic, and Space Sciences, University of Michigan, 2455 Hayward Street Ann Arbor, MI 48109-214, USA, Email: tkilleen@umich.edu), R. M. Johnson, W. Skinner, C. Edmonson, Q. Wu, R. Niciejewski, and S. I. Azeem (all at: Space Physics Research Laboratory, Department of Atmospheric, Oceanic, and Space Sciences, University of Michigan, 2455 Hayward Street Ann Arbor, MI 48109-214, USA)

The TIMED Doppler Interferometer (TIDI) will investigate the dynamics and energetics of the Earth's mesosphere and lower thermosphere - ionosphere. Launch is currently scheduled for May 18, 2000. TIDI measurements will enable a global description of the vector wind and temperature fields, as well as important information on gravity waves, species densities, airglow and auroral emission rates, noctilucent clouds, and plasma drifts. TIDI will scan the terrestrial limb through four identical imaging telescopes: viewing geometry will be at +/- 45 and +/- 135 degrees to the satellite velocity vector. Measurements will be combined to form horizontal velocity vector wind profiles. The vertical resolution will be 2.5 km at the lower altitudes and accuracies will approach 2 m/sec and 2 K for wind and temperature measurements under optimum viewing conditions. A novel adaptation of a circle-to-line interferometer design is incorporated into the detection system permitting simultaneous viewing through all four telescopes. This talk will describe the instrument design and capabilities and highlight anticipated scientific results. Attention will also be given to aliasing issues.

JSM01/E/09-A1 Invited 1550

MEDIUM-SCALE WAVES TRAPPED AROUND THE MID-LATITUDE TROPOPAUSE

Kaoru SATO (Department of Geophysics, Faculty of Science, Kyoto University, Kyoto 606-8502, Japan, email: sato@kugi.kyoto-u.ac.jp)

Using recently available fine time resolution data from regional prediction model (time intervals of 3 h) and MST radar observation (3 min), medium-scale (zonal wavelengths of 2000-3000km) waves with periods of about 1 day trapped around the mid-latitude tropopause were discovered in early 1990's (Sato et al., 1993). Subsequent studies using 6 hourly objective analysis data and hourly regional climate model data showed that the medium-scale waves are ubiquitous in both hemispheres (Hirota et al., 1995; Yamamori et al., 1997; Yamamori and Sato, 1998; Sato et al., 1999). The eastward phase speed is about 20m/s which is twice as large as that of synoptic-scale (4000-5000km) waves. The wave structure is almost neutral.
The meridional gradient of quasi-geostrophic (QG) potential vorticity (PV) has a sharp positive peak in the vertical around the tropopause on the poleside of westerly jet, due to the westerly shear around a discontinuous change of static stability. The medium-scale waves can be regarded as neutral waves trapped in the positive maximum of PV gradient. The features of trapped waves analyzed using a 1-d QG model are similar to the observation. A re-examination of PV conservation equation indicates that the restoring effect to produce wave motions is attributed not to the meridional advection but to the vertical advection of background Ertel PV (Matsuno et al., 1999).
This theory shows that the intrinsic frequency does not depend on the wavenumber, namely, the intrinsic zonal group velocity is zero. This characteristic is consistent with 2-d spectra obtained by ECMWF global operational data. The intrinsic wave period is about 2 days suggesting possible contribution of medium-scale waves to the stratosphere and troposphere exchange.

JSM01/W/47-A1 1620

PLANETARY WAVE INTERACTIONS IN THE ANTARCTIC STRATOSPHERE AND THEIR ROLE IN THE BREAKDOWN OF THE AUSTRAL POLAR VORTEX

Mark HARVEY (Cooperative Research Centre for Southern Hemisphere Meteorology, Building 70, 3rd Floor, Monash University, Clayton,Victoria 3168, Australia. Email: mark@vortex.shm.monash.edu.au

Variations in zonal wave 1 geopotential height amplitude on timescales of 10-14 days have frequently been observed in the Antarctic winter and spring stratosphere. In a number of studies, these variations have been linked to interactions between stationary planetary wave 1 and eastward travelling wave 2. Results presented here indicate this process is a common feature, particularly during spring, and plays an important role in the seasonal breakdown of the Austral polar vortex. In many instances, such variations in zonally resolved waves appear related to irreversible 3-way interactions between a travelling and stationary anticyclone and the polar vortex. A few such episodes are discussed using both zonal and vortex-centred diagnostics.

JSM01/W/28-A1 1640

A STUDY OF THE BREAKDOWN OF THE SOUTHERN HEMISPHERE POLAR VORTEX

Dr Gregory ROFF (Bureau of Meteorology Research Centre, Melbourne, Australia; CRC for Southern Hemisphere Meteorology, Monash University, Melbourne, Australia,
email: greg@vortex.shm.monash.edu.au), Dr Elisa Manzini (Max Planck Institute for Meteorology, Hamburg, Germany, email: elisa@vortex.shm.monash.edu.au) and Mark HARVEY (CRC for Southern Hemisphere Meteorology, Monash University, Melbourne, Australia,
email: mark@vortex.shm.monash.edu.au)

This study aims to investigate the role played by planetary - gravity wave interaction during the breakdown of the southern hemisphere stratospheric polar vortex, which generally occurs in October, using model simulations and observations.
The model simulations available are two versions of the MPI middle atmosphere ECHAM model (Manzini and McFarlane, 1998) as well as the BMRC atmospheric model, BAM, (Bourke 1998) which has recently been extended into the stratosphere. The model intercomparison enables us to obtain an indication of the robustness of the results as well as the dependence of the results on model features. The comparison with observations uses large scale analysed datasets (UKMO, NCEP-CPC, and GASP) to validate the simulated synoptic character of the circulation breakdown.
In this study we use elliptical diagnostics (Waugh, 1997) to compare the simulated vortex breakdown with that shown in the observed datasets. The elliptical diagnostics are calculated for several levels in the atmosphere which enables us to follow the decay of the vortex as a function of both height and time.

JSM01/W/05-A1 1700

STRATOPAUSE SUDDEN WARMINGS ON THE NORTHERN HEMISPHERE -WHEN DO THEY END UP IN A MAJOR STRATOSPHERIC WARMING?

P. BRAESICKE and U. Langematz Institut fuer Meteorologie, FU Berlin Carl-Heinrich-Becker-Weg 6-10, 12165 Berlin

Sudden warmings in the stratopause region are a well known phenomenon in middle atmosphere dynamics. The ability to observe these warmings in detail is limited. Using a ten year integration of the Berlin climate-middle atmosphere model the sudden warmings in the stratopause region and their relation to major stratospheric warmings will be analyzed. The good spatial and temporal resolution of the model can be used for a comprehensive hemispheric diagnostics. The magnitude and temporal development of the simulated events are in good agreement with observations. From the computation of the amplitudes of planetary

waves, the calculation of the EP flux diagnostics and the thermal budgets, we investigate the necessary conditions for stratopause warmings to propagate downward and end up in a major stratospheric warming. First results indicate that preconditioning of the lower stratosphere is an important factor.

JSM01/E/01-A1 1720

TRAVELLING WAVE-PATTERNS BETWEEN TROPOSPHERE AND STRATOSPHERE

Gerhard SCHMITZ, Norbert Grieger (Institut fuer Atmosphaerenphysik an der Universitaet Rostock, Schlossstr. 6, 18225 Kuehlungsborn, Germany, email: schmitz@iap-kborn.de)

The stratospheric circulation is determined by stationary and transient wave processes. On the basis of NCEP RE analyses geopotential fields, covering 1958-1997, travelling wave patterns between troposphere and stratosphere have been found using Principal-Oscillation-Patterns(POP)-method. The vertical propagation of these patterns depends on the analysed oscillation period and shows a distinctive dependence on the geographical longitude. Only over the North-Atlantic region, in the exit region of subtropical jet stream, travelling "wave packets" have been found, which propagate into stratospheric heights. The wave-patterns show characteristics of baroclinic wave life cycles with polewards respectively equatorwards directed Eliassen-Palm-Flux components. An interpretation of patterns has been given with model-experiments on the basis of a simple GCM. The difference in the vertical wave-energy-propagation over the North-Atlantic- respectively Pacific region is due to the regional zonal wind in the upper troposphere and have been discussed with a linear wave propagation model up to mesospheric heights, too.

Tuesday 20 July AM

TIDES

JSM01/L/01-A2 Invited 0930

VARIABILITY OF SIMULATED MIGRATING AND NON-MIGRATING TIDES IN THE MLT REGION

Saburo MIYAHARA (Department of Earth and Planetary Sciences, Kyushu University, Fukuoka 821-8581 Japan, email: sbm@rossby.geo.kyushu-u.ac.jp)

It is discussed about the variability of numerically simulated migrating and non-migrating tides in the MLT region, based on the recent analyses of output data of Middle Atmosphere Circulation Model at Kyushu University (MACMKU) . It will be shown that non-migrating tides are highly variable for both the amplitudes and phases. Origin of the variability will be discussed related to excitation forcings.

JSM01/E/07-A2 1000

AN EMPIRICAL GLOBAL MIGRATING DIURNAL TIDE WIND MODEL FOR THE UPPER MESOSPHERE/LOWER THERMOSPHERE

Yuri PORTNYAGIN and Tatyana Solovyova (both at Institute for Experimental Meteorology, Lenin str. 82, 249020, Obninsk, Kaluga reg., Russia, email:portnyagin@iem.obninsk.ru)

An empirical climatic zonally averaged diurnal tide wind model for the 80-100 km height region is presented. The model is constructed from the fitting of monthly mean diurnal wind oscillation parameters measured by MF and meteor radars at more than 40 stations, well distributed over the globe. The model is constructed for all months of the year and extends from 80 deg.N to 80 deg.S. The height-latitude contour plots of monthly mean amplitudes and phases of the diurnal wind oscillations are analyzed to reveal the main features of the seasonal and latitudinal variations of these parameters. The results of a comparison between the presented ground-based model and those constructed using the UARS wind measurement data show some significant differences. Possible origin of these differences, including the effects of non-migrating diurnal tides, is discussed.

JSM01/E/26-A2 1020

DIURNAL VARIATIONS IN THE RATE OF DISSIPATION OF TURBULENT ENERGY IN THE EQUATORIAL UPPER MESOSPHERE

R.G. ROPER (School of Earth and Atmospheric Sciences, Georgia Institute of Technology, Atlanta, GA 30332-0340 USA, email roper@eas.gatech.edu) J.W. Brosnahan (LaSalle Research Corporation, 24115 Weld County Road 40, LaSalle, CO 80645-9521, email broz@csn.org)

The diurnal variations of the rate of dissipation of turbulent energy over Arecibo (18°N, 67°W) for the AIDA '89 campaigns from April 1 to 11 and May 2 to 9, 1969 have been estimated using a structure function approach applied to imaging Doppler interferometry (IDI) data. The source of the individual scatterers identified by IDI is postulated as resulting from wave - wave interaction within the gravity wave spectrum producing localized, decaying patches analogous to ocean whitecaps. There is a tendency for the turbulence to maximize in the morning and the evening. Values of the rate of dissipation of turbulent energy range from < 5 mW kg-1 to 100 mW kg-1, with the latter probably an overestimate. Local Richardson numbers have been calculated, but it does not appear that the mean flow is the source of the turbulent energy, although the mean wind is capable of helping to destabilize the atmosphere. Emphasis is placed on the fact that any radar measurement of turbulence is an upper limit, because of the inhomogeneity of the turbulence in both space and time.

JSM01/W/62-A2 1110

CORRELATIONS OF GRAVITY WAVES, TIDES AND PW IN THE MESOSPHERE: OBSERVATIONS USING MAINLY THE MLT-MF RADARS IN THE NORTH-AMERICAN/PACIFIC SECTOR

Alan MANSON, Chris Meek (Institute of Space and Atmospheric Studies, University Of Sask., Canada, email: manson@dansas.usask.ca); Chris Hall (Auroral Observatory, University of Tromso, Norway, email: chris.hall@phys.uit.no); Wayne Hocking, John MacDougall (Dept. of Physics and Astronomy, University of Western Ontario, Canada, email: whocking@danlon.physics.uwo.ca); Steve Franke, (Space Science and Remote Sensing Laboratory, University of Illinois, USA, email: sfranke@uiwpls.ece.uiuc.edu) Dennis Riggin, Dave Fritts (Colorado Research Associates, Boulder, USA, email: riggin@colorado-research.com) Bob Vincent (Dept. of Physics and Mathematical Physics, University of Adelaide, Australia, email: rvincent@physics.adelaide.edu.au) Maura Hagan (NCAR, Boulder,USA email: hagan@ucar.edu)

Measurements in the Mesosphere and Lower Thermosphere (MLT), from MF Radars (MFR) located from the Arctic to the Tropics are used to study gravity waves (GW) and their variability : Tromso, 70N, Saskatoon, 52N, London, 43N, Urbana, 40N, Hawaii, 22N, Xmas Is.,2N. GW-band time series (10-100min, 2-6 h), their spectra and their 12,24,48 h oscillations are used. 50d sequences of data from 3 seasons are selected, which themselves are marked by strong differences in winds and tides. The scenario at Saskatoon has recently been published (JASTP,60, p1089), and results from the other stations are quite similar: the modulation of GW by the longer period waves is quite spasmodic. Events of a few days are easily found, but the processes are generally intermittent, suggesting that the wave sources themselves are also intermittent in strength and direction. Results of the new correlation-vector technique, which locates the direction of highest correlation between the hourly mean winds and their variances, over 10 days, are also discussed; this method also assesses the GW modulation by all waves from GW, tides and PW (10d). Interesting differences emerge between high and low latitudes.

JSM01/E/04-A2 1130

ON THE LONGITUDINAL STRUCTURE OF THE TRANSIENT DAY-TO-DAY VARIATIONS OF THE SEMIDIURNAL TIDE IN THE MID-LATITUDE LOWER THERMOSPHERE

Eugeny MERZLYAKOV and Yuri Portnyagin (both at Institute for Experimental Meteorology, Lenin str.82, 249020, Obninsk, Russia, e-mail: portnyagin@iem.obninsk.ru) Christoph Jacobi (Institute for Meteorology, University of Leipzig, Germany) Nicholas Mitchell (Department of Physics, University of Wales, Aberystwyth, UK) Heinz Muller (Cranfield University, RMCS Shrivenham, Swindon, UK) Alan Manson (Institute for Space and Atmospheric Studies, University of Saskatchewan, Saskatoon, Canada) Antonina Fahrutdinova (Kazan State University, Kazan, Russia) Werner Singer and Peter Hoffmann (both at Institute of AtmosphericPhysics, Kuehlungsborn, Germany)

During the DYANA campaign (January-March 1990) the coordinated meteor radar and MF wind measurements at the several mid-latitude stations (Sheffield, Kuehlungsborn, Collm, Obninsk, Kazan, Volgograd and Saskatoon) were carried out. All of these stations are situated in the Northern Hemisphere in a comparatively narrow mid-latitudinal belt. Using the S-transform technique the corresponding hourly mean wind data were analyzed to reveal the main features of the day-to-day semidiurnal tide wind variations and their londitudinal structure. It is shown that these variations have a periodic structure with the periods near to those simultaneously observed in the prevailing wind variations and of typical for the free (normal) atmospheric modes (about 5, 7, 10 and 16 days). The oscillations of the semidiurnal tide amplitudes as well as of the prevailing wind, have a definite transient nature, appear sporadically, existed during several periods and have a specific longitudinal structure.
For example, it is estimated that the near 7-day semidiurnal tide amplitude oscillation is westward-propagating one and has the zonal wave-number s=2 or 3 while the corresponding near 7-day oscillation of the prevailing wind is characterized by the zonal wave-number s=0. Some related problems of semidiurnal tide modulation by planetary waves are discussed.

JSM01/W/104-A2 1150

FIRST AIRGLOW OBSERVATION RESULTS FROM 7.4 S

R. A. BURITI (Dpto Física, CCT/UFPB, Campina Grande, PB, Brazil, 58109-970), H. Takahashi, D. Gobbi (Instituto Nacional de Pesquisas Espaciais, INPE, Sao Jose dos Campos, SP, Brazil)

The Cariri Airglow Observatory has been started working since November, 1997. This observatory has a multi-filter photometer to measure the airglow emission intensities OI5577, OI6300, NaD, OH(6,2) band, O2 Atmospheric (0,1) band , and the OH and O2 rotational temperatures. The observatory is located at Sao Joao do Cariri, the driest region in the Northeast of Brazil at 7.4 S, 36.5 W. Continuous observation from day to day (13 days around the new moon period) make it possible to study nocturnal, day to day and seasonal variation of the airglow intensities. The nocturnal variations of the mesospheric emissions show strong seasonal dependence, maxima during the equinox and minima in the solstices, and the phase of maxima shifting from month to month. It indicates that tidal oscillation is important factor in the equatorial mesosphere. The thermospheric OI 6300 emission also shows significant seasonal variation. Salient features of the seasonal dependency will be presented and discussed in terms of the atmospheric dynamical processes.

JSM01/W/11-A2 1210

TIDES (24-HOUR, 12-HOUR, 8-HOUR) AND TIDAL VARIABILITY IN THE MESOSPHERE AND LOWER THERMOSPHERE AT 53.5 DEG N, 3.9 DEG W BETWEEN 1990 AND 1994

A.G. BEARD, N.J. Mitchell, P.J.S. Williams (Prifysgol Cymru Aberystwyth, Penglais, Aberystwyth, Ceredigion, SY23 3BZ, UK; email: agb@aber.ac.uk) and H.G. Muller (The Royal Military College of Science, Cranfield University, SN6 8LA,UK)

Four and a half years of data from a meteor radar based at Sheffield, UK representing measurements of neutral wind velocity in the meteor region above 53deg 27min N,3deg 53min W, are analysed to produce tidal climatologies. The terdiurnal tide is a constant feature of the analysed neutral winds and its characterisation is given special consideration. Comparisons are made with other published studies and possible reasons for differences between them are discussed. Tidal variability is also studied both in the long-term and the short-term. Causes of this variability are discussed, including the possibility that some of the observed variability is an artefact of the analysis. The non-linear wave-wave interactions that could occur between the tides are considered and the possibility that the presence of a small winter quarterdiurnal (6-hour) tide could be partly due to such a coupling between the diurnal and terdiurnal tides is discussed.

GRAVITY WAVES

JSM01/W/03-A2 Invited 1400

GRAVITY WAVE MOMENTUM, HEAT AND ENERGY FLUXES IN THE MESOSPHERE

R.L. WALTERSCHEID, The Aerospace Corporation, M2-260, P.O. Box 92957, Los Angeles, CA 90009 USA (email: Richard.Walterscheid@aero.org)

Gravity wave transports of momentum, sensible heat and energy alter the background atmosphere when waves violate the nonacceleration conditions. The wave fluxes of heat and momentum force the mean state by causing a redistribution of heat and momentum, while the energy flux adds heat to the mean state through the viscous dissipation of kinetic energy. Observations of wave fluxes indicate a strong influence of waves on the mean state of the middle atmosphere, especially the upper mesosphere. Recent and past measurements of wave fluxes and the implications of these measurements for the mesosphere will be reviewed.

JSM01/E/03-A2 Invited **1430**

A GLOBAL MORPHOLOGY OF GRAVITY WAVE ACTIVITY IN THE STRATOSPHERE REVEALED BY THE GPS OCCULTATION DATA (GPS/MET)

Toshitaka TSUDA and Masahiro Nishida (Radio Atmospheric Science Center, Kyoto University Uji, Kyoto 611-0011, Japan, Email: tsuda@kurasc.kyoto-u.ac.jp, nishida@kurasc.kyoto-u.ac.jp) Christian Rocken and Randolph H. Ware (GPS/MET Project, GPS Science and Technology (GST) Program, UCAR, Boulder, CO 80307-3000, Email: rocken@unavco.ucar.edu, ware@unavco.ucar.edu)

Profiles of atmospheric temperature in the upper troposphere and stratosphere have been obtained by means of a radio occultation observation of GPS (Global Positioning System) signals (GPS/MET; GPS Meteorology) during April 1995 and February 1997. From each GPS/MET temperature profile we have extracted meso-scale temperature perturbations with a vertical scale ranging from 2 to 10 km, and defined the potential energy, Ep, from the temperature variance, which is assumed to be caused by atmospheric gravity waves. We have analyzed the latitude-longitude distribution of Ep at 20-30 km during northern hemisphere winter (from November to February). The large Ep values are generally detected at low latitudes between 25N and 25S, centered around the equator, and they are particularly enhanced over the regions of intense convections. Latitude and longitude variations of Ep are determined at 15-45 km altitude. At middle latitudes, Ep was larger in winter months in each hemisphere. Ep tends to become larger over continents than over the Pacific ocean, which suggests the generation of mountain lee waves due to interaction between the mean winds and topography.

A STATISTICAL STUDY OF GRAVITY WAVES IN THE POLAR REGIONS BASED ON OPERATIONAL RADIOSONDE OBSERVATION DATA

Motoyoshi YOSHIKI and Kaoru Sato (both at Department of Geophysics, Faculty of Science, Kyoto University, Kyoto 606-8502, Japan, email: yoshiki@kugi.kyoto-u.ac.jp)

Gravity waves in the Antarctic and Arctic lower stratosphere are examined based on operational radiosonde observation data at 32 stations over 10 years of 1987-1996. The rotation of hodograph with height indicates that most gravity waves propagate energy upward. Both potential and kinetic energies of gravity waves vary annually taking their maximum in winter in the Arctic and in spring in the Antarctic. The vertical flux of zonal momentum estimated using a statistical method by Vincent et al. (1997) which assumes universal gravity wave spectra is mostly negative and large in winter in both hemispheres, which shows the dominance of gravity waves propagating westward relative to the mean wind. The spring maximum as observed in gravity wave energy in the Antarctic is not clear in the profile of momentum flux. Momentum flux at Scandinavian stations is generally larger than that at Antarctic stations located at almost the same latitudes. In the Antarctic, the warming in the spring occurs earlier at higher altitude, and hence, the region with high static stability propagates downward. The region with large gravity wave energy in the spring propagates also downward following the movement of the high static stability region. Moreover, the high stability area moves horizontally gradually from 135E 50S to 45W 70S through the south pole in spring. The gravity wave energy enhancement coincides with the stability maximum at each station. The ratio of zonal to meridional wind variances depends strongly on location in the Antarctica, indicating that the dominant direction of gravity wave propagation is different.

HIGH ARCTIC OBSERVATIONS OF GRAVITY WAVES AND STRATOSPHERIC WARMING

Thomas J. DUCK (CRESTech & Dept. of Physics and Astronomy, York University, Toronto, Ontario, Canada, M3J 1P3; e-mail: tomduck@lidar.crestech.ca); James A. Whiteway (Dept. of Physics, University of Wales, Aberystwyth, Ceredigion, UK, SY23 3BZ; e-mail: jjw@aber.ac.uk); Allan I. Carswell (CRESTech & Dept. of Physics and Astronomy, York University, Toronto, Ontario, Canada, M3J 1P3; e-mail: carswell@lidar.crestech.ca)

Measurements of stratospheric temperatures and gravity wave activity have been obtained by a Rayleigh lidar stationed in the Canadian High Arctic at Eureka (80 N, 86 W) during each Winter since 1993. The stratospheric conditions above Eureka have proved to be particularly interesting due to the strong influence of the Arctic stratospheric vortex, an enormous cyclone some 4000 km across with peak wind speeds often in excess of 300 km/h. Movements of the vortex from its quiescent position over the pole have allowed measurements to be obtained inside the vortex core, within its Westerly jet, and outside of the vortex altogether.
Observations in the vortex core and jet were collected and examined separately in an effort to resolve some average Wintertime trends in each region. During November and much of December, stratospheric temperatures in the vortex core were seen to remain at relatively constant and cool temperatures. However, a strong intra-vortex warming of roughly 30 K occurred annually in late December, and was sustained through the end of observations in late March. The warming first appeared in the upper stratosphere, and then propagated down to altitudes below 30 km. An increased level of gravity wave activity was detected in the vortex jet during the warming. The coincidence of these two events suggests that they were related by the principle of "downward control"; i.e., that increased gravity wave momentum deposition near the stratopause forced flow into the vortex core where it descended and warmed adiabatically. These observations have implications for our understanding of "sudden stratospheric warming" events, and the ozone depletion problem.

LARGE SCALE WAVES IN THE WINTER POLAR MESOSPHERE

G. M. Fisher (Space Physics Research Laboratory, Department of Atmospheric, Oceanic, and Space Sciences, University of Michigan, 2455 Hayward Street Ann Arbor, MI 48109-214, USA, Email: fisherg@umich.edu), T. L. KILLEEN, R. J. Niciejewski, and Q. Wu, (all at Space Physics Research Laboratory, Department of Atmospheric, Oceanic, and Space Sciences, University of Michigan, 2455 Hayward Street Ann Arbor, MI 48109-2143, USA, Email: tkilleen@engin.umich.edu, niciejew@umich.edu, qwu@umich.edu

Mesospheric wind data were measured by a Fabry-Perot Interferometer (FPI) at Resolute Bay, NWT, Canada (74 N). The OH(7,3) (892 nm) emission Doppler winds were analyzed for planetary scale oscillations throughout the months of December-March during 1995/96 and 1996/97. The FPI has a circle-to-line interferometric optical system (CLIO) which allowed for 9 orders of the OH(7,3) emission to be collected simultaneoulsy by the CCD system. A full scan of the instrument involved measurements in the four cardinal directions and the zenith. Each of these scans required a 90 second integration.
Winds were derived from the OH data (from a height of about 86 km) using a least squares fit. A Lomb-Scargle spectral analysis was performed to derive the frequency peaks present in the time series of the wind data. Large scale oscillations were observed within 2 years of data. Different techniques of analyzing non-linear interactions between planetary waves (16 day, 8 day, 5 day) and the 12 h wave were used. An analysis of the 12 h wave amplitude modulation and the frequency offset was performed.

CO-ORDINATED MESOPAUSE REGION WIND MEASUREMENTS OVER EUROPE IN SUMMER 1998

Ch. JACOBI (Institute for Meteorology, University of Leipzig, Germany email: jacobi@rz.uni-leipzig.de) Yu.I. Portnyagin, E.M. Merzlyakov, T.V. Solovjova (Institute for Experimental Meteorology, Obninsk, Russia, email: portnyagin@iem.obninsk.ru) B.L. Kashcheyev, A.N. Oleynikov (Kharkov State Technical University of Radioelectronics, Ukraine, email: ort@khture.kharkov.ua) D. Kürschner (Institute for Geophysics and Geology, University of Leipzig, Germany) N.J. Mitchell, A.G. Beard (Department of Physics, University of Wales, Aberystwyth, UK, email: njm@aber.ac.uk)

In July and August 1998, mesopause region wind measurements were carried out in by meteor radars at Obninsk, Russia and Kharkov, Ukraine, and by the LF D1 windprofiler at Collm, Germany. Two radars at Pykkvibaer, Iceland, and Hankasalmi in Finland also made additional measurements. The strongest feature within this period is a quasi 2-day wave that appeared in the second half of July. This wave was nearly phase-locked in the zonal component. Phase comparison between Collm, Obninsk, and Kharkov for the zonal component reveal a zonal wavenumber between 4 and 5. Comparison of the wave event with results from previous years shows the regular interannual variability of the quasi 2-day wave intensity, which is possibly connected with the solar cycle through wave-mean flow interaction in the stratosphere/mesosphere. The meridional phase during the event changes by about 0.25 h/day, so that the meridional period is slightly longer than the zonal one. The quasi 2-day wave event is connected with an increase of the semidiurnal tidal amplitude at Collm, but a decrease of the amplitude at Obninsk and - less strong - at Kharkov. This hints to a wave-tidal interaction through the modulation of the background wind field, which is influenced by the quasi 2-day wave.

THE RESONANT RESPONSE OF THE ATMOSPHERE TO THE LOWER BOUNDARY FORCING FOR WESTWARD ZONAL WAVE NUMBER ONE AND THE PERIOD VARIED FROM 6 TO 24 HOURS.

A.I. POGORELTSEV (Institute of the Ionosphere, Ministry-Academy of Science of the Republic of Kazakhstan, Almaty, 480068, Kazakhstan; e-mail: pogor@ionos.alma-ata.su)

Experimental studies of the dynamics in the mesosphere and lower thermosphere (MLT) region show the presence of the large horizontal wind oscillations over South Pole with periods less than and/or about 12 hours (Hernandez et al., Geophys. Res. Lett, 20, 1787, 1993; Forbes et al., Geophys. Res. Lett., 22, 3247, 1995; Hernandes et al., Geophys. Res. Lett., 23, 1079, 1996; Portnyagin et al., Ann. Geophys., 16, 828, 1998). These oscillations were interpreted as manifestation of westward planetary waves with zonal wave number one, and a variety of mechanisms have been proposed to explain these observed features. Numerical simulations of the natural oscillations of the ionosphere-thermosphere- mesosphere system (Meyer and Forbes, J. Atmos. Solar-Terr. Phys., 59, 2185, 1997) provide strong evidence for a normal mode interpretation. However, the result of these simulations show that resonant atmospheric response at periods shorter that 24 hours is dominated only for the MLT forcing and is not observed in the case of the lower boundary forcing. Using a global model of planetary waves (Pogoreltsev and Sukhanova, J. Atmos. Terr. Phys., 55, 33, 1993), we investigate the resonant response of the atmosphere to the symmetric and asymmetric lower boundary forcing for westward zonal wave number one and the period varied from 6 to 24 hours. The results of simulations show that there is not any resonant response for periods between 14 and 24 hours, and that there exist well defined maxima in response at 13.7 and 9.0 hours for symmetric forcing and 10.9 and 7.5 hours for asymmetric forcing. These maxima can be identified with 1st and 2nd symmetric and asymmetric gravitational normal modes of the atmosphere. The dependence of the response magnitude on the latitudinal structure of the vertical motions at the lower boundary was investigated and it has been shown that relative value of the maxima is determined mainly by the projection of the lower boundary forcing onto the corresponding eigenfunction of LaPlace's Tidal Equation. The vertical structure of the gravitational modes shows that magnitude of the horizontal wind perturbations increases with the altitude and relatively small disturbances in the lower atmosphere can provide substantial oscillations in the MLT region. These results provide further evidence for support a normal mode interpretation of the observed short period oscillations of the horizontal wind over South Pole.

SEASONAL VARIATIONS OF 3.0-3.8 DAY ULTRA KELVIN WAVES OBSERVED WITH A METEOR WIND RADAR AND RADIOSONDES IN INDONESIA

Shuji YOSHIDA, Radio Atmospheric Science Center, Japan Email: yoshida@kurasc.kyoto-u.ac.jp

This presentation is concerned with observations of the long-term behavior of Kelvin waves with the wave period ranging from 3 to 4 days, which are generally called an ultra-fast Kelvin (UFK) wave. Horizontal wind velocity at 74--110 km altitudes observed with a meteor wind radar (MWR) near Jakarta (6.4S, 106.7E) for five years during November 1992 and December 1997 and daily radiosonde profiles in Bandung (6.9S, 107 .6E) collected between October 1993 and March 1996 and have been analyzed. In the mesosphere and lower thermosphere (MLT) region, the UFK wave activity, defined by the spectral density of zonal wind perturbations at the 3.0--3.8 day period, clearly dominated by a semiannual periodicity, strongly suggesting an interaction between UFK waves and MSAO. However, an exact mechanism is uncertain. We also have investigated seasonal variation of 3.0--3.8 day oscillations of zonal winds in the stratosphere, excluding gravity wave components, but, we have not detected an evidence of semiannual periodicity. The UFK wave activity in the MLT region exhibited intraseasonal variations (20--33 days), which showed some correlation with the amplitudes of zonal wind in the troposphere.

A POSSIBLE MECHANISM FOR GENERATION OF 20- AND 30-HOUR WAVES IN THE NEUTRAL WIND OF LOWER THERMOSPHERE

D. PANCHEVA (Geophysical Institute, Bulg. Acad. Sci., "Acad. G. Bonchev str.", bl.3, Sofia, Bulgaria) G. Beard (The University of Wales, Aberystwyth, Dept. of Physics, Aberystwyth, Ceredigion SY23 3BZ, U.K.)

A peculiar feature of dynamics in the mesosphere/lower thermosphere region above Bulgaria is the presence of strong oscillations with periods 20 hours and 30 hours, especially in the zonal wind component. Bispectral, correloperiodogram and wavelet analyses of the data indicate that these signals are not simply the result of a nonlinear interaction between the diurnal tide and a 5-day wave. Bispectral analysis reveals that there is a strong interaction occurring involving the semidiurnal tide and the 20- and 30-hour signals. On the basis of this evidence, a mechanism is proposed in which the 20- and 30-hour waves, initially produced as "sum and difference" secondary waves by a 5-day wave/diurnal tide coupling, interact with the semidiurnal tide. The mathematical relationship between these waves results in a feedback mechanism being established in which energy from the semidiurnal tide is channelled into the 20- and 30-hour

waves. Wavelet analysis reveals a period in which the initial 5-day wave/diurnal tide coupling could have occurred. The correloperiodogram analysis supports the proposed mechanisms and lends evidence against the theory that the large 20- and 30-hour waves are simply the result of a strong 5-day wave/diurnal tide interaction lower down in the atmosphere.

SIMULTANEOUS MEASUREMENTS OF THE MESOPAUSE TEMPERATURE PROFILES WITH A SODIUM TEMPERATURE LIDAR AND THE OH(6,2) AND O2(0,1) ROTATIONAL TEMPERATURES AT 23 DEGREES

S Paulo P. BATISTA,Barclay R. Clemesha, Delano Gobbi, Maria P. P. M Jorge, Hisao Takahashi and Igor Veselovskii (both at ,Instituto Nacional de Pesquisas Espaciais, C.P. 515, S. J. dos Campos, SP, BRAZIL) Email: pbatista@laser.inpe.br

The mesopause temperature profile has been measured at São José dos Campos (23.2 degree S, 45.9 degree W) for a total of 15 nights from July to October 1998. The technique used is the measurement of the Doppler temperature of the sodium atoms present in the atmospheric sodium layer with a Lidar. This Doppler temperature is measured by commuting the multi-line output of the laser separated by 1.98 pm between a position where the lines coincide or not with the NA D2 hyperfine lines by controling the pressure in a Fabry-Perot interferometer. During 8 of the 15 days of Lidar temperature data, simultaneous measurements of the rotational temperature of the OH(6,2) band at 775.0 nm and the O2(0,1) Atmospheric band at 864.5 nm were obtained at a nearby station Cachoeira Paulista (22.7 degree S, 45.2 degree W), with a tilting filter photometer. There is a fair agreement between the OH temperature and the gaussian weighted temperature calculated using the LIdar temperatures centered on 87 km and with a half-width of 5 km, consistent with rocket measurements for the OH emission profile, for most of the days. But no consistent combination of height and half-width can reproduce the absolute value and variation of the o2(0,1) temperature, suggesting that transition probabilities used form determining the latter may need to be revised.

THE MESOSPHERIC SODIUM LAYER AT 23°S

Dale SIMONICH (Instituto Nacional de Pesquisas Espaciais-INPE, São José dos Campos 12201-970, SP, Brazil, email simonich@laser.inpe.br) Barclay Clemesha (Instituto Nacional de Pesquisas Espaciais-INPE, São José dos Campos 12201-970, SP, Brazil, email clem@laser.inpe.br)

We present here a comparison of 20 years of mesospheric sodium measurements (685 nights) with our previous paper covering the first 5 years of these measurements referred to as paper 1 (Simonich et al. J. Geophys. Res. 84.A4, p1543, 1979). The average of all of the daily profiles shows a small increase in the peak density (from 3 to 4 x 10-9 m-3) with a very similar shape i.e. a peak at around 91 km. (as opposed to 95 in paper 1) and a secondary maximum at about 85km. The center of mass of this layer was 93 km and its abundance was a little less than 5 x 10-13 m-2. The monthly average profiles for these data show a somewhat different behaviour. Paper 1 showed a broad layer from equinox to equinox with a short minimum in December and slightly increased peak densities around the equinoxes. The more complete data still show a broad maximum but now the peak density is confined to the spring equinox (Southern Hemisphere) and is a little greater than in paper 1. The abundance curves are similar except for the larger abundance in September. Averaging the data into yearly profiles shows a mostly uniform profile with a minimum height in 1983 and a peak height in 1989. The peak density occurred in 84 and 89. There is a gradual rise in the layer from 85 to 89. The abundance seems to show a gradual overall reduction during the period. Fitting a DC level plus a 1 and 11 year cosines to the daily average abundance shows that there seems to be a solar cycle variation in the abundance. The curve has minimums of the 11 year cycle in early 77 and 88 while the minims of the solar cycle occurred in mid 76 and early 86.

SEASONAL VARIATIONS IN AIRGLOW INTENSITIES AND TEMPERATURES AT EL LEONCITO, 1997 - 1999

Juergen SCHEER (PRONARP-CONICET, J. Alvarez 1218, 1414 Buenos Aires, Argentina, Email: jurgen@caerce.edu.ar)

A new run of airglow observations of the OH and O2 emissions and rotational temperatures from El Leoncito, Argentina, in the context of the Planetary Scale Mesopause Observing System, will have nearly completely documented the annual cycle of variations in the mesopause region. The emerging patterns of the intensity variations are different for both emissions. A seasonal oscillation with maxima in April and October and minima at the solstices dominate the behaviour of the O2 Atmospheric band. This is consistent with many previous observations of the green atomic oxygen line, also at similar Southern Hemisphere midlatitudes. The OH emission, also but more weakly dependent on the atomic oxygen concentration, shows a grossly similar behaviour, but with certain distinctive features, probably due to its lower altitude. The rotational temperatures lack the seasonal variations one would expect, at least for the 86 km level.

WINDS AND WAVES AT 50-100 KM OBSERVED WITH MF RADAR AT POKER FLAT AND COMPARISON WITH SIMULTANEOUS RAYLEIGH LIDAR OBSERVATIONS

Y. MURAYAMA, K. Igarashi, K. Mizutani (all at Communications Research Laboratory, Koganei, Tokyo 184-8795 JAPAN, email: murayama@crl.go.jp) Richard Collins (Geophysical Institute, University of Alaska Fairbanks, Fairbanks, AK 99775-7320 USA, email: rlc@hoffa.gi.alaska.edu)

Poker Flat MF radar was constructed in October 1998, as part of the comprehensive arctic middle atmosphere observation program by Communications Research Laboratory of Ministry of Posts and Telecommunications of Japan, in co-operation with Geophysical Institute of Univ. of Alaska Fairbanks. The radar operates with the frequency of 2.43 MHz and peak power of 50 kW since then, which continuously conducts the mesospheric and lower thermospheric wind velocity observation, as well as differential absorption experiment (DAE) for D-region electron density estimation. The wind data in October-November 1998 showed surprisingly larger altitude coverage of 50-100 km (daytime) and 60-100 km (night time) than existing radars. Gravity wave and/or tidal structures can be seen with consistent behaviour of mean wind and fluctuation fields below and above the 60 km altitude. In this study, we conduct simultaneous observations with the MF radar and Rayleigh lidar both at Poker Flat in January 1999, to examine gravity wave fields in wind velocity and temperature, which should be connected by the polarization relation of the gravity wave. Also detailed analysis of the MF radar winds and vertical/temporal wave structure will be presented.

OPTICAL AND RADAR MEASUREMENTS OF MESOSPHERIC TIDES AT DAVIS, ANTARCTICA.

P.A. GREET (1), G.B. Burns(1), W.J.R. French(1), D.J. Murphy(1), P.L. Dyson(2), R.A. Vincent(3) (1) Australian Antarctic Division, Channel Highway, Kingston, Tas. 7050, Australia. (2) School of Physics, La Trobe University, Bundoora, Vic. 3083, Australia. (3) The University of Adelaide, Adelaide, South Australia 5005, Australia.

Davis, Antarctica (68.6°S, 78.0°E), hosts a number of instruments for middle and upper atmospheric studies including a high-resolution Fabry-Perot spectrometer (FPS), a Czerny-Turner grating spectrometer(CZT), and a medium-frequency (MF) radar. Observations of the OH (6-2) emission by the FPS yield mesospheric winds and OH intensities; by the CZT, OH intensities and rotational temperatures. The MF radar measures mesospheric winds from 80-100 km. The CZT and MF radar run routinely but the FPS data is campaign based and reliant on good optical observing conditions. A number of campaigns with reasonable FPS OH data have been obtained in 1997 and 1998. Tidal analyses of data from the three instruments will be presented.

THE MEAN CIRCULATION, TIDES, AND PLANETARY WAVES IN THE EAST-SIBERIAN LOWER THERMOSPHERE

Edward KAZIMIROVSKY and Galina Vergasova (Institute of Solar-Terrestrial Physics, Russian Academy of Sciences, P.O.Box 4026, 664033, Irkutsk, Russia, email:edkaz@iszf.irk.ru)

Ionospheric drift measurements in the LF range, which refer to altitudes between 80 and 100 km, enable the circulation in the lower thermosphere to be permanently monitored. From many years (1975-1996) of such continuous daily measurements on Observatory Badary near Irkutsk, Russia (52 N,102 E) results have been obtained on prevailing zonal and meridional wind, semidiurnal tidal wind components and variations with planetary wave periods. We present the climatic norms for the wind field parameters, their seasonal, intraseasonal and inter-annual variations, their possible long-term trends and dependencies on the solar cycle. We consider the geographical nonzonality of the lower thermosphere wind field, including the response to the stratospheric quasi-biennial oscillations (QBO) and sudden stratospheric warmings.

JSM01/E/10-A2 Poster **1600-12**

INTERANNUAL, SEASONAL AND INTERANNUAL VARIABILITIES IN LOW LATITUDE MESOSPHERIC TIDES

S. GURUBARAN (Equatorial Geophysical Research Laboratory, Indian Institute of Geomagnetism, Krishnapuram, Tirunelveli 627 011, India, email gurubara@md3.vsnl.net.in) R. Rajaram (Indian Institute of Geomagnetism, Colaba, Mumbai 400 005, email rrajaram@iig.iigm.res.in)

Atmospheric tides are the one of the principal means of transferring energy and momentum between different regions of the atmosphere. Tidal perturbations, generated in the lower and middle atmosphere, grow in amplitude as they propagate upwards, and participate in governing the heat and momentum budgets of the upper atmosphere. Observational aspects of the tides were brought out in the past by the varieties of radars and instruments on board satellites. The studies revealed variability in mesospheric tides on different spatial and temporal scales. The causative mechanisms responsible for the tidal variabilities, however, are not known.
The medium frequency (MF) radar observations of mesospheric tidal winds over more than five years, made from the low latitude site, Tirunelveli (8.7 degrees N, 77.8 degrees E), India, are reported in the present work. The variabilities on different time scales are examined in detail. The seasonal variabilities are rather complex. The prominent feature in the observations is the interannual variability in the diurnal tide. The tidal amplitudes are largest in the intraseasonal time scales in the zonal component than in the meridional component, the distinct periods observed being 90 and 60 days. Since similar variabilities are noticed in the mean zonal flow, tidal-mean flow interactions might have resulted in the observed intraseasonal variability in the tidal amplitudes.

ON SOME VARIABILITIES IN MIDDLE ATMOSPHERE DYNAMICS OVER SOUTH EASTERN EUROPE

Petio Simeonov, Staycho KOLEV and Lubka Milenkova (National Institute of Meteorology and Hydrology, Bulgarian Academy of Sciences, Sofia-1784, Bulgaria, email: Petio.Simeonov@meteo.bg, Stayko.Kolev@meteo.bg)

The basic wind and air temperature characteristics (representing the dynamic in the middle atmosphere) are obtained on the base of radio and rocketsounding data from Ahtopol station during December 1982 - March 1992.
The seasonal and annual vertical profiles of the wind (zonal and meridional components) up to 60 km are shown. Westerlies prevail in the annual distribution of zonal wind velocities. Mean monthly velocities vary between 9 and 57 m/s (in the summer) and reach up to 74 m/s in the winter. The values of meridional wind velocities are about 0 m/s up to 30 km altitude and reach up to 12 m/s over this level. The set of statistical characteristics are obtained concerning the time-space variability of the wind. The cross sections of monthly wind velocities distribution show the seasonal variability in middle atmospheric dynamics.
The temperature vertical profiles (seasonal and annual) are framed up to 75 km in the troposphere and stratosphere are framed. Annual and seasonal temperature trends at 25, 45 and 65 km levels are studied. The tendency of cooling in the high stratosphere is found out after 1985, more underlined in the springtime and summer season. The vertical cross section of monthly temperature distribution shows the seasonal passage in middle atmosphere over Balkan region in Southeastern Europe.

MEAN WIND AND TIDAL FEATURES IN THE HIGH LATITUDE AS SEEN BY A NEW MF RADAR AT POKER FLAT, ALASKA (65.1N, 147.5W)

Kiyoshi IGARASHI and Yasuhiro Murayama (both at Communications Research Laboratory, Koganei, Tokyo 184-8795, Japan, email igarashi@crl.go.jp) Done Rice and Brenton J. Watkins (both at Geophysical Institute, University of Alaska Fairbanks, Fairbanks, AK 99775-7320, USA, email ddr@flux.isr.alaska.edu)

We have constructed a new MF radar system at Poker Flat, Alaska (65.1N, 147.5W). This radar started operation on 16 October, 1998, for studies of the mesosphere and lower thermosphere region at high latitude as a collaboration project between Communications Research Laboratory, Japan and Geophysical Institute, USA. This radar is operated at frequency 2.430 MHz and peak power 50kW. Wind measurements by FCA and electron density measurements

by a differential absorption method are conducted alternately. From the first data in October, 1998 we found strong 12 hour oscillations and long-period oscillations in the mesospheric wind. In this paper we will introduce this new MF radar system and discuss features of mean winds, tidal and planetary waves in the high latitude based on this radar observations.

Wang (Both At School of Earth And Atmospheric Sciences, Georgia Institute of Technology, Atlanta, Ga 30332-0340 U.S.A., E-Mail: Cunnold@Eas.Gatech.Edu), A.E. Dessler (Dept. of Meteorology, University of Maryland, College Park, Md 20742, U.S.A., E-Mail: Dessler@Atmos.Umd.Edu), J.C. Gille, W.J. Randel (Both At National Center For Atmospheric Research, Boulder, Co 80307, U.S.A., E-Mail: Gille@Acd.Ucar.Edu, Randel@Acd.Ucar.Edu), R.G. Grainger, S.M. Wheaton, (Both At Department of Physics And Astronomy, University of Canterbury, Private Bag 4800, Christchurch, New Zealand, E-Mail: R.Grainger@Phys.Canterbury.Ac.Nz), H.C. Pumphrey, Dept. of Meteorology, Univ. of Edinburgh, Edinburgh Eh9 3jz, Scotland, E-Mail: Hcp@Met.Ed.Ac.Uk).

The UARS (Upper Atmosphere Research Satellite) reference atmosphere project has developed a number of climatological datasets characteristic of the stratosphere (and mesosphere) during the UARS mission. These data are based on the unique, detailed, near-global observations from the chemical constituent sounders on UARS and include ozone and related chlorine and nitrogen species, sulphate aerosol, dynamical tracers and temperature. For this reason, they represent a major step forward in describing the middle atmosphere through simultaneous measurements of many species. The fields consist of monthly zonal means in both pressure and theta vertical co-ordinates where the theta co-ordinate data has been mapped using equivalent latitude techniques. Estimates of variability are also provided. The data will be presented along with methodologies and comparisons to previously available reference datasets. The new datasets will also be placed within the context of the atmospheric conditions prevailing during the UARS mission.

SEASONAL VARIATION OF GRAVITY WAVE ACTIVITY IN THE UPPER MIDDLE ATMOSPHERE IN CENTRAL EUROPE

Jaroslava Boskova, Jan LASTOVICKA (Institute of Atmospheric Physics, Bocni II, 141 31 Prague 4, Czech Republic, e-mail: jla@ufa.cas.cz)

The results of various authors on the seasonal variation of gravity wave activity in the middle atmosphere do not provide a consistent pattern. However, it is evident that the seasonal variation is height-dependent and it may be regionally dependent, as well, perhaps due to a regional variation of gravity wave sources. Here we analyze five years (1989-1993) of continuous gravity wave data inferred from the LF radio wave absorption in the night-time lower ionosphere (~90-100 km) in Central Europe (50N, 16E). Previous analyses were made only from the point of view of summer-winter difference on a substantially smaller data set. They did not find a detectable difference. They pointed out the importance of the effect of the length of night on the results due to limited persistency of wave events. This effect is now very carefully evaluated for the 5-year data series analyzed.

WAVE ACTIVITY IN THE STRATOSPHERE OVER SPRING NORTH POLAR REGION DERIVED FROM OZONESONDE MEASUREMENTS AT FAIRBANKS IN APRIL 1997

Kazuo SHIBASAKI, Kokugakuin University, Email: skazuo@kokugakuin.ac.jp

Global distribution of gravity wave activity in the stratosphere is the key to understand the role of gravity wave on dynamical processes in the Earth's atmosphere. Recently many observational evidences have been reported on the behaviour of gravity wave activities. These data were obtained with a variety of instruments. However, few data have been collected in the polar region. We made ozonesonde measurements as a part of ADEOS validation campaign in Fairbanks, Alaska during April 1997. We present the characteristics of wave structure deduced from ozonesonde measurements made at collar region of northern polar vortex. Wave characteristics were examined using both the temperature and ozone vertical profiles. We show a spectral analysis result, which shows wave structures of a vertical wavelength of about 3km. These wavy structures may be attributed to gravity wave activity. Wavy structures are clearly recognized in the temperature profile. Although they are not so clear in the ozone profiles partly because of the variable layer structures of ozone in the lower stratosphere due to active horizontal transport process, a peak at wavelength of 3 km can be calculated from spectral analysis of ozone profiles. Correlation between the wavy structures seen in the temperature and ozone profiles is discussed in this paper. Also reported in this paper is the preliminary analysis result of the ozonesonde measurements scheduled to be carried out in mid-March 1999 at Fairbanks.

MESOSPHERE FRONTAL GRAVITY WAVES, AND SOLAR ECLIPSE AT NOON

J. Delloue (Valensole, Haute Provence, France), D.C. Fritts colo. Res. Ass., USA), Th. Farges (LDG/DASE-CB3, France),C Lathuillere LIS/Grenoble, France), G. Thuillier, S.A. Verrieres CNRS, France) and P.M. VILA (CETP/CNRS, Saint-Maur-des-Fosses, France).

The traveling modes of ionospheric frontal wave have diverse source processes. The least elucidated are mesospheric shear effects now evidenced on the average Windii Hrdi data. We here present Summer midlatitude and associated low-latitude wind profiles from the Windii database. On the 11 August 1999 the Euro-pean zone swept by the noontime Solar Eclipse near 50=B0 North latitude will simultaneously create i)a deep conductivity shock at E-layer levels and ii)a subsequent bow-wave front at hundreds km distance from the edge of the totality zone. Traces of this front will be searched by the HF radar at Valensole (Haute Provence), and if possible in the early evening by the Michelson OHP interferometer (Manosque, Haute Provence, France). Experimental results from these experiments and from other European networks will be later usable to discuss the coupling model of Fritts (1993).

PRELIMINARY RESULTS OF THE AIRGLOW AND TEMPERATURE OBSERVATIONS BY MORTI AT THE ALMATY SITE (43.6 N, 76.6 E)

V.M. AUSHEV, A.I. Pogoreltsev, and V.V. Vodjannikov (all at Institute of the Ionosphere, Ministry-Academy of Science of the Republic of Kazakstan, Almaty, 480068, Kazakstan; e-mail: pogor@ionos.alma-ata.su); R.H. Wiens and G.G. Shepherd (both at Institute for Space and Terrestrial Science, York University, 4850 Keele St., North York, Ontario, Canada, M3J 3K1, e-mail: rudy@stpl.cress.yorku.ca)

Preliminary results of analysis of the molecular oxygen nightglow emission rate and rotational temperature observed in Almaty by Mesopause Oxygen Rotational Temperature Imager (MORTI) during 1997-1998 period are discussed. The Lomb-Scargle periodogram analysis was applied to assess the statistically significant oscillations present in the data. A quadratic fit was subtracted from each data set to remove trends whose periods were commensurate with the data set length. Two groups of statistically significant peaks appear in the power spectra. The lower frequency group corresponds to the periods of 5-9 hours. These variations are most likely due to the tidal (6 and 8 hours) oscillations similar to reported by Wiens et al. (Geophys. Res. Lett., 22, 2637, 1995) and Ozonovich et al. (Planet. Space Sci., 45, 385, 1997) and/or perhaps due to the gravitational normal modes (Meyer and Forbes, J. Atmos. Solar-Terr. Phys., 59, 2185, 1997; see also Pogoreltsev, report submitted at this symposium). The higher frequency group corresponds to the periods of 2-3 hours, and these variations are due to the IGW propagation at the mesopause heights. COPHASE method proposed by Posmentier and Herrmann (J. Geophys. Res., 76, 2194, 1971) was applied to obtain IGW characteristics from MORTI data. It has been shown that the azimuth of wave propagation and the horizontal phase speed obtained by COPHASE technique are more reliable then estimations of these values obtained by least squares method, which is traditionally used for analysis of MORTI data.

EIKONAL SIMULATIONS OF THE SPECTRUM PRODUCED BY THE PROPAGATION OF SMALL-SCALE INTERNAL GRAVITY WAVES THROUGH LARGE-SCALE INTERNAL WAVE FIELDS

R.L. WALTERSCHEID, The Aerospace Corporation, M2-260, P.O. Box 92957, Los Angeles, CA 90009 USA (Richard.Walterscheid@aero.org)

A small-scale internal gravity wave packet sees a time- and space-dependent background as it propagates upward through a field of large-scale internal gravity waves. The time and space dependency of the background causes the wave packet to migrate in frequency-wave number space. In time-dependent wave backgrounds, waves can propagate through levels that would be critical in stationary horizontal flow. In wave backgrounds, wave removal at such levels depends on the initial wave-packet amplitude. We have performed eikonal calculations for large numbers of wave packets propagating through various realizations of background wave spectra. It is found that the migration of wave packets in both wavenumber and frequency and the initial wave amplitudes help shape the wave spectra.

QUASI-UNIVERSAL M^{-3} VERTICAL WAVENUMBER SPECTRA GENERATED BY ISENTROPIC ADVECTION BY A SUPERPOSITION OF SINUSOIDAL GRAVITY WAVE DISPLACEMENTS

Stephen D. ECKERMANN, E. O. Hulburt Center for Space Research, Code 7641.2, Naval Research Laboratory, Washington DC 20375

We present results of a two-dimensional model of isentropic advection of air parcels by a superposition of sinusoidal wave displacements due to hydrostatic gravity waves. Data are gridded at high vertical resolution and used to generate potential temperature, displacement and velocity perturbation profiles. As amplitudes increase, wave perturbation profiles distort due to advection of air parcels across the phase fronts of other waves. At saturation amplitudes near overturning, the spectra of these profiles attain quasi-universal M^{-3} shapes similar to observations. Possible relationships to other theories of gravity wave spectra in the atmosphere and oceans will also be discussed.

SMALL SCALE WIND STRUCTURE IN THE MESOSPHERE

R. R. CLARK, (Electrical and Computer Engineering, University of New Hampshire, Durham, NH 03824, email: ron.clark@unh.edu) J. E. Salah, L. P. Goncharenko, (both at Haystack Observatory, Massachusetts Institute of Technology, Westford, MA 01886, email: jes@haystack.mit.edu)

Observations of small scale structure in the mesophere winds with the UNH meteor wind and the Millstone IS radar will be presented. Attention is given to the measurement error associated with the radars and the possible errors introduced by known wind components. The spacial resolution of these measurements is approximately 2 km. The rms velocity errors vary but are generally 7 m/s for the meteor radar and 25 m/s for a 2 minute measurement with the IS radar. Observations have been made in a common volume with both instruments and both show random variations in the wind measurements that are greater than the predicted error from the measurement process. Measurements indicate that the roughness of the wind structure can change hourly. These results should be useful when one is trying to compare wind measurements made with instruments, which use different techniques.

SEASONAL VARIATIONS OF WIND VELOCITY AND TEMPERATURE VARIANCES OBSERVED WITH RADIOSONDES IN INDONESIA

Atsushi SHIMIZU, Radio Atmospheric Science Center, Japan, Email: shimizu@kurasc.kyoto-u.ac.jp

We continued radiosonde soundings once a day for about 30 months during October 19, 1993 and March 11, 1996, in Bandung, Indonesia (6.9 S, 107.6 E), and obtained total of 785 profiles of horizontal winds and temperature at 0--38km, and the same number of humidity profiles below 10 km. We first show in this presentation the climatological characteristics of zonal winds, precipitable water vapor content (PWC) and Brunt-Vaisala frequency squared, N^2, in the troposphere and lower stratosphere. PWC shows a clear annual cycle between dry and rainy seasons, centered in July--October and December--March, respectively. The N^2 variations were particularly enhanced in the upper troposphere (11--14 km), and the seasonal cycle of N^2 is anti-phase to that for PWC. We have further analyzed the seasonal variations of wind velocity and temperature perturbations with a vertical scale of 2 km, which is used as an index of gravity wave activity. Annual cycle of the gravity wave activity is clearly recognized in the entire troposphere, which is anti-phase to the seasonal variations of PWC, that is, it is in-phase to the N^2 variation in the upper troposphere. The gravity wave energy seems to be proportional to the background N^2 value, as suggested by a saturated gravity wave model. In the lower stratosphere the annual cycle of the gravity wave activity disappears, but the long-term variations are related to the QBO structure.

INITIAL RESULTS OF THE OPTICAL MESOSPHERE THERMOSPHERE IMAGERS (OMTI): SIMULTANEOUS IMAGING OBSERVATION OF FOUR AIRGLOW LAYERS AROUND THE MESOPAUSE

Kazuo SHIOKAWA, Mitsumu Ejiri, and Tadahiko Ogawa (Solar-Terrestrial Environment Laboratory, Nagoya University, 3-13, Honohara, Toyokawa, Aichi 442-8507, Japan, Email: shiokawa@stelab.nagoya-u.ac.jp) Takuji Nakamura and Toshitaka Tsuda (Radio Atmospheric Science Center, Kyoto University, Uji 611-0011, Japan, Email: nakamura@kurasc.kyoto-u.ac.jp) Rudolph H. Wiens (Center for Research in Earth and Space Science, York University, Ontario M8V 3E5, Canada, Email: rudy@stpl.cress.yorku.ca)

The Optical Mesosphere Thermosphere Imagers (OMTI) have been developed to investigate the dynamics of the upper atmosphere through nocturnal airglow emissions. The OMTI consist of an imaging Fabry-Perot interferometer, three all-sky cooled-CCD cameras, three tilting photometers, and a Spectral Airglow Temperature Imager (SATI) with two container houses to install them in. These instruments measure wind, temperature and 2-dimensional airglow patterns in the upper atmosphere at multi-wavelengths of OI (557.7nm and 630.0nm), OH(6-2) bands, O2(0,1) bands, and Na (589.3nm), simultaneously.
Using four all-sky cooled-CCD cameras (three from OMTI and one from Kyoto University), small-scale wave structures are observed in the airglow images at four wavelengths (OI, OH, O2, and Na emissions) around the mesopause region, during the Japanese PSMOS campaign on January-March, 1998 at Shigaraki (35N, 136E). We found an event during which gravity wave breaking occurs in the images. Vertical propagation and breaking of the gravity waves will be discussed using these image data and simultaneous wind and temperature data obtained by the MU radar.

WAVE STRUCTURES IMAGED NEAR INFRARED NIGHTGLOW AT YAKUTSK

P.P.AMMOSOV, G.A.Gavrilyeva (Institute of Cosmophysical Research and Aeronomy. 31, Lenin Ave., Yakutsk, 677891, Russia, e-mail: g.a.gavrilyeva@sci.yakutia.ru)

A digital all-sky imager for the study of the propagating internal gravity wave parameters and their sources is made and is installed at the station Maimaga (j=63N; l=129,5E; F=56; L=199,7). The instrument consists of the lens "fish eye" with angle of view 180° and CCD-camera which is cooled up to -50°C and is interfaced with personal computer. Numerous wave patterns in the near infrared nightglow (600-1000) nm show that the short period gravity waves are commonplace over Yakutia. It is shown that in the most of cases the waves propagate to zonalward.

AVERAGE SEASONAL VARIATIONS OF IGW INTENSITY AND MOMENTUM FLUXES IN THE MESOSPHERE REGION FROM THE MU RADAR OBSERVATIONS IN 1986 - 1997

Nikolai M GAVRILOV (Department of Atmospheric Physics, Saint-Petersburg University, Petrodvorets, 198904, Russia, Email: gavrilov@snoopy.phys.spbu.ru); Shoichiro Fukao and Takuji Nakamura (both from Radio Atmospheric Science Center, Kyoto University, Uji, 611 Kyoto, Japan, Email: fukao@kurasc.kyoto-u.ac.jp)

Averaged seasonal variations of intensities of wind variations and vertical flux of horizontal momentum produced by internal gravity waves (IGWs) with periods 0.2 -- 1 hr and 1 -- 6 hr are studied at the altitudes 65 - 80 km using data of measurements with the Middle and Upper (MU) atmosphere radar at Shigaraki, Japan (35° N, 136° E) during 1986 -- 1997. Simple numerical frequency filters are applied to separate wind variations having different periods. Wind variances and momentum fluxes are calculated using standard technique with pairs of the radar antenna beams inclined in opposite directions from zenith. Daily values of wind variances in every frequency band are averaged for each corresponding month over the whole period of the MU radar observations from 1986 to 1997. Mean IGW intensity has a maximum in summer and comparable maximum in winter, the winter values having big interannual variations. Mean zonal wave momentum flux is directed to the west in winter and to the east in summer - opposite to the mean wind in the middle atmosphere.

PARAMETRIZATION OF THE INTERNAL GRAVITY WAVE FORCING IN THE MIDDLE ATMOSPHERE

A.BELYAEV (Federov Institute of Applied Geophysics, Rostokinskaya ul.9, Moscow 129128 Russia Email: belyaev@rc.msu.ru)

Momentum exchange between internal gravity waves and background atmosphere flow is simulated. Simulations using the original IGW parameterization allowing wave destruction on the critical levels are effected in the framework of the one-dimensional atmosphere model. It is shown that acceleration or deceleration of the background flow by wave forcing is depended on the direction of the mean wind vertical shift. Wave force has the same sign as the mean wind in the stratosphere and opposite in the upper mesosphere-lower thermosphere.

MOMENTUM FLUXES DUE TO OROGRAPHIC EFFECTS

Rita Margarida CARDOSO (Centro de Geofisica da Universidade de Lisboa, R. da Escola Politecnica 58, 1250 Lisboa, Portugal, email: rcardoso@fc.ul.pt); Pedro M.A. Miranda (Faculdade de Ciencias da Univesidade de Lisboa, Campo Grande, Edificio C2, 1700 Lisboa, Portugal, pmiranda@fc.ul.pt)

The generation of gravity waves with wavelengths that allow for vertical transport of energy and momentum are one of the possible effects of orography. These waves may be responsible for dramatic changes in the flow around mountains. The horizontal dimension of the mountain plays an important role in the influence of the Coriolis force on the flow, and its height is crucial for determining flow splitting and wave breaking. In linear flow, the drag on the mountain due to an asymmetry of the pressure field around it, is equal to the upward flux of momentum due to gravity waves.
The present study focuses on the onset of different flow regimes due different horizontal mountain scales, including rotation, surface friction and thermal effects. Data from a field experiment in the Island of Madeira and from the PYREX campaign are used and compared with results from both linear and non-linear simulations of flow past realistic orography.

ALIGNMENT OF MOUNTAIN LEE-WAVES STUDIED USING MST RADAR AND NOAA AVHRR IMAGES

R.M. WORTHINGTON (Department of Physics,University of Wales, Aberystwyth, Dyfed, SY23 3BZ, U.K.) email: rrw@aber.ac.uk

Alignment of atmospheric mountain-waves is a significant parameter in e.g. represention of wave drag in numerical weather models, and to predict PSCs or wave-breaking turbulence. The MST radar at Aberystwyth (52.4N, 4.1W) is used to measure long-term mountain wave alignment and its relation to background wind direction, using a method based on the tilting of VHF-radar scatterers by the mountain waves. Secondly, the alignment is also measured from wave clouds on more than 2 years of satellite images, and combined with UK Meteorological Office synoptic data. The two independent methods show the horizontal component of the mountain wave vector is, on average, aligned with the wind direction in the middle of the boundary layer, i.e. between the directions of the surface and geostrophic winds. For mountain waves above the Welsh mountains, the wind direction in the boundary layer appears to be a more important factor on the wave alignment than the direction of mountain ridges.

OROGRAPHIC BUOYANCY WAVES IN PRESSURE-CO-ORDINATE DYNAMICS

Aarne MÄNNIK, (Tartu University, Tähe 4, Tartu, 51010, Estonia, email: aarne@aai.ee) Rein Rõõm (Tartu Observatory, Tõravere, Tartumaa, 61602, Estonia, email: room@aai.ee)

Estimation of the accuracy of different pressure coordinate models is carried out, modeling buoyancy wave generation by orography. Evaluated models are: the elastic nonhydrostatic model (EFM), the anelastic nonhydrostatic model (AEM) and the hydrostatic primitive equation model (HSM). These models are compared to the exact, nonfiltered, nonhydrostatic, pressure-coordinate dynamics (ExM). All model equations are linearized, a wave-equation for vertical displacements of air particles is derived, and stationary solutions for each model are compared for uniform flow over given smooth orography.
Modeling reveals that compressible (ExM, EFM) and incompressible models (AEM, HSM) are different at horizontal scales longer than 700 km. Differences are especially large in vertical velocity field (up to 100 %) at the medium and upper levels of the atmosphere, where incompressible models give systematic reduction of wave amplitudes. All models are effectively incompressible and coincide with high precision in the region 10 - 700 km. The first critical scale is at 10 - 20 km, below which the HSM fails. The second critical scale is at 100 m (moderate winds) - 1000 m (strong winds), below which the AEM becomes inconsistent with the other models in temperature fluctuation presentation. The EFM represents a universal approximation, valid at all scales.

THE FIRST DETECTION OF FREE OSCILLATIONS OF THE ATMOSPHERE IN THE 1 - 2 H PERIOD RANGE

L.N. Petrova and G.M. SHVED (Institute of Physics, St.Petersburg State University, St.Petersburg-Petrodvorets 198904, Russia, email: shved@lmupa.phys.spbu.ru)

The frequency spectra of seismic oscillations in the 1 - 2 h period range have been derived for four runs by seismograph with vertical pendulum in St.Petersburg (60N, 30E) of the 30-90 h duration. Oscillations with steady frequencies have been detected in the 0.155 - 0.290 mHz range. Most of them is thought to be global normal modes of the atmosphere. This conclusion bases on the following:(i) The number of the oscillations detected is approximately equal to a theoretically predicted number of the normal modes.(ii) In the 0.250 - 0.290 mHz subrange the oscillations are spaced at the 0.008 mHz intervals predicted.

JSM01/C/MW07/E/02-A2 Poster **1600-32**

PENETRATING THE EARTH'S FREE OSCILLATIONS WITH THE 54 MIN PERIOD INTO THE ATMOSPHERE

G.M. SHVED, L.N. Petrova and O.S. Polyakova (Institute of Physics, St.Petersburg State University, St.Petersburg-Petrodvorets 198904, Russia, email: shved@lmupa.phys.spbu.ru)

The most low-frequency mode of the Earth's free oscillations is the spheroidal mode 0S2 with period of about 54 min. The diurnal rotation of the Earth splits the mode 0S2 into 5 components spaced about 50 s apart, which are indexed by m = -2, -1, 0, 1, 2 in order of increasing frequency. The synchronous measurements by a microbarograph and seismograph with vertical pendulum have been analysed to determine a phase difference between ground pressure oscillations and seismic oscillations at the frequencies of the 0S2 components. A certain phase relationship has been derived by comparing the phase difference for m>0 with that for m<0. This relationship is a further proof of penetrating the Earth's 0S2 mode into the atmosphere. Moreover, it is the first observational manifestation of the second Pekeris normal mode of global atmospheric oscillations with the 54 min period.

OBSERVATIONS OF GRAVITY WAVE FLUXES AND TURBULENT DISSIPATION AT THE MU RADAR OBSERVATORY, JAPAN

Dennis M. RIGGIN (Colorado Research Associates,Boulder, Colorado 80301, USA, email: riggin@colorado-research.com) Toshitaka Tsuda (Radio Atmospheric Science Center, Kyoto University, Uji, Kyoto 611-0011, Japan, email: tsuda@kurasc.kyoto-u.ac.jp)

A measurement campaign was conducted with the MUradar at Shigaraki, Japan during Oct. 26-Nov. 5, 1996. The campaign combined high-resolution (150 m) Doppler wind radar measurements with temperature measurements made with the RASS (radio acoustic sounding system) and radiosonde balloon. In height, the RASS temperature measurements reached about 12 km, while the Doppler wind measurements extended into the lower stratosphere up to about 20 km. The results provide a comprehensive picture of the small-scale motion field with estimates of momentum flux, heat flux and the turbulent energy dissipation rate. The campaign was conducted during disturbed meteorological conditions characterized by a strong upper tropospheric jet and frontal passage. Relationships between the small-scale structure and the background fields are considered.

STUDIES OF ATMOSPHERIC GRAVITY WAVES AT MIDDLE-EUROPE AND NORTHERN SCANDINAVIA

Kathrin SCHULZ-SCHOELLHAMMER, Werner Singer, Peter Hoffmann, and Ralph Latteck, Leibniz-Institut fuer Atmosphaerenphysik an der Universitaet Rostock (e.V.), Schloss-Str. 6, D-18225 Kuehlungsborn, Germany

Gravity wave characteristics (e.g. vertical wave number spectra, propagation direction, momentum fluxes) have been derived from high-resolution balloon soundings of wind and temperature in the tropo- and lower stratosphere and from VHF radar measurements at mid latitudes (Lindenberg 52N14E, Kuehlungsborn 54N12E) and at arctic latitudes (Andenes 69N16E). A climatology of gravity wave activity over flat land terrain at Lindenberg has been established on the basis of a one year data set of 6-hourly soundings. The studies at arctic latitudes are restricted to wintertime and are directed to the relation between gravity wave activity and occurrence of polar stratospheric clouds. In addition, case studies on wave activity during the passage of fronts and during the presence of jet streams in the tropopause region will be discussed for both locations.

HOW SIMPLE CAN SIMPLE GRAVITY WAVE PARAMETERIZATIONS AFFORD TO BE?

Christopher D WARNER and Michael E McIntyre, Centre for Atmospheric Science, D.A.M.T.P., University of Cambridge, Silver Street, Cambridge CB3 9EW, UK

An "ultra simple spectral gravity wave parameterization" (USSP) has recently been developed and tested in the UK Met. Office Unified Model. This parameterization has been developed from a full ``power spectral'' model of gravity wave spectral propagation and breaking by making simplifications analogous to those used in the popular Hines scheme. But such simplifications lead to significant discrepancies between simple gravity wave parametrizations, including full gravity wave models, and ours. We compare simple gravity wave models with our full model, and investigate strategies for improving simple models without incurring excessive additional computational cost.

NUMERICAL STUDY OF THE LOCAL EFFECTS OF GRAVITY WAVE AND TIDAL INTERACTIONS

Han-Li LIU, Maura E. Hagan, Raymond G. Roble HAO/NCAR, Boulder, CO, USA

Gravity wave and tidal interactions may play an important role in the formation of the mesospheric inversion layer, and observations have also shown that this type of inversion layer is highly dynamic. Our work is a numerical investigation of such processes. We employed a two-dimensional nonlinear gravity wave/turbulence model along with global-scale wave model (GSWM-98) diurnal tidal winds and temperatures at different latitudes and different seasons to study the propagation of a gravity wave in a tidal wind field. A mesospheric chemistry model, adapted from the NCAR TIME-GCM, is coupled to the dynamics model and used to study the associated changes in chemical species and exothermic heating. Model results show that the gravity wave stability, momentum flux, and heat flux are strongly affected by the background mean state and tidal wind temperature, and are therefore seasonally and latitudinally dependent. The advective processes in the wave breaking region produce net cooling, while large non-uniform turbulence mixing can produce a large heating rate. Such processes may lead to an inversion layer (or layers) accompanied by cooling region(s). These region(s) descends with the breaking level(s), which are in turn dependent on the tidal wind and temperature. Therefore, such heating/cooling regions may bear the characteristics of the tidal wave. Furthermore, the inversion layer thus generated corresponds closely with mean wind acceleration and the wind shear associated with it, strong non-uniform turbulence layer, and chemical species changes. The wind, turbulence density, and species changes may be used as diagnostic parameters to test the theory with observations.

A SPECIFIC INSTABILITY OF THE NONISOTHERMAL ATMOSPHERE

Olga SAVINA (Department of General and Applied of Physics, State Technical University, Minina st. 24, Nizhny Novgorod, 603600, 0Russia, Email: savina@appl.sci-nnov.ru)

In this work we discuss the problem of the instability of acoustic-gravity waves in the atmosphere with a realistic temperature distribution. For an analytical approximation of the real altitude profile of the atmospheric temperature we found an exact solution for the altitude dependence of a perturbation of the vertical speed in the atmosphere and an expression for the cut-off frequency of the fast branch of acoustic gravity waves. It is shown that this frequency can be smaller than the Brunt-Vaisala frequency. In this case the instability of acoustic gravity waves is possible. On the basis of these results we conclude that this instability realizes at altitudes about one hundred kilometers. It is shown that the frequency of these unstable waves is about the Brunt-Vaisala frequency and the increment of this instability depends on the temperature gradient.

JSM01/W/18-A3 **0940**

STUDY OF THE INTERNAL GRAVITY WAVES ABOVE ESRANGE (67.56 N, 21,04 E)

K. STEBEL and S. Kirkwood, IRF, Box 812, S-981 28, Kiruna, Sweden

Internal gravity waves are e.g. formed at orographic obstacles or at tropospheric weather systems. They effect the general circulation due to momentum and energy transport through the atmosphere. If they pass into the stratosphere localised cooling accompanied by rapid cooling rates can induce polar stratospheric cloud development, leading to an increased ozone reduction above the polar regions.
The 52 MHz MST radar ESRAD (ESrange RADar) is located at Esrange (67.56 N, 21.04 E), about 30 km east of Kiruna, in northern Sweden. It is in operation since July 1996. On many occasions quasi-stationary internal gravity waves have been identified in the radar data. Vertical velocity variations in a region just over the tropopause show the wave propagation to the stratosphere. The radar-data reveal the morphology of the tropopause and show frontal systems, which drift over the radar site. Additionally, we can observe evidence for the downward transport of lower stratospheric air into the troposphere.
The continuous operating VHF radar allows us not only to analyse individual cases but also to study seasonal variations. Here, we present a radar study of the dynamics of the tropopause region above Esrange. We use weather chart and satellite images for interpretation of our data. The wave characteristics in the stratosphere are further studied utilizing radio- and ozonesonde data.

PSMOS

JSM01/W/30-A4 **1000**

THE PLANETARY SCALE MESOPAUSE OBSERVING SYSTEM (PSMOS): OVERVIEW AND STATUS

Gordon G. SHEPHERD (Centre for Research in Earth and Space Science, YorkUniversity, Toronto, M3J 1P3, Canada, Email: gordon@windii.yorku.ca) andMaura Hagan (High Altitude Observatory, National Center for AtmosphericResearch, Boulder, Colorado, USA Email: hagan@hao.ucar.edu)

The Planetary Scale Mesopause Observing System (PSMOS) is a new project approved by SCOSTEP, involving 53 scientists from 15 countries. It came about in part because of new information on planetary scale features observed with the UARS satellite, but more generally from a recognition of the impossibility of correctly resolving the spatial and temporal structures of these features with measurements from a single satellite. Thus the PSMOS project is founded on the basis of ground-based observations, organized into latitude bands, each with the best possible longitudinal coverage. Both radar and optical observations will be combined in this planetary scale description. The stations are organized into four zones; tropical, mid-latitude, mid-to-high latitudes and polar. Winds, temperatures and airglow emission rates will be measured from existing sites, but additional stations are being added to fill longitude gaps. The scientific results will include: 1. A determination of the dynamics of the mesopause region, by decomposition of the observations into the mean flow, planetary scale perturbations,tides and gravity waves, 2. A determination of the zonally averaged temperature trend, with its separation from the influence of solar variability and other dynamicaleffects and 3. A determination of gravity wave characteristics and their zonal variability, with a goal of identifying their sources. Following the official beginning of PSMOS activity at the DYSMER meeting held in Kyoto, Japan in March 1998, a major campaign has been initiated and six specific sub-projects identified. An overview of the objectives of PSMOS is presented, and the status of the current work described. For further information see: http://www.hao.ucar.edu/psmos/home.html

JSM01/E/25-A3 **1020**

PSMOS PROJECT ON DAY-TO-DAY VARIATIONS IN RELATION TO PLANETARY SCALE PROCESSES

Juergen SCHEER (PRONARP-CONICET, J. Alvarez 1218, 1414 Buenos Aires, Argentina, Email: jurgen@caerce.edu.ar) and Alan Manson (ISAS, University of Saskatchewan, 116 Science Place, Saskatoon, SASK, S7N-5E2, Canada, Email: manson@dansas.usask.ca)

We report on a project within the Planetary Scale Mesopause Observing System (PSMOS) destined to analyze sudden strong day-to-day variations and their relation to planetary scale dynamics. Day-to-day variations are believed to be a manifestation of planetary waves with periods of two days to more than a month. The airglow data set being accumulated at El Leoncito, since the start of PSMOS again contains a number of examples of very marked changes in nocturnal mean parameters that often persist for only one night, but that must be considered, due to the large number of individual measurements involved, as highly significant. Given the considerable amplitude of the variations, this is in fact the most reliable information that can be derived from the data. Radar observations are also showing the non-linear interactions between tides/PW which can lead to groups of days with unusually large wind perturbations. In a conventional spectral analysis, these events would either have an overwhelming impact, or would have to be eliminated as "outliers" or transients. The aim of the study is therefore to compare the occurrence characteristics of these powerful "transients" at different sites, their global distribution, and to investigate their relation to planetary scale phenomena. It includes different physical parameters, and is in principle not limited to optical and radar observations. The springtime transition is included in this study because it is phenomenologically, and probably also physically, related. This study is already under way, using the PSMOS database already acquired. We therefore expect to be able to present some first results.

JSM01/C/GA2.15/W/80-A3 **1100**

GRAVITY WAVE PARAMETERIZATION AND PSMOS STUDIES.

Nikolai M. GAVRILOV (Saint-Petersburg State University, Atmospheric Physics Department, Petrodvorets, 198904, Russia, E-mail: gavrilov@snoopy.phys.spbu.ru) Mike J. Taylor (Utah State University, Space Dynamics laboratory, Logan, Utah, USA, Email: mtaylor@cc.usu.edu)

The main problems concerning parameterization of gravity waves (GWs) are discussed with reference to the PSMOS project. The key directions of GW studies essential for their parameterization include the following: (1)Coordinated observations of gravity waves (GWs) in the middle atmosphere with global networks of radar, optical and other facilities to map mesospheric GWs. (2) Study GW characteristics and climatology at different latitudes and longitudes. (3) Trends and interannual variations of GW activity from long-term data sets and their role in changes of general circulation and quasi-stationary planetary waves. (4) GW modulation by global-scale waves and GW influences on tidal and transient planetary waves. (5) Sources of mesospheric GWs located in the lower, middle and upper atmosphere. (6) GW breaking and the generation of turbulence. (7) Modeling and parameterization of nonlinear wave-wave and wave-mean flow interactions which involves GW parameterization into numerical models of general circulation, thermal regime and composition of the middle and upper atmosphere. Plans for GW studies aimed at developing realistic gravity wave parameterization as part of the PSMOS project are discussed with reference to current capabilities.

JSM01/W/105-A3 **1120**

OH ROTATIONAL TEMPERATURE MEASUREMENTS OF LONG AND SHORT PERIOD GRAVITY WAVES AT MID-LATITUDES USING THE CEDAR MESOSPHERIC TEMPERATURE MAPPER

M.J. TAYLOR and W.R. Pendleton, Jr., (both at Space Dynamics Laboratory and Physics Department, Utah State University, Logan, UT, USA, Email: mtaylor@cc.usu.edu)

A high sensitivity solid state "Mesospheric Temperature Mapper" has been used to investigate the rotational temperature signatures of long (several hour) and short (<1 hour) gravity waves inducedin the OH (6,2) band emission at the ~87 km level. The imaging system is capable of measuring OH rotational temperature with a precision of better than 2 K every 3 minutes. Since its development in 1996/97 image measurements have been made from mid-latitude observatories at Bear Lake UT, Ft. Collins, CO and most recently from the Starfire Optical

Range, NM, USA. These observations have revealed a wealth of long and short period wave phenomena including marked terdiurnal oscillations in temperature around the spring and fall equinoxes with peak-to-peak amplitudes of 8-12 K and superimposed quasi-monochromatic wave events of periods as short as ~5 min. The relationship between the ~8-hour period waves and the diurnal and semi-diurnal tides will be discussed with reference to recent "24-hour" lidar studies of tides. The effects of the short-period gravity waves on the OH temperature and intensity will be discussed using novel two-dimensional maps of the wave field.

JSM01/W/01-A3 1140

SEASONAL VARIATION OF GRAVITY WAVES OBSERVED WITH AIRGLOW IMAGING AT SHIGARAKI, JAPAN (35N, 136E)

T. NAKAMURA, A. Higashikawa, R. Maekawa, T. Tsuda, (Radio Atmospheric Science Center, Kyoto University, Uji, Kyoto 611-0011, Japan, e-mail nakamura@kurasc.kyoto-u.ac.jp) M. Ejiri, M. Taguchi, S. Okano, (National Institute of Polar Research, Itabashi, Tokyo, Japan) K. Shiokawa, and T. Ogawa (STE lab., Nagoya University, Toyokawa, Aichi, Japan)

A long term CCD imager observation of OH airglow started in November 1996 at the MU radar site of Shigaraki, Japan. Gravity wave (GW) patterns in the images of the first 18 months have been analyzed. From more than 500 of GW events, seasonal variations of short period (5 - 30 min) and small scale (5 - 60 km horizontal wavelength) have been studied. For the waves with horizontal wavelengths larger than 17 km, horizontal propagation direction showed clear eastward/westward preference in summer/winter, respectively, suggesting that these waves are generated in the lower atmosphere and filtered out by the middle atmosphere winds. However, waves with shorter horizontal wavelengths did now show clear preferential direction as well as seasonal variation, which indicates that they are generated in the mesosphere. It is also notable that the waves with small horizontal wavelengths (<17km) and slow horizontal phase speeds (< 30 m/s) were mainly seen in summer/winter but not in equinoctial months. Intrinsic parameters of the waves are also studied using the wind measurement by the MU radar. Since January 1998, a new allsky imager of Kyoto Univ/NIPR and three other allsky imagers of Nagoya Univ. have been operated to observe allsky images of airglow around the mesopause region. 2-D and 3-D spectra of airglow images of OH, Na, O2 and OI(5577) have been studied and seasonal variations have also been detected.

JSM01/E/23-A3 1200

HRDI OBSERVATIONS OF THE O2(0,0) ATMOSPHERIC BAND NIGHTGLOW: A SEVEN-YEAR CLIMATOLOGY

Julie F. KAFKALIDIS, Gregory M. Fall, Paul B. Hays (all at Space Physics Research Laboratory, University of Michigan, 2455 Hayward Street, Ann Arbor, MI 48109-2143, USA, email: juliek@umich.edu)

A climatology of an extensive multi-year and near-global data set of O2 (0,0) Atmospheric band nightglow measurements collected by HRDI/UARS is presented. The measurements span all latitudes from 72S to 72N, and data are available for nearly all months between November 1991 and the present (1999).
Two operational modes on HRDI are used to observe the O2 nightglow emission layer. A combined wind/photometric mode measured the emission brightness at low horizontal resolution (~500 km) from late 1991 through 1995, and intermittently thereafter. Much higher spatial resolution (~50 km) and a broader range of local time coverage has been achieved since March 1996 by using the HRDI photometer channel and sacrificing the ability to measure nighttime winds.
This seven-year climatology of the monthly averaged O2 nightglow data greatly extends and expands upon an early survey of HRDI nightglow data by Burrage et al. (JGR 99, 15017-15023, 1994). We describe the brightness variations with latitude and local time with an emphasis on the seasonal and interannual variability revealed in this longer data set. In addition to tidal variations in the brightness (i.e. those dependent on latitude and local time), strong non-tidal variations are observed around the globe. A statistical method was used to separate these perturbations from the tidal and seasonal effects. Climatology of these perturbations is presented, and their possible origins in terms of gravity wave and planetary wave forcing are discussed. The daily variations accompanying these global patterns are rendered in fine spatial detail by the high-resolution data. Examining periods in which both high- and low-resolution data were gathered on alternating days assesses daily and small-scale variability within the monthly climatological average.

JSM01/W/94-A3 1220

EVIDENCE FOR PLANETARY WAVE OSCILLATION OF THE UPPER ATMOSPHERIC AIRGLOW EMISSIONS OBSERVED FROM THE EQUATORIAL REGION.

H. TAKAHASHI (Instituto Nacional de Pesquisas Espaciais, INPE, Sao Jose dos Campos, SP, Brasil, E-mail: hisao@laser.inpe.br), R. A. Buriti (Universidade Federal de Paraiba, Campina Grande, PB, Brasil, E-mail: rburiti@df.ufpb.br), D. Gobbi and P. P. Batista (both at Instituto Nacional de Pesquisas Espaciais, INPE, Sao Jose dos Campos, SP, Brasil, E-mail: delano@laser.inpe.br, pbatista@laser.inpe.br)

The upper mesospheric airglow emissions, OI 557.7 nm, NaD 589.3 nm, OH (6,2) and O2 Atmospheric (0,1) band, and the thermospheric OI 630.0 nm emission have been measured by using a ground-based multichannel airglow photometer in the equatorial region, Sao Joao do Cariri (7 S, 37 W), Brazil. Good weather condition made it possible to study nocturnal and day to day variation of the emission rates continuously for more than 12 days per month from January to December 1998. It is found that there is an oscillation of 2 to 3 day period in the mesospheric emissions and 5 to 7 day oscillation for the thermospheric emission. The amplitudes of oscillation are larger at equinox condition than solstices. These long period oscillations are well known in the wind field as planetary waves. In case of the airglow, however, little observational evidence has been reported (Ward et al., GRL, 24, 1127-1130, 1997). Wave characteristics and source of the oscillation will be discussed.

GRAVITY WAVE FORCING AND THE RESIDUAL CIRCULATION: SOME OBSERVATIONAL AND MODELING CONSTRAINTS

M. J. ALEXANDER, L. Bruhwiler, and K. Hamilton

Constraints on gravity wave momentum fluxes in the lower stratosphere are now emerging that have implications for wave forcing in the middle atmosphere. The forcing drives mean-flow accelerations and zonal-mean meridional circulations known as the residual circulation. The constraints arise from the combined results of observational and modeling studies. Simple models can relate an input gravity wave momentum flux spectrum as a function of phase speed to the effects of the dissipation of these waves in the middle atmosphere. Momentum flux as a function of phase is however difficult to determine from observations directly. Some techniques of combining modeling with observational constraints to constrain the momentum flux spectrum will be described. Another approach usinfg global data to constrain large-scale wave effects on the mean and inferring the effects of the smaller-scale gravity waves as the residual will also be described. Preliminary tests of these constrained momentum flux spectra input into a gravity wave parameterization in a general circulation model will be shown with emphasis on the resulting residual circulation in both the stratosphere and esosphere.

JSM01/E/31-A3 Invited 1430

DOWNWARD CONTROL AND THE ROLE OF GRAVITY WAVES IN MIDDLE ATMOSPHERE CLIMATE

Bryan N. LAWRENCE (Department of Physics and Astronomy, University of Canterbury, Christchurch, New Zealand. Email: b.lawrence@phys.canterbury.ac.nz)

In this presentation results will be presented from a number of multi-year simulations of the middle atmosphere using a three-dimensional mechanistic model of the stratosphere and mesosphere. The model uses a prescribed tropospheric lower boundary, and has the Hines parameterization of gravity waves.
The control simulations use a geographically isotropic gravity wave source and two different upper boundary conditions for the parameterization. It will be seen that these control simulations differ from each other in a way that can be explained by using results from Downward Control theory. They also differ from simulations which have used latitudinal and time-varying gravity wave sources. Some simulations also exhibit systematic differences in planetary-wave behaviour which are attributed to the gravity waves changing the propagation regime in which the planetary waves exist. Other examples of wave-mean flow interaction will be shown, including the presence of a realistic QBO-like feature in these simulations.

JSM01/W/63-A3 1500

WHERE IN THE MIDDLE ATMOSPHERE IS CHAOTIC ADVECTION RELEVANT?

T.G. SHEPHERD, J.N. Koshyk (both at Department of Physics, University of Toronto, Toronto M5S 1A7 Canada, email tgs@atmosp.physics.utoronto.ca) and K. Ngan (Department of Geophysical Sciences, University of Chicago, Chicago, IL 60637 USA)

Several studies of tracer transport in the lower stratosphere have shown that horizontal tracer evolution is primarily controlled by the large-behaviour is consistent with the concept of "chaotic advection", wherein the Eulerian velocity field is spatially coherent and temporally quasi-regular on time scales over which the Lagrangian evolution is chaotic. In this study, winds from a middle atmosphere general circulation model are used to study tracer evolution in the stratosphere and mesosphere. It is found that the concept of chaotic advection is relevant in the stratosphere but not in the mesosphere. The explanation for this behaviour is the increased strength of gravity-wave activity in the mesosphere as compared with the stratosphere, which is reflected in shallower energy spectra and a stronger divergent component to the flow.

JSM01/W/17-A3 Invited 1540

MECHANISMS FOR TRANSPORT OF TRACE CHEMICAL SPECIES IN THE MIDDLE ATMOSPHERE

Anne K. SMITH, Atmospheric Chemistry Division National Center for Atmospheric Research Boulder CO 80307 USA

It is well known that the distribution of long-lived chemical constituents in the middle atmosphere such as water depends on transport by waves and the mean circulation. Transport can also have an impact on the distribution of shorter lived species whose photochemical time scales are a day or less. This paper will discuss transport mechanisms that are active in the middle atmosphere, with emphasis on the altitudes above the stratopause. Specific examples from observations and numerical models will illustrate transport by inertially unstable circulations and by migrating tides.

JSM01/W/33-A3 1610

THE INTERACTION OF CHEMICAL HEATING AND MESOSPHERE / LOWER THERMOSPHERE CIRCULATION BY TRANSPORT OF ATOMIC OXYGEN

Xun ZHU (JHU/APL, Johns Hopkins Rd., Laurel MD 20723-6099; Phone: 443-778-8764; e-mail: xzhu@grant.jhuapl.edu), Jeng-Hwa Yee (JHU/APL), Darrell F. Strobel (JHU)

Chemical heating in the upper mesosphere and lower thermosphere will influence the dynamical circulation in the mesosphere. Both the heating rate magnitude and its morphology are primarily determined by the atomic oxygen distributions. But, above the mesopause, the chemical timescale of the atomic oxygen is longer than the hemispheric exchange timescale by transport. Hence, the chemical heating above the mesopause will be determined by the dynamics. The JHU/APL fully coupled 2-dimensional model is used to study the interaction of between the chemical heating and mesospheric dynamical circulation. The model produces a latitudinal chemical heating rate that largely cancels the gradient in net radiative heating rate around the mesopause region. This interaction is also examined observationally with the chemical heating rates inferred from the nightglow emissions by the High Resolution Doppler Imager (HRDI) instrument onboard the UARS satellite. Furthermore, using the solar UV spectral irradiance measured by UARS instruments we also simulate the solar cycle variations in Lyman alpha radiation and in Schumann-Runge continuum and investigate its effect on the mesospheric circulation due to changes in the chemical heating rate.

JSM01/W/24-A3 1630

ROLE OF THE NONLINEAR HADLEY CIRCULATTION IN TROPICAL UPWELLING

Kirill SEMENIUK and T. G. Shepherd (both at Department of Physics, University of Toronto, 60 St. George Street, Toronto, Ontario, M5S 1A7, Canada, email: kirill@atmosp.physics.utoronto.ca)

The Brewer-Dobson circulation is driven primarily by extratropical wave drag. This drag acts as a sort of ``vacuum pump" in producing upwelling in the tropical stratosphere. It is believed to account for the seasonal cycle in temperatures above the tropical tropopause (Yulaeva et al., 1994) and the ``tape recorder" effect in tropospheric water vapour transport into the stratosphere (Mote et al., 1996).
But the dynamics of tropical upwelling are not well understood. The latitudinal profile of the upwelling inferred from observations has the upwelling maximum occurring on the summer side of the equator. This pattern cannot be explained by the observed extratropical wave drag

distribution. Extratropical wave drag also cannot account for annual mean tropical upwelling which is suggested by the ``tape recorder". Without nonlinearity or viscosity the annual mean meridional circulation obeys the downward control principle of Haynes et al. (1991) and is confined to the extratropical latitudes of the wave drag, which drives it.
It is argued here that a key missing ingredient in explaining tropical upwelling is the balanced response to equatorially asymmetric radiative forcing, which Dunkerton (1989) termed the Nonlinear Hadley Circulation (NHC). Through nonlinearity, the NHC gives rise to annual mean upwelling at the equator. We examine the contribution of the NHC to upwelling and its interaction with the wave-driven circulation in a zonally symmetric model the existence of the NHC in a middle atmosphere GCM is also considered.

JSM01/W/10-A3 1650

THE EXTENDED CANADIAN MIDDLE ATMOSPHERE MODEL: FIRST RESULTS

William E. WARD (CRESS/CRESTech, York University, Toronto, Canada,
email: william@stpl.cress.yorku.ca), V.I. Fomichev, S.R. Beagley, J.C. McConnell (all at EATS, York University, Toronto, Canada), N.A. McFarlane (CCCma, Atmospheric Environment Service, Victoria, Canada)

The Extended Canadian Middle Atmosphere Model is a general circulation model with an upper boundary at about 200km. It is a modified version of the Canadian Middle Atmosphere Model (CMAM). It is being developed to allow the investigation of phenomena near the mesopause without the influence of the sponge layer usually present in GCM's which extend to these heights. The model currently includes a full infra-red, UV and EUV radiative transfer model, a parameterized orographic gravity wave scheme and viscous and diffusive processes appropriate to the lower thermosphere. Gravity wave parameterizations and neutral chemistry near the mesopuase are currently being implemented. The topic of this paper is the first runs of this model without these latter effects included. The general characteristics of the circulation, which develops under these conditions, will be discussed and compared to earlier runs of the CMAM under similar conditions.

JSM01/W/46-A3 1710

COMPARISON OF SIMULATIONS WITH THE HINES GRAVITY WAVE DRAG PARAMETRIZATION AND RAYLEIGH FRICTION IN THE UKMO UNIFIED MODEL

D. STAINFORTH, W. Norton (AOPP, University of Oxford, UK, email: das@atm.ox.ac.uk)

The Hines gravity wave drag parameterisation scheme from the ECHAM/MA model has been implemented in a 54 level version of the UKMO Unified Model with a top boundary near 0.01 hPa. The parameterised gravity waves are launched near the surface with a globally uniform strength. The sensitivity of the simulations to changes in gravity wave source strength has been examined. It has been found that limiting the maximum vertical wavelength of the parametrised gravity waves to around 20-km improves the simulation. Comparison with simulations of the Unified Model which use Rayleigh friction show that the Hines scheme correctly produces middle atmosphere jets which slope equatorward with height and produces a much better simulation of the breakdown of the southern hemisphere winter jet. The evolution of the tropical winds from different model runs will be presented.

JSM01/W/44-A3 1730

CALCIUM IN THE UPPER ATMOSPHERE

John PLANE and Rosemary Rollason (School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, UK, email: j.plane@uea.ac.uk) Michael Gerding and Ulf von Zahn (Leibniz Institute for Atmospheric Physics, University of Rostock; Kuelungsborn, Germany)

A major question in the chemistry of the mesosphere is why calcium is depleted by more than two orders of magnitude compared to sodium and iron, all of which are produced by meteoric ablation. Furthermore, recent lidar measurements have shown that in contrast to the other meteoric metals, the Ca density actually increases in summer when the mesopause is coldest: We have carried out a laboratory kinetic study on the reactions of CaO together with ab initio quantum calculations to establish the nature of the temporary reservoirs and sinks for the metal. The results indicate that switching between formation of calcium carbonate (CaCO3) and calcium hyroxide (Ca(OH)2) at low temperatures is the key to this mystery. A new atmospheric model of calcium will be presented which also includes a full treatment of the ion-molecule chemistry, since uniquely among the metallic ions, Ca+ can be observed by lidar and a full set of simultaneous Ca/Ca+ observations has been acquired.

VARIABILITY AND TRENDS

JSM01/W/34-A3 Invited 1750

WATER VAPOUR TRENDS IN THE LOWER STRATOSPHERE: WHAT ARE THE DYNAMICAL IMPLICATIONS?

Karen H. ROSENLOF (CIRES/University of Colorado/NOAA Aeronomy Laboratory Mail Stop R/E/AL6 325 Broadway Boulder, Colorado 80303 USA)

Trends in water vapor in the stratosphere may be an indication of temporal changes in tropical tropopause characteristics or in the large scale mean meridional circulation of the stratosphere. Satellite data (HALOE) and Northern Hemisphere middle latitude balloon data (CMDL) from the past 20 years show a slight increase with time in lower stratospheric water vapour. These trends are larger than accounted for by the observed increase in tropospheric methane over the same time period.
However, it is important to note that the magnitude of the water vapour trends from different instruments vary significantly. Additionally, in situ measurements taken from a NASA ER-2 high altitude aircraft do not show the same trends, and at some levels show a decrease. There are also substantial differences in the actual value of water vapour measured by in situ aircraft instruments during the same time period.
In this presentation, water vapour data from a variety of in situ and satellite sources will be compared. Both recent data and measurements published in scientific papers going back to the 1950's will be used in this study. The zonal mean circulation deduced from stratospheric water vapour measurements will be presented. Finally, possible mechanisms to explain the observed trends will be explored.

VARIABILITY AND TRENDS

JSM01/W/52-A4 Invited 0930

VARIABILITY AND LONG-TERM TRENDS IN STRATOSPHERIC CONSTITUENTS

William J. RANDEL (NCAR, PO Box 3000, Boulder, Colorado, 80307-3000, USA,
email: randel@ucar.edu)

Long records of satellite constituent measurements show strong seasonal and interannual variations, which reflect transport and chemistry effects. Ozone and nitrogen dioxide observations from SAGE II, and long-lived constituents (CH4 and H2O) from HALOE will be presented to document seasonal and interannual signals. The seasonal variations are closely tied to well-known stratospheric circulation patterns. One particularly large interannual signal is that associated with the stratospheric quasi-biennial oscillation (QBO), and the near-global QBO patterns in constituents are shown to be linked with QBO circulation anomalies. Low-frequency variations and trends in the constituent data will also be discussed.

JSM01/E/37-A4 1000

A COMPARISON BETWEEN THE 70 HPA MONTHLY MEAN TEMPERATURE ANOMALY FIELDS FROM THE NCEP REANALYSIS AND MSU CHANNEL 4

M.Alejandra Salles, Pablo O. CANZIANI, Rosa H. Compagnucci, Grupo de Atmosfera Media Departamento de Ciencias de la Atmosfera, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Pabellon II, Ciudad Universitaria, 1428 Capital Federal, Argentina

The monthly mean temperature anomaly fields at 70 hPa for the NCEP reanalysis are compared with those obtained by the MSU Channel 4. The aim of this study is to analyse the quality of the lower stratospheric temperature product of the NCEP reanalysis, given that this product, which spans the period 1958-1997, could be used to study periods before the MSU became operational in 1979. This is also an indirect contribution to the adjustment, on a climatic scale, of the model used in the reanalysis. In order to obtain the spacial patterns of the anomaly fields the T-mode Principal Component Analysis is applied i.e. the correlation between spatial fields used as variables. The NCEP reanalysis temperatures corresponding to the period 1979-1997 are considered and the annual cycle is removed, in a manner similar to that applied to the MSU data i.e. using the period 1982-1991 as the reference period. The results for both samples are compared and the main difference is that the reanalysis product overestimates the zonal flow, giving a larger weight to the corresponding anomaly pattern.

JSM01/W/39-A4 1020

OZONE TREND ANALYSIS BASED ON EMPIRICAL ORTHOGONAL FUNCTIONS

Frans J. M. ALKEMADE (IMAU, Instituut voor Marien en Atmosferisch onderzoek Utrecht, Postbus 80005, 3508 TA Utrecht, The Netherlands, Email: frans_a@knoware.nl) Guus J. M. Velders (RIVM, Postbus 1, 3720 BA, Bilthoven, The Netherlands, Email: Guus.Velders@rivm.nl).

A new approach for ozone trend analysis, in connection with the isolation and identification of low frequency ozone fluctuations, is applied to the Nimbus7 TOMS data (version 7) from 1978 to 1992 and to the UARS/MLS data from 1991 to 1996. This new approach is based on the use of the Principal Components (PCs), found by an Empirical Orthogonal Function (EOF) decomposition, as representative functions in a Multi Linear Regression (MLR) analysis. The main results are:- Apart from the commonly identified components of ozone variability (i.e. the seasonal cycle, the Quasi Biennial Oscillation (QBO), the El Nini/Southern Oscillation (ENSO), and the solar cycle), there exists a globally coherent oscillation in stratospheric ozone, having an average period of 1.7 +/- 0.15 year, and causing local deviations in the ozone field of up to 18 Dobson Units. Using EOF decomposition, a detailed spatial pattern in ozone of this oscillation could be extracted from the TOMS and UARS/MLS data. In terms of explained variability it is about half as important as the Quasi Biennial Oscillation (QBO). The 1.7 year oscillation can be identified as an interference effect between the QBO and the seasonal cycle. - A Multi Linear Regression (MLR) trend analysis that avoids the use of the commonly applied external representative functions (i.e. the 50 mbar Singapore zonal winds for the QBO, the 10.7 cm solar flux for the solar cycle, and the SOI-index for the ENSO), but is instead based on the first four Principal Components of the EOF analysis (associated to the three components of ozone variability mentioned above, plus the 1.7 year oscillation), leads to a more reliable trend detection in total ozone (in terms of smaller sigmas and a greater consistency). - The EOF based trend analysis leads to the detection of a significant ozone depletion (between 1987 and 1992) throughout the tropics, indicating an average ozone loss (between 30S and 30N of 0.9% +/- 0.2% per decade.

TRANSPORT TIME SCALE

JSM01/W/06-A4 Invited 1100

TRANSPORT TIME SCALES IN THE MIDDLE ATMOSPHERE: THEORY, MODELS, AND MEASUREMENTS

Darryn WAUGH (Department of Earth and Planetary Sciences, Johns Hopkins University, Baltimore, MD 21218, USA)

In this talk I will review the use of time scales to quantify the transport within the, real and simulated, middle atmosphere. The theoretical framework of a statistical distribution of transit times, the so called "age spectrum", will be discussed. The age spectrum provides information on the aggregated effect of the different transport processes within the middle atmosphere, and is a valuable tool for interpreting tracer data and diagnosing model transport. Tracer observations can be used to infer an aspect of the age spectrum, in particular the mean transit time (the "mean age"), or in some cases the shape of the spectrum. These observations can then be used to quantify the role of different transport processes; in particular the role of advection, vertical diffusion, and horizontal mixing within the tropical stratosphere. The observed time scales also provide stringent tests of model transport. This was highlighted in the recent NASA Models and Measurements II (MMII) study, in which observations and over 20 models were compared and several deficiencies in the model transport identified.

JSM01/W/25-A4 1130

LARGE SCALE TRANSPORT IN A MIDDLE ATMOSPHERE MODEL VISUALIZED BY A MULTI-YEAR SIMULATION OF THE SF6 TRACER

E. MANZINI and J. Feichter (Max Planck Institute for Meteorology, Bundesstrasse 55, 20146, Hamburg, Germany)

A multi-year simulation of a passive tracer, with emissions linearly increasing with time aimed at representing the evolution of the sulfur hexaflouride, SF6, a compound of anthropogenic origin, has been performed. The general circulation model used is the MAECHAM4 model, middle atmosphere version with top at 80 km. General circulation models of the middle atmosphere are now starting to be coupled with models of the evolution of the chemical constituents of the atmosphere. Given the complex feedbacks in such coupled models, it is important to evaluate the transport characteristic with passive tracers, to focus on the role of dynamical processes and on the implictions of model biases.
Comparison with measurements of SF6 from aircraft mission (Project AIRSTREAM) indicates a good agreement between the simulated and observed vertical structure of the tracer concentrations in the upper troposphere and lower stratosphere. Given a reasonably realistic simulation of the SF6 evolution, the multi-year simulation has been further analyzed. While most previous works have focused on events, here a climatological perspective is pursued. An attempt is made to evaluate the long term effect of the opposite drive of quasi-isentropic planetary wave mixing and residual mean circulation on tracer distribution. From the model results, subtropical and polar barriers in meridional transport can be detected in both the meridional gradient of potential vorticity and the relative change in latitude of the SF6 concentration, thus providing a dynamical interpretation for the distribution of the age of stratospheric air evaluated from the SF6 tracer. For comparison, the potential vorticity and its gradient are also computed from the ECMWF reanalysis (15-years). It has been found that the strength in the potential orticity gradient and the location of its maxima in the model and in the reanalysis are in good agreement.

JSM01/W/41-A4 1150

THREE-DIMENSIONAL SIMULATION OF LONG-LIVED AND SHORT-LIVED TRATOSPHERIC CONSTITUENTS MEASURED BY CRISTA

M. RIESE (Physics Dep., University of Wuppertal, Gauss-Str. 20, 42097 Wuppertal, Germany) X. Tie, G. Brasseur (National Center for Atmospheric Research, P.O. Box 3000, Boulder, Colorado 80307-3000, USA) D. Offermann, G. Lehmacher, and V. Kuell (Physics Dep., University of Wuppertal, Gauss-Str. 20, 42097 Wuppertal, Germany)

The CRISTA experiment was flown on the Space Shuttle missions STS66 and STS85. During operating periods of about a week each, thermal emissions of several trace gases were measured with unprecedented horizontal resolution. The first flight was performed in early November 1994 during a period of disturbed dynamical conditions characterized by relatively large wave activity and associated exchange of tropical and extra-tropical air.
The detailed structure of the constituent distributions has been modeled with the NCAR ROSE model, which is driven by assimilated winds and temperatures provided by the UK meteorological office. The modeled trace gas distributions capture much of the measured structures. In addition, CRISTA trace gas data have been assimilated into the ROSE model by using a sequential technique. Some results are presented with emphasis on the nitrogen family and the partitioning of its members.
The assimilated distributions of long-lived species have been used for transport and budget studies based on the transformed Eulerian-mean (TEM) conservation equation. The high resolution distributions measured by CRISTA are ideally suited to assess effects of eddy transport, which are directly calculated from fluctuations of the measured trace gases, winds, and temperatures.
Resulting trace gas budgets of CFC-11 and methane will be discussed as well as forecast capabilities of the trace gas assimilation system.

JSM01/P/02-A4 1210

INVESTIGATION OF HIGH-LATITUDE TRACER CHARACTERISTICS DURING FINAL WARMING IN THE SOUTHERN STRATOSPHERE BY USING ILAS AND OTHER SATELLITE DATA

Wookap CHOI and Sumi Kim (Department of Atmospheric Sciences, Soeul National University, Soeul, 151-742, Koera, Email: wchoi@plaza.snu.ac.kr)

Distributions of tracers in the stratosphere were investigated from November 1996 to June 1997 by analysing the Improved Limb Atmospheric Spectrometer (ILAS) and the halogen occultation experiment (HALOE) data. Both instruments are complementary in terms of the latitude coverage and their observations reveal the spatial distributions of tracers at different latitudes. Latitude-height and longitude-height sections were used to investigate characteristic behavior of tracers during the transition period between spring and summer. Concentrations of both tracers at high latitudes. The tracers also show temporal variations in wave number of the dominant planetary wave. The number one and two patterns repeat before the summer pattern finaly sets in. The same feature is also observered in the geopotential height, potential vorticity and the meridional wind by the United Kingdom Meteorological Office (UKMO) data. Transport by eddy flux calculated by the UKMO and satellite data was also investigated following the changing wave pattern. Eddy flux plays asignificant role in transport of trace species in the merional direction.

CONDENSED MATTER IN THE STRATOSPHERE

JSM01/W/21-A4 Invited 1400

FORMATION OF AND REACTIONS ON CONDENSED MATTER

Thomas PETER (Institute for Atmospheric Sciences, ETH, Hoenggerberg HPP, CH-8093 Zurich, Switzerland, email: peter@mpch-mainz.mpg.de)

Within the last five years research on the thermodynamics, nucleation kinetics and chemical kinetics of the ternary system sulfuric acid /nitric acid / water in the temperature regime 180-300 K has laid the basis for understanding the microphysics and heterogeneous chemistry of stratospheric aerosol and cloud particles. Laboratory work, field studies and theoretical investigations revealed that ternary solution droplets do not freeze readily despite massive supercoolings with respect to acidic hydrates. At the same time the solubility of reactive gases like HCl and HOCl in the droplets increases dramatically under such conditions. The chemistry of heterogeneous chlorine activation, which is mainly responsible for the formation of the ozone hole, therefore takes place principally in/on the liquid phase, and not surface-catalyzed on solids as was thought not long ago. Conversely, the small number of frozen particles may assume large radii and sediment out, leading to denitrification, i.e. the removal of reactive nitrogen from the affected air masses. This may lead to an enhancement of ozone loss. The interplay between liquid and solid particles with their clearly separated influences on the ozone layer will be discussed. In a future stratosphere cooled by greenhouse gases, decreases in the chlorine atmospheric burden could be partly compensated by increases of chlorine processing in liquid particles and denitrification due to more frequent formation of solid particles.

JSM01/E/28-A4 1430

CLOUD DETECTION IN THE UPPER TROPOSPHERE AND LOWER STRATOSPHERE BY CRISTA 1 AND 2

Reinhold Spang, Gunnar EIDMANN, and Dirk Offermann (Physik Department, University of Wuppertal, Gauss-Str. 20, 42097 Wuppertal, Germany, email: spang@wpos2.physik.uni-wuppertal.de)

The Cryogenic IR Spectrometers and Telescopes for the Atmosphere instrument (CRISTA) was flown in November 1994 and August 1997 during the space shuttle missions STS66 and STS85. CRISTA is a limb scanning experiment that measures the thermal emissions of 18 trace gases with high spatial resolution in three dimensions. During the second CRISTA mission a measurement mode with extra high spatial and temporal resolution was applied in the Indonesian sector of the tropics. First results will be shown.
Radiance fields and spectra show clear indications for deep convection clouds in the tropics (CRISTA 1/2). Cloud maps were derived on a daily basis. They are quite different in November and August. Comparisons with the AVHRR, GMS and GOES cloud observations and SAGE II observations of subvisible cirrus clouds will be presented. Indications of different cloud types in the CRISTA data will be discussed. Backward trajectories are used to determine the origin of the cloud formation.

JSM01/W/08-A4 1450

OBSERVATIONS OF POLAR STRATOSPHERIC CLOUDS.

J.J. REMEDIOS, (Aopp, Dept. Of Physics, Oxford University, Parks Road, Oxford Ox1 3pu, U.K., E-Mail: J,Remedios1@Physics.Ox.Ac.Uk), A. Beyerle (AWI, Potsdam, Telegrafenberg, A43, D-14473 Potsdam, Germany, e-mail: gbeyerle@awi-potsdam.de), C. David (CNRS, Institut Pierre-Simon Laplace, Universite Paris VI - B.102, 75252 Paris Cedex 05, France, e-mail: christine.david@aero.jussieu.fr), D. Fonteyn (BIRA, Ringlaan 3, Brussels-1180,Belgium, e-mail: Dominique.Fonteyn@bira-iasb.oma.be), R.G. Grainger (Department of Physics and Astronomy, University of Canterbury, Private Bag 4800, Christchurch, New Zealand, e-mail: r.grainger@phys.canterbury.ac.nz), N. Larsen (DMI, Lyngbyvej 100, DK-2100 Copenhagen, Denmark, e-mail: nl@dmi.dk), M. Wirth,(Arbeitsgruppe LIDAR, DLR, Oberpfaffenhofen, D-82234 Wessling, Germany, e-mail: Martin.Wirth@dlr.de)

Within the last few years, it has become clear that there are still many difficult questions regarding the formation and composition of polar stratospheric clouds (PSCs). Although both observations and microphysical models have become more sophisticated, it has been difficult to consistently analyse the data to provide the most information obtainable from a particular measurement. Complicating factors include he large differences in wavelength coverage, spatial coverage and temporal sampling between various lidars, and between lidars and satellite instruments. The POSTCODE (Polar Stratospheric Clouds and Ozone Depletion) project is developing an integrated code capable of calculating microphysical, optical and chemical properties of the clouds. Examples of polar stratospheric cloud observations will be used to demonstrate the potential of this code, to illustrate the different attributes of lidar and satellite instruments, and to indicate our current understandings of PSC behaviour. An overview will be provided of the importance of measurement location, sampling, and ancillary chemical measurements, and of the chief questions concerning PSC formation.

JSM01/W/04-A4 1510

THE SEASONAL EVOLUTION OF WATER VAPOR AND AEROSOLS IN THE ANTARCTIC AS OBSERVED BY THE POLAR OZONE AND AEROSOL MEASUREMENT (POAM III)

Gerald E. NEDOLUHA, Richard M. Bevilacqua, Karl Hoppel, Mark Daehler, Eric P. Shettle (Naval Research Laboratory, Code 7220, Washington DC 20375-5320, USA,
Email: nedoluha@wvms.nrl.navy.mil), and Mike D. Fromm (Computational Physics, Inc., 2750 Prosperity Ave., Fairfax VA, USA)

The Polar Ozone and Aerosol Measurement (POAM) III has been making occultation measurements at high northern and southern latitudes since April 1998. We shall present measurements of stratospheric water vapor and aerosols from 65S-88S, illustrating descent in the vortex and dehydration in the lower stratosphere. In the upper stratosphere water vapor acts as a tracer, and in September and October the water vapor profile exhibits an unusual double peaked structure, with mesospheric air mixing in from midlatitudes providing a high altitude peak while air that has descended within the vortex produces a low altitude peak. In the lower stratosphere aerosol optical depth measurements begin to show a significant increase in June when the first PSCs appear, but dehydration does not occur until July when the aerosol optical depths begin to exceed a threshold value. The availability of simultaneous aerosol and water vapor measurements thus makes it possible to study the growth of PSCs, and to distinguish different types of PSCs by determining which ones cause significant dehydration. Most of the water vapour lost during PSC formation is not recovered when temperatures rise above the frost point in October, hence the PSC formation process appears to be a sink for middle atmospheric water vapor. Assuming that the POAM water vapour measurements are representative of water vapor within the vortex, we can estimate the importance of this process to the middle atmospheric water vapor budget.

STRATOSPHERIC PHOTOCHEMISTRY

JSM01/W/60-A4 Invited 1550

ATMOSPHERIC PHOTOCHEMISTRY OF OZONE IN THE NEAR-ULTRAVIOLET REGION

Yutaka. MATSUMI (Solar-Terrestrial Environmental Laboratory, Nagoya University, 3-13, Honohara, Toyokawa 442-8507, JAPAN, email: matsumi@stelab.nagoya-u.ac.jp)

The overwhelming route to OH formation in the Earth's lower atmosphere is through the reaction of an electronically excited oxygen atom, O(1D), which is formed from the solar photolysis of ozone. Ozone in the stratosphere itself screens the atmosphere below from most solar UV radiation needed to produce O(1D). Therefore, how ozone dissociates when it absorbs the solar radiation in the longer wavelength edge of its absorption (_ > 300 nm) is a crucial piece of information.

(1) O3 + h_ Æ O(1D) + O2(a1_g)
(2) O3 + h_ Æ O(3P) + O2(X3_g-)

The channel (1) is important, since the product O(1D) can react with H2O and produce OH radicals, which has a photon energy threshold at 310 nm. The channel (2) does not result in the OH formation. Recent laboratory studies reveal that fairly amounts of O(1D) are produced in the O3 photolysis even at wavelength longer than the threshold. In the wavelength range of 310-320 nm the O(1D) atoms are produced through the channel (1) by the efficient photoabsorption from the O3 vibrationally excited states which are thermally populated in the atmosphere.

Furthermore, the O(1D) atoms are produced by the spin-forbidden channel above 320 nm:

(3).O3 + h_ Æ O(1D) + O2(X3_g-)

These two processes were previously thought to be negligible. They could enhance the balance of OH formation, particularly at high latitudes in the troposphere from late autumn to early spring. This will affect the lifetime of short lived species such as CO, a common pollutant, and also control the cleansing power of the lower atmosphere at a level which was previously underestimated.

JSM01/W/101-A5 Poster **1620-01**

ON TRACER SENSITIVITY TO TRANSPORT COEFFICIENTS IN TWO-DIMENSIONAL MODELS

SHUHUA LI, CRC for Southern Hemisphere Meteorology, Monash University, Australia; Darryn W. Waugh, Department of Earth and Planetary Science, Johns Hopkins University, USA

Recent comparisons of modelled and observed stratospheric mean age show large differences between models and data as well as between individual models, indicating serious problems with model transport. We explore the sensitivity of the mean age to different components of the transport by examining the effect of varying the transport coefficients within a single two-dimensional model. The mean age is shown to be sensitive to changes in advective circulation or diffusion coefficients, with the sensitivity largest for changes in the circulation strength. In most cases the magnitude but not the spatial distribution of the mean age changes. However, if the horizontal mixing is made very small within middle latitudes or large within low latitudes there are large changes in the shape of age isopleths. The effect of these changes in transport on chemically-active long-lived tracers is also examined. It is found that the lower stratospheric concentrations are relatively insensitive to the transport changes if these changes do not alter the general shape of age/tracer isopleths. Significant changes occur only when the transport coefficients are modified so as to change the spatial distribution of the mean age (and chemical tracers).

ROUND-BASED MILLIMETER-WAVE MONITORING OF OZONE IN THE UPPER STRATOSPHERE AND MESOSPHERE AT TSUKUBA, JAPAN

Tomoo NAGAHAMA, Hideaki Nakane (National Institute for Environmental Studies, Onogawa 16-2, Tsukuba, Ibaraki 305-0053, Japan, email: nagahama.tomoo@nies.go.jp) Mariko Minomiya (Global Environmental Forum, Inarimae 24-18, Tsukuba, Ibaraki 305-0061, Japan) Hideo Ogawa and Yasuo Fukui (Department of Astrophysics, Nagoya University, Nagoya 464-8602, Japan)

We report on ground-based millimeter-wave observations of the upper stratospheric and mesospheric ozone conducted at the National Institute for Environmental Studies (NIES) in Tsukuba, Japan (36N, 140E) since October 1995. Spectral data were obtained by using the millimeter-wave radiometer equipped with the superconducting mixer receiver and the AOS spectrometer. Vertical profiles of ozone mixing ratio from 38 to 76 km were retrieved with an error of ~10%. In the time series of the ozone mixing ratio observed during more than 27 months, seasonal and short-term variations in the upper stratosphere and mesosphere are clearly detected. The annual variation is generally consistent with the climatological models, and the semi-annual variation in the upper mesosphere is similar to that of the SME data except that the ozone mixing ratio in the spring measured with SME is ~70% larger than that in autumn while those with the radiometer are almost same. Sudden enhancement of ozone in the upper stratosphere is well correlated with the decrease of temperature measured with the co-located lidar. Further details of the ozone variations and comparison with theoretical models are presented.

ROCKET MEASUREMENT OF MIDDLE ATMOSPHERIC OZONE CONCENTRATION PROFILE BY KSR-Y

Su Jeong Son, Yong Ha Kim (both at Department of Astronomy and Space Science, Chungnam National University, Taejen, Korea, email: sjson@jupiter.chungnam.ac.kr, yhkim@jupiter.chungnam.ac.kr); Jhoon Kim and Gwang Rae Cho(both at Korea Aerospace Research Institute, Taejon, Korea, email: jkim@kari.re.kr)

KSR-Y(Korean-Scientific Rocket-¥±), a two-stage sounding rocket of KARI(Korea Aerospace Research Institute) was launched successfully at the Korean Peninsula onJune 11, 1998. The apogee of the rocket was 137 km and the total flight time was 365seconds. For the ozone measurement mission, 8-channel UV and visible radiometerswere onboard the rocket. The rocket measured in situ stratospheric and mesosphericozone density profile over Korea during its ascending phase using the radiometer andtransmitted the data to ground station in real time. The maximum ozone density occurs near 25 km. Retrieved profile has a random error(1¥ò) of approximately 15% for altitude below 20km, 7% between 20-50 km and 10% greater than 50 km. Comparisons with Dobson spectrophotometer, ozonesonde, and HALOE onboard the UARS are shown together. Our results are in reasonable agreements with others.

DIABATIC CROSS-ISENTROPIC DISPERSION IN THE STRATOSPHERE

J.A. KETTLEBOROUGH, British Atmospheric Data Centre, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon, OX11 0QX, UK

The evolution of tracers with respect to isentropic surfaces can be described by mean descent across the surfaces and dispersion about the surfaces. In some circumstances the dispersion can be modelled by a vertical diffusion coefficient.
Trajectories calculated from United Kingdom Meteorological Office analyses are used to determine the conditions under which a diffusive model is valid. When the dispersion is diffusive a diffusion coefficient is derived from the trajectory statistics. Trajectories have been calculated at different altitudes and different times of year. These calculations reveal the altitudinal and seasonal dependence of and interhemispheric differences between the derived diffusion coeffiecients.

WAVE-INDUCED TRANSPORT IN AN IDEALIZED STRATOSPHERE

D. PENDLEBURY and T. G. Shepherd (both at Department of Physics, University of Toronto, 60 St. George Street, Toronto, Ontario, Canada, M5S 1A7, email: diane@atmosp.physics.utoronto.ca)

The global mass circulation in the stratosphere is caused in part by the downward control principle introduced by Haynes et al. (1991). Extratropical stratospheric wave drag, produced by the breaking and dissipation of planetary waves, acts as a pump, drawing tracers from the equator to the pole and resulting in the observed Brewer-Dobson circulation.
At present, the theoretical understanding of this process has limitations. Although it can be shown, under certain assumptions, that the Lagrangian velocities and the transformed Eulerian mean velocities are the same and correspond to the wave drag, it is not clear that this relationship holds in general. Thus, while the existence of the wave-induced circulation is not under debate, its quantitative determination remains problematic. Previous studies have been linear and used Newtonian cooling together with Rayleigh drag. While the relaxational character of the radiative cooling is a reasonably acceptable approximation, Rayleigh drag is not. It is quite clear that in the atmosphere the mechanism for planetary-wave dissipation is a nonlinear process involving wave breaking, the development of small scales and their subsequent dissipation.
This paper will detail some of the problems with the traditional assumptions and present numerical results using a 3D primitive equations model aimed at quantifying the connection between wave driving and Lagrangian transport in the strongly nonlinear regime. The effects of realistic radiative transfer, which act preferentially on the small vertical scales that develop due to the wave breaking process, are also considered.

A PRELIMINARY NUMERICAL EXPERIMENT OF AN ARCTIC OZONE LOSS BY THE CHEMICAL TRANSPORT MODEL

Toru SASAKI, Hisashi Kato, Atsuya Kinoshita, Kazuaki Akagi (Japan Meteorological Agency, Otemachi 1-3-4, Chiyodaku, 100-8122, JAPAN, Email: tsasaki@naps.kishou.go.jp) and Toshiki Iwasaki (Geophysical Institute, Graduate School of Science, Tohoku University, Aoba-ku, Sendai, 980-8578, JAPAN, Email: iwasaki@wind.geophys.tohoku.ac.jp)

We are developing a chemical transport model (CTM) for the purpose of operational analyses of stratospheric ozone at the Japan Meteorological Agency (JMA). The CTM consists of the transport model developed at the Meteorological Research Institute (MRI) and the chemical model developed at the National Center for Atmospheric Research (NCAR). The transport model is being improved at the JMA and Tohoku University (Iwasaki et al., 1999, submitted to MW03 session). The present version of the model has 16 layers between the surface and the altitude of 10 hPa, and 5 or 2.5 degree resolution in latitude and longitude. The chemical model considers about 40 species and their relating gas phase and heterogeneous reactions on the surface of PSCs and sulfate aerosols. The transport model uses the semi-Lagrange scheme in horizon and box scheme in vertical. The CTM uses the meteorological data from the numerical weather prediction model of the JMA.
Though the CTM is still on the developing stage, a preliminary numerical experiment for the period of 1997 northern winter/spring was done. Ozone depletion in the arctic region is partly simulated, but the loss amount is not enough, because of the insufficient chlorine oxygen density. The reason may be an insufficient transport of rich chlorine from the upper layer.

JSM01/W/56-A4 Poster **1620-07**

QUANTIFYING ATMOSPHERIC TRANSPORT WITH AIRBORNE TRACER OBSERVATIONS

F. L. MOORE 1,2, E. A. Ray 1,2, G. S. Dutton 1,2, D. F. Hurst 1,2, P. A. Romashkin 1,2, J W Elkins 2, D. W. Fahey 3, M. C. Volk 4 1 CIRES, University of Colorado, Boulder, CO 803092 NOAA/CMDL, 325 Broadway, Boulder, CO 803033 NOAA/AL, 325 Broadway, Boulder, CO 803034 Institut fuer Meteorologie und Geophysik, Universitaet Frankfurt, Georg Voigt Strasse D-60325 Frankfurt am Main, GERMANY

The quality of an assessment on the environmental impact of existing aircraft and the proposed High Speed Civilian Transport (HSCT) fleet is limited by our ability to quantify stratospheric transport. The Lightweight Airborne Chromatograph Experiment (LACE) instrument, on board the Observations of the Middle Stratosphere (OMS) gondola platform, was designed and flown specifically to do this. LACE currently measures halon 1211, chlorofluorocarbons (CFC-11, CFC-113, and CFC-12), (CH3CCl3), carbon tetrachloride (CCl4), nitrous oxide (N2O), and sulfur hexafluoride (SF6) with a typical precision of between 1% and 4%. Mixing of air from mid-latitudes into the region of tropical upwelling with time scales between 1 and 2 years have been inferred from the LACE data by using a model analogous to the method of {Volk et al.} (Science, 272, 1763, 1996). The integrated fraction of mid-latitude air accumulating in the tropical upwelling region is also estimated to approach 50% at 20 km and up to 90% at 32 km. This quantifies the dominant mechanism for vertical transport of mid-latitude stratospheric pollutants to the upper stratosphere. The mean age of an air mass sampled in the stratosphere has been estimated from measurements of SF6 through the use of CMDL's historical record of the tropospheric global mean. This measured mean age is older than predicted by most models, particularly at altitudes above 20 km. Mean age estimates derived from LACE SF6 measurements are in agreement with mean age estimates from simultaneous CO2 measurements at all altitudes and latitudes, which do not contain vortex air. In vortex air, comparisons of mean age estimates derived from CO2 measured with an older mean age derived from SF6 data reveals a quantifiable (mesospheric) loss for SF6. An upper estimate of the SF6 global lifetime and estimates of mass flux across the vortex barrier are in principle possible.

TRACER TRANSPORT MECHANISMS IN THE SUBTROPICAL MIDDLE ATMOSPHERE

Lesley GRAY (Rutherford Appleton Laboratory, Chilton, Didcot, Oxon., OX11 0QX, U.K. Tel: +44 1235 446745, Fax: +44 1235 445848, e-mail: lesley.gray@rl.ac.uk).

Observations of long-lived trace gases from the Upper Atmosphere Research Satellite (UARS) exhibit an interesting 'staircase' feature in the Northern Hemisphere in winters in which the quasi biennial oscillation (QBO) is in an easterly phase. The staircase feature includes (a) an asymmetrical off-equatorial peak in the tracer isolines in the summer hemisphere above about 8 mb, with steep isolines over the equator forming a vertical 'equatorial cliff', (b) a region of almost horizontal isolines forming a 'subtropical ledge' between 8-15 mb and 0-20N, (c) a region of almost vertical isolines forming a 'subtropical cliff' in the Northern Hemisphere between pproximately 20-30N and 15-70 mb. The origin of each of these features is investigated, using both observational data and model studies. The fact that the staircase feature is strongly asymmetric about the equator suggests that isentropic mixing may be responsible for this feature, since it is strong in the winter hemisphere and weak in the summer hemisphere. However, we use the model to show that advection by the local QBO-induced circulation is more important than isentropic mixing. In particular, the steep isolines that form the 'cliff' regions are due to meridional overturning by the QBO circulation. They are not due to the sharpening of gradients at the subtropical edge of the surf zone caused by isentropic mixing.

A PRINCIPAL COMPONENT ANALYSIS OF TOTAL OZONE OVER THE SOUTHERN HEMISPHERE AS SEEN BY TOMS

Pablo O. CANZIANI, Diego C. Araneo, Rosa H. Compagnucci, Grupo de Atmosfera Media Departamento de Ciencias de la Atmosfera, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Pabellon II, Ciudad Universitaria, 1428 Capital Federal, Argentina

The behaviour of the Southern Hemisphere total ozone as measured by the TOMS family of sensors is studied using the Principal Component Analysis method. The aim of the study is to determine the predominant structures in the distribution of the total ozone and the variability and trends since late 1978, when TOMS NIMBUS became operational. The results of the PC analysis are discussed to which are the dominant structures and variability with respect to the lower stratospheric temperature as measured MSU Channel 4 temperature retrievals. The role of changes in dynamics and chemistry on the variability of the ozone distribution is discussed.

JSM01/E/36-A4 Poster **1620-10**

TEMPERATURE TRENDS AT 70HPA USING MSU CHANNEL 4 RETRIEVALS

Rosa H. COMPAGNUCCI, M.Alejandra Salles, Pablo O. Canziani, Grupo de Atmosfera Media Departamento de Ciencias de la Atmosfera, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Pabellon II, Ciudad Universitaria, 1428 Capital Federal, Argentina

MSU Channel 4 monthly temperature anomaly fields are used to analyse the trends in temperature in the lower stratosphere. Principal Component Analysis is used to study these fields over the Southern Hemisphere for the period 1979-1997. The time series at each grid point (i.e. 5184 pints for the 2.5x2.5 degree grid) are used as variables for the S-mode analysis. The first 5 components explain 75% of the observed variance and correspond to the predominant features if the temporal temperature in the Southern Hemisphere. The first and most importance variance corresponds to time series for grid points located at subtropical latitudes, and show the impact of the significant impact of two major volcanic events: the eruptions of El Chichon and Pinatubo. The 2nd principal component corresponds to temperature variability at high latitudes. It does not appear to show links with low latitude stratospheric processes. The 3rd and 4th components do not show any clear trends, while the 5th one yields a spectral peak in the same frequency band as the Quasi-Biennal Oscillation. The grid points associated with the latter are located at very low latitudes and those associated at mid-latitudes are in antiphase with respect to the equatorial grid points. It has been possible to identify real time series in the original data, which are in excellent agreement with the time series resulting from the PC analysis. It was possible to obtain regional characterizations of the behaviour of the temperature in the lower stratosphere over the Southern Hemisphere.

AN OZONE AND CLO MEASURING PROJECT AT LAS CAMPANAS OBSERVATORY IN CHILE

Yasuo FUKUI, Hideo Ogawa and Kecheng Xiao (Three at Department of Astrophysics, Nagoya University, Nagoya 464- 8602, Japan). Yasunobu Iwasaka (Solar-Terrestrial Environment Laboratory, Nagoya University, Nagoya 464-8602, Japan). Hideaki and Tomoo Nagahama (Both at National Institute for Environmental Studies, Onogawa 16-2, Tsukuba, Ibaraki 305-0053, Japan)

In the last ten years, interests in measurements of stratospheric minor constituents have increased considerably. In 1997, Nagoya University and NIES started a joint research project to develop a high sensitive ground-based millimeter wave receiver capable of detecting thermal emission from the rotational lines of chlorine oxide(ClO) and other stratospheric minor constituents. We already constructed ozone sensors (110.8 GHz) employing SIS receivers. In this project, we shall develop a 200-300 GHz SIS receiver system. The receiver noise of SIS mixer is expected to be better than 50 K(SSB) at 230 GHz. In 1999, we will install this instrument at Las Campanas Observatory at altitude of ~2300m(S29, W71.) in Chile. This is a place suitable to measure ClO and ozone because of the dry weather. This project is a first dedicated effort to measure these stratospheric molecules in South America where the southern hemisphere vortex sometimes tends to move away from the South Pole, and should be able to provide valuable information on the behavior of ClO and ozone, helping our better understanding of the movement of the ozone hole.

JSM01/W/14-A4 Poster **1620-12**

WHAT CAUSES THE ARCTIC POLAR COOLING OF THE 1990'S?

William J. RANDEL (NCAR, PO Box 3000, Boulder, Colorado, 80307-3000, USA, email: randel@ucar.edu) Darryn W. Waugh (Dept. of Earth and Planetary Science, Johns Hopkins University, Baltimore, MD, 21218, USA, email: waugh@jhu.edu)

Record cold temperatures have been observed in the springtime Arctic polar stratosphere during the 1990's. The 1990's decadal average temperature is significantly colder and the vortex persists longer into spring than can be explained by 'natural' year-to-year variability. This suggests a change in climate forcing in this region. Possible contributions to this forcing are analyzed, including: 1) coupling with the polar troposphere, 2) planetary wave forcing across the tropopause, and 3) radiative cooling due to ozone depletion and/or greenhouse gas increases. While each of these effects may contribute to the observed changes, close correspondence with trends in the Antarctic suggests that the radiative response to ozone loss is a major factor in the observed Arctic cooling.

JSM01/W/70-A4 Poster **1620-13**

LIGHTNING OVER THE NORTH ATLANTIC- IMPLICATIONS ON THE NITROGEN OXIDES (NOX) BUDGET AT CRUISING ALTITUDE

Dominique JEKER and Johannes Staehelin (Institute for Atmospheric Physics, ETH Zuerich, 8093 Zuerich, Switzerland e-mail: jeker@atmos.umnw.ethz.ch and staehelin@atmos.umnw.ethz.ch)

In the frame of the EU project POLINAT 2 we carried out fully automated measurements of nitrogen oxides (NO, NO2) and ozone (O3) from aboard a commercial Swissair B-747 airliner on 85 flights between Zürich (Switzerland) and destinations at the Eastern United States in the period of August 13 to November 23, 1997. The tropospheric NOx concentrations exhibited a log-normal probability density function and confirm the patchy occurrence of large NOx plumes found during the NOXAR (Nitrogen Oxides and Ozone along Air Routes) campaign in 1995/96. In August of both years the plumes were concentrated above the US continent, suggesting that lifted air from the polluted planetary boundary layer and/or lightning produced NO lead to the characteristic maximal mean NOx concentration below the tropopause. In autumn and winter, large parts of the enhanced NOx concentrations can most probably be attributed to lightning activity and to air transported upward from the polluted US boundary layer, induced by convective motion and frontal activity above the warm Gulf Stream current. We present two case studies of lightning events in thunderstorms above the North Atlantic where the relative importance of the ground sources is comparatively small and we show with images of the optical transient detector (OTD) satellite that the elevated NO concentrations can most probably be attributed to lightning activity. We then try to generalize the findings of these two case studies by statistically investigating the entire POLINAT 2 dataset.

REVISION OF THE O3 TREND ANALYSIS AT THE JUNGFRAUJOCH STATION

M. DE MAZIÈRE, M. Van Roozendael, O. Hennen, (all at Belgian Institute for Space Aeronomy, Ringlaan 3, B-1180 Brussels, Belgium), P. Demoulin, and E. Mahieu (both at Institue of Astrophysics and Geophysics, University of Liège, 5 Avenue de Cointe, B-4000 Liège, Belgium)

Two NDSC qualified instruments, namely a SAOZ and a Fourier-Transform spectrometer (FTS), measure vertical column amounts of O3 on a regular basis at the International Scientific Station of the Jungfraujoch. The SAOZ O3 time series is derived from UV-Visible zenith-sky measurements during every morning and evening twilight, and starts in mid 1990. The FTS time series contains daily averages of O3 derived from high-resolution infrared solar absorption spectra on clear-sky days, and starts in 1985. For both techniques, the retrieval methods have been improved during the last years. In particular for the FTIR retrieval, a recently developed climatological tropopause dependent model for the a priori vertical O3 profiles has been implemented. Here we present the homogenized time series, based on these latest algorithm revisions. The observed long-trem O3 trend above the Jungfraujoch will be discussed, and some particular periods like the aftermath of the Pinatubo eruption will be highlighted.

SAOZ NO2 MEASUREMENTS AT ABERYSTWYTH

Aidan GREEN and Geraint Vaughan (both at Department of Physics, University of Wales, Aberystwyth, SY23 3BZ, UK, Email: acg@aber.ac.uk and gxv@aber.ac.uk)

The SAOZ UV-visible zenith-sky spectrometer has been measuring NO2 vertical columns at Aberystwyth (52.4N, 4.2W) since March 1991. NO2 is of interest due to its important role in the photochemistry of ozone. The spectrometer measures spectra of scattered sunlight from the zenith-sky, and NO2 is derived from the region 405-498nm.
The time-series of data clearly shows the effect of the eruption of Mount Pinatubo in 1991, the increased level of stratospheric aerosol clearly causing a marked decrease in measured NO2 levels. Also apparent is the gradual return to, and exceeding of, pre-Pinatubo NO2 levels showing that the stratosphere was not free of aerosol even before Pinatubo.

OZONE DURING THE WINTERS 1991/92 TO 1998/99 : A COMPARATIVE STUDY

F.M.O'Connor, G.Vaughan and M.Hatcher

Eight years of ozonesonde data and ECMWF potential vorticity fields are used to perform a comparative study of northern hemisphere winters in mid- and high latitudes. The effect of synoptic-scale dynamics on the ozone evolution in the lower stratosphere is removed by expressing ozone mixing ratio in isentropic-PV coordinates. Clear differences are revealed between different winters, especially at high latitudes where chemical destruction is greatest. This study is also extended to sub-tropical latitudes, where trends in ozone should be caused primarily by dynamics.

POLAR PROCESSES

JSM01/W/26-A5 Invited **0830**

STUDIES OF POLAR PROCESSES IN THE LOWER STRATOSPHERE USING UARS MLS OBSERVATIONS

Michelle SANTEE (Jet Propulsion Laboratory, Pasadena, CA, 91109, USA;
email: mls@praxis.jpl.nasa.gov)

The Microwave Limb Sounder (MLS) experiments provide vertical profiles of atmospheric composition, temperature, and pressure by measuring millimeter- and submillimeter-wavelength thermal emission from the limb of Earth's atmosphere. The first MLS experiment in space was launched on the NASA Upper Atmosphere Research Satellite (UARS) in September 1991. One of the major objectives of UARS MLS is to improve understanding of stratospheric ozone, particularly the chlorine-catalyzed destruction of ozone in the polar regions of both hemispheres. In addition to measuring ozone, UARS MLS has obtained the first global observations of stratospheric ClO, the predominant form of reactive chlorine involved in ozone depletion. HNO3, which plays several pivotal roles in determining the cumulative amount of ozone loss, is also measured in the lower stratosphere. HNO3 is a key component of the polar stratospheric clouds (PSCs) that form in the low temperatures of polar winter, on which the heterogeneous reactions leading to chlorine activation occur. In addition, photolysis of HNO3 enables a major pathway for chlorine deactivation. It has been argued that denitrification, the permanent removal of reactive nitrogen from the lower stratosphere as HNO3-containing PSC particles gravitationally settle out, facilitates persistence of enhanced ClO abundances and thus increases ozone destruction. UARS MLS has obtained global measurements of O3, ClO, and HNO3 through six complete annual cycles in both hemispheres (and is still taking data, although with greatly reduced sampling frequency), making this data set uniquely suited to addressing some unresolved issues in stratospheric ozone depletion. Here we review results from some recent analyses of UARS MLS data, which include inferring information about PSC composition and formation processes in both hemispheres, investigating the degree of denitrification in Antarctica and its influence on lower latitudes, studying interhemispheric differences and interannual variability in chlorine activation, denitrification, and ozone depletion and the relative importance of denitrification in regulating the extent and duration of enhanced ClO, and discussing the implications of these findings for future Arctic ozone loss.

POLAR STRATOSPHERIC CLOUDS IN THE SOUTH POLAR REGION MEASURED BY CRISTA 2

Reinhold SPANG, Gunnar Eidmann, and Dirk Offermann (Physik Department, University of Wuppertal, Gauss-Str. 20, 42097 Wuppertal, Germany, email: spang@wpos2.physik.uni-wuppertal.de)

The CRyogenic IR Spectrometers and Telescopes for the Atmosphere instrument (CRISTA) was flown in November 1994 and August 1997 during the space shuttle missions STS66 and STS85. During the operation periods of around one week CRISTA has measured the thermal emissions of several trace gases with high spatial resolution in three dimensions.
During the CRISTA 2 mission significant indications of polar stratospheric clouds were found in the south polar region. Two PSCs were observed with unexpectly large horizontal dimensions (>2000 km). The temporal evolution of the clouds in the background temperature field will be presented as well as its influences on several trace gases (e.g. ozone, HNO3 and ClONO2).
One of the PSCs dissolves during two days. Possible mechanisms will be discussed. For a short time CRISTA has used a measurement mode with extra high spatial resolution (8 km long-track) in the region of the second cloud. This allows the observation of a possible inner structure of the PSC.

JSM01/E/16-A5 0920

CHEMICAL-RADIATIVE INTERACTION IN THE WINTER POLAR STRATOSPHERE

I.A. MACKENZIE and R.S. Harwood (both at Department of Meteorology, University of Edinburgh, JCMB, King's Buildings, Edinburgh, EH9 3JZ, UK, email: iam@met.ed.ac.uk)

Several recent northern and Southern Hemisphere winters were simulated with a mechanistic model of the middle Atmosphere incorporating a comprehensive, interactive Chemistry scheme. The extent of chemical feedback from stratospheric polar ozone depletion, i.e. self-perpetuation of the ozone destruction processes via the radioactively-induced Stratospheric cooling, is examined. Dynamical changes arising from the ozone loss and their impact on ozone transport in the polar region are also investigated. The results from the two hemispheres are compared, as are the results from northern hemisphere winters with different dynamical conditions as governed by the observed geopotential forcing applied to the model's lower boundary. The results suggest that, for different reasons, chemical feedback does not have a major impact on ozone destruction in either the current northern or southern winters. Nevertheless, there might be significant feedback if an unprecedented cold Arctic winter were to occur in the near future while the stratospheric chlorine and bromine loadings remain near their peak.

JSM01/W/29-A5 0940

COUPLED CHEMISTRY IN THE CCSR/NIES AGCM AND THE IMPACT OF SULFATE AEROSOL ON CLIMATE

Masayuki TAKIGAWA, Masaaki Takahashi (both at the Center for Climate System Research, University of Tokyo, 4-6-1, Komaba, Meguro-Ku, Tokyo, 153-8904, Japan.
e-mail: takigawa@ccsr.u-tokyo.ac.jp ; masaaki@ccsr.u-tokyo.ac.jp) and Hideharu Akiyoshi (National Institute for Environmental Studies, 16-2, Onogawa, Tsukuba-Shi, Ibaraki-Ken, 305-0053, Japan. e-mail: hakiyosi@nies.go.jp)

A new middle-atmosphere general circulation model that includes the photochemistry for ozone and other chemical species (25 photolysis and 59 gaseous reactions) has been constructed. The dynamical, radiative, chemical processes of the model are fully interactive.
The chemical scheme treats Ox-HOx-NOx-ClOx chemistry for the stratosphere, and predicts the concentrations of 31 chemically reactive gases. Nineteen photolysis rates are calculated by using the chemical species predicted in the model. However, the absorption of shortwave radiation for wavelength less than 200 nm is neglected in the radiation scheme of the original CCSR/NIES AGCM. Therefore, four parameterized photodissociations are included in the GCM (e.g., the photolysis of the oxygen by the radiative absorption in the Schuman-Runge band).
The distributions of long-lived species show good agreement with those from satellite observations in a climatological sense, and those of short-lived species are also compared to those observations. For example, the number density of OH in the upper stratosphere nearly equals to that from balloon observation.
Simple SOx chemistry and the heterogeneous reactions with the stratospheric sulfate aerosols are being considered in the model. The effect of aerosols on the radiation is coupled to the radiation scheme in the GCM. The impact of the sulfate aerosols on the climate, after several years of the eruption of volcanos, will be estimated by using the model.

JSM01/W/116-A5 1000

INTERANNUAL VARIABILITY OF ARCTIC POLAR VORTEX AND ITS EFFECTS ON OZONE

Hideaki NAKANE, Alexei. Kournossenko, Alexander Lukyanov, Hideharu Akiyoshi (National Institute for Environmental Studies, 16-2, Onogawa, Tsukuba, Ibaraki 305-0053 Japan,
e-mail: nakane@nies.go.jp) and M. Ninomiya (Global Environmental Forum, 24-18 Inarimae, Tsukuba, Ibaraki 305-0061 Japan, e-mail: ninomiya@nies.go.jp)

The minimum temperature in the Arctic polar vortex in winter-spring period is close to the threshold of generation of Polar Stratospheric Clouds (PSCs). This results in the large variability of ozone depletion in the Arctic region. We developed a method to visualize the duration, size and strength of the polar vortex and applied it to the 40 years NCEP data. The variability of the characteristics of the Arctic polar vortex will be discussed. Ozone vertical profile data obtained by long-term measurements were analyzed. The relations between the characteristics of the Arctic polar vortex and the variations in the ozone data will be discussed.

JSM01/W/32-A5 Invited 1040

MODELLING OF OZONE WITHIN AND OUTSIDE THE POLAR VORTEX

Martyn CHIPPERFIELD (The Environment Centre, University of Leeds, Leeds, LS2 JJT, UK, Email: martyn@lec.leeds.ac.uk).

The stratospheric circulation at high latitudes during winter is dominated by the polar vortex, a region of strong westerly winds which leads to some isolation of this air from mid-latitudes. Chemical ozone depletion is known to occur within both polar vortices during late winter and spring. This loss is triggered by cold temperatures which permit the formation of polar stratospheric clouds (PSCs). Within the strong Antarctic winter polar vortex, this chemical depletion removes essentially 100% of the ozone between about 15 and 22 km between late August and early October. The Arctic polar vortex is generally weaker, but displays much more interannual variability. This interannual variability modulates chemical loss (by controlling the extent of PSCs) but also modifies the absolute amount of ozone through different transport. A strong, isolated vortex leads to cold temperatures, but also results in only weak descent. Both of these processes act to cause low ozone columns.
I will discuss model studies which have quantified the springtime chemical ozone depletion within Arctic (and Antarctic) vortex. I will also discuss how transport affects ozone in the Arctic winter stratosphere. In particular, I will discuss how recent studies with a three-dimensional (3D) chemical transport model (CTM), reveal the relative contributions of chemistry and transport in producing the low average Arctic ozone columns observed during the mid-late 1990's. I will also discuss how polar ozone may evolve in the future, as stratospheric climate-change interacts with polar chemistry.

JSM01/W/16-A5 1110

THE IMPACT OF OBSERVED OZONE AND CO2-TRENDS ON THE STRATOSPHERIC CIRCULATION IN THE BERLIN GCM

Ulrike LANGEMATZ (Institut fuer Meteorologie, Freie Universitaet Berlin, Carl-Heinrich-Becker-Weg 6-10, 12165 Berlin, Germany email: lang@strat01.met.fu-berlin.de)

Recent assessments of stratospheric temperatures have revealed a cooling of the lower stratosphere over the Antarctic and in northern middle/high latitudes in the spring seasons. One explanation for this might be the radiative effects of a concurrent ozone decrease observed since 1979.
The question of a direct relationship between the observed ozone and temperature trends is studied here with the help of two 20-year integrations of the Berlin Climate-Middle-Atmosphere-model. A reference simulation using a climatological ozone distribution of the 1980s was compared with a run using an observed ozone trend scenario based on measurements between 1979 and 1996. The analysis focusses on radiative and dynamical interactions. Special attention will be paid to the impact of the ozone decrease on the interannual variability in the stratosphere, such as the occurrence of sudden stratospheric warmings and the timing of the polar vortex breakdown in spring.A possible modification of the ozone signal by the increasing amount of greenhouse gases will be investigated using a third model experiment, in which, in addition to the ozone change, the global CO2 increase since 1979 was incorporated.

JSM01/E/02-A5 1130

INTERANNUAL VARIABILITY OF VERTICAL DESCENT RATE IN THE ANTARCTIC POLAR VORTEX

Nozomi KAWAMOTO (Department of Geophysics, Faculty of Science, Kyoto University, Kyoto 606-8502, Japan, email: kawamoto@kugi.kyoto-u.ac.jp) Masato Shiotani (Graduate School of Environmental Earth Science, Hokkaido University, Sapporo 060-0810, Japan, email: shiotani@ees.hokudai.ac.jp)

To estimate a descent rate in the Antarctic polar vortex, we analyze the long-lived trace gas data derived from the Halogen Occultation Experiment (HALOE) for the 6 year period 1992 to 1997. Comparing methane profiles between the Antarctic autumn (February-March) and spring (September-October), we calculated an average descent rate in the lower stratosphere for each of the 6 winters. We found that it shows large year-to-year variations (1.8-1.2 km/month) which consist of a decreasing trend and a biennial cycle for the period we analyzed. The Antarctic stratopause during the mid-winter in years with large descent rate is warmer than in years with small one. It brings early downward and poleward movement of the westerly jet in the upper stratosphere through the thermal wind relation. Consequently, in years with large descent rate, wave activity is enhanced in early winter and it remains until late winter resulting from wave-mean flow interaction. It is also found that the descent rate is larger when planetary-scale wave amplitude is larger over the winter season. The variability seen in the descent rate also corresponds to the QBO for this period. The descent rate is larger in winters of 1992, 1994 and 1996 when the equatorial zonal flow is in easterly phase of the QBO.

JSM01/E/27-A5 1150

EVIDENCE FOR DYNAMICAL CHANGES AT THE EDGE OF THE ANTARCTIC STRATOSPHERIC VORTEX IN WINTER

Howard ROSCOE, Catherine Fowler, Jonathan Shanklin, Jules Hill (All at British Antarctic Survey/NERC, Madingley Rd, Cambridge CB3 0ET, UK, email: h.roscoe@bas.ac.uk

Measurements of ozone South of 60deg latitude in Antarctica during early winter show an increase, consistent with the observed descent of stratospheric air and the convergence, which must accompany descent aloft. In the 1960s and 1970s, the rate of increase of ozone at both Faraday (65degS) and Halley (76degS) was between 6.9 and 9.2 DU/month, with an estimated error of less than 3 DU/month (one-sigma). In the 1980s and 1990s, this increased to 18.6 q7.2 DU/month near the vortex edge at Faraday and at Syowa (68degS); but it decreased to -1.2 q4.7 DU/month at Halley in the vortex core. Either the rates of descent are now different inside and outside the stratospheric vortex in winter; or, more likely, the vortex edge now experiences greater convergence at the expense of the vortex core. The measurements (Lunar Dobson, plus SAOZ at Faraday in the 1990s) do not have sufficient time resolution to show whether the change is coincident with the appearance of the ozone hole or with increased CO2, execpt that the SAOZ measurements show the rate of increase to vary substantially from one year to another. GCM calculations byMahlman et al (1994) predicted such a change due to the ozone hole, but it is not clear what mechanism in the model gave rise to the changes. Such feedbacks between chemistry or radiation and dynamics in the Antarctic stratosphere are important because they may affect recovery of the ozone hole as the provisions of the Montreal Protocol become increasingly effective.

JSM01/W/02-A5 1210

TRANSPORT AT THE POLAR VORTEX EDGE AND THE INDUCED EXCHANGE OF MASSES

R. ALFIER, Institut für Meteorologie, Freie Universität Berlin, Germany S. Leder, Institut für Meteorologie, Freie Universität Berlin, Germany S. Pawson, Universities Space Research Association, Greenbelt, USA K. Ketelsen, Cray Research Inc. München, Germany

The transport at the Polar Vortex Edge and the exchanged masses are investigated for typical dynamical situations in northern winter. Fine structures in the transport of tracers (like water vapour) have been modeled with a 3-dimensional model. Typical observed 200hPa geopotential height fields are used to force the model. The different amounts of exchanged masses are investigated in the experiments. The mechanistic (primitive equation) model was setup in a high resolution (1.4 deg X 1.4 deg horizontal; 1.6km vertical) form. With an accurate semi-Lagrangian transport scheme the model is well adapted for this studies.

OZONE CHANGES IN THE STRATOSPHERE

JSM01/W/37-A5 Invited 1400

OZONE LOSS IN THE ARCTIC STRATOSPHERE AS OBSERVED BY MATCH

M. REX (Alfred Wegener Institute, now at JPL, 4800 Oak Grove Dr., Pasadena, CA 91109-8099, USA, e-mail: mrex@caesar.jpl.nasa.gov), P. von der Gathen, A. Schulz, J. Steger, H. Gernandt, N.R.P. Harris, E. Reimer, A. Beck, R. Alfier, M. Chipperfield, I. Kilbane-Dawe, M. Allaart, M. Alpers, H. De Backer,

D. Balis, B.R. Bojkov, G.O Braathen, J. Cisneros, H. Claude, F. O'Connor, J. Davies, H. Dier, V. Dorokhov, H. Fast, A. Gamma, S. Godin, G. Hansen, E. Kyrö, Z. Litynska, I.S. Mikkelsen, M.G. Molyneux, G. Murphy, H. Nakane, C. Parronodo, F. Ravegnani, S.J. Reid, M. Rummukainen, P. Skrivankova, C. Varotsos, C. Vialle, P. Viatte, J. Wenger, V. Yushkov, C. Zerefos.

Wintertime ozone loss takes place in the stratospheric polar vortices of both hemispheres. Compared with the Antarctic, the ozone layer in the Arctic is much more variable and the degree of chemical ozone loss is smaller, making it more difficult to separate chemical ozone loss from changes due to dynamical influences and to quantify the chemical contribution to observed changes. In recent years, a number of techniques have been developed and now we are able to derive a detailed picture of the chemical ozone loss for a number of recent Arctic winters. The presentation will focus on the Match technique that is based on the coordinated launches of several hundreds of ozone sondes per winter from a network of about 35 stations in northern latitudes. With the Match technique it is possible to measure stratospheric chemical ozone loss rates as a function of time and altitude with high vertical resolution. Match campaigns have been used to quantify the chemical ozone loss for six Arctic winters since 1991/92. The degree of chemical ozone loss is highly variable from winter to winter with largest losses observed for the coldest stratospheric winters, when local chemical losses exceeded 60 % and ozone column losses of more than 30 % have been measured. The timing and vertical extend of the observed chemical ozone loss agrees qualitatively well with model predictions, however current chemical models considerably underestimate the observed rate of chemical ozone loss.

JSM01/W/61-A5 1430

SEASONAL EVOLUTION OF OZONE-METHANE CORRELATIONS N THE POLAR REGIONS

D. SANKEY and T. G. Shepherd (Department of Physics, University of Toronto, 60 St. George street, Toronto, Ontario, Canada, M5S 1A7. email: sankey@mam.physics.utoronto.ca)

Correlations with long-lived chemical tracers are way of eliminating short-term dynamical ariability in the atmosphere. Plumb and Ko 1992) showed that a necessary condition to roduce a compact correlation between two tracers s that the lifetimes of the tracers involved must e longer than the quasi-horizontal mixing time. A recent application of such correlations is that of Mueller et al (1996), who used the evolution of a measured relationship between ozone and methane in the Arctic polar vortex to quantify the Arctic ozone loss due to chemistry alone. Their analysis assumes several things. One assumption is that a compact correlation exists when the initial measurement is made. This requires either that a correlation exists when the polar vortex is formed, which seems unlikely due to the short lifetime of ozone under sunlight conditions, or that a correlation forms in the early winter inside an isolated dark vortex. A second assumption is that a compact correlation is maintained even after the rapid destruction of ozone. There are not sufficiently extensive simultaneous measurements of ozone and methane to determine whether a well-defined correlation exists. Therefore data from a comprehensive middle atmosphere GCM (the Canadian Middle Atmosphere Model) are used to provide a surrogate dataset. The validity of the Mueller et al. approach is first examined by considering the correlations between ozone and methane in the Antarctic polar vortex. The Antarctic provides an ideal environment for compact correlations to occur because the vortex is much more stable than in the Arctic. The results suggest that although there is no correlation between ozone and methane when the vortex is formed, there is sufficient time for one to form through early winter. The situation for the Arctic vortex is much less clear due to the lower stability of the vortex.

JSM01/E/40-A5 1450

THE EFFECTS OF MIXING ON TRACER RELATIONSHIPS INSIDE THE POLAR VORTICES

Alan PLUMB (Massachusetts Institute of Technology, Cambridge MA, USA) Darryn Waugh (Johns Hopkins University, Baltimore MD, USA) and Martyn Chipperfield (University of Cambridge, UK)

Quantitative estimates of ozone loss and of denitrification within the polar vortices, whether based on trajectory-following or tracer correlation methods, implicitly ignore the effects of mixing. Accumulating observational evidence indicates that, on the contrary, mixing has a substantial impact on tracer budgets in the vortex. A single mixing event across the vortex edge will produce an anomalous mixing line, joining vortex and exterior air, on a tracer-tracer diagram. However, different lines would be produced at different altitudes, which the limited available observations indicate does not occur. A simple model of continuous mixing across the vortex edge shows that distinct tracer-tracer relationships are formed within the vortex, and that the separation from midlatitude relationships is greatest when the mixing is weak. The evolution of tracer relationships in a three-dimensional chemical transport model shows the development, though the winter, of anomalous relationships within the Arctic vortex.

JSM01/W/55-A5 1510

4.5 YEARS OF OZONE LAYER OBSERVATIONS OVER LAUDER, NEW ZEALAND

E.J. BRINKSMA, J.W. Hovenier, W. Hogervorst (Vrije Universiteit, De Boelelaan 1081, 1081 HV Amsterdam, The Netherlands, Email: ellen@nat.vu.nl) D.P.J. Swart, J.B. Bergwerff (RIVM, Postbus 1, 3720 BA Bilthoven, The Netherlands)

Altitude profiles of the ozone density have been measured with lidar over Lauder, New Zealand (45S, 170E) since late 1994. An overview of these measurements will be presented, showing both the long-term (seasonal) variation and variations on a much shorter time scale. A few cases in which the ozone layer changed rapidly (timescale of days) will be highlighted. For example, the record low ozone column density that was observed in August of 1997 will be explained by first focusing on the ozone profiles, which indicate at which altitudes changes took place. Then, by an analysis of the potential vorticity and ozone fields, we will show that these changes were caused purely by an unusual dynamical situation: In the lower stratosphere tropical ozone poor air was observed over Lauder, while simultaneously high-latitude ozone poor air was observed in the middle stratosphere. Other cases that might be presented are the detection of laminae of chemically depleted ozone poor air, originating from the springtime vortex, and cases of rapid changes in the ozone column density.

JSM01/W/27-A5 1530

OZONE PROFILE TREND ANALYSIS OF THE SWISS RECORDS

Andrea K. WEISS and Johannes Staehelin (both at Institute for Atmospheric Physics, ETH, CH-8093 Zuerich, Switzerland, email: weiss@atmos.umnw.ethz.ch and staehelin@atmos.umnw.ethz.ch)

Chemical destruction in the stratosphere and natural variability must be separated from methodical insufficiencies as well as instrumental drifts and shifts to prove ozone profile trends in order of some percent per decade.
Height dependent ozone trends above Switzerland can be derived from the balloon soundings of Payerne, Umkehr measurements of Arosa, and satellite overpasses of SAGE and SBUV.We found striking differences between the trends derived from Umkehr measurements and balloon soundings. This difference is not only present in Switzerland, but were noted also in global data in a recent assessment. The results are tuneable trends, especially for the climate relevant ozone in the height of the Troposphere.
With statistical homogeneity tests we identified breaks in the measurement series relative to each other. A trend analysis combining all methods is performed, showing the best possible estimates of ozone profile trends in Switzerland as well as the height dependent uncertainties.

JSM01/W/97-A5 Invited 1610

MIDDLE ATMOSPHERIC CHEMISTRY AND DYNAMICS: UNDERSTANDING THE DISTRIBUTION AND TRENDS OF STRATOSPHERIC OZONE

Roderic JONES (Cambridge University Centre for Atmospheric Science, Department of Chemistry, Lensfield Road, Cambridge CB2 1EW, UK, Email: rlj1001@cam.ac.uk)

Stratospheric ozone provides an essential shield against short-wavelength solar radiation. In absorbing both solar and longwave IR radiation it has a major influence on the temperature structure and thus the circulation of the middle atmosphere.
Anthropogenic activity, coupled with natural events, have over the past decades lead to dramatic and highly significant changes in the distribution of stratospheric ozone, with negative ozone trends evident over large parts of the globe. The magnitudes of these trends vary with both latitude and altitude, reflecting the differing destruction mechanisms involved. It is now also appreciated that changes in lower stratospheric ozone may have ameliorated, albeit temporarily, the effects of greenhouse warming, while the potential effects of climate change on the distribution of stratospheric ozone have yet to be quantified reliably.
In this presentation, the chemical and dynamical factors which control the distribution and seasonal evolution of stratospheric ozone will be summarised. Our understanding of the origins of the observed trends in ozone will then be reviewed, and the current appreciation of likely future changes in ozone will be discussed.

JSM01/L/30-A5 1640

EFFECTS OF ELEVATED SULFATE AEROSOL ON MIDDLE ATMOSPHERE CHEMISTRY AND DYNAMICS: 3-D COUPLED MODEL SIMULATIONS

JASSIM AL-SAADI, R. Bradley Pierce (both NASA Langley Research Center, Hampton, VA, 23681, USA), T. Duncan Fairlie (STC, Hampton, VA), Mary Kleb, William Grose (both NASA Langley Research Center, Hampton, VA), and V. Lynn Harvey (SAIC, Hampton, VA)

The NASA Langley Research Center IMPACT model is used to examine the effect of enhanced stratospheric aerosol loading on the dynamical evolution and chemical composition of the stratosphere following a large tropical volcanic injection. The IMPACT model is a three-dimensional general circulation model (GCM) with coupled dynamics, radiation and chemistry. The chemistry component explicitly transports 24 chemical families and individual species, and includes parameterizations of heterogeneous chemical processes on sulfate aerosols and polar stratospheric clouds. The ozone distribution predicted by the model is used in the determination of stratospheric radiative heating. Aerosol perturbation simulations are compared with a multiple-year control simulation in which a background surface area density distribution is used. The influence of enhanced aerosol on heterogeneous chemical processing is simulated using a three-dimensional climatology of surface area density developed using observations made from the HALOE, SAGE II, and SAM satellite instruments following the June 1991 eruption of Mount Pinatubo. Radiative effects of the enhanced aerosol loading are represented by monthly-mean zonally-averaged heating perturbations obtained from a study conducted with the ECHAM-4 GCM. These simulations allow assessment of the relative contributions of heterogeneous chemical processing and direct aerosol radiative effects to the dynamical and chemical characteristics of the middle atmosphere. Model results are compared with observational data including TOMS total ozone and species observed by instruments on the UARS satellite.

JSM01/E/15-A5 1700

UPPER AND LOWER STRATOSPHERIC OZONE CHANGES 1979-1994: THE ROLES OF VARIABLE TRANSPORT AND TEMPERATURE

LINWOOD B. CALLIS (Atmospheric Sciences Division, NASA Langley Research Center, Hampton, VA 23681-0001, e-mail: lbc@jaguar.larc.nasa.gov)

Changes in upper and lower stratospheric ozone during the period 1979-1994 are imperfectly understood. Deviations in upper stratospheric O3 cannot be fully explained by the effects of the solar UV variations and trace gas effects, and those in lower stratospheric O3 cannot be fully explained by heterogeneous chemical destruction associated with Clx and Brx. In the present analysis SBUV and SBUV O3 data are used with NMC temperature and layer thickness data, and MSU temperatures, to gain an understanding of the role variations in these quantities have on stratospheric O3 changes. Trend analysis is carried out by least squares fitting of time series of O3 with only constant, linear, and annual and semi-annual terms included. The residuals then contain the effects of the 11-year solar cycle, the QBO, and any other processes (dynamical or chemical) which may affect stratospheric O3. These residuals are analyzed with temperature and thickness data. In addition, diabatic transport fields have been diagnosed on a monthly basis from 1979 through 1996 using observed temperatures and climatological O3, CO2, and H2O distributions together with a radiative transfer code. These transport fields are discussed and have been used in a contemporary 2-D photochemical transport model to determine calculated O3 trends due only to variations in the transport and temperature fields. The calculated results reveal significant trends and multi-year deviations in column and local level O3 up to the global scale. These results are also discussed.

JSM01/W/15-A5 1720

CONSTRAINING UNCERTAINTIES IN THE PHOTOCHEMICAL MODELLING OF FUTURE OZONE CHANGES BY UARS OBSERVATIONS

Frans J. M. Alkemade (IMAU, Instituut voor Marien en Atmosferisch onderzoek Utrecht, Postbus 80005, 3508 TA Utrecht, The Netherlands, Email: frans_a@knoware.nl) Guus J. M. VELDERS (RIVM, Postbus 1, 3720 BA, Bilthoven, The Netherlands, Email: Guus.Velders@rivm.nl).

The chemical modelling of stratospheric ozone depletion is analyzed (using the Cambridge/RIVM 2-dimensional chemical transport model) in order to find the connection between the uncertainties in a selected set of pivotal reaction rate constants and the associated uncertainty in the long term ozone change predictions. A comparison between the modelled 1992 atmosphere and the concentrations of a number of species measured by several instruments onboard the UARS satellite is used to constrain this uncertainty. Sensitivity studies for varying reaction rate constants are performed, aimed at the long term ozone change prediction and at the 1992 stratospheric concentrations. The main results are:-
A long term ozone change prediction (from 2000 to 2050), based on the same reactionrate data and a specific emission scenario that are used by the ozone panel [WMO, 1999], contains an error of at least 100\%, due to the reported uncertainties in the chemical input parameters.

A comparison between the model and the UARS data can constrain the uncertainties in a number of reaction rate constants that have a relatively large influence on the calculation of future ozone changes. The five most important are:

N2O + O(1D) --> 2 NO (error reduced from 30% to 7%)
O3 + foton --> O2 + O (error reduced from 10% to 3%)
HCl + OH --> H2O + Cl (error reduced from 20% to 4%)
ClO + OH --> HCl + O2 (error reduced from 100% to 8%)
NO2 + foton --> NO + O (error reduced from 10% to 7%)

- This reduction of the errors in the reaction rate constants reduces the associated error in the long term modelled ozone change by a factor of about two. The revised prediction for the percentual change in the globally averaged total ozone field (year 2050 ozone minus year 2000 ozone) now becomes: 1.6% +/- 0.8%. (It was 1.6% +/- 1.7%)

JSM01/W/101-A5 1740

A THEORETICAL 2-D PHOTOCHEMICAL MODEL OF MINOR CONSTITUENTS DISTRIBUTION IN THE MIDDLE ATMOSPHERE

MANOHAR LAL and R. Rajaram, Equatorial Geophysical Research Laboratory, Indian Institute of Geomagnetism, Krishnapuram BO,Maharajanagar PO,Tirunelveli-627011, India

Production and loss rate of several species belonging to NOx, HOx, and Ox group have been calculated using the family method. The computed production and loss rates have been used as input in solving the continuity equation of 2-D photochemical model. The continuity equation was solved by using alternating direction implicit method. Input parameters such as temperature, meridional velocity, vertical velocity were taken from CIRA-92. The vertical eddy diffusion coefficient was taken from Ebel, and the horizontal diffusion coefficient taken as a constant value of 10(9) cm2s-1 in the present work. The chemical reactions and their reaction rates taken from JPL compilation. The photodissociation coefficients were used by the package developed by Arve Kylling and his group. We have derived the ozone and nitrogen dioxide latitude-altitude cross-sections and studied its diurnal and latitudinal variability. The ozone mixing ratio calculated by our model for 25 km altitude shows the value of about 2.4x10-6 at equator and increases upto about 4.4x10-6 at the polar region. Also the peak ozone density has been found at about 70 deg latitude. The present calculation does not, however, show any secondary peak in the mesospheric region.

PHYSICS AND CHEMISTRY OF THE EARTH'S INNER CORE

LARS STIXRUDE, Dept. of Geological Sciences, University of Michigan, Ann Arbor, MI 48109-1063, USA, stixrude@umich.edu

The structure of the earth's inner core is now known to differ from the homogeneous, isotropic picture we had only a decade ago. Recent seismological observations, when combined with knowledge of the physics of iron, have important implications for our understanding of the dynamics of the inner core, its interaction with the geomagnetic field, and its composition and temperature. The extreme pressure and temperature conditions of the inner core present substantial challenges. In this context, first principles theory provides the ideal complement to laboratory studies of iron, and a powerful probe of the earth's most remote regions. The first principles approach that we have used is based on Density Functional Theory and state-of-the-art computational methods for solving the quantum mechanical equations that reduce approximations to the minimum (LAPW). The theoretical results are found to be in excellent agreement with laboratory measurements, including the results of static and dynamic compression experiments, phase equilibria, and magnetism. Among the contributions of this approach to our understanding of the core are: 1) Placing new constraints on the crystalline structure of the inner core. The bcc phase can be essentially ruled out as an inner core constituent. The origin of its stability - its strong magnetism - vanishes at high pressure, rendering it mechanically unstable at core pressures. 2) An understanding of the first-order anisotropy of the inner core in the intrinsic crystalline anisotropy of iron. The single-crystal anisotropy of hcp iron agrees remarkably well with that observed for the inner core, indicating a strongly textured aggregate. 3) The composition of the inner core is found to contain a small amount of light alloying elements. Future directions, including the prediction of high temperature elasticity will be discussed.

JSS02/W/14-A1 1115

PARAMETER DEPENDENCE OF CONVECTION DRIVEN SPHERICAL DYNAMOS WITH APPLICATIONS TO THE GEODYNAMO

F.H. BUSSE, E. Grote and A. Tilgner (Institute of Physics, University of Bayreuth, D-95440 Bayreuth, Germany. E-mail: busse@uni-beyreuth.de Telephone No: +49 921 553 329 Fax No: +49 921 552 999)

A systematic study of the generation of magnetic fields by convection flows has been done in dependence on the Taylor number T, the Rayleigh number R, the Prandtl number P and the magnetic Prandtl number Pm. In different ranges of the parameter space dipolar, quadrupolar or hemispherical dynamos are preferred. The time dependence is usually chaotic, but steady (except for drifting nonaxisymmetric components) dynamos can also be found. The ratio of magnetic to kinetic energies exhibits the Prandtl number scaling expected on the basis of the magnetostrophic approximation, but other features indicate a significant dependence on P. Quadrupolar and hemispherical dynamos, for example, exhibit dynamo waves propagating in latitude which strongly depend on the inertial terms in the equations of motion. The results indicate that the geodynamo is characterized by a large effective Prandtl number suggesting compositional buoyancy as dominant energy source. Effects of boundary conditions and buoyancy distributions will be discussed and be related to conditions in the Earth's core.

JSS02/E/18-A1 1145

PHASE DIAGRAM OF IRON, REVISED-CORE TEMPERATURES

Thomas J. AHRENS Lindhurst Laboratory of Experimental Geophysics, Seismological Laboratory 252-21, California Institute of Technology, Pasadena, CA 91125 Kathleen G. Holland Sandia National Laboratory, MS George Q. Chen (Present address: The Santa Cruz Operations, Inc.)

Shock-wave experiments on iron preheated to 1573 K conducted from 14 to 73 GPa, yield new data for sound velocities in the gamma- and liquid-phases. Melting was observed in the highest pressure (~71 plus/minus 2 GPa) experiments at shock temperatures of 2775 plus/minus 160 K. This melting point is close to those measured by Boehler [1993], Saxena et al.[1993], and Jephcoat and Besedin [1997] and suggest the melting curve of gamma-iron is some ~500 degrees C lower than that of Shen et al. [1998] at 80 GPa. We speculate that the sub-solidus phase in the Earth's outer core could be the double hexagonally close-packed (d_c hp) beta-phase [Saxena et al., 1996], and its onset would reconcile the static and dynamic data for iron's melting curve at core pressures. Based on upward pressure and temperature extrapolation of the melting curve of gamma-iron, the estimated inner core-outer core boundary (ICB) temperature is 5500 plus/minus 400 K, which is similar to earlier results based on gamma-iron data and well below temperatures inferred from shock-temperature data. The temperature at the core-mantle boundary (CMB) on the outer core side is then calculated to be 3930 plus/minus 630 K, and the thermal boundary layer at the core-mantle boundary has a temperature difference between 400 and 1400 C, considerably lower than 1000-2000 C range estimated by Williams [1998], based on the higher temperatures inferred from shock temperature data.

JSS02/W/07-A1 1215

SIMULATING THE GEODYNAMO

Paul ROBERTS (Institute of Geophysics and Planetary Physics, UCLA, Los Angeles, CA 90095,USA, email: roberts@math.ucla)

Over the past four years, several groups have presented the results of their three-dimensional geodynamo simulations, some of which will be compared and contrasted in this presentation. The day seems to be approaching when comparisons between the behaviours of different simulations will reveal new facts about the deep interior of the Earth, now and in the geological past. Such information will follow from varying the parameters defining a model to make it behave increasingly like the observed geomagnetic field. An example is given in the second part of this presentation.
Most geodynamo models are spherically symmetric in structure, but recently Glatzmaier, Coe and Roberts have investigated how lateral inhomogeneities in the thermal state of the lower mantle affect convection and field generation in the core. Eight different patterns of heat flux from the core to the mantle were imposed over the core-mantle boundary. Spontaneous reversals occurred in seven of these cases. The results provide insight into why the frequency of geomagnetic reversals, as seen in the paleomagnetic record, can be so different during different geological epochs. When the structure of the lower mantle constrains the pattern of heat flux from the core to differ significantly from what is preferred by the dynamics of the core, the fluid flow and magnetic field are considerably more stochastic than they are when in harmony. This results in more frequent magnetic reversals of longer durations, and during the constant polarity intervals between reversals a magnetic field of smaller intensity and greater secular variability is found. These and other results of varying the parameters of the Glatzmaier-Roberts geodynamo model will be described.

CHEMICAL BONDING AND ELECTRONIC STRUCTURE IN THE EARTH'S DEEP INTERIOR

David M. SHERMAN (Department of Earth Sciences, University of Bristol, Bristol UK BS8 1RJ; email: dave.sherman@bris.ac.uk)

During the past 50 years, it has been proposed that pressure-induced changes in the electronic structures of geochemical components affect the physics and chemistry of the Earth's mantle and core. Changes in chemical bonding may change the siderophile and lithophile behaviour of metals and consequently determine how elements such as K, Ni and Co are partitioned between the core and mantle. Arguments about the nature of the light element in the core rest on pressure-induced changes in bonding and phase equilibria in the Fe-S-O-Si system. Changes in the electronic structures of transition metal oxides and silicates must be known before we can predict transport properties such as radiative thermal conductivity and electrical conductivity. In recent years we have been able to address these fundamental problems in mineral physics through the application of first-principles electronic structure calculations using density functional theory. This talk will give an overview of the current state of approximation being used and an assessment of the reliability of calculated phase stabilities and elastic properties. Recent work, for example, has provided constraints on core composition. In the near future, ab initio calculated thermoelastic properties will allow us to fit PREM to a mineralogical model. More fundamentally, however, is the emerging qualitative picture that theory is giving us about the crystal chemistry and electronic structure in the Earth's mantle and core. In particular, transition metal oxides, silicates and sulphides show a breakdown of the ligand field theory (crystal field theory) picture and the onset of intermediate spin states stabilized by metal-metal bonding.

JSS02/W/01-A1 1425

ON A FUZZY CORE-MANTLE BOUNDARY

Ed J. GARNERO (Arizona State University, Dept of Geology, BOX 871404, Tempe AZ 85287 USA, email: garnero@asu.edu), Raymond Jeanloz (UC Berkeley, Dept of Geology and Geophysics, Berkeley, CA 94720 USA, email: jeanloz@uclink.berkeley.edu), Lianxing Wen (Carnegie Institute, Dept of Terrestrial Magnetism, 5241 Broad Branch Rd Washington DC 20015 USA, email: wen@clrs1.ciw.edu)

The detailed nature of Earth's core-mantle boundary (CMB) likely plays an integrated role in important processes related to the evolution and dynamics of the entire interior. Seismic imaging experiments of the CMB region have resulted in models of a thin (5-50 km) intermittent layer at the base of Earth's mantle having ultralow seismic velocities. The ultralow velocity zones (ULVZ) are generally located beneath lower mantle regions containing reduced wavespeeds, as depicted by tomographic studies. Studies of ULVZ have included analyses of SPdKS, PcP, ScP, and PKP, and argue for Vp depressions of 10% or more, relative to the overlying mantle, and Vs reductions of up to three times that of Vp; the possibility of a density increase in the ULVZ has also been explored. Partial melt of some lowermost mantle constituent has emerged as a likely explanation

of the ultralow velocites, with the strong possibility of a chemical contribution (such as byproducts from chemical reactions between the core and mantle.) Subsequent work has demonstrated that strong trade-offs exist between ULVZ thickness and properties (Vp, Vs, and density). Here we extend the trade-off space to include a "fuzzy CMB", i.e., a thin transition zone from mantle to core properties (around 2 km), and a thin zone in the outer core containing non-zero Vs, i.e., a core-rigidity zone (CRZ) of thickness less than a few km. 2-D synthetic seismograms demonstrate how non-planar structures (e.g., domes) can also enhance waveform anomalies. Anomalous ULVZ structure, a fuzzy CMB, or CMB underplating (CRZ) -- which could have significant implications for geomagnetism and geodynamics -- can individually or collectively perturb the seismic wavefield previously used to image ULVZ structure. Thus, given the uncertainties, a fuzzy CMB (with possible mantle or core-side boundary layer structure) can also explain the data. In non-ULVZ regions the CMB can be 'sharp', with transition thicknesses of a few hundred meters or less.

JSS02/W/13-A1 1450

USING GEOMAGNETIC OBSERVATIONS TO INFER THE PROPERTIES OF MANTLE AND CORE MATERIALS

Stephen ZATMAN (Department of Geology and Geophysics, University of California, Berkeley, California, 94720, USA, email:zatman@seismo.berkeley.edu)

The time varying geomagnetic field ought to be a useful tool for deducing the physical properties of the Earth's deep interior. In practice it has been difficult to use geomagnetic data in this way because it has not always been clear how to interpret the data. Attempts to do so have often led to findings that are more like suggestions than hard results. The answer is to find sensible questions whose answer can be directly related to observables in the field (and ideally observables with unique physical interpretations).
In order to do this, it is important to understand the core dynamics that cause the observed secular variation. The decadal variation is thought by many to be related to ìtorsional oscillationsî (twisting motions between cylinders within the core about the axis of rotation): assuming that this is true allows us to estimate the timescale of magnetic diffusion within the mantle (by comparing estimates of the angular momentum in the core with changes inthe mantle rotation rate), which constrains mantle conductivity. Application of this method suggests a diffusion timescale of around half a year. Buffett proposed that the core and mantle might be dynamically coupled via gravitational coupling of the inner core to lateral density variations in the mantle. In turns out that if true, this makes predictions concerning the variation of the magnetic field near the Earth's poles that depend on the viscosity of the inner core. Preliminary results suggest that the core is rigid on the timescale of motions within the core (perhaps 100-1000 years), although modelling difficulties may be hard to rule out.

EXTREMES IN COMPLEX STRUCTURES AT THE CMB

D. V. HELMBERGER, I. Sidorin, L. Wen, S. Ni, J. Ritsema, and M. Gurnis Seismological Laboratory 252-21 California Institute of Technology, Pasadena, CA 91125, USA

We investigate some small scale seismic zones embedded in the large scale circum-Pacific Belt (Down-welling) and some slow zones beneath Europe and Africa (Up-welling) as delimited by long wavelength tomography. Using the results from dynamic modeling, Sidorin et al. (1998, 1999), we can perform a mapping of tomographic models into a physical model containing localized velocity gradients and a superimposed 1% phase change. This jump is temperature-dependent occurring 250 km above the CMB beneath the fastest regions (Caribbean, etc.) and drops to less than a 100 km away from these regions. The observed seismic triplication data, Scd, is explained well by 2D synthetics generated from these models showing its intermittent character which is controlled primarily by local velocity gradients. A review of the most anomalous seismic data and possible models associated with ultra-low velocity zones (ULVZ's) will be presented including distortions in SKS (SKPdS, etc.), precursors to PcP, ScS, PKP and anomalies in PKP branches. The African structure appears the most distinct with sharp features producing multi-pathed ScS and SKS behavior. Some 2D models are presented but these features prove difficult to constrain because of the overlying mega-plume complexity. Using forward modeling, we estimate that this structure extends halfway to the surface with rapidly varying ULVZ's at its base. As discussed in previous studies, some trade-offs occur in thickness but Gaussian-shaped structures with lateral dimensions of 50 to 300 km prove effective.

JSS02/E/06-A1 1600

FINE-SCALE STRUCTURE AT THE CORE-MANTLE BOUNDARY

Bruce BUFFETT (Department of Earth and Ocean Sciences, University of British Columbia, Vancouver, BC, V6T 1Z4, Canada, email: buffett@eos.ubc.ca)

Indications of unusual physical properties within a few tens of kilometers of the core-mantle boundary are found in several disparate observations. Waveforms of seismic waves that travel along partially diffracted paths indicate ultra low velocities in a layer that is probably less than 40 km thick. Independent observations of the Earth's nutation suggest high electrical conductivities in a layer that may be only a few hundred meters thick. Mechanisms that are proposed to explain these thin layers include partial melt in the mantle and chemical reactions between the mantle and liquid core. Ponding of partial melt at the base of the mantle is sufficient to explain the low velocity layer, but no entirely satisfactory explanation has been given for the anomalous conducting layer. Increases in conductivity due to partial melt appear to be too small and the conductive products of chemical reactions are not readily drawn into the mantle. We examine the possibility that a conducting layer develops at the top of the core through precipitation of dissolved mantle components. The combined effects of cooling and fractionation due to inner-core growth cause sediment of buoyant particles to settle at the top of the core. We assume that this layer of sediment forms a porous medium in which the high electrical conductivity is caused by liquid iron in the pore volume. Models for the Earth's nutation are used to establish the porosity, rheological properties and thickness of the layer needed to explain the observations. We use these estimates to infer the P and S wave velocities in the layer. Low P wave velocities relative to the overlying mantle occur because of the high density of liquid iron. Even lower S wave velocities are expected if the layer is poorly consolidated. Speculations about the evolution of porosity in the layer are based on comparisons of the rates of viscous compaction and sedimentation.

JSS02/W/02-A1 1620

CORE-MANTLE: PHASE RELATIONS AND CHEMICAL INTERACTION

Reinhard BOEHLER and Valerie Hillgren (both at Max-Planck Institut fuer Chemie, 55020 Mainz, Germany, email: boe@mpch-mainz.mpg.de)

In contrast to previous predictions, the solidus temperature of the lower mantle is substantially below the melting temperature of (Mg,Fe)SiO3-perovskite. New measurements on a pyrolytic mantle composition in the diamond cell agree with the shock melting temperature for olivine, leading to a solidus temperature at the core-mantle boundary (135 GPa) of about 4300 K which is close to the core temperature. From these results recent observations of an ultra-low velocity zone at the bottom of the mantle may be explained by partial melting of normal mantle material. The eutectic melt is most likely rich in dense (Mg,Fe)O-magnesiowuestite which may gravitationally segregate from the less-dense perovskitic material.
New shock measurements on iron support the melting temperatures obtained from diamond cells, which leads to a rather simple phase diagram of iron. This weakens the case for a new high pressure phase observed in some cases in the diamond cell and yields a melting temperature at the inner core boundary near 5000 K. The Grueneisen parameter obtained from the Lindemann relation and the melting slope is in agreement with estimates using other methods.
We present new data on the chemical interaction of potential mantle and core materials. Oxygen and Silicon by themselves are solvable in liquid iron in only subpercent amounts. The solubility of oxygen increases in the presence of sulphur. Under increasingly reducing conditions silicon is dissolved but we also observe an increase in the solubility of calcium and this in conflict with geochemical observations. If during core formation silicon would have been dissolved in liquid iron under strongly reducing conditions, core and mantle would be is drastic disequilibrium. A chemical reaction would deplete the bottom part of the lower mantle in iron, and this is in conflict with the distribution of seismic velocities. Thus, a combination of oxygen and sulphur is likely to explain the density deficit in the outer core.

JSS02/W/18-A1 Invited 1640

SOLUBILITY OF SILICON AND OXYGEN IN THE EARTH'S CORE

C.K. Gessmann (1), (2), M. Kilburn (2) , B.J. Wood (2) and D.C. RUBIE (1). (1) Bayerisches Geoinstitut, University of Bayreuth, D-95440 Bayreuth, Germany, (2) Department of Earth Sciences, University of Bristol, Wills Memorial Building, Queens Road, Bristol BS8 1 RJ, U.K., christine.gessmann@bristol.ad.uk.)

In order to help identify the nature of the light component(s) in the Earth's core, we determined the solubilities of silicon and oxygen in liquid Fe-rich metal up to 23 GPa and 2400 °C using piston-cylinder and multianvil apparatus. Metal powders, doped with various siderophile and light elements were used as starting materials and were contained in MgO capsules. A wide range of oxygen fugacities was imposed by varying the composition of the starting material. The experimental results reveal that the solubilities of Si and O in liquid metal vary systematically as a function of pressure, temperature and oxygen fugacity. The solubility of Si increases significantly with decreasing oxygen fugacity (at constant P and T), with increasing pressure (at constant T and fO2) and with increasing temperature (at constant P and fO2). The solubility of O in liquid metal also increases with increasing temperature, but varies inversely with Si solubility as a function of fO2 and pressure.
These results, if extrapolated to higher pressures and temperatures, suggest that significant amounts of Si can be dissolved in liquid metal even at 'moderate' oxygen fugacities, i.e. values that were likely during core formation. However, because of their inverse solubility behaviour, it is unlikely that the presence of both Si and O contribute significantly to the density deficit in the Earth's core. Additional model calculations based on available thermodynamic data allow extrapolation of these results up to core pressures and temperatures with the aim of better constraining the composition of the Earth's core.

JSS02/W/11-A1 1700

THE EFFECT OF D" STRUCTURE ON CORE PHASES: CONSEQUENCES FOR INNER CORE ANISOTROPY

Ludovic Breger, Barbara ROMANOWICZ and Hrvoje Tkalcic (Seismological Laboratory, Univ. of California, Berkeley, CA, 94720, USA, email: barbara@seismo.berkeley.edu)

We have assembled a representative global dataset of differential PKP(AB)-PKP(DF) travel times to study structure and anisotropy in the deep inner core. The reference PKP(AB) phases, which sample the outer core, are known to be strongly affected by propagation through D", and this contributes to the dispersion in the measurements. On the other hand, recent results based on the study of S wave data indicate the existence of strong lateral variations in D", particularly in the vicinity of the two large low velocity "plumes" under the pacific and Africa. By modifying an existing global tomographic model in a simple manner, which consists in saturating regions of low P velocity in D" of amplitude larger than 0.8% to 2%, and adding patches of Ultra Low Velocity Zones (ULVZ) where they have been documented in studies by Garnero and collaborators, we show that we are able to explain most of the long wavelength trends as well as a large fraction of the dispersion in our global PKP(AB)-PKP(DF) dataset. In particular, our modified deep mantle model is able to explain the trend of travel time residuals with angle of the propagation path in the inner core with respect to the earth's rotation axis, without need for a contribution from inner core anisotropy. The uneven distribution of data, with most polar paths sampling D" in the region of the giant plumes biases the observations, leading to an apparent trend with angle. We show that similar effects can explain the trends observed in PKP(BC)-PKP(DF) phases, and in particular are responsible for the different character of observations in the "western" and "eastern" hemisphere, as documented by Tanaka and Hamaguchi (1997). We therefore infer that inner core anisotropy may have been strongly overestimated, and that structure in D" and the mantle is largely responsible for the travel time anomalies observed.

JSS02/L/01 1720

COMPLEX STRUCTURES AT THE BASE OF THE MANTLE AS REVEALED BY SEISMIC PHASES SAMPLING THE DEEP MANTLE AND CORE

Barbara Romanowicz, Ludovic BREGER and Hrvoje Tkalcic

A preferred interpretation of anomalous splitting of modes sensitive to core structure has been in terms of inner core anisotropy, providing a unified explanation of these data and observed trends in PKP waves, which travel faster on polar than on equatorial paths. We reexamine this interpretation, as well as alternative ones, in the light of our recent results which indicate that simple, smooth models of inner core anisotropy that might account for normal mode splitting are in contradiction with some PKP observations. By inverting a dataset comprising modes that are sensitive only to the mantle and outermost core as well as modes sensitive to both mantle, outer core and inner core structure, we show that (1) inner core anisotropy improves the overall fit to data compared to a model with aspherical structure restricted to the mantle; (2) when mode 3S2 is excluded from the dataset, simple models with heterogeneity in the outer core fit the data consistently better than simple inner core anisotropy models; (3) when mode 3S2 is included, overall residual variances are smallest for inner core anistropy models. However, the splitting of 3S2 is fit at the expense of that of the 5S mantle mode branch, sensitive to P-velocity in the mantle. (4) outer core models are more stable and consistent with each other than inner core models, when different subsets of core modes are inverted (i.e. modes with small versus large sensitivity in the inner core). (5) Lateral heterogeneity in the mantle alone (in particular D") cannot consistently account for the splitting of all modes. Simple anisotropic models of the inner core are therefore not sufficient to simultaneously explain the splitting of spheroidal mantle and core modes, and a combination of deep mantle and outer

core structure contributes significantly to the pattern of splitting. A possible model which could explain most of the core data could comprise a zone of low density material confined to the tangent Taylor cylinder in the outer core. On the other hand, preliminary tests indicate that 3S2 is particularly sensitive to shear in the outer core. We conjecture that a small amount of shear in a stagnant layer at the top of the outer core could help reconcile the splitting observations for 3S2 and other core and mantle modes

JSS02/E/14-A1 **1740**

IN SITU X-RAY OBSERVATIONS OF PHASE TRANSFORMATIONS IN MANTLE MINERALS AND ROCKS AT THE NEW SYNCHROTRON RADIATION FACILITY, SPRING-8

TETSUO IRIFUNE, Toru Inoue, Nobumasa Nishiyama, Koji Kuroda (Department of Earth Sciences, Ehime University, Matsuyama 790-8577, Japan, Email: irifune@dpc.ehime-u.ac.jp), Ken-ichi Funakoshi (Japan Synchrotron Radiation Research Institute, Kamigori 679-5198, Japan), Wataru Utsumi (Japan Atomic Energy Research Institute, Kamigori 679-5198, Japan)

Observations of phase transformations in olivine (Mg2SiO4), pyroxenes (MgSiO3 and Mg0.5Ca0.5SiO3) and a pyrolite composition have been successfully made at pressures to 25 GPa and temperatures to 2300K, using a combination of the newly constructed 1500 ton multianvil apparatus (SPEED-1500) and the third-generation large synchrotron radiation source (SPring-8). Precise determination of the phase boundaries of spinel to postspinel in Mg2SiO4 and ilmenite to perovskite in MgSiO4 yielded Clapeyron slopes consistent with those of quench experiments (Ito and Takahashi, 1989), while there was significant discrepancy in the transformation pressures between these two studies.
The decomposition of Mg0.5Ca0.5SiO3 diopside and glass into MgSiO3 orthorhombic and CaSiO3 cubic perovskites was confirmed by the same technique, which is in contrast to some earlier results using quench technique. Further, the phase transformations in a pyrolite composition were observed in a pressure range 20 - 25 GPa and at a temperature of 1873K, conditions close to those of the 660 km seismic discontinuity.
The results were generally consistent with those of quench experiments (Irifune, 1994), but the transformation pressures were again lower by 2 GPa than these results. Some geophysical implications and technical problems are discussed on the basis of the present in situ X-ray

JSS02/W/16-A2 **0930**

PHASE TRANSITIONS AND MINERALOGICAL COMPOSITION OF THE EARTH'S MANTLE

Jan MATAS (1), Yanick Ricard (1), Francois Guyot (2), and Philippe Gillet (1) (1) Ecole Normale Superieure de Lyon, 46, allee d'Italie, 69007 Lyon, France. (2) Institut de Physique du Globe, 4, place Jussieu, 75005 Paris, France.

Several major discontinuities have been identified in the Earth's mantle. They are hypothesised to result from phase transitions of mantle rocks. A precise knowledge of the properties of mantle rocks at various pressures and temperatures is requested for determining the mantle composition and for evaluating the effects of phase transitions on the global dynamics. We propose a self consistent method for computing the thermodynamic properties of various solids at high pressures and at high temperatures. A numerical code based on a free-energy minimisation at various temperatures and pressures is developed for computing the equilibrium mineralogical composition for a given bulk mantle composition. Phase diagrams of mantle solid solutions are proposed for the system MgO, FeO, CaO, Al2O3, and SiO2. Comparing computed and observed transitions checks the thermodynamic models of mantle minerals. Several models of bulk mantle compositions, such as pyrolite or piclogite, are considered. Various thermochemical and thermoelastic properties of the mantle are then obtained as a function of depth.
The mantle minerals are present in solid solutions and, thus, the phase transitions are not univariant. Our code allows us to compute corresponding thickness of major phase transitions. The decomposition of garnets into silicate perovskites and magnesiowustite at the depth of 660 km, induces a thick discontinuity by about 40 km. Using the free-energy minimisation method, we compute adiabatic temperature profiles, which leaves mantle entropy constant with depth. Corresponding adiabatic density, bulk modulus and bulk sound velocity are deduced and compared to those deduced from seismological studies. Effect of latent heat of different phase transitions on the temperature profile, i.e. Verhoogen effect, is discussed in details. The temperature increases by about 50 K at the depth of 410 km due to the transition of olivine to wadsleyite. On the other hand, the decomposition of ringwoodite into silicate perovskite and magnesiowustite at the depth of 660 km results in a temperature decrease by about 70 K.

JSS02/W/03-A2 **1000**

JOINT SEISMIC TOMOGRAPHY FOR P AND S VELOCITIES: CHEMICAL ANOMALIES IN THE LOWER MANTLE

G. MASTERS, H. Bolton. and Gabi Laske (IGPP, Scripps Inst. of Oceanography, U.C. San Diego SIO-0225, La Jolla, CA 92093; ph. 619-534-4122; e-mail: gmasters@ucsd.edu)

Over the past 15 years, we have accumulated large data sets of hand-picked long-period absolute and differential travel times, surface wave phase and polarisation, and free oscillation structure coefficients. These data have been inverted in a variety of ways for 3D structure in the mantle with our current modelling focussing on joint inversions of shear and bulk sound speed using models parameterised with 5 degree blocks. The resulting models are robust and are relatively independent of inversion technique provided that enough data of different types are included. The lower mantle of these (and almost all recent) models are characterised by slab-like fast regions surrounding broad regions of slow material with a strong increase in the amplitude of heterogeneity towards the base of the mantle with a particularly large increase in the amplitude of slow anomalies in S velocity. The bulk sound speed tends to be positively correlated with the shear velocity in the upper mantle but becomes increasingly negatively correlated as one descends through the lower mantle. This is largely due to the fact that the amplitudes of the broad slow P anomalies do not generally increase as rapidly as the amplitudes of the slow S anomalies. Our results admit the following general conclusions. The properties of the fast slab-like anomalies in the lower mantle are consistent with a thermal origin while the broad slow anomalies are at least partially chemical in origin or are associated with near-melting behaviour of some of their components. The near-melting explanation is less likely as there is no compelling evidence for low Q regions in the lower mantle, which would most likely accompany a region of partial, melt. We therefore speculate that the broad slow regions correspond to upwelling which is entraining chemical heterogeneity from the core-mantle boundary region. We also note that there is little evidence for a strong internal boundary layer separting the lower and upper mantle though we do observe some weak decorrelation of structure in this region.

A GEODYNAMICALLY SELF-CONSISTENT MANTLE VISCOSITY PROFILE

J.X MITROVICA (Department of Physics, University of Toronto, Toronto, Canada, M5S 1A7, 416-978-4946, email: jxm@physics.utoronto.ca) A.M Forte (Institute de Physique du Globe de Paris, Dept. de Sismologie, 4 Place Jussieu, Paris 6, 75252 France) Karin Wieczerkowski (University of Muenster, Institute of Planetology, Wilhelm-Klemm-Strasse 10, Muenster D-48149, Germany)

One of the important outstanding issues in mantle rheology is the apparent disagreement between the radial viscosity profiles inferred on the basis of observables associated with mantle convection and glacial isostatic adjustment (GIA). We report here on ongoing efforts to address this issue using inverse procedures applied simultaneously to these two data sets. The GIA data set we employ includes post-glacial relative sea level variations at a globally distributed network of sites as well as a newly derived relaxation time spectrum for Fennoscandia. The convection observables include long-wavelength free-air gravity harmonics and plate motions. The inversions also incorporate geodetic constraints on CMB topography and a wide range of seismic data. We conclude that the discrepancy noted above is an artifact of model parameterisations used in previous studies; these parameterisations have not taken into account the unique revolving power of the two data sets. We find that a simultaneous reconciliation of the GIA and convection data sets (to a level similar to those obtained from independent inversions of the data types) is possible using multi-layer models characterized by a significant increase (1-2 orders of magnitude), with depth, in the mantle. Furthermore, we will present results based on regional subsets of the GIA data which indicate to what extent lateral heterogeneities in rheology need to be invoked to reconcile the totality of the GIA data set.

PHASE TRANSFORMATIONS: IMPLICATIONS FOR MANTLE STRUCTURE

Donald J. WEIDNER (CHIPR and Dept. of Geosciences, State University of New York, Stony Brook, NY 11794, Email:dweidner@sunysb.edu) and Yanbin Wang (Consortium for Advanced Radiation Sources, The University of Chicago)

The role of phase transformations on radial and lateral velocity and density variations in the Earthís mantle is examined. Pyrolite is taken as a reference chemical composition. Specific attention is given to the chemical interaction among the multiple components in the entire system. In particular, aluminum influences the width and depth of the 410-km discontinuity. The velocities and density at the 410-km discontinuity are rather insensitive to lateral variations of the temperature aside from the change in the depth of the discontinuity. Formation of CaSiO3 perovskite may be an important contributor to the 520-km discontinuity. Aluminum also plays a major role in defining the character of the 660-km discontinuity. Slight variations in Al content or temperature from the reference model changes the magnitude of the 660 velocity increase by a factor of two. Ilmenite forming phase transitions will introduce lateral velocity variations resulting from lowered temperatures that can be mistaken as a slab sitting on the 660-km discontinuity. These many different implications result from considering the whole chemical system.

JSS02/E/07-A2 **1145**

EFFECTS OF PHASE TRANSFORMATIONS ON LATERAL AND RADIAL VARIATION IN MANTLE RHEOLOGY

Shun-ichiro KARATO (University of Minnesota, Department of Geology and Geophysics, Minneapolis, MN 55455, U.S.A., Email: karato@tc.umn.edu)

Phase transformations are among the most important factors that may affect rheological properties of deep mantle thereby control the style of mantle convection. Phase transformations in a descenidng slab may cause rheological anomalies that may influence its fate upon subduction and could lead to deep earthquakes. Phase transformations in other general areas may cause global rheological layering that may affect the style of mantle convection. Using laboratory data and theoretical models, I will discuss some of the important issues on this topic. The most important is the development in high pressure, high temperature deformation technique which allows us to directly investigate the role of phase transformations on rheology. Such a technique allows us to investigate rheological properties at least up to 16 GPa and 2000 K. We now have direct experimental data on the effects of olivine-ringwoodite, olivine-wadsleyite transformations on rheology under the transition zone conditions. These studies show dramatic weakening associated with grain-size reduction, but both experimental and theoretical modelling show that such effects are sensitive to the temperature at which a phase transformation occurs. Combining these laboratory data with theoretical models of grain-size evolution associated with a phase transformation, we construct a model for rheological structure of subducted slabs. The model predicts that cold slabs are weaker than moderately warm ones and consequently the 660-km discontinuity will work as a rheological filter for convection current. The model also suggests a complicated rheological structure characterised by high energy dissipation in a wide (~40-50km) regions in a deep slab, providing a possible explanation for wide fault widths for deep earthquakes. Mineral physics basis for a possible weak layer in the deep mantle will also be discussed. "Transformational plasticity" (enhanced plasticity due to large internal stress/strain) and weakening due to grain-size reduction are shown to be difficult to cause global weak layer because these mechanisms work only at relatively low temperatures.

SEISMOLOGICAL CONSTRAINTS ON UPPER MANTLE ANISOTROPY

Jean-Paul MONTAGNER, Laurent Guillot (all in Dept. Seismology, Institut de Physique du Globe, 4 Place Jussieu, 75252 Paris cedex 05, France, jpm@ipgp.jussieu.fr), Philippe Gillet and Daphne-Anne Griot (both at Laboratoire de Sciences de la Terre, ENS-Lyon, 46 Allee d'Italie, 69364 - Lyon cedex 07, France)

Mantle mineralogy and its different phase constituents are relatively well known. But the proportion of the different minerals and their lateral heterogeneities is still subject to debate. Isotropic velocity Vp and Vs alone, do not enable to separate temperature and chemical heterogeneities, but the joint use of Vp, Vs velocities and anisotropic parameters enable to undertake such an investigation. First of all, we updated the elastic tensors of the competing petrological models (pyrolite and piclogite). By considering a simple model of convection and by assuming some mechanisms of alignment of minerals, we show how to calculate the corresponding seismic observables, travel times of body waves and surface waves dispersion curves. It is demonstrated that seismic observations should enable to discriminate between different etrological models. A preliminary application to actual data will be presented.

PERIDOTITE XENOLITHS FROM PLIOCENE BASANITE OF THE DZHILINDA RIVER

(VITIM VOLCANIC FIELD): STRATIFICATION OF UPPER MANTLE AND CRYPTIC METASOMATISM

Konstantin LITASOV, Yury Litasov, Vladimir Malíkovets (Institute of Geology SB RAS, Koptyuga ave., 3, 630090 Novosibirsk, Russia, email: kostik@uiggm.nsc.ru) Alexey Mekhonoshin (Institute of Geochemistry SB RAS, Favorsky st., 1a, 664033, Irkutsk, Russia, email: mekhonos@igc.irk.ru)

The abundant mantle xenoliths were found in Pliocene basanites of the Dzhilinda River (Vitim volcanic field). Two main and one detached peridotite groups were recognized: (1) spinel and garnet-spinel lherzolites with coarse-grained protogranular texture (two pyroxene temperature T=1060-1210˚C, Brey, Kohler, 1990); (2) spinel peridotites with various textures from protogranular to tabular equigranular (T=790-910(C); (3) mosaic equigranular lherzolite (T=710-750(C).
Trace element data were obtained by ion microprobe for 13 clinopyroxenes from different peridotite groups. Group 1 clinopyroxene shows HREE depletion due to a garnet control, Ba, Th, Nb depletion and Be, Zr, Ti negative anomaly. Group 2 clinopyroxene contains higher amounts of HREE and similar depletion and anomaly as in the group 1 for other elements. Both the groups also contain clinopyroxene moderately enriched in LREE. Texturally, it corresponds to deformed varieties of the group 1 and tabular equigranular varieties of the group 2. The group 3 clinopyroxene shows depleted patterns with positive Nb, Be, Ti anomalies and light negative Zr anomaly, suggesting rare HFSE cryptic metasomatism.
Peridotite xenoliths of the Dzhilinda River are representatives of temperature-stratified mantle column with different degree signs of cryptic metasomatism caused by melt percolation. Our data for cpx may partly characterise metasomatizing agents. The first one causes light enrichment of peridotite in LREE. The second agent probably is a specific depleted HFSE- and Zn-bearing melt/fluid.

GEOCHEMISTRY OF LOWER CRUSTAL XENOLITHS FROM ALKALINE BASALTS, VITIM VOLCANIC FIELD, SIBERIA

Konstantin LITASOV (Institute of Geology SB RAS, Koptyuga ave., 3, 630090 Novosibirsk, Russia, email: kostik@uiggm.nsc.ru)

Among the lower crust-uppermost mantle xenoliths in Late Cenosoic alkaline basalts of the Vitim volcanic field (VF), three groups are recognised: (1) garnet granulites; (2) garnet-bearing clinopyroxenites and gabbro; (3) spinel websterites. T-P data evidence for the presence of intrusive bodies, lenses and veins of cumulate rocks at the depth 35-45 km in the lower crust along the Moho, which are underlay by spinel lherzolites. Calculated temperatures of cumulate formation range from 800 to 1020oC. Most of xenoliths have metamagmatic cumulative microstructure and their formation is corresponded to underplating of mantle melts.
Electron and ion microprobe study of clinopyroxene suggest that garnet clinopyroxenite and gabbro of group 2 correspond to most differentiated cpx-megacrysts (Al_2O_3=9-9.6 and 8-8.5%, TiO_2=1.5-1.8 and 1.6-1.8%, (La/Yb)n=9-16 and 5-6 ppm, Cr=71-420 and 55-380 ppm correspondingly). Spinel websterite of group 3 correspond to CrDi-pyroxenite (same Al_2O_3=5-7% and TiO_2=0.3-0.7%, (La/Yb)n=0.7-1.6 and 0.3-2, Cr=600-1200 and 1800-4000 ppm). Garnet granulite of group 1 has intermediate characteristics but tend to Cr-rich group.
Using geochemical data we suppose that the formation of lower crustal rocks composing xenoliths of the VF is connected with following processes: (a) crystallization of last stage basaltic residue melts after megacryst series formation comagmatic to the host basaltic rocks (group 2); and (2) crystallization of melts comagmatic to the green series pyroxenites (group 3). The formation of garnet granulites of group 1 may be connected with both processes.

MONITORING OF SURFACE TILTS AND EFFECTIVE VISCOUS OF FAULTS ZONE

Vladimir Timofeev (Institute of Geophysics UIGGM SB RAS, Pr.Koptiug 3, 630090, Novosibirsk, Russia, email: sari@uiggm.nsc.ru) Bernard DUCARME (Observatoire Royal de Belgique, Avenue Circulaire 3, 1180, Bruxelles, Belgium, email: B.Ducarme@oma.be)

Results of the monitoring of Baikal rift surface tilts (1985-1998) are discussed. Measurements with quartz tiltmeters were into 90-metres old underground gallery built in Archean marble rocks. The analysis of 13-years meridian's direction tilt and the seismological stress analysis are presented for Talaya station (51.68 N, 103.65 E). Viscous Voigt-Kelvin model are used for the interpretation of tilt's data with north-south stress equal zero for post 1989 year's period. This result was used for effective viscous term determination for fault zone. The determination was made by attenuation tilt curve or by time delay curve at the period when the stress was equal zero. We determined the time delay term T=6 years and the effective viscous term 3x 1018 Paxs for main Sayan fault zone. The additional tectonic stress was determined from monitoring data. The tectonic stress was near 2 MPa.

INNER CORE'S SEISMIC VELOCITY ANISOTROPY IS CAUSED BY ITS ROTATION

Bin LIU, Qunshan Zhang, Rongshan Fu (Dept. of Earth and Space Sci., Uni. of Sci. and Tech. of China, Hefei 230026, P. R. China)

The earth's inner core has a differential rotation relative to the outer earth with an angular velocity of about 3% faster. The relative linear velocity between solid inner core and molten outer core is the biggest at equator and zero at pole areas. According to the theory on crystal growth, when crystallising from molten, the crystal growth speed is proportional to the relative linear speed between solid and molten crystal. So when solid inner core grows in molten outer core, it grows faster at equator than at polar areas. Since the inner core is at a high pressure and high temperature condition, it shows intense plasticity in geological timescale. Under gravitational force the inner core remains quasi-orbicular, with a substance flow from the fast growing equator part to polar areas, forming an axisymmetric rheologic field. The accompanying axial symmetric stress field makes c-axes of hcp iron composing the solid inner core align with inner core's rotating axis, resulting in the observed seismic anisotropy in the inner core The symmetric axis of the seismic anisotropy should coincide with the inner core's rotating axis. If it is true, as a deduction, the differential rotation observed by Song et al. (1996) and Su et al. (1996) is not really the rotation of the inner core relative to the outer earth and should be the precession of the inner core's rotating axis relative to the outer earth. Su et al. (1996) found that the angle between the inner core's symmetric axis of seismic anisotropy and the axis of the earth has an undulation with a period of about 8.39 years. This may be the nutation of the inner core's rotating axis accompanying the precession. Since the molten outer core is liquid with coefficient of kinematic viscosity can be as low as 3*10**(-7)m**(2)s**(-1) - 2*10**(-5)m**(2)s**(-1), it is quite possible for the inner core to move almost freely inside the earth.

ALKALINE CARBONATE - SILICATE REACTIONS AT THE MANTLE - PLUME INTERFACE IN EXPERIMENTS UP TO 10 GPA: NEW MINERALS, LIQUID IMMISCIBILITY, DIAMOND - PRODUCING MELTS

Yuriy LITVIN (Institute of Experimental Mineralogy,RAS,Chernogolovka, Moscow District - 142432, Russia, email: litvin@iem.ac.ru)

For simulating an interaction of alkaline - fluid agents of active plumes with the mantle wallrocks, the system Mg_2SiO_4 (forsterite) - K_2CO_3 - Na_2CO_3 - K_2SiO_3 was chosen. Melting relations of the system were experimentally studied at 4 GPa, 1100 - 1600oC at the forsterite - K_2CO_3 - K_2SiO_3 and forsterite - Na_2CO_3 - K_2SiO_3 joins. Essential distinction in chemical behaviour of K - and Na - carbonate agents, a responsibility of K - components for the processes of carbonation of the lithosphere and effects of carbonate - silicate liquid immiscibility which as discussed (Wyllie, 1996) are important in mantle petrology, the formation of plausible mantle minerals, such as Ma_2MgSiO_4 silicate and $K_2Mg(CO_3)_2$ carbonate (melt of the latter is effective for diamond growth) were revealed. The patterns of the mantle - plume interaction must be supplemented with the formation at 4 - 7 GPa and higher pressures of $Ma_2Mg_2Si_2O_7$ phase (plausible mineral) together with pyropic garnet ($Mg_2Al_2Si_3O_{12}$) and enstatite on the Mg_2SiO_4 (forsterite) - $NaAlSi_2O_6$ (jadeite) join (Gasparik, Litvin, 1997), and the peritectic reaction Mg_2SiO_4 (forsterite) + alkaline melt = $Na_2Mg_2Si_2O_7$ phase found in experiments on the $MgSiO_3$ (enstatite) - $NaAlSiO_4$ (nepheline) pseudo binary join (Litvin et al., in the press). Growth of diamond both spontaneous and seeded was discovered in experiments at 8 - 10 GPa in the $Na_2Mg(CO_3)_2$ - $K_2Mg(CO_3)_2$ - C system (Litvin et al., 1998) formation of which is realistic for the mantle - plume interface of the deep Earth's hot spots. The experimental data reported are applicable to the problem of primary stages of genesis of intraplate alkaline rock series and characterisation of the lithosphere - astenosphere boundary.

INVERSION OF THE VISCOSITY STRUCTURE OF THE MANTLE

Shaoxian ZANG and G. C. Chen (both at Department of Geophysics, Peking University, Beijing 100871, China, email: sxzang@ibmstone.pku.edu.cn)

Seismic tomographic results provided 3-D velocity structure of the mantle. How to use the seismic tomographic results to study the viscosity structure of the mantle has attracted big attention from geoscientists. In this paper the viscosity structure of the mantle was studied using the geoid anomaly and seismic tomographic data.
Firstly, the viscosity structures of eleven-homogeneous-layered mantle were studied. The density distributions for eleven homogeneous layers of mantle were obtained using the seismic tomographic results: MDLSH model (Tanimoto, 1990) and SH425.2 model (Su and Dziewonski,1991). The viscosity distributions of eleven layers were obtained using geoid anomaly by genetic algorithm. The results for the two seismic models are basically coincident with each other. Secondly, for utilizing the 3-D seismic tomographic data, we divided the mantle into two parts according to the seismic tomographic data: Pacific area, where the velocity anomaly is negative and normal area, which excepts Pacific. Then density and the viscosity distribution of eleven layers for the two areas were obtained respectively by same data and algorithm as the first step. The result shows that the viscosity in the Pacific area is generally lower than another area. Finally, the result were discussed and pointed out some studies should been done such as seeking more accurate relation between velocity and density in the Earthís interior and more constrains on the viscosity structure.

PHYSICAL AND MINERALOGICAL MODELS OF THE MANTLE

V. PANKOV, A. Kalachnikov and A. Babeyko (all at United Institute of Physics of the Earth, Russian Academy of Sciences, B. Gruzinskaya 10, Moscow, 123810 Russia, email: Pankov@uipe-ras.scgis.ru)

Based on experimental P-V data or evidence on bulk modulus and its pressure derivative, the method of potentials (Zharkov and Kalinin, 1971) is applied to the determination of equation of state (EOS) for a set of phases in the MgO-FeO-SiO_2 system. The complete phase diagram is calculated by using the algorithm of Capitano and Brown (1987). Concentrations of phases and components in the mantle are estimated from its seismic and thermal models using the derived EOS' and phase stability fields. Depth distributions of various thermodynamic characteristics are calculated for the inferred compositional models. In certain cases, this approach allows estimation of the depth distribution of convective temperature gradient. Possible decomposition of perovskite to oxides at the mantle base and geodynamic consequences of the inferred models are discussed.

ELASTICITY AND ITS TEMPERATURE VARIATION OF MODIFIED SPINEL MEASURED AT AMBIENT CONDITION

Isao SUZUKI, Norihito Mayama, Kousuke Shono, (Department of Earth Sciences, Okayama University, Okayama 700-8530, Japan, E-mail: isuzuki@cc.okayama-u.ac.jp) and Tomoo Katsura, Akira Yoneda (Institute for Study of the Earth's Interior, Misasa, Tottori 682-0193, Japan, E-mail: tkatsura @msews1.misasa.okayama-u.ac.jp ; yoneda@misasa.okayama-u.ac.jp)

The elasticity data of minerals such as olivine, modified spinel and spinel phases have basic importance to study the composition of the Earth's mantle. Here modified spinel with natural olivine components was synthesised at high pressure. The polycrystalline specimen was shaped into a sphere and elasticity was measured with the resonant sphere technique, RST. Temperature variations of frequencies of lower eight oscillatory modes were traced between 5 and 45 deg. C. Bulk and rigidity moduli change smoothly with temperature. The Anderson Gruneisen parameters have magnitudes of 4.6, 4 and 6.77, respectively for adiabatic and isothermal conditions. These values are compared with those of mantle candidate minerals. For example, the high temperature phase (>700 deg.C) of spinel $MgAl_2O_4$ shows similar magnitudes of the parameters, 4.72 and 6.37, respectively.

INNER CORE ROTATION FROM GEOMAGNETIC ESTWARD DRIFT AND A STATIONARY SPHERICAL VORTEX IN EARTH'S CORE

C. V. VOORHIES (Geodynamics Branch, Code 921, NASA's Goddard Space Flight Center, Greenbelt, MD 20771 USA; email: voorhies@geomag.gsfc.nasa.gov)

The idea that geomagnetic westward drift indicates convective levelling of the planetary momentum gradient within Earth's core is pursued in search of a differentially rotating mean state, upon which various oscillations and secular effects might be superimposed. The desired

state conforms to roughly spherical boundary conditions, minimises dissipative interference with convective cooling in the bulk of the core, yet may aide core cooling by depositing heat in the uppermost core and lower mantle. The variational calculus of stationary dissipation applied to a spherical vortex within the core yields an interesting differential rotation profile akin to spherical Couette flow boundaed by thin Hartmann layers. Four boundary conditions are required. To concentrate shear induced dissipation near the core-mantle boundary, these are taken to be: (i) no-slip at the core-mantle interface; (ii) geomagnetically estimated bulk westward flow at the base of the core- mantle boundary layer; (iii) no-slip at the inner-outer core interface; and, to describe magnetic locking of the inner core to the deep outer core, (iv) hydrodynamically stress-free at the inner-outer core boundary. By boldly assuming the axial core angular momentum anomaly to be zero, the super- rotation of the inner core is calculated to be at most 1.5 degrees per year.

LOW-RESISTIVITY STRUCTURES AS CONVERTERS OF SEISMIC WAVES' ENERGY INTO ELECTROMAGNETIC SIGNALS.

OLEG NOVIK (Moscow State Geol. Prospect. Acad., 117246, POB 51, Russia.
email: onovik@glasnet.ru) Sergey Ershov (Keldysh Institute for Appl. Mathematics of Russian Academy of Sciences, Moscow) Irina Mikhaylovskaya (Moscow State University. email: irina@nw.math.msu.ru).

Trying to clear out the physical nature of electromagnetic (em) and temperature (t) signals observed in seismically active regions (some of them occurred to be precursors to earthquakes), we use the theory of magnetothermoelasticity to construct the mathematical model and calculate the elastic-em -t field interaction caused by displacements (ampl. freq. and duration are of order of a few cm, Hz and sec resp.) in the upper mantle domain of a model lithosphere zone containing the low-resistivity structures (LRS) in this domain and in the crust. According to MT-soundings in seismic regions, the LRSs' conductivity is 0.1 to 0.5 S/m and cross-section sizes and depths are of order of 10 km or mo-re. It is clear from the computed pictures of the evolution of the interacting fields that em-signals arises near the contacts of the seismic waves' (s.w., from upper mantle in our runs) fronts with the boundaries of LRSs, as a result of their deformations in presence of geomagnetic field. The em- emission into atmosphere arises during the diffraction of s. w. by LRSs (60 pT at the Earth's surface and 10 pT at the height of 30 km). The t-signal (up to 0.02 K in the sedimentary layer) propagates together with the s.w. and is not influenced by ionosphere. The main frequencies of the computed em and t-signals (ULF field oscillations) are nearly the same as ones of displacements and are changing, together with the amplitudes, because of changing of displacements at the depth. The computed em and t-signals' amplitudes, frequencies, the delay of the seismic wave arrival at the surface in regard to em-signal and its delay in regard to beginning of displacements are of orders observed.

EVIDENCE FOR METASOMATISM OF THE TRANSITION ZONE BY CARBONATE MELTS ORIGINATING IN THE LOWER MANTLE

Tibor Gasparik (CHiPR and Department of Geosciences, State University of New York, Stony Brook, NY 11794, USA, email: gasparik@sbmp04.ess.sunysb.edu)

Since the origin of some inclusions in diamonds can be traced to the lower mantle, the source of the kimberlitic melts carrying them to the surface should also be in the lower mantle. To test this hypothesis, experiments were conducted at 20-23 GPa and 1600-1700(C with simplified analog mantle compositions including carbonates. The experimental products contained small amounts of carbonate melt, suggesting that the temperatures in the transition zone (410-660 km) should be high enough to exceed the carbonate solidus. Starting material with a high content of MgSiO3 and low concentrations of Na, K, Ca, Fe and Al produced mostly garnet at 22 GPa, but mostly MgSiO3 perovskite and no garnet at 23 GPa. The main difference in the composition of the carbonate melts was in the sodium content, which was low at 22 GPa but high at 23 GPa. This is the well-known consequence of sodium being highly incompatible in perovskite but highly compatible in majorite garnet. Thus, the sodium-rich carbonate melts originating in the lower mantle do not have the kimberlite composition but could become kimberlitic on passing through the transition zone by loosing sodium to majorite garnet. The resulting metasomatism taking place over a long period of time could modify the transition zone to sodium enriched compositions consistent with the compositions of inclusions in diamonds from the transition zone. For example, the origin of the NaPx-En garnet inclusion found by Wang and Sueno (Min. J. 18, 9, 1996), with the approximate composition 16 mol % Na2MgSi5O12 and 84 % Mg4Si4O12, was experimentally constrained to the pressure range of 16-22 GPa. The type III inclusions reported by Hutchison (Ph.D. Thesis, 1997) have the composition of garnet coexisting with CaSiO3 perovskite at 22 GPa (En40Di20Jd40).

DO MANTLE PLUMES CONTRIBUTE TO THE ORIGIN OF LIFE AND QUANTUM JUMPS IN THE EVOLUTION?

U. RAVAL

Some plumes originate from deep interior e.g. D" layer. Since earth's core is relatively rich in Fe, Ni & S, their local concentrations may indicate plume activity. The thermo-chemical conditions - following magmatic upwelling consisting of pressured gas beneath ocean - could transform the prebiotic aminoacids into peptides. Some minerals in volcanic vents (pyrite etc.) can act as catalyst for production of ammonia from nitrogen. Association of plume and life processes is supported by: a) the texa of the cellurarly preserved filamentous microbes is found in Apex basalts from W. Australia and b) Stromatolites in Pilbara region occur in cherts of Warrawoona group. Other similar areas may be Onverwacht group (S. Africa), Garbenschieft (Greenland) and other LIPs. This suggests a significant role of plumes in the thermophilic origin of life.

Other significant correlations are i) plume event (2.7 Ga) which is characterised by suboxic and intense hydrothermal activity, highly sulphurous carbonaceous sediments (BIFs) and bacterial remains, ii) Stromatilite peak at ~1.2 Ga and iii) Pan-African thermal event at the PreCambrian-Cambrian boundary. Further, a strong association is videnced between major biodiversifications and LIPs. These spatio-temporal correlations between plumes and fillips in the evolution deserve detailed follow ups.

EXPECTED TIME-VARIATIONS OF NEUTRON MONITOR COUNTING RATE CAUSED BY COSMIC RAY PARTICLE ENERGY CHANGE IN THE PERIODS BEFORE AND DURING THUNDERSTORMS

LEV DORMAN (IZMIRAN, Technion and Israel Cosmic Ray Center, affiliated to Tel Aviv University; Current address: P.O.Box 2217, Qazrin 12900, ISRAEL; email: lid@physics.technion.ac.il); Irina Dorman (Institute of History of Science and Technology, Russian Academy of Science, Staropansky 1/5, Moscow 103012, RUSSIA); N. Iucci and M. Parisi (Terza Universita di Roma, Dipartimento di Fisica "E. Amaldi", Via della Vasca Navale 84, 00146 Rome, Italy); G. Villoresi (IFSI/CNR-Frascati c/o Terza Universita di Roma, Dipartimento di Fisica "E. Amaldi", Via della Vasca Navale 84, 00146 Rome, Italy)

On the basis of theoretical model (Dorman and Dorman, 1995, 1999) of atmospheric electric field effect in the neutron monitor counting rate, we calculate the expected cosmic ray time variations in the periods before and during thunderstorms. According to Wallace and Hobbs (1977) the charge of clouds on the altitude 7-12 km can be reach the value about +24 coulombs, and on lower altitudes about -20 coulombs. The rate of charge generation is about one (coulmb/cub.km)/min. Our calculations show that neutron monitors one minute data can be used to obtain important information on atmospheric electric field space-time distribution.

ON THE POSSIBILITY OF ATMOSPHERIC ELECTRIC FIELD EFFECT IN THE COSMIC RAY NEUTRON COMPONENT

LEV DORMAN (IZMIRAN, Technion and Israel Cosmic Ray Center, affiliated to Tel Aviv University; Current address: P.O.Box 2217, Qazrin 12900, ISRAEL; email: lid@physics.technion.ac.il), Irina Dorman (Institute of History of Science and Technology, Russian Academy of Science, Staropansky 1/5, Moscow 103012, RUSSIA)

It is well known that about 0.07 of neutron monitor counting rate caused by negative soft muons captured by lead nucleons and formed mesoatoms with generation of several MeV energy neutrons from lead. In this case the neutron monitor or neutron supermonitor works as analyzer which detects muons of only one, negative sign. It is very important because the atmospheric electric field effect have opposite signs for positive and negative muons that main part of this effect in the muon telescope or in ionization chamber is compensated and we can observe only small part of total effect for one sign muons. On the basis of our general theory of cosmic ray meteorological effects with taking into account of negative soft muon acceleration and deceleration in the Earth atmosphere (in dependence of direction and intensity of electric field) we discuss the possibility of existing this effect in cosmic ray neutron component and made some rough estimations.

AN OVERVIEW OF PROCESSES AFFECTING THE GLOBAL ELECTRIC CIRCUIT

M.J. RYCROFT (International Space University, Boul. Gonthier d'Andernach, 67400 Illkirch, France, e-mail: rycroft@isu.isunet.edu)

A review is attempted of the important physical processes in the atmosphere (e.g. aerosols, C.T.R. Wilson's currents upwards from thunderstorms, point discharge currents, fair weather air-Earth currents, cloud-to-ground lightning discharges) and the magnetosphere (e.g. interhemispheric coupling, dynamo actions) which - by Ohm's law and Maxwell's laws - maintain the ionosphere at a potential ~ + 250 kV with respect to the Earth. The diurnal and seasonal variations of the global electric circuit, temporal variations of atmospheric conductivity associated with energetic charged particle precipitation and different solar-terrestrial physics phenomena (e.g. Forbush decreases, solar cycle), and spatial variations (e.g. with altitude, geomagnetic latitude, geographic longitude) are considered. A conceptual model of the global electric circuit in terms of electrical resistances in series and in parallel, in parallel with capacitors representing atmospheric layers ~ a scale height apart, is developed. Its value is tested against observations both ancient and modern. Some interesting and important areas for future research on variations of the global electric circuits are suggested, such as effects associated with sprites (positive cloud-to-ground discharges), cirrus clouds and long term climate changes.

JSM03/E/03-A1 **1010**

LIGHTNING-INDUCED DISTURBANCES OF THE MIDDLE ATMOSPHERE

Umran S. INAN (Space, Telecommunications and Radioscience Laboratory, Stanford University, Stanford, CA 94305, USA, tel 650-7234994, fax 650-7239251, email: inan@nova.stanford.edu)

Electrodynamic coupling between tropospheric thunderstorms and the middle atmosphere, dramatically evidenced in sprites and elves, is now believed to widely occur, supported by both large and relatively small thunderstorm complexes. While initial observations of these luminous phenomena appeared to suggest that they were only triggered by positive cloud-to-ground discharges in mesoscale convective systems, it is now known that sprites can on occasion be also triggered by negative discharges and that elves may in fact be triggered much more often than previously believed, by nearly all positive and negative lightning discharges having peak currents in excess of several tens of kiloamperes. Furthermore, radio remote sensing observations of the lower ionosphere suggest that the ambient electron population may be quiescently heated throughout the many hour duration of a typical thunderstorm. Successive triggering of of elves by electromagnetic pulses radiated by lightning discharges may also be accompanied by accumulation of ionization changes, leading to the production of ionospheric "bubbles" above thunderstorm regions. In this paper, we review recent experimental and theoretical results, with an eye towards assessing global effects of thunderstorm driven electrodynamic coupling between upper atmospheric regions.

JSM03/W/04-A1 1100

VLF SPRITES

Prof Richard DOWDEN (LF.EM Research)

Sprites are luminous columns stretching form thundercloud top (sometimes) to the base of the ionosphere and are associated with cloud-ground lightning. Sprite columns are highly conducting and so scatter VLF communications transmissions propagating in the Earth-ionosphere waveguide. Such scattered waves, interfering with the direct waves, produce "VLF sprites" as phase and amplitude perturbations of the VLF transmission. The VLF scattering is in all directions, almost equally on average, though the scatter pattern for any individual sprite has many lobes and minima as expected for the lateral structure of the sprite (e.g., random array of columns). The decay of the scattered signal, due to the decay of the sprite plasma, is logarithmic not exponential. This is expected for a vertically extensive (~40 km) plasma because, although the plasma at any given altitude decays exponentially, the decay rate decreases exponentially with altitude with a scale height of about 3.5 km. In contrast, scattering from plasma produced by electron precipitation is in the forward direction and the scatter signal decays exponentially. This is as expected for a smoothly varying, laterally extensive plasma body (or depression of the ionospheric base) of little vertical extension. The above description and explanation of VLF sprites is not generally accepted and so will be justified here.

CURRENT IDEAS ABOUT JETS

A I SUKHORUKOV (Max-Planck-Institute for Aeronomie, D-37191 Katlenburg-Lindau, Germany, email: sukhorukov@linmpi.mpg.de)

Blue jets are the narrowly collimated, a few km wide beams of light propagated from the top of the thundercloud to the top stratosphere with velocity of about 100 km/s [Wescott et al., GRL, 22, 1209, 1995]. Several ideas have been proposed to explain this unusual phenomenon. Most of them suggest that the blue jet is a likely manifestation of the breakdown phenomenon in the stratosphere. Yet the observations are still scarce, and the nature of the blue jets is still not clear. In this talk, an assessment will be given of the present state of the blue jet theories.

LIGHTNING CONTINUING CURRENTS AS A SOURCE OF SPORADIC MAGNETIC EVENTS IN THE ULF FREQUENCY RANGE AND EXCITER OF IONOSPHERIC ALFVEN RESONATOR

P.P BELYAEV, S.V. Isaev and M.N. Yakunin (Radiophysical Research Institute (NIRFI), B. Pecherskaya St., 25, N.Novgorod, 603 600, Russia, Email: belyaev@nirfi.sci-nnov.ru)

Among a lot of natural sporadic emissions observed on the quiet magnetic background which originates from worldwide thunderstorm activity, we can consider an electromagnetic radiation of local (10-100km) thunderstorm cell as an extremely intensive sporadic event also. In case, the observed magnetic field spectral density can also be expressed as B(f)=B*f^(-2) at the frequencies f higher than 1-2 Hz. Usually, a lifetime of this enhancement of magnetic noises, accompanying cell, is varied from 0.5 to 1.5 hours. The nature of a phenomenon consists in an excitation of magnetic fields by well known continuing currents of lightning flashes. Multicomponent measurements (two induction magnetometers, vertical electric field sensor, pressure sensor) carried out at the middle latitudes alloowec us to separate the eletromagnetic, acoustic and seismic phenomena produced by visible lighting flashes and to make simplest estimations of current amplitudes (I=50-150 Å) and duration 0.1-2 sec). In accordance with approximation I(t)=I*[exp(-t/t1) – exp(t/t2)], where t1=(0.1-2)sec, t2=(0.05-0.1)sec, the ULF induction like magnetic field spectrum of a single flash is described by equation H(f)=H/[(1/t1-2pif)(1/t2-2pif)]and we obtain the observed frequency dependence of magnetic field. Not every flash is accompanied by measurable continuing current. Frequently, in cases of well-structured thunderstorm clouds but without visible cloud-to-ground lightnings and thunders, intensive electric pulses were detected only in absence of observable magnetic activity. For daytime conditions, with moving away or decay of thunderstorm both, magnetic and electric intensities decreases, saving a smooth spectral form described above. In contrary, for nightime one, for distance thunderstorm when lightnings are behind the horizon, magnetic spectra((never vertical electric one) of flashes exhibit clear evident resonance structure, the same as observed before formation of cell.

JSM03/W/03-A1 1420

3-D SIMULATIONS OF ELVES AND SPRITES

H.L. ROWLAND, R.F. Fernsler, and C.L. Siefring (Plasma Physics Division, Naval Research Lab, Washington, DC 20375 USA, email: rowland@nrl.ppd.navy.mil)

We present the first 3-D simulations of the formation of elves and sprites by lightning discharges. The code is a full-wave model using Maxwell's equations. The currents are calculated using Ohm's law. The ionization, attachment, electron collision rate, and optical emissions are calculated from swarm data.
The threshold for breakdown and the formation of elves by the EMP of the lightning return stroke is in good agreement with theory and earlier simulations (fI > 1e5 kA/s , where f is the frequency of the EMP and I is the current). A cloud-to-cloud discharge because of reflections from the ionosphere can form a pair of tubes at the bottom of the D region parallel to the direction of the discharge.
The threshold for the initial formation of sprites depends upon the D region electron density but is approximately LQ > 300 km-C (where L is the length of the discharge and Q is the charge moved by the lightning current). The sprite forms around 80 km altitude. Larger LQ extends the sprite to lower altitudes. The altitude of the bottom of the sprite depends upon the feedback between the 3-D focusing of the quasistatic field by the sprite, which then lets the sprite form at a lower altitude.

JSM03/E/07-A1 1450

THREE-DIMENSIONAL SIMULATION OF UPPER ATMOSPHERIC IONISATION ABOVE A HORIZONTAL LIGHTNING DISCHARGE

Michael J. RYCROFT (International Space University, Boul. Gonthier d'Andernach, 67400 Illkirch, France);Mengu Cho (Kyushu Institute of Technology, 1-1 Sensui Tobata-ku, Kitakyushu 804, Japan)

In an attempt to understand the spatial structure of sprites, the effects of a horizontal lightning discharge on the upper atmosphere have been studied by a three-dimensional computer simulation. The lightning discharge is modeled by a combination of the vertical return stroke current and the horizontal discharge, which travels with a finite velocity (6 x 107 m/s). The electromagnetic wave radiated by the lightning current heats the upper atmosphere and ionises it at heights of 75 km and above. Interference between the electromagnetic waves radiated by the discharge current, those reflected by the ground, and those reflected by the ionosphere produce a non-uniform ionisation pattern at heights above 80 km even for a single line current source in the thundercloud. Non-uniform ionisation due to such interference occurs with a spatial scale of a few km when the electromagnetic waves have strong components from 5 to 50kHz.

JSM03/E/01-A1 1510

TESTS OF C.T.R. WILSON'S PREDICTIONS FOR SPRITES BASED ON SCHUMANN RESONANCE OBSERVATIONS OF VERTICAL CHARGE MOMENTS

Earle WILLIAMS (Parsons Laboratory, Massachusetts Institute of Technology,Cambridge, MA 02139 USA, email: earlew@ll.mit.edu)

Based on the simple observation that the electric field of an electrostatic dipole falls off less rapidly with altitude Z (~1/Z to the third power) than the dielectric strength of the atmosphere (~ exp(-Z)), C.T.R. Wilson essentially derived quantitative criteria for sprites more than 60 years prior to their formal discovery. In this talk, observations of transient electromagnetic excitations of the Earth-ionospheric cavity from MIT's Schumann resonance station in Rhode Island, USA are described. Calibrated measurements of positive ground flashes coincident with sprites observed by W. Lyons and his colleagues from Colorado, USA are used in conjunction with the normal mode equations to infer the vertical charge moments for these energetic discharges. The observed charge transfer is found to be sufficiently fast to validate the electrostatic assumption in Wilson's theory. The observed charge moments (in the range 500 C-km to several thousand C-km) are not adequate to induce conventional air breakdown at observed sprite altitudes (~ 60km) but are sufficient to cause breakdown by the electron runaway process. Distinct differences in the charge transfer behaviour in ground flashes inducing sprites and elves will also be considered.

JSM03/E/06-A1 1600

SPACE-TIME STRUCTURES OF SPRITES AND ELVES OBSERVED AT COLORADO, USA AND HOKURIKU, JAPAN

Hiroshi Fukunishi (Department of Geophysics, Graduate School of Science, Tohoku University, Sendai 980-8578, Japan, email: fuku@pat.geophys.tohoku.ac.jp)

To observe the rapid space-time structures of sprites and elves, we developed 16-channel array photometers using multianode photomultipliers and operated these photometers and CCD cameras at Yucca Ridge Field Staion (40.7 N, 104.9 W), Colorado during the SPRITES'96, '97 and '98 campaigns. We also operated these instruments at Dodaira Observatory (36.0 N, 139.2 E) in December 1998 and January 1999, and succeeded for the first time in observing wintry sprites and elves above the Sea of Japan near the Hokuriku region. The obtained data clearly demonstrated that sprites can be classified into two categories, column-sprites and carrot-sprites, which exhibit differnt space-time development. Column-sprites are always accompanied by preceding elves and characterized by an initial downward development starting around 80-90 km altitude. On the other hand, carrot-sprites are characterized by an initial upward development starting around 50 km altitude and occurrences of preceeding elves are rare. It was also found that the delay time from the onset of the causative sferics to the emission peak of sprites is almost constant (about 1 ms) for column-sprites, while it ranges from 2 to 150 ms for carrot-sprites. These differences can be interpreted by the difference in the time constant of charge removal by cloud-to-ground discharges in the quasi-electrostatic (QE) model proposed by Pasko et al. (1996, 197). The development of elves is consistent with the electromagnetic pulse (EMP) model proposed by Inan et al. (1996).

JSM03/W/05-A1 1630

UNUSUALLY LOW ALTITUDE SPRITE EMISSIONS OBSERVED IN THE NITROGEN FIRST POSITIVE BAND EMISSION AT 665 NM

M.J. TAYLOR and R.M. Dial (both at Space Dynamics Laboratory and Physics Department, Utah State University, Logan, UT, USA, Email:mtaylor@ccusu.edu), M. Heavner, D. Sentman, E. M. Wescott and D. R. Moudry (all at Geophysical Institute, University of Alaska, Fairbanks, AK, USA)

During the Sprites'96 campaign conducted at Yucca Ridge, Colorado over 500 Sprites were imaged in the nitrogen first positive band emission using an intensified Isocon TV camera and a bare CCD imager both fitted with band-limited interference filters centered at 665 nm. Many of the Sprites were found to exhibit "red" tendril-like structures that extended down from the mesosphere well into the stratosphere, where the emission is expected to be strongly quenched, with some terminating below ~ 40 km. On at least two occasions a most unusual Sprite form was observed in addition to the main Sprite discharge. The red emission appeared to originate from well below the main body of the Sprite, in closer proximity to the cloud tops, and then to grow upwards to form a well-defined "narrow" channel with a broad "head" that terminated at tendril heights. The University of Alaska has observed a similar event previously in white light during airborne observations. In this paper we discuss the properties of these unusual events focussing on their form, altitudinal extent and apparent temporal durations.

JSM03/W/02-A1 1650

HIGH SPEED VIDEO OF SPRITES AND ELVES

Mark STANLEY, Paul Krehbiel, Marx Brook, Charles Moore, and William Rison (Physics Department, New Mexico Tech, Socorro, NM 87801, USA, email: stanley@ibis.nmt.edu). Bill Abrahams (Speed Vision Technologies, 990 Highland Drive, Suite 212m, Solana Beach, CA 92075, USA, email: speedwilly@aol.com)

In early October 1997, high speed light-intensified video was acquired which showed the development of sprites and elves at frame rates of 1000-4000 per second. The sprites began as a narrow and often non-continuous column at an altitude above 66 km. Most columns were at least partially composed of a highly transient luminous structure commonly known as a "tendril" which propagated downwards at average velocities between 0.01 and 0.1 the speed of light. Tendril luminosity was dominated by that from a compact downward-propagating head, which strongly suggests that tendrils are a form of streamer breakdown. In some sprites, upward developing structures forked outwards from within or below the column sometime after tendrils appeared. These structures propagated with average velocities approximately 0.1 that of light and were accompanied by significant persistence within the sprite's "head". The upward developing structures appear to be produced by fast streamer breakdown.
Elves appear to develop horizontally away from the camera over the course of 1 millisecond with insignificant luminosity overlap between frames. A thin arc could be observed on the far side of the elf in later frames. The observed development sequence is in agreement with EMP-based theoretical predictions.

ORAL AND POSTER PRESENTATION

JSM03/W/01-A1 1720

OPTICAL FLARES IN NIGHT SKY RADIATION

A.V.MIKHALEV and E.S.Kazimirovsky (Institute of Solar-Terrestrial, Russian Academy of Sciences, P.O.Box 4026, 664033, Irkutsk, Russia, email: mikhalev@iszf.irk.ru)

When investigating the optical self-radiation of the Earth's upper atmosphere at night, some publications point out the existence of irregular spikes on recorded optical signals interpreted as optical flares. This report analyzes and discusses the above mentioned phenomenon using data from ground-based photometer and TV observations of the Earth's upper atmospheric self-radiation in principal emission lines which were carried out in midlatitudes (52N, 103E) during 1987-1998.
Optical flares with durations of tens and hundreds of milliseconds are recorded in different ranges of optical spectrum, including near infrared and ultraviolet regions, have a diurnal and seasonal variations, and are recorded in the absence of thunderstorm activity over the region of observation. With the exception of the most intense flares, they have typical intensities comparable with night airglow intensities. The analysis of likely sources suggests what optical flares can be caused by cosmic X-ray and gamma-emission bursts, lightning discharges at high altitudes, microbursts of electron fluxes, and by other phenomena. The optical flares under discussion in this report are interpreted in terms of microbursts of precipitating electron fluxes and are likely to be associated with thunderstorm activity at a geomagnetically conjugate point of the terrestrial magnetosphere.

JSM03/E/04-A1 Oral and Poster 1730

ROLE OF NEGATIVE IONS IN FORMATION AND DEVELOPMENT OF POSITIVE STREAMER OVER THUNDERCLOUD

Andrew PASTERNAK(Space Research Centre, Bartycka Str.18-a,Warsaw, 00716, Poland, E-mail: andrew@cbk.waw.pl)

During last years different types of high altitude discharges are intensively investigated (Red Sprites, Blue Jets etc). Many theoretical models are proposed. In most cases authors propose huge electrical fields or high energy runaway electrons as initial conditions for streamer formation. Existence of large number of negative ions in atmospheric air (in value ranging from 100-1000 ions per sm3) can plays important role in streamer development. Unfortunately, our knowledge about atmospheric ions behaviour is insufficient,expecially in strong electrical field. In some experimental works it has been clearly demonstrated that the major source of initial electrons is by detachment from atmospheric negative ions which exist in the gap before the impulse is applied. The main mechanism of electron detachment is three-bodies collision but in srong electrical field negative ions can lose electons without collisions, since energy of coupling is small. Such mechanism can be of vital importance in the streamer development. In this article a numerical model of the positive srteamer formation has been developed consisting of conservation equation for electrons, positive and negative ions and Poisson equation. It's shown, that additional source of electrons has essential influence on picture of streamer generation.

EXCHANGE BETWEEN STABLE BOUNDARY LAYER AND SNOW AND ICE SURFACES

JSM04/W/02-A2 0930

SURFACE-LAYER FLUX PROFILE RELATIONSHIPS IN THE ARCTIC FROM THE SEBA EXPERIMENT

C. W. FAIRALL (Environmental Technology Laboratory, NOAA, Boulder, CO 80304, USA, email: cfairall@etl.noaa.gov) P. O. G. Persson (Cooperative Institute for Research in Environmental Sciences, NOAA/ETL, Boulder, CO 80303, USA, email: opersson@etl.noaa.gov) E. L. Andreas (US Army Cold Regions Engineering and Research Laboratory, Hanover, NH, 03755-1290, USA, email: eandreas@crrel.usace.army.mil) P. S. Guest (US Naval Postgraduate School, Monterey, CA, 93950, email: guestps@ibis.met.nps.navy.mil)

From November 1997 to October 1998 the Surface Heat Budget of the Arctic (SHEBA) surface flux group made a variety of micrometeorological measurements on the Arctic icecap as part of ice station SHEBA. The ice station was launched at 143 W and 75 N and ended at 166 W and 80 N. The measurements included 5 levels of sonic anemometers and mean T/RH sensors, one fast hygrometer, upward and downward solar and IR fluxes, and snow/ice temperatures. We believe this is the first multi-level set of eddy-correlation flux data obtained over an entire annual cycle on the ice cap. In this paper we will describe an analysis of the turbulence statistics and mean profiles in the context of Monin-Obukhov similarity theory. The emphasis will be on evaluation of various dimensionless stability functions. We will also discuss deficiencies of MO scaling and examine other types of scaling (e.g., the local similarity scaling of Nieuwstadt).

JSM04/W/08-A2 0950

AN EXTENDED SIMILARITY-THEORY FORMULATION FOR THE STABLY STRATIFIED ATMOSPHERIC SURFACE LAYER

Sergej Zilitinkevich (Department of Earth Sciences - Meteorology, Uppsala University, Villavaegen 16, S-752 36 Uppsala, Sweden, email: sergej@big.met.uu.se) Pierluigi CALANCA (Department of Geography, Swiss Federal Institute of Technology, Winterthurerstr. 190, CH-8057 Zurich, Switzerland, email: calanca@geo.umnw.ethz.ch)

A similarity theory formulation for the wind and temperature profiles in the stably stratified atmospheric surface layer (ASL) is developed with due regard to the effect of the free-flow stability on the ASL. For the sake of simplicity the dry ASL is considered, although the treatment is immediately extended to cover the et ASLs. In the revised log-linear flux-profile relationships, empirical coefficients traditionally considered as universal constants, such as the slope factors in the z-less stratification layer (beyond the logarithmic layer), become functions of the dimensionless number S = N L/u*, where N is the Brunt-Vaisala frequency in the free flow, L is the Monin-Obukhov length, and u* is the friction velocity. This new formulation leaves room for occurrence of well-developed turbulence at much higher Richardson numbers, Ri, than has been suspected. Moreover, it results in a pronounced dependence of the turbulent Prandtl number, Pr, on Ri in a wide range of Ri, including the z-less stratification layer in correspondence with long-standing mpirical evidence. The traditional Monin-Obukhov similarity theory disregards the above essential features of the stably stratified ASL. New data from measurements over a slightly inclined plateau in West Greenland provide experimental support for the proposed theory.

JSM04/E/01-A2 1010

AN INTERCOMPARISON BETWEEN THREE MODELS OF BLOWING SNOW IN THE ATMOSPHERIC BOUNDARY LAYER

Jingbing XIAO (Dept. of Earth and Atmospheric Sciences, York University, 4700 Keele Street, Toronto, Canada, M3J 1P3, Email: jingbing@yorku.ca). Richard Bintanja (Institute for Marine and Atmospheric Research Utrecht, Email: r.bintanja@phys.uu.nl). Stephen Dery (Dept. of Atmospheric and Oceanic Sciences, McGill University, Quebec, Email: steph@zephyr.meteo.McGill.CA). Graham Mann (Environment Centre, University of Leeds, Email: gmann@lec.leeds.ac.uk). Peter A. Taylor (Dept. of Earth and Atmospheric Sciences, York University,Toronto, Email: pat@yorku.ca)

Blowing snow is a common phenomenon in many high latitude regions. Over parts of the Arctic and Antarctica, climatology suggests that blowing snow can occur on one out of three days. During blowing snow events, the sublimation of blowing snow particles can be a significant source of water vapor and sink of sensible heat. Near the windy and relative warm coast of Antarctica, sublimation of suspended snow can reach 17 cm/year Snow Water Equivalent (SWE). Model simulations indicate that the vertically integrated sublimation rate can reach 2-4 mm/day SWE under strong wind conditons, corresponding to a heat flux of 72-128 W/m2.
The physics of blowing snow is complex, and accurate blowing snow observations are hard to make. Several numerical models have been developed and their applications include helping to evaluate and design field experiments and to evaluate the sensitivity of the sublimation rate to various parameters. However, different models may give different results under given conditions. For example, the sublimation rate in a column of blowing snow calculated by the PBSM (Prairie Blowing Snow Model) is much higher that estimated by a fetch dependent blowing snow model PIEKTUK-F when the wind speed is at 20 m/s under certain conditions (Dery et al., 1998). Hence, the model intercomparisons and verification become especially necessary.
In idealised circumstances, blowing snow can be considered as a one-dimensional, time-dependent process. In this work,three one-dimensional time-dependent models have been intercompared. They are PIEKTUK-T developed by the group at York University in Canada (Dery et al., 1998), WINDBLAST developed by the group at Leeds University in United Kingdom (Mann, 1998) and SNOWSTORM developed by the group at Utrecht University in The Netherlands (Bintanja). These three models all show that the sublimation is a self-limiting process. As time increases after snow has become mobile, the sublimation rate first increases, reaches a maximum value and then decreases due to the increase of relative humidity and decreases of temperature. However, the value of the sublimation rate is not the same. Similarities and differences in model predictions will be reported and explanations considered.

JSM04/W/09-A2 1030

MESOSCALE MODELING OF GREENLAND'S KATABATIC WINDS AND THEIR INFLUENCE

Keith M. Hines, Lin Li and David H. BROMWICH (all at Byrd Polar Research Center, The Ohio State University, Columbus, OH 43210, USA, e-mail: bromwich@polarmet1.mps.ohio-state.edu)

Simulations performed at 40 km resolution with the Penn State/NCAR MM5 modified for ice sheet meteorology detail the influence of Greenland's topography and katabatic winds on synoptic and mesoscale atmospheric phenomena in the North Atlantic sector. Months simulated include January 1990 during a winter with a large positive phase of the North Atlantic Oscillation and April and May 1997 at the time of the Katabatic Wind and Boundary Layer Front Experiment around Greenland (KABEG) study. The simulations are compared to standard meteorological analyses by ECMWF and to 1997 observations at automatic weather stations in Greenland . Additionally, the University of Bonn compares katabatic wind simulations with MM5 to similar simulations with the NORLAM model. The simulations detail the frequent track of cyclones to the east of Greenland and have demonstrated the need for very high vertical resolution to adequately capture the katabatic boundary layer.

JSM04/E/06-A2 1120

MEASUREMENTS AND NUMERICAL SIMULATIONS OF THE KATABATIC WIND OVER GREENLAND

GUENTHER HEINEMANN and Thomas Klein, Universitaet Bonn, Auf dem Huegel 20, D-53121, Bonn, Germany

The katabatic wind system over Greenland is studied by means of surface and aircraft measurements, and by numerical simulations using the mesoscale model NORLAM. Measurements were carried out during the aircraft-based experiment KABEG'97 in the area of southern Greenland. The aircraft data allow the investigation of 3D structures of the katabatic wind, and can also be used for the validation of the boundary layer structures simulated by the numerical model. Comparisons of the numerical model results with AWS show good agreement in general. The validation of the simulations using aircraft profiles yields the result, that the correct simulation of the observed low-level jet in the stable boundary layer is highly sensitive to the correct simulation of the synoptic forcing above the boundary layer. The katabatic wind dynamics are also investigated using measurements and model results, showing that the classical katabatic force is the main driving mechanism for the flow regime.

JSM04/E/09-A2 1140

LONG-TERM MEASUREMENTS OF THE SURFACE ENERGY BALANCE AT HALLEY, ANTARCTICA

J.C. KING and P.S. Anderson (both at British Antarctic Survey, Cambridge CB3 0ET, UK, email: j.c.king@bas.ac.uk)

Halley Research Station (75oS, 26oW) is situated on an expansive and uniform ice shelf and is thus an ideal location for making measurements of surface fluxes that are representative of a wide area. Continuous measurements of surface fluxes have been made at this site since 1995, using both eddy-correlation and profile techniques. Radiation measurements were added in 1996. We describe the instrumentation used and the problems encountered with making long-

term flux measurements in a harsh polar environment. Data from the first three years of measurements will be presented. During winter, the mean net radiative cooling of the snow surface exceeds the measured net turbulent heat flux plus snowpack heat flux by about 10 W/m^2. Reasons for this apparent lack of closure of the surface energy budget are investigated.

JSM04/W/07-A2 1200

IMPLEMENTING AND TESTING OF A NEW SNOW SCHEME SAST IN SIMPLIFIED SIMPLE BIOSPHERE MODEL (SSIB)

Shufen Sun and YONGKANG XUE(both at Department of Geography, University of Maryland, College Park, MD 20742,USA Tel: 301-405-5880; fax: 301-314-9299,email: yxue@geog.umd.edu)

Based on up to date comprehensive and complex snow cover schemes, a Simple Snow-Atmosphere-Soil Transfer Model (SAST) has been developed. This model includes most important physical processes for simulation of seasonal snow cover change. The model also makes substantial simplification and improvement. For example, based on the analysis of the effect of vapor phase change and vapor movement on mass and energy balances, a formulation of effective heat conductivity has been derived which simplifies the description of complex processes without loss of accuracy. Base on analyses of diurnal and seasonal variations of snow temperature, an efficient snow cover layering system has been developed for better prediction. The volumetric specific enthalpy instead of temperature is used as the prognostic variable. It simplifies the formulations in phase change processes and reduces the computational procedures with an efficient implicit one step test numerical scheme. The SAST is coupled with SSIB to improve the SSIB prediction potential in snow cover regime. The coupled model includes the vegetation regime, snow cover regime and ground surface regime. Their physical properties are described by the mass and energy balance equations, respectively. Snow cover interacts with both vegetation cover above and ground surface below. In the coupled model, the snow surface temperature and canopy temperature are solved simultaneously to ensure the energy and water conservation in the vegetation-snow interface, which is crucial in the study of snow effects in global as well as regional climate models. The SAST model has been tested in off line model by using long term Russian and France field data. The results show its potential in predicting seasonal snow cover change. These two data sets along with the German snow data will be tested further to validate and evaluate the coupled SSiB/SAST model.

JSM04/W/06-A2 1220

AIR-SNOWPACK CHEMICAL INTERACTIONS AT LOW ACCUMULATION RATE SITES IN ANTARCTICA

Eric W. WOLFF, Anna E. Jones and Andrew M. Rankin (all at British Antarctic Survey, High Cross, Madingley Road, Cambridge CB3 0ET, UK, email: e.wolff@bas.ac.uk)

Understanding the processes that govern uptake of chemicals onto snow is fundamental to interpreting deep ice core records in terms of atmospheric chemical changes. For aerosol species, dry deposition processes dominate below a threshold snow accumulation rate. Ventilation by wind-pumping through topographic features is one dry deposition mechanism that could be important, but we show that it is unlikely to be at a site such as Dome C, Antarctica, which has a very low snow accumulation rate (about 30 kg m-3). We discuss the conditions (changed meteorology and surface roughness) that could make the wind-pumping mechanism dominate. For some gaseous species, post-depositional changes determine the ice core concentration. We investigate the case of nitrate, which shows large losses at a site such as Dome C, and discuss the possible controls on the nitrate concentration.

JSM04/E/04-A2 1240

AIR-SNOW EXCHANGE STUDIES OF NITROGEN SPECIES AT NEUMAYER, ANTARCTICA.

A.E. JONES, P.S. Anderson, H.K. Roscoe (British Antarctic Survey, NERC, Madingley Road, Cambridge, UK); R. Weller, H-W. Jacobi, G. Koenig-Langlo (Alfred-Wegener Institute, Am Handelshafen 12, Bremerhaven, Germany)

Processes of chemical exchange between air and snow surfaces at high latitudes will affect both ambient concentrations of trace gases and the incorporation of the chemical signature into ice cores. In order to understand both polar tropospheric chemistry and the ice core record it is therefore necessary to understand the complex exchange mechanisms involved at the snow/air interface.
We report here on measurements made during Austral summer 1999, at the German Antarctic research base, Neumayer. An earlier campaign, designed to study the speciation within the NOy family, detected a diurnal variation in NOy with apparent links to processes at the snow surface. As part of a follow up campaign, we made measurements at Neumayer specifically to look for fluxes of nitrogen species into and out of the snow pack, with high time resolution gradient measurements of NO and NOx combined with meteorological data to derive fluxes. We present our results, and discuss possible influences on local photochemistry and the ice core nitrate record.

POLAR OCEAN – ATMOSPHERE INTERACTIONS

JSM04/E/05-A2 1420

REDISTRIBUTION OF SOLAR RADIATION IN THE BARENTS SEA MARGINAL ICE ZONE DURING MELTING SEASON.

Reinert KORSNES (Norwegian Polar Institute, Polar Environmental Centre, N 9005 Tromso, Norway, Email: Reinert.Korsnes@npolar.no) Alexander P. Makshtas (Arctic and Antarctic Research Institute, 38 Bering str., St. Petersburg, 199397, Russia, Email: maksh@aari.nw.ru)

Peculiarities of directional and spectral distributions of solar radiation under Arctic sea ice conditions are described based on field measurements during the Russian-Norwegian expedition"Barex-95" in the sea ice marginal zone of the Barents sea in the melting season. The results point out the importance of complex experimental investigations of radiation in the polar atmosphere under cloud and fog conditions. Cloud/fog conditions and the state of the sea ice surface control angular distribution of incoming solar radiation and its absorption by different types of sea ice covers (leads, melt ponds, wet snow and hummocks). A stochastic model of cloudy atmosphere is used to reproduce experimental data and to estimate sensitivity to angular and spectral distributions of solar radiation on the heat budget of the sea ice cover. An algorithm developed by Podgorny and Grenfell is modified to calculate melt pond bottom albedo and cardioidal radiance distribution parameters from hemispherical-directional reflectance distribution measurements.

JSM04/W/05-A2 1445

A GCM STUDY OF THE SENSITIVITY OF THE ANTARCTIC SEA ICE DISTRIBUTION TO SNOW COVER

Xingren WU (Antarctic CRC and Australian Antarctic Division, Hobart, Tasmania, Australia, email: x.wu@utas.edu.au) William F. Budd (Antarctic CRC, Hobart, Tasmania, Australia, email: w.f.budd@utas.edu.au) Victoria I. Lytle (Antarctic CRC and Australian Antarctic Division, Hobart, Tasmania, Australia, email: v.lytle@utas.edu.au) Robert A. Massom (Antarctic CRC, Hobart, Tasmania, Australia, email: r.massom@utas.edu.au)

This work estimates the effect of a snow layer and its depth on sea ice thickness accretion and ablation, using both a simple thermodynamic model and a coupled atmosphere-sea ice model including feedback and ice dynamics effects. The thermodynamic sea ice model is a 2-layer version model which treats snow, sea ice and snow-ice explicitly. The coupled model allows snow-ice to form when the snow cover is flooded. When snow is disregarded in the coupled model the averaged Antarctic sea ice becomes thicker. When only half of the snowfall predicted by the atmospheric model is allowed to accumulate on the ice surface, The sea ice gets thicker in most of the Weddell and Ross Seas but thinner in East Antarctic in winter, with the average slightly thicker. When twice as much snowfall as predicted by the atmospheric model is assumed to accumulate on the ice surface sea ice also gets much thicker due to the large increase of snow-ice formation. In this study we have also tested the use of a lower mean value of thermal conductivity of snow in the coupled model, namely 0.16 W/(mK) instead of the standard value 0.31. This value is based on the most recent observations in the eastern Antarctic and Bellingshausen and Amundsen Seas. We have found that the sea ice thickness distribution changes greatly, with the ice becoming thinner by about 0.2 m in the Antarctic and about 0.4 m in the Arctic on average.

JSM04/E/03-A2 1510

ROUGHNESS-DEPENDENT AIR - SEA ICE MOMENTUM FLUXES IN LARGE-SCALE MODELS

Nadja Steiner, Markus HARDER, Peter Lemke, Sandra Schuster (Institute of Marine Research at the University of Kiel, Germany, Duesternbrooker Weg20, D-24105 Kiel, Germany, email: nsteiner@ifm.uni-kiel.de,mharder@ifm.uni-kiel.de)

A quantitative relationship between observed sea-ice roughness and simulated large-scale deformation work is established in order to provide new means for model validation and a better representation of the sea ice component in coupled climate models. Sea ice roughness is introduced as an additional prognostic variable in the dynamic-thermodynamic Kiel Sea-Ice Simulation (KISS) with a viscous-plastic rheology. Ice roughness is defined as the accumulated work of internal forces acting upon an ice volume, given in energy per area. A fraction of this total deformation work is transformed into potential energy stored in pressure ridges. Observable quantities, such as mean pressure ridge height, ridge frequency as well as volumetric and areal fractions of deformed ice are derived from the simulated sea ice roughness by using observed ridge geometries and distribution functions. Roughness-dependent drag coefficients are introduced to account for the effect on the momentum exchange between ocean and atmosphere due to the form drag of roughness elements. Drag coefficients are parameterized as functions of deformation energy and ice concentration representing contributions of form drag due to pressure ridges and floe edges. This results in spatially and temporally varying drag coefficients, and yields significant differences in the magnitude and direction of ice drift velocities. A comparison with observed buoy drift velocities leads to an optimized parameterisation. The simulations indicate that the inclusion of sea-ice roughness provides for a more realistic representation of the boundary layer processes in climate models.

JSM04/W/12-A2 1535

EVALUATION OF HEAT FLUXES IN THE WEDDELL SEA USING BUOY DATA

O. EISEN (1) and C. Kottmeier (1,2) (1) Institute for Meteorology and Climate Research, Universit‰t Karlsruhe, Kaiserstr. 12, D-76133 Karlsruhe, Germany, (2) Institute for Meteorology and Climate Research, Forschungszentrum Karlsruhe, Hermann-von-HelmholtzPlatz 1, D-72344 Eggenstein-Leopoldshafen, Germany.

The surface energy balance of open and refrozen leads in sea ice is evaluated for a good areal coverage in the Weddell Sea for the winter period using a kinematic-thermodynamic sea ice model forced by data from drifting buoys. Additionally, two case studies reveal the influences of oceanic heat flux and tidal motion in specific regions. The relative contribution of open and refrozen leads to the total net heat flux increases from 30 % (10 - 15 W m~2) in the eastern Weddell Sea to 70 % (30 W m~2) in the western Weddell Sea and is on average about twice the areal lead percentage. Both, atmospheric forcing and the lead percentage cause this pattern. The monthly winter ice production in leads increases from 10 cm in the eastern part to 30 cm over the western shelf. The oceanic heat flux reduces the ice production under thick ice significantly and thus emphasizes the importance of leads for the total ice production. In the western Weddell Sea leads induced by motion in the diurnal and semi-dinrnal band contribute 7 % to net heat flux, 12 % to ice production and 37 % to the salt mass released during ice growth. The results emphasize the importance of leads for the interaction of ocean, sea ice and atmosphere.

JSM04/W/01-A2 1620

INVESTIGATIONS OF ATMOSPHERE/ICE/OCEAN INTERACTIONS USING SATELLITE SOUNDER DATA IN POLAR REGIONS

FRANCIS, Jennifer (Institute of Marine and Coastal Sciences, Rutgers University, 71 Dudley Road, New Brunswick NJ 08901-8521 USA. E-mail:francis@imcs.rutgers.edu Telephone No: 732-708-1217 Fax No: 732-872-3088)

A wealth of new information is available from a recently completed 18-year data set of Arctic atmospheric and surface products derived from the TIROS Operational Vertical Sounder (TOVS). The TOVS Pathfinder data set comprises temperature and moisture profiles, cloud parameters, and surface characterists at a 100-km spatial and daily temporal resolution, north of 60 degrees northlatitude. We combine these fundamental variables with surface pressures and upper-level winds fromthe NCEP Reanalysis project to derive 10-meter wind fields, advected heat and moisture, and P-E. From the cloud information and atmospheric profiles we compute surface radiation fluxes. In this presentation we will describe the TOVS Pathfinder data set and present examples of air/ice/ocean exchange studies using these data.

JSM04/W/04-A2 **1645**

AIR-SEA-ICE INTERACTIONS OVER THE RONNE POLYNYA, ANTARCTICA

I. A. Renfrew and J. C. King, British Antarctic Survey, High Cross, Madingley Rd, Cambridge CB3 0ET, UK, email: i.renfrew@bas.ac.uk

Surface fluxes of heat and moisture are estimated for the coastal polynya that skirts the Ronne Ice Shelf, in the Weddell Sea, Antarctica. The air-sea-ice interactions of this region are responsible for changes in the surface waters that lead to the formation of Antarctic Bottom Water, an important water mass in the global thermohaline circulation. Automatic weather station (AWS) data have been used to generate a year long climatology of surface fluxes over the polynya. A simple one-dimensional convective boundary layer model has been developed. The model uses surface meteorological observations to grow a mixed layer over the polynya, and hence allow estimates of the surface sensible heat flux with fetch. The model has been tested with in situ data obtained from the Ronne Polynya Experiment (ROPEX) cruise of February 1998. The AWS data have been compared to ECMWF analysis products, with the aim of extending the flux climatology. Unfortunately the comparison illustrated a serious problem in the ECMWF model which was, until April 1998, treating the permanent ice shelves as sea-ice. This allowed an erroneous upward heat transfer through the sea-ice into the boundary layer, and meant that the model atmosphere was up to tens of degrees too warm.

JSM04/W/10-A2 **1710**

AIR-SEA-ICE INTERACTION PROCESSES IN THE SOUTHERN OCEAN

XIAOJUN, Yuan, Lamont-Doherty Earth Observation, email: xyuan@ldeo.colombia.edu

Air-sea-ice interaction processes in the Southern Ocean are investigated utilizing space-observed surface winds, sea ice concentration, and sea surface temperature (SST) from September through December, 1996. The sea ice edge (SIE) shows three ice-extent maxima around the Antarctic during September and October when sea ice coverage is maximum. They are located in the central Indian Ocean, east of the Ross Sea, and in the eastern Weddell Gyre. During September and October, most of the strong and long lasting storms initiate northeast of the three sea ice maxima. Such spatial distributions of storms and sea ice reflect coupling processes of the air-sea-ice interaction. A relatively stable, wave number 3 atmospheric circulation pattern that is believed to be fixed by the land-ocean distribution prevails during the ice maximum season. The ice-extent maxima coincide with strong southerlies and divergent wind fields associated with this pattern, which suggests that the mean atmospheric circulation determines the ice distribution. The ice-extent maxima can enhance the regional meridional surface pressure gradient and therefore strengthen the westerly winds north of the ice edge. The decreasing ice extent east of the ice maxima creates a local zonal thermal gradient which enhances local southerlies. This positive feedback between the wave pattern in the mean atmospheric circulation and ice distribution partially causes the eastward propagation of the ice maxima and also provides a favorable condition for cyclogenesis northeast of the ice-extent maxima. The mechanism of the cyclogenesis is the baroclinic instability caused by the cold air blown from the ice pack to the warm open-ocean waters. Where the SST is warmest off the SIE and the southerlies are the strongest, the potential for cyclogenesis is most likely. This is consistent with the observations.

JSM04/W/11-A2 **1735**

AIR-SEA ICE INTERACTIONS SIMULATED WITH A REGIONAL CLIMATE MODEL FOR THE NORTH ATLANTIC AND THE ARCTIC

Hauke BERNDT, Markus Harder, Michael Hilmer, Rolf Jürrens, and Peter Lemke (all at Institut für Meereskunde, Universit‰t Kiel, Germany, email: hberndt@ifm.uni-kiel.de)

The atmospheric conditions in the Arctic and the Atlantic north of 35˚ N are investigated with the regional climate model REMO. REMO is based on the limited area numerical weather predictions system EM/DM of the Deutscher Wetterdienst (DWD). For the model the same physical parameterizations as implemented in the MPI global climate-model ECHAM4 are used. The modeled domain is resolved with a mesh of 145x121 grid points and a mesh-size of 0.5˚ on a rotated spherical grid. The model is forced with boundary conditions from the NCEP/NCAR-reanalyses project. Different validations of REMO have been performed by comparing the model results with meteorological observations from the cruise of RV/KNORR during February/March 1997 in the Labrador Sea, accumulation measurements of snow over the glacial areas of Greenland and observed and modeled precipitation over Greenland. Comparing our results with the forcing global dataset we see horizontal patterns with higher detailed structures e.g. of precipitation in the coastal regions of Greenland which lead to major improvements of the simulated hydrological cycle. Driving REMO with ice-thickness distributions from a viscous-plastic sea-ice model leads to more realistically results. With the implementation of partial ice cover for a better representation of the heat fluxes in mixed grid boxes of sea ice and open water we expect further improvements e.g. in the marginal ice-zone. This work is a first step towards a fully coupled regional atmosphere-ice-ocean climate model for the North Atlantic and Arctic which is going to be set up at the Institut für Meereskunde.

ESTIMATION OF VERTICAL EDDY VISCOSITY COEFFICIENTS BY A ONE-DIMENSIONAL DATA ASSIMILATION MODEL WITH THE ADJOINT EQUATION

Shin'ichi SAKAI (Environmental Science Department, Central Research Institute of Electric Power Industry, 1646 Abiko, Abiko City, Chiba, 270-1194, JAPAN, email: s-sakai@criepi.denken.or.jp)

The vertical eddy viscosity or the surface wind drag coefficients is significant parameter in the coastal ocean model. The field investigation of these parameters is however very difficult, so the actual value of these parameters are still unknown. A variational approach with the adjoint equation is useful to estimate these model parameters. At first, the basic behaviours of the assimilation model were investigated through the identical twin experiments with varying the initial values of control variables, the observation period, and the spatial or temporal intervals of observation data. The main results are as follows: (a) the underestimated conditions of the initial values of the control variables tend to make calculation stable, (b) the appropriate temporal interval of the observation data is 1/5 times as short as the characteristic time scale of the forcing term (wind), (c) the surface current data is especially important in this type of wind forcing model, and (d) the observation period must be longer than the characteristic time scale of the forcing term. Next, the assimilation of in situ data was conducted by using the current data measured by HF ocean radar (-1m) and the moored currentmeter(-2, -5,-10m) in the sea off Fukushima, the open sea in the western Pacific. Two days data were assimilated when the continuous northern wind averaged 5m/s was dominant. The results showed the vertical eddy viscosity coefficients were of the order of 10^(-3) (m^2/s) and the surface wind drag coefficient was about 1.1 * 10^(-3) which were consistent with the past investigation results. One of the advantages of the data assimilation is to estimate the vertical or horizontal profile of the eddy viscosity coefficients.

ESTIMATES OF AIR-SEA HEAT FLUXES USING THE VARIATIONAL ASSIMILATION SYSTEM FOR THE 1-DIMENSIONAL MIXED LAYER MODEL

YOICHI ISHIKAWA, Toshiyuki Awaji, Masatora Iida, Teiji In (Department of Geo physics, Kyoto University, Kyoto 606-8502, Japan, Email: ishikawa@kugi.kyoto-u.ac.jp), and Bo Qiu(Depar tment of Oceanography, University of Hawaii at Manoa, Hawaii)

The ocean surface mixed layer plays a crucial role in the climate system through the air-sea interactions and hence it is strongly desired to construct the 4-dimensional data assimilation system capable of proving the integrated data set of the mixed-layer temperature and depth and the air-sea heat flux. In this study, a data assimilation system using the 1-dimensional bulk mixed layer model with the variation adjoin method is constructed to estimate the net air-sea heat flux as well as the mixed layer variables from observations of the mixed-layer temperature. When the mixed layer model is designed to reproduce the seasonal cycle of the mixed layer variability, it is required to use quite different equations governing the model variables in the deepening and the shoaling phase. Thus the data assimilation system shows strong non-linearity, causing a difficult situation in obtaining the optimum solution. In this study, the problem associated with the strong non-linearity is solved by the scaling of the gradient of the cost function, which has the potential to reduce the distortion of the Hessian matrix. Furthermore, the incremental method is applied to the minimisation of the cost function. To confirm the effectiveness of our approach, identical twin experiments are carried out by assimilating the simulated mixed-layer temperature into the model before conducting the assimilation of real data. The result shows that the RMS error of the estimated surface heat flux in our approach is 8 W m-2, while the RMS error using the previous approach is much larger, about 40 W m-2. Our assimilation system is applied to estimation of the net air-sea heat flux in the equatorial Pacific using the mixed layer temperature measured by the TOGA-TAO buoy. The estimated surface heat flux is compared with the heat flux obtained by in-situ observations, showing good agreement especially on seasonal time scales. The RMS difference between both values low-pass filtered over 90 days is 28 W m-2. Also, other mixed-layer variables such as the mixed-layer depth show very similar tendency to in-situ observations despite the assimilation of the mixed-layer temperature alone.

JSP05/W/04-A1 **0910**

RECONSTRUCTION OF SUBSURFACE GEOCHEMICAL FIELDS USING ASSIMILATION OF UPPER OCEAN DATA

M. IKEDA (Graduate School of Environmental Earth Science, Hokkaido University and Frontier Research System for Global Change, Sapporo, Japan, email: mikeda@ees.hokudai.ac.jp) and Y. Sasai (Graduate School of Environmental Earth Science, Hokkaido University)

Oceanographic data are collected much more extensively from the surface than subsurface. A data assimilation method is proposed for determining geochemical fields in the subsurface. The method is tested with a bulk mixed-layer model. The period from fall to winter and the subpolar North Pacific Ocean are chosen, in which the ocean interacts most extensively with the atmosphere via mixed layer development. In addition to physical properties, CO2 and Alkalinity are also considered as model variables. Total carbonate and pCO2 increase in fall through winter, as the mixed layer develops and entrain carbonate-rich subsurface water.
A cost function has squared differences between data and a model solution. Initial values and subsurface properties are chosen as control variables. The seasonal evolutions of the physical properties are well reproduced even without data assimilation. If we attribute the mismatch of the chemical properties to the subsurface chemical data, zonal variabilities become remarkable in the subsurface ocean. The total carbonate is high in the northwest region, suggesting high biological productivity. In the eastern Pacific, alkalinity is low, suggesting high alkalinity pump effects.

JSP05/E/08-A1 **0930**

INVERSE ESTIMATION OF SEA SURFACE HEAT FLUXES OVER THE EQUATORIAL PACIFIC OCEAN

DONGLIANG YUAN and Michele Rienecker

In this study, we use the Poseidon quasi-isopycnal ocean model and the Reynolds weekly-mean sea surface temperature data combined with TOGA-TAO subsurface temperature observations to estimate the surface heat fluxes over the equatorial Pacific ocean. A variational data assimilation method optimizes the model initial temperature state and the sea surface heat fluxes simultaneously through assimilation of surface and sub-surface temperature data. Because the Reynolds sea surface temperature compilation is weekly, only monthly mean sea surface heat fluxes are obtained. The variational scheme is implemented on a thermodynamic sub-model of the Poseidon model. The velocity field that advects the temperature in the sub-model is provided by a full forward run of the model. After the variational assimilation, the optimized initial temperature state and the sea surface heat fluxes are substituted back into the full run of the forward model to modify the velocity fields used in the next round of variational assimilation. The iteration stops when the differences between two successive estimates of the sea surface heat fluxes satisfy a convergence criterion. The optimized sea surface heat flux will be compared with other estimates.

STRUCTURAL MODEL ERROR, THE LINEAR RANGE, AND VARIATIONAL ASSIMILATION

J.A. HANSEN (1,2) and L.A. Smith (2) (1) Rutherford Appleton Laboratory, Space Science Department, Chilton/Didcot, OXON, OX11 0QX, UK, (2) Mathematical Institute, University of Oxford, Oxford, OX1 3LB, UK. E-mail: J.A.Hansen@rl.ac.uk Telephone No: (01235) 446 220 Fax No: (01235) 445 848)

The perfect model assumption places an operational limit on four dimensional variational

assimilation. Models are wrong. Four-dimensional variational assimilation assumes models are right, specifically a model trajectory exists which is consistent with observations and their associated uncertainty. When model error is large, minimising the cost function defined by model/data misfit can result in analyses that differ significantly from both observations and truth. We present the impact of different levels of structural model error in a simple model on 4D-Var assimilation results as a function of assimilation window length, and demonstrate the importance of the type of model error considered (structural vs. parametric). Model error also impacts the linearity assumption intrinsic to the 4D-Var approach. While a difference between the linearisation of a model about a model state and the linearisation of a system about a system state need not limit the 4D-Var minimisation process, it will impact the quality of uncertainty estimates produced by the resulting Hessian, and can limit the effectiveness of an incremental 4D-Var approach.

JSP05/E/10-A1 Invited **1010**

4 DIMENSIONAL DATA ASSIMILATION FOR THE LAND SURFACE PROCESSES

Ken-ichi Kuma Numerical Prediction Division Japan Meteorological Agency

For the atmosphere and the ocean, 4DDA is widely used to give the initial condition for the numerical integration. Although the land surface 4DDA has been recently introduced in several modelling centers, it is still far behind to the atmosphere and the ocean. Two main purposes for the land surface 4DDA are 1) Improvement of predictability for the atmosphere in various time scale and 2) Monitoring the land surface processes including hydrosphere, cryosphere, and biosphere for global domain. There are several difficulties for the land surface 4DDA. 1) Numerical model is not well defined by the physical law. 2) Observation and data exchanges are not well established. 3) Some processes highly depend upon locality.
The most fundamental problem will be the issue related with the observation. If we consider the feasibility of the observation system, we must rely upon the remote sensing from the satellite as well as promotion of in-site data exchange. Passive microwave sensors provide the snow amount for dry snow, surface soil moisture for bare land surface. As to the canopy-covered region, the key information derived by the satellite is on photosynthesis process. Our ultimate goal for the land surface 4DDA is to assimilate the data related with photosynthesis process with the soil-vegetation-atmosphere transfer system model. This will enable us to monitor the carbon cycle as well as the hydrological cycle for the global domain.

JSP05/W/17-A1 Invited **1050**

ATMOSPHERIC DATA ASSIMILATION AT JAPAN METEOROLOGICAL AGENCY (JMA)

Nobutaka MANNOJI (Numerical Prediction Division, Japan Meteorological Agency, 1-3-4 Oote-machi, Chiyoda-ku, Tokyo 100-8122, JAPAN, email: nmannoji@npd.kishou.go.jp)

ERS-2 scatterometer data have been assimilated operationally in the T213L30 global model since July 1998. The feature in assimilating ERS-2 data at JMA is that not only the sea surface wind data but also the sea surface pressure data are assimilated. The sea surface pressure data are retrieved from the ERS-2 sea surface wind data referring to the surface pressure observation by buoys and ships. We found that that ERS-2 data have large positive impact in the Southern Hemisphere and small positive impact in the Northern Hemisphere and the Tropics, not only on the surface field but also on the upper air field. One-dimensional variational method (1DVAR) to assimilate TOVS radiance data is now being developed. An experiment in which retrieved temperature is assimilated through optimum interpolation method into the global model showed that 1DVAR has positive impact in the Southern Hemisphere, negative impact in the Tropics and neutral impact in the Northern Hemisphere. The method is being improved and will be in operation in 1999. Kanto Area Meso-scale Experiment (KAMEX), an observational system experiment (OSE) over Kanto Plain for meso-scale forecast, is now being performed. We are investigating impact of obervational data such as the wind profiler, doppler radar, ACARS, sea surface wind by NSCAT and ERS-2, precipitable water by GPS and SSM/I, and moisture bogus data derived from GMS. Three-dimensional variational method for global analysis is now being developed with a low resolution (T63L30L) model. The method will be in operation in 2000 including variational assimilation of TOVS radiance data.

JSP05/E/07-A1 Invited **1110**

MRI/JMA OPERATIONAL OCEAN DATA ASSIMILATION SYSTEM -COMPASS-K-

Masafumi KAMACHI (Meteorological Research Institute, 1-1 Nagamine, Tsukuba 305-0052, Japan, email: mkamachi@mri-jma.go.jp) Tsurane Kuragano and Jiang Zhu (both at Oceanographic Research Department, Meteorological Research Institute, 1-1 Nagamine, Tsukuba 305-0052, Japan, email: tkuragan@mri-jma.go.jp) Noriya Yoshioka and Satoshi Sugimoto (both in the Japan Meteorological Agency, 1-3-4 Ohtemachi, Chiyoda-ku, Tokyo 100-8122, Japan, email: yoshioka@naps.kishou.go.jp) Francesco Uboldi (FISBAT-CNR, Dipartmento di Fisca, Via Irnerio, 46, I-40126 Bologna, Italy, email: uboldi@pinocchio.fisbat.bo.cnr.it)

An ocean data assimilation system, COMPASS-K (the Comprehensive Ocean Modeling, Prediction, Analysis and Synthesis System in the Kuroshio-region), is developed at the Meteorological Research Institute. The system is for understanding ocean variability, an operational system in the Japan Meteorological Agency, and for the GODAE project.
The model is an eddy resolving version of an MRI-OGCM. Space-time decorrelation scales of ocean variability are estimated with TOPEX/POSEIDON (T/P) altimeter data. The scales show inhomogeneous and anisotropic features and give information about an error covariance matrix in an optimum interpolation process. Subsurface temperature and salinity fields are evaluated from T/P altimetry with a correlation scheme and assimilated into the model with a nudging scheme.
Seasonal and interannual variations in the western North Pacific are investigated. Realistic space-time distribution of the physical quantities, the path of Kuroshio and its separation from Honshu are captured well. The assimilation results give useful information about an effect of eddy-mean flow interaction to Kuroshio meander and dynamical insights of the separation.

JSP05/E/03-A1 **1130**

TEST AND IMPLEMENTATION OF A MESOSCALE DATA ASSIMILATION CHAIN FOR VERY SHORT RANGE FORECAST PURPOSES.

Pier Paolo Alberoni, STEFANO COSTA, Tiziana Paccagnella, Paolo Patruno (both at Servizio Meteorologico Regionale, A.R.P.A. Emilia-Romagna, Bologna, Viale Silvani, 6, 40122 Italy, email: p.alberoni@arpamet.regione.emilia-romagna.it) Vincenzo Levizzani (Institute FISBAT-CNR, Bologna, via Gobetti 101, 40129, Italy, email: v.levizzani@fisbat.bo.cnr.it and EUMETSAT, Darmstadt, Germany)

The growth of observational capability over the last decades allows a detailed description of atmospheric structures, from large-scale phenomena to cloud features. The integrated use of whole information available bring together a NWP techniques, to produce very short range forecast (vsrf) product operationally, is till now a challenge for the forecaster community. The coupling of a powerful mesoscale analysis tool with our limited area model (LAMBO) make up the base of SMR vsrf system.
The Local Analysis and Prediction System (LAPS) has been developed by NOAA-FSL as an integrated system to ingest and analyse meteorological data from different observational sources. The system is able to ingest all kinds of data routinely available, i.e. mesonet and regular surface data, radar and profiler data and satellite imagery. LAPS combines and harmonises the dataset to obtain surface and 3D fields of meteorological parameters, that is temperature, pressure, humidity, wind, cloud and other derived variables.
The resulting fields are finally fed into LAMBO, as a very detailed initialisation in order to produce a very short-range forecast. The analysis and assimilation cycles are carried out every hour. The overall system and some examples of forecast products will be presented.

JSP05/W/10-A1 **1150**

FES98, A REVISED HYDRODYNAMIC AND ASSIMILATION MODEL FOR THE OCEANIC TIDES

F. Lyard (email: Florent.Lyard@cnes.fr), F. Lefevre (email: Fabien.Lefevre@cnes.fr), C. Le Provost (email: Christian.Le-Provost@cnes.fr) and F. Ponchaut (email: ponchaut@cnes.fr) (all at LEGOS/GRGS, UMR5566 CNES-CNRS-UPS, 14 Avenue E. Belin, 31400 Toulouse, France)

A new set of solutions from our FE hydrodynamic tidal model coupled with a revised data assimilation software has recently been made available as the FES98 solutions. The CEFMO model, previously used to compute the FES94.1 solutions, was improved to allow us to compute tidal solutions at a global scale without adding extra continuity conditions at the basin open limits. "Open limit constraints" free solutions, forced only by the astronomical potential and secondary effects (loading and self-attraction), were computed for the main tidal components. The assimilation method, based on the representer approach, has been used to compute the FES95.2 solutions in a multi-basin version also. Thus it was revised in a similar fashion as the hydrodynamic model. As an immediate benefit, the pathologic behaviour of the assimilation model over some places, due to the addition of continuity conditions into the asssimilation problem, has vanished. For instance, the anomalous resonance observed over some specific coastal areas in FES95.2 were eliminated. A careful selection of in situ tide gauge data from different data banks (IAPSO, WOCE and BHI) allowed us to build a collection of about 800 data for the assimilation model. Referred as FES98, the new assimilation solutions are available on a 0.25x 0.25 degrees gridded version of the full finite element solutions. They are totally independent of altimetric measurements, and are as much accurate as the best available altimetric empirical solutions. In addition to the new solutions, the assimilation model gives us some insight look on the model, like the prior and posterior error covariances. These aspects will be discussed as well as the FES98 model improvements compared to FES94 and FES95.

Monday 19 July PM

Presiding Chair: Dr MASA KAMACHI

EXPERIMENTAL SEASONAL CLIMATE FORECASTS

SEGSCHNEIDER, J (European Center for Medium-Range Weather Forecasting, Shinfield Park, Reading, Berks, Rg2 9ax, UK. E-mail: ned@ecmwf.int Telephone No: 01180 9499 257 Fax No: 01180 986 9450)

Experimental seasonal climate forecasts as they are currently issued on a quasi-operational basis at ECMWF require an initialization. For the oceanic component of the coupled forecast system this is provided by an ocean analysis where subsurface temperature data are assimilated into a global ocean model using an optimum interpolation scheme. Altimeter data provide additional information about the upper ocean heat content. To make use of this information TOPEX/Poseidon and ERS1/2 data are assimilated into the HOPE ocean model by vertical adjustment of the density profiles. Coupled forecasts started from the so-obtained ocean analysis allow a first estimate of the impact on the forecasted SST. The analysis is global, but the focus of this study is the equatorial eastern Pacific, where impact of oceanic conditions on seasonal prediction of climate is largest. Cross-comparisons of TAO/XBT analysis with T/P sea level and T/P analysis with TAO/XBT temperatures show that both assimilation of subsurface temperature and altimeter data improve the ocean analysis as compared to the control (no assimilation). Forecasts of Nino 3 SSTA initialized from altimeter assimilation ocean analysis are closer to observed SSTA than the control forecasts, but because of the probabilistic nature of the problem it is not yet possible to decide whether forecasts are improved compared to those initialized from subsurface temperature assimilation analysis. However, some of the altimeter initialized forecasts are closer to observed SST than the best member of the ensemble of subsurface temperature initialized forecasts. Therefore, and to enlarge the ensemble spread of the forecasts in general, a combination of the two data sources in the ocean analysis will be a next step.

REVERSE INTEGRATIONS OF AN ICE-SHEET MODEL USING A KALMAN FILTER

RICHARD C.A. HINDMARSH, British Antarctic Survey, High Cross, Madingley Road, Cambridge, England CB30ET. E-mail: rcah@bas.ac.uk . Telephone No: +44 1223 221 495 Fax No: +44 1223 362 616

The best constraints of time-dependent ice-sheet behaviour come from the dated marginal retreat sequences following the last glacial maximum. Typically, they comprise geological deposits which define the margin position and which can be dated directly or correlated with dated sites using varve deposits. Excellent sequences are obtainable from Scandinavia and Northern America.
These sequences have been modelled using forward techniques, but the approach used in this paper is to use a Kalman filter integrated backwards in time to force the model to match the margin position. The ability of the Kalman filter to constrain dynamics on unstable manifolds means that reverse integrations oft he essentially diffusive ice-sheet equation can be carried out in this way. The theory for applying the extended Kalman filter is outlined and some examples are presented.

REGIONAL STUDIES AND APPLICATIONS WITH A VARIABLE RESOLUTION STRETCHED GRID DATA ASSIMILATION SYSTEM

Michael FOX-RABINOVITZ (Department of Meteorology/ESSIC, University of Mary-land, College Park, MD 20742, USA, Email: foxrab@atmos.umd.edu) Dick Dee and Lawrence Takacs (both at General Sciences Corporation,6100 Chevy Chase Drive, Laurel, MD 20707,USA,
Email: ddee@dao.gsfc.nasa.gov, ltakacs@dao.gsfc.nasa.gov)

The variable resolution stretched grid (SG) version of the Goddard Earth Observing System

(GEOS) Data Assimilation System (DAS) incorporating the GEOS SG-GCM, is used for regional analysis, forecast, and climate appli- cations. The region of interest with enhanced horizontal resolution, mostly used in experiments, is a rectangle over the U.S. The SG-DAS is capable of reproducing regional mesoscale fields, patterns and diagnostics that are not produced by the medium uniform resolution run with the same amount of grid points as for the SG. The SG-DAS regional analyses and diagnostics are used for: validation of regional climate simulation experiments produced with the SG-GCM for the U.S.1988 summer drought; and are planned to be used for atmospheric chemistry transport experiments. Also, a case study is conducted on a super-typhoon development in December 1997. The SG-DAS appears to be a viable candidate for a variety of regional studies and applications.

CORRECTING SALINITY USING T-S RELATIONS DURING ASSIMILATION OF THERMAL PROFILE DATA.

ALBERTO TROCCOLI and Keith Haines , (Department of Meteorology, University of Edinburgh, Kingís Buildings - Mayfield Road, Edinburgh EH9 3JZ (UK). E-mail: alberto@met.ed.ac.uk Telephone No: 0131 650 5041 Fax No: 0131 650 5780)

Ocean data assimilation has been continuously investigated over the last decade. Most research has focussed on either satellite altimeter data or near surface temperatures, as measured by either eXpendable BathyThermographs (XBT) or moored buoys. Recently it has been realised that salinity also plays an important role determining density and circulation not only at high latitudes, (e.g. Reverdin et al., 1997), but also in the tropics (e.g. Donguy, 1994). However, little attention has been paid to updating salinity (S) in ocean circulation models used for data assimilation (DA). This is mainly due to the paucity of salinity data. As a result, the easiest solution is usually adopted, namely salinity is left unmodified by DA (i.e. preserving the a priori S(z) profile). But this may lead to increased errors in the velocity field (Cooper, 1988). We will present a simple approach using in situ T-S relations to including salinity field adjustments when only temperature measurements are available. This DA method is then applied to an ocean general circulation model in a twin experiment framework. The true and the parallel runs differ by the external forcings. Simulated XBT data are inserted along selected sections. Results show that S(z) is generally largely improved along those sections. We also address how these changes reflect upon the downstream water properties and whether we can learn something useful from recording the modifications introduced by the assimilation.

JSP05/W/18-A1 1520

DIAGNOSING VERTICAL VELOCITIES USING THE QG OMEGA EQUATION: AN EXAMINATION OF THE ERRORS DUE TO SAMPLING STRATEGY

J. T. ALLEN, D. A. Smeed, A. J. G. Nurser and J. W. Zhang (Southampton Oceanography Centre, Southampton , UK, SO14 3ZH, email: jta@soc.soton.ac.uk) M. Rixen (G.H.E.R., Universite de Liege, Belgium)

Vertical motion at the mesoscale plays a key role in ocean circulation, ocean-atmosphere interaction, and hence the control of climate variability. It is not yet possible to measure vertical velocities less than 1000 m day-1 directly. However, by assuming quasi-geostrophic (QG) balance, they can be diagnosed from the geostrophic velocity field and suitable boundary conditions. Significant errors in the accuracy of this diagnosis arise from the necessary compromise between spatial resolution and synopticity of a hydrographic survey. Observations of a numerical ocean model have been made on similar temporal and spatial patterns to observations made of the real ocean during a typical mesoscale physics research cruise. The balance between the number of observations and the synopticity of observations effects the apparent flow and in particular the diagnosed vertical motion. A combination of effects can typically lead to errors of 85% in the estimation of net vertical heat flux. An analytical two layer model is used to understand the sources of the components of this error and suggest key parameters for the design of mesoscale sampling.

JSP05/W/13-A1 1600

THE IMPACT OF ANISOTROPIC ERROR CORRELATION

R. SWINBANK (Universities Space Research Association, NASA Goddard Space Flight Center, Greenbelt, MD 20771, USA; email: swinbank@dao.gsfc.nasa.gov) L.P. Riishojgaard, R. Menard (both at JCET, NASA GSFC, Greenbelt, MD 20771, USA; email: riishojgaard@dao.gsfc.nasa.gov, menard@dao.gsfc.nasa.go)

Most data assimilation systems assume isotropic forecast error correlations, but results from two dimensional Kalman Filter experiments indicate that the correlations can be far from isotropic. In this paper we use a simple two-dimensional data assimilation system, which analyses trace chemical species such as ozone, to assess different approaches to modelling the error correlations. We compare assimilation results using isotropic correlations with results obtained using different approaches to modelling anisotropic correlations: first, using correlations based on the concentrations of the trace chemicals, and secondly using an advective correlation model. We show that these relatively cheap ways of modelling anisotropic correlations give objectively better results than using isotropic correlations. We discuss the possible extension of these approaches to a full 3-D meteorological data assimilation system.

JSP05/W/12-A1 1620

THE USE OF DIRECT NEURAL NETWORK INVERSE MODELS IN DATA RETRIEVAL AND ASSIMILATION

Dan CORNFORD and Ian T Nabney (Neural Computing Research Group, Aston University, Aston Triangle, Birmingham B4 7ET, UK, Email:d.cornford@aston.ac.uk)

The increasing volume of remotely sensed data available for use in Numerical Weather Prediction (NWP) models provides a challenge to data assimilation systems. It is not always feasible to assimilate the remotely sensed variables directly since their relation to the meteorological variables is typically complex and non-linear. Often the 'forward sensor model' relating the meteorological variables to the sensor measurements is available; however, inversion of this model is computationally expensive and often done in 'ad-hoc' ways.
Using the example of satellite scatterometer data we show how direct neural network inverse models allow inference of the local conditional probability of a surface wind vector over the ocean given the local scatterometer observation. The inverse models can then be used in several ways: as preconditioners to any retrieval/assimilation algorithm; and, using the scaled likelihood method, for inference in a Bayesian retrieval procedure. The procedure we have developed permits the retrieval of the wind fields without background information, and can thus be performed independently of the NWP model. The Bayesian retrieval procedure uses a Gaussian Process based prior wind field model which resolves scales relevant to NWP models and has been extended to include fronts. Thus these winds could be used directly in the assimilation procedure, saving time by considerably reducing the burden of forward model inversion in a variational assimilation system.

JSP05/E/09-A1 1640

STATISTICAL ESTIMATION OF THE GRIN FUNCTION

Leonid I.Piterbarg (Center of Applied Mathematical Sciences, USC, Los Angeles, USA, email: Piter@cams.usc.edu) Sergei V.SEMOVSKI (Limnological Institute SB RAS, P.O.Box 4199 Irkutsk 664033 Russia, email: Semovsky@lin.irk.ru)

The general statement for heat transport is the equation dT/dt=LT+w. If linear operator L is independent of time, random field w is stationary by time and sequence of field observations T(x,y,t) is available, then statistical procedure is presented for estimation of Green function. Leith (1975) proposed method for delta-correlated noise, based on multivariate correlation matrix calculation. Piterbarg & Semovski (1987) considered finite correlation case, the method is based on calculation of multivariate spectra.
Grin function estimation can be used for simulation of transport for arbitrary initial conditions. Estimation of advection field, diffusion, feedback factors can be derived. However, the procedure can also used for "teleconnection" description. Some functionals, derived from Grin function estimation, can be used for description of different characteristics of process under study, including spreading of elementary heat impulse, "sensitivity" and "influence" functions. Examples of Grin function computation are presented for few model cases. Statistical estimation of Grin function has been used for description of anomalies formation of sea surface temperature for the North Pacific, global surface temperature analysis and "influence function" calculation for the Central Siberia.

JSP05/W/05-A1 1700

THE DETERMINATION OF SURFACE IRRADIANCE DIURNAL CYCLES BY ASSIMILATION OF JOINT GROUND-BASED AND REMOTE SENSING DATA

Oleg Pokrovsky , Nadya Korolevskaya (Main Geophysical Observatory, Karbyshev str.7, St.Petersburg, 194021, Russia, e-mail: pokrov@main.mgo.rssi.ru)

Subsystem of surface radiative budget (SRB) is one of the most important modules in global observational system (GOS). Ground-based actinometrical network (AN) does not meet such important requirements, as uniformly coverage and spatial density. Satellite data could be potentially to compensate the lack of observational information. Now AN and satellite data are used in separate mode. AN data are implemented for calibration and validation aimes. But the most promising approach could be based on simultaneous assimilation of both kind of data, as only in this case known mutualy supplement features (relatively high accuracy of AN data and global uniformly coverage, accompanied by increasing of spatial resolution and density of satellite data) could give some synergy effect. Assimilation method should overcome principal difference of these two kind of data to supply the radiative fields, having sufficient diurnal resolution. It has been developed the retrieval method of diurnal cycles of surface radiation budget variables based on satellite observation dataset. The method has been examined by means of the simulation of satellite measurement dataset ERBE and ScaRaB. It has been elaborated a statistical model of surface downward irradiance (SDI) diurnal cycles including a classification into cases of the clear sky, overcast cloudness and some cases of partly cloudness. The complete set of classes changes in wide range from 3 in the winter up to 6 in the summer. To achieve an effective classification by using the method of the discriminant analysis it is necessary to have at least five satellite measurements per day in July and three instantaneous observations - in March. When the classification procedure has been performed it is necessary to consider the retrieval problem of missing diurnal cycle values. Having the 3-5 satellite observations during a day the retrieval of not only daily sums but also the diurnal distributions of irradiance could be effective. So, for example, in July the relative retrieval error decreases to 20-30 %, and in March - to 10-20 %. The study conducted has shown that some reserve for the increasing of the retrieval accuracy is connected to an optimum choice of satellite observation instants during a day.

JSP05/W/08-A2 0930

THE PERFORMANCE OF ALTIMETER DATA ASSIMILATION IN THE OCCAM GLOBAL OCEAN MODEL

Alan FOX and Keith Haines (Department of Meteorology, University of Edinburgh, King's Buildings, Edinburgh, EH9 3JZ, UK. Email: A.D.Fox@ed.ac.uk). Beverly de Cuevas and Dave Webb (Southampton Oceanography Centre, Empress Dock, Southampton SO14 3ZH, UK)

Sequential assimilation of TOPEX/POSEIDON and ERS-1 altimeter data every 10 days into the OCCAM 1/4 degree global ocean model has been performed from the beginning of 1993. The assimilation method uses mapped sea level anomalies provided by CLS and a mean sea level which has been corrected with hydrographic data in the western boundary current separation regions. An error analysis on the surface height fields is performed with the model errors calculated at low resolution on each assimilation using an adaptive method. Surface height updates thus calculated are projected vertically into the model interior using the Cooper and Haines water property preserving method. The principle aims of our assimilation system are two-fold: firstly, to produce improved analyses of surface and subsurface ocean fields; and secondly, using the analyses produce useful forecasts of the ocean. Changes to fields and transports introduced by the altimeter assimilation are highlighted via comparisons with an OCCAM control simulation. Bearing our aims in mind, the performance of the assimilating model is assessed by comparisons with independent XBT data and WOCE hydrographic and ADCP sections, and the ability of the system to predict sea level changes on the 10-40 day timescale is demonstrated.

JSP05/W/07-A2 0950

ALTIMETER ASSIMILATION IN A GLOBAL OCEAN MODEL: MODEL ERROR ESTIMATION.

Keith Haines and Alan FOX (Department of Meteorology, University of Edinburgh, King's Buildings, Edinburgh, EH9 3JZ, UK. Email: A.D.Fox@ed.ac.uk)

Sequential assimilation schemes in oceanography rely on some estimation of model error at assimilation time. The Kalman Filter represents the optimal estimate, but remains computationally unfeasable in any realistic application. An alternative approach is described in which model errors are estimated by application of a simple consistency condition between the known model-data misfits and observational errors, and the unknown model errors at each assimilation time. This calculation is performed at low resolution and results in an adaptive estimate of model error.

The technique is described in relation to assimilation of mapped altimetry data into the OCCAM, 1/4 degree, 36 level, global ocean model. Surface height updates found using the estimated model errors are projected vertically into the interior using the Cooper and Haines water property preserving method. Results of experiments assimilating TOPEX and combined TOPEX+ERS1 altimetry data over the period 1993-1995 are shown. At various times short 'forecast' runs are also performed with durations of up to 2 months. In a useful dual application, the model error estimation procedure described can also be used to gauge forecast skill.

JSP05/W/03-A2 1010

WHAT CAN WE LEARN BY ASSIMILATING ALTIMETRY?

JENS SCHROETER, Bernadette Sloyan and Martin Losch (Alfred Wegener Institute for Polar and Marine Research, Postfach 12 01 61, 27515 Bremerhaven,Germany. Email: jschroeter@awi-bremerhaven.de Telephone No: +49-(0)471-4831 762 , Fax No: +49-(0) 471-4831 797)

The assimilation of satellite altimetry referenced to a geoid is discussed. The first problem that stands out in this context is the geoid error which can dominate the sea-surface-height data to be assimilated and make this information almost useless. The second major problem is the fact that good resolution and high quality geoid models like EGM96 include information about an oceanic climatology. By assimilating altimetry referenced to such a geoid we implicitely assimilate ocean climatology. We apply a box-inverse model of the southern ocean and show how only the long wavelength information of the altimeter data can be used for assimilation. The change in the models inverse solution and in the associated error covariance is presented. The possible impact by future satellite gravity missions on our results will be dicussed.

DATA ASSIMILATION FOR INITIALIZING COUPLED CLIMATE PREDICTIONS

Antonio J. BUSALACCHI (Laboratory for Hydrospheric Processes, NASA Goddard Space Flight Center, Greenbelt, MD, 20771, USA, Email: tonyb@neptune.gsfc.nasa.gov)

At the beginning of CLIVAR, data assimilation in support of coupled climate prediction is proving to be the link that binds the modeling and observational components of interannual climate research. Initialization studies of coupled ocean-atmosphere prediction models have become an active area of research in the past few years now that the Tropical Pacific Ocean Observing System has a reached a mature stage of deployment. Data assimilation into coupled forecast models of seasonal to interannual climate variability can take the form of assimilation (OI or adjoint) of in situ and remotely sensed data into the ocean model in a stand-alone mode to improve initial conditions (e.g., reduce systematic biases), for parameter estimation, or as part of a coupled initialization procedure. This presentation will discuss the prospects for improved prediction skill as a result of data assimilation approaches to initializing coupled climate models. Predictions of the 1997-1998 El Nino will be used to illustrate how forecast skill was enhanced as a result of various approaches to assimilating surface wind, sea level, subsurface thermal structure and sea surface temperature observations.

JSP05/E/05-A2 1130

ASSIMILATION OF ALTIMETER DATA IN A TROPICAL PACIFIC OGCM

PETER MCLEAN and Mike Davey, UK Meteorological Office, London Road, Bracknell, Berkshire, RG12 2SZ, UK

A Tropical Pacific OGCM has been used to simulate temperature and currents inthis region. The OGCM used in the UK Met. Office has some systematic errors in common with other similar models, with sea surface temperatures having a warm bias in the central and eastern equatorial Pacific. The thermocline in the analysis is also too diffuse which in turn leads to a too weak equatorial undercurrent. Interannual variability of sea surface temperature in different regions of the equatorial Pacific follows the trends of observed anomalies, but underestimates some warm and cold events. Topex Poseidon altimeter data which is produced in gridded format by CLS was assimilated into the tropical Pacific OGCM to try to improve the analysis. Results suggest that there is a tightening of the thermocline so that subsurface temperatures more closely resemble those observed, and that sea surface temperature anomalies are closer to those observed for example during the 1997 El Nino event. However altimeter assimilation was found to be of less use away from the equator with little improvement in the analysis in the subtropical regions.

JSP05/W/13-A2 1150

VARIATIONAL ADJUSTEMENT OF TSUNAMI PARAMETERS BY ASSIMILATION OF TIDAL STATIONS DATA

Carlos A.L. PIRES (Centro de Geofisica da Universidade de Lisboa, Rua da escola Politecnica 58, 1250 Lisboa Codex, Portugal, email: cpires@fc.ul.pt); Pedro A M Miranda (Centro de Geofisica da Universidade de Lisboa, Rua da escola Politecnica 58, 1250 Lisboa Codex, Portugal, email: pmiranda@fc.ul.pt)

Time series at tidal stations constitute a potential source of information that may be assimilated into oceanic models. That information is too restrictive too infer the full dynamical state of the sea with any assimilation technique. However, it can be relevant or even sufficient in cases where a simplified hydrodynamical model can be applied and initial conditions can be described by a small set of parameters. Both conditions are nearly satisfied in the case of large tsunami events. We develop a four-dimensional (4DVAR) data assimilation scheme for tsunami signs (after a tide removal) at tidal stations along the Iberian Peninsular and North Africa for the Gorringe Bank large earthquake of February 1969. Observations are assimilated into a shallow-water model for a period covering the first two or three significant waves in each station. Minimisation is performed in a functional space of 9 parameters using the well known Okada formulas described a simple tsunami source. This method is able to recover parameter values that are comparable to those obtained by pure geophysical inversion techniques and can eventually be used to complement them.

EFFECTS OF HIGH-ENERGY PARTICLES ON SPACECRAFT AND AIRCRAFT ELECTRONICS

D.J.RODGERS and C.S.Dyer (DERA, Farnborough, UK)

Spacecraft and high-altitude aircraft have, in common, a reliance on complex electronic systems and an environment bathed in ionising radiation. This environment comprises the trapped proton and electron populations of the Van Allen belts, solar energetic particles and galactic cosmic rays. Variations in these populations occur over a wide range of time-scales and present a challenging problem for space weather forecasting. In addition, secondary populations are generated by atmospheric and spacecraft interactions. Radiation effects include 'single event effects', total dose effects, noise and internal dielectric charging. These effects and resulting electronic anomalies are described with reference to in-flight observations.

JSA06/W/03-A1 Invited 0855

SPACE ENVIRONMENT EFFECTS AND THE ANIK-F SATELLITE DESIGN

Robin GUBBY (Space Systems Department, Telesat Canada,1601 Telesat Court, Gloucester, Ontario K1B 5P4, Canada, email: r.gubby@telesat.ca;), Bill Willis, (Member of Technical Staff Survivability Activity, Hughes Space & Communications Company, 2060 E. Imperial Highway Los Angeles, California 90009, USA; email: www@mail.hac.com)

In spite of much knowledge gained over the past three decades, space environment effects continue to be a major cause of anomalies in communications satellites. The two most common causes of anomalies are surface charging and deep dielectric (dis)charging, but other effects, such as total radiation dose, must be accounted for in the design, particularly in the solar arrays and electronics. Many space environments are difficult to predict accurately, for example the peak intensity of the developing Solar Cycle 23, and in particular the radiation dose to be expected from it. The recent Leonid storm provides an example of the extreme variation possible between predictions and reality. In early 2000, Telesat Canada will launch the Anik-F satellite, which is currently under construction at Hughes Space and Communications Company, and which will be one of the most powerful communications satellites ever built. It is designed to operate trouble-free for at least 15 years. The ways in which the space environment can affect a satellite and how these effects will be countered in the Anik-F design are reviewed.

JSA06/W/16-A1 0915

CORRELATION BETWEEN MAGNITOSPHERE STORMS AND SPACECRAFT CHARGING FOR RUSSIAN HIGH ALTITUDE SATELLITES

Vladimir I. GUSELNIKOV and Yury M. Prokopiev (Novosibirsk State University, Pirogova 2, Novosibirsk, 630090, Russia, email: vgusel@phys.nsu.ru, uprok@phys.nsu.ru) Oleg S. Grafodatsky (Scientific Production Association of Applied Mechanics (NPO PM), Lenina 52, Krasnoyarsk-26, 662990, Russia, email: 434graf@npopm.krasnoyarsk.su)

During the 20 years, the interaction of magnetosphere plasma with space crafts has been investigated. We present here the results of high altitude spacecraft charging investigation for Russian high altitude satellites and mutual correlation between charging value and geomagnetic activity. The spacecraft charging experiments were made on the serial communication and navigation satellites GORIZONT, GLONASS, GALS, and EXPRESS designed by NPO PM. Electric field strength at various points of spacecraft, potential difference between it's isolated parts, plasma fluxes and electromagnetic noise intensity in circuits and antennas were measured. The project "Patrol system" was started on space crafts EXPRESS-11 (1994-067A) and GALS-12 (1995-63A). Measurements of electric field strength were made by means of vibration type probes (DEP). The measured field range is 0-100 kV/m. We introduced an effective index ED (Electrisation Disturbances) for describing spacecraft charging. The index ED was calculated for flight data from both satellites on the base of the electric field strength value, frequency of polarity change, duration of high level period. We determined this parameter as a value in range from 1 to 10. Mutual correlation for D-index and Cp-index, ED-index and Ap-index were calculated. Correlation interval was ranged from -5 to +5 days. The correlation coefficient reach maximum at the interval equal zero. The noticeable maximum reflects presence of correlation between DE and Ap indexes. Correlation between DE and Cp indexes shows even bigger value.

JSA06/L/06 Invited 0935

OBSERVATIONS OF HIGH-LEVEL CHARGING ON THE FREJA S/C IN POLAR LEO

WAHLUND, J-E; Carozzi, T; Eriksson, A.I.; Holback, B., and Wedin, L.(Swedish Institute of Space Physics, Uppsala, Sweden) Andersson, L.(Swedish Institute of Space Physics, Kiruna, Sweden) Cook, D. (Air Force Research Laboratory (AFRL), Hanscom AFB, MA, USA) Hilgers, A. (ESTEC, Noordwijk, Holland) Laakso, H. (Finish Meteorological Institute, Helsinkii, Finland) Svensson, U. (SAAB-Ericsson Space, Sweden)

A total of 291 charging events have been detected onboard the Freja spacecraft in the altitude interval 1000 - 1800 km from the time period October, 1992, to April, 1994, during declining solar activity conditions. The Freja satellite orbited Earth with a 63 degree inclination, and had 73 kg of state-of-the-art plasma instrumentation available for studying the characteristics of the charging events that occurred simultaneously as auroral inverted-V type energetic electron precipitation hit the spacecraft. Negative charging levels exceeding -2000 Volts were recorded despite the fact that the Freja spacecraft was designed to be as electromagnetically and electrostatically clean as possible with highly conductive ITO surface coatings among other precautions. Several of the plasma instruments experienced severe operation disturbances

during most charging events. Results from both a statistical investigation and a detailed charging event study will be presented. It is found that auroral inverted-V type electrons in the energy range above about 5 keV cause the charging on Freja. Most charging events occurs during eclipse, even though a few existed during sunlight conditions when the energy peak of the inverted-V electrons was larger (10-15 keV). The cold thermal plasma density did not usually decrease significantly as compared to surrounding levels during the charging events. On the other hand, a threshold density of about 2000cm(-3) existed, above where no charging events occurred. The effect of the magnetic field and other possible secondary electron emission effects were investigated. We compared the observed results with the charging codes SURCHG and POLAR, which is presented in an accompanied abstract. The current feature of the Polar code could not fully account for the highest charging levels observed. We finally conclude that high-level charging is still of concern regarding operation of spacecrafts and payload in polar LEO.

JSA06/W/11-A1 Invited 0955

LESSONS FROM CRRES ON SPACE RADIATION HAZARDS

D.H. BRAUTIGAM (Air Force Research Laboratory, Hanscom AFB, MA 01731, USA, email: brautigam@plh.af.mil)

The Combined Release and Radiation Effects Satellite (CRRES) was a unique experiment which provides valuable lessons about the space radiation environment and its effects on technological systems in space. The tremendous value of CRRES resides in the fact that it flew not only the technologies to be space-tested, but also an extensive suite of instruments to accurately specify the damage-causing radiation environment. CRRES was launched into a geosynchronous transfer orbit on 21 July 1990, one year following the maximum of solar cycle 22, and returned data for approximately 14 months. It was first exposed to eight months of a relatively quiet magnetosphere, followed by a very active six months which was initiated by the much documented March 1991 storm. This large magnetic storm, accompanied by a solar proton event, was responsible for creating a temporary proton and electron belt within the typically benign slot region. This very dynamic radiation environment, with its various particle populations, was responsible for a number of observable total dose effects, charging / discharging phenomena, single event effects, and assorted anomalies within the spacecraft instrumentation and technology test bed. This exceptional combination of technologies, instrumentation, and dynamic radiation environment will be reviewed, with attention given to lessons learned and how CRRES has changed our perspective on magnetospheric radiation hazards.

JSA06/W/27-A1 1035

GIC RISK IN THE UK: GEOMAGNETIC VARIATIONS, GEOLOGY AND SURFACE ELECTRIC FIELDS

David BEAMISH (Fluid Processes and Waste Management Group, British Geological Survey, Keyworth, Nottingham, NG12 5GG, England), Toby Clark, Ellen Clarke and Alan THOMSON (Global Seismology and Geomagnetism Group, British Geological Survey, West Mains Road, Edinburgh, EH9 3LA, Scotland. email: a.thomson@bgs.ac.uk)

The geomagnetic induced current (GIC) risk in the UK is assessed with reference to known examples of GICs in the power grid operated by National Grid plc. A simplified three-dimensional geology model is used to provide an indication of the surface electric field for various amplitudes and wavelengths of the external magnetic field variation. It is found that the conductivity contrast between seawater and the onshore geology produces enhanced E-fields around the coast. A simple measure of the power of the changing magnetic field is used to determine the risk to the power grid from rapid magnetic variations, according to season and local time. Monitoring and forecasting of this power index is suggested as a means of gauging the likely risk to high-cost power industry equipment.

JSA06/L/02-A1 1055

GIC IN NATIONAL GRID'S TRANSMISSION SYSTEM

Jon LAVER (The National Grid Company plc, Engineering & Technology, Kelvin Avenue, Leatherhead, Surrey KT22 7ST. U.K.Email:Jon.Laver@ngc.co.uk)

Some data from the previous sunspot maximum (Cycle 22) are available and briefly reviewed. Several incidents at the time were attributed to the effects of Geomagnetic Induced Currents (GIC) in the Transmission System. These are described in some detail together with the effects of several subsequent severe storms. National Grid is taking the forthcoming Cycle 23 seriously. Amongst several in-depth studies and initiatives taken include determining what the likely magnitudes and effects of the GIC will be on both primary plant (mainly Supergrid Transformers) and secondary plant (mainly protection equipment). Further studies have assessed what mitigation measures might be implemented.
Following upon the impact assessment study, a real-time data acquisition system is currently being commissioned at a number of sites. This will record quasi-DC currents in Supergrid transformers together with associated plant parameters, include some geophysical parameters, and will telemeter all this data back to a central system.
A forecasting system is also being implemented, inputting available near real-time and forecast data. The physical model of the transmission system also constructed should then express this as equivalent surface electro-telluric fields throughout the country. Using this model's output together with conventional network analysis, magnitudes of induced quasi-DC currents in nodes of the transmission system may thenbe determined.

JSA06/L/03-A1 Invited 1115

POSSIBILITY OF PREDICTING THE MAGNITUDE OF GIC IN PIPELINES

S. O. OGUNADE, (Department of Physics, Obafemi Awolowo University, Ile-ife, Nigeria.)

In the equatorial and auroral zones Geomagnetically Induced Currents (GICs) are known to accelerate the corrosion process in oil and gas pipelines. Using a numerical model the horizontal H- and D-components of the magnetic field due to a buried pipeline under a sheet current source are obtained. A relationship is established between the horizontal components of the magnetic field obtained and the pipe-to-soil potential. A further relationship is found to exist between the pipe-to-soil potential and the current induced in the pipeline.
The pipe-to-soil potential measured for pipelines in Nigeria are correlated to Kp and Dst geomagnetic indices for the period 1993 to 1997. The trend of the result indicates a possibility of predicting the magnitude of geomagnetically induced currents in pipelines from real-time geomagnetic indices.

APPLICATION OF DSTL THEORY TO STUDIES OF GEOMAGNETIC EFFECTS ON PIPELINE NETWORKS

Anitti PULKKINEN(1), David Boteler(2), Risto Pirjola(1), Ari Viljanen(1) (1) Finnish Meteorological Institute, Geophysical Research Division, P.O. Box 503, FIN-00101 Helsinki, Finland (2) Geomagnetic Laboratory, Geological Survey of Canada, 7 Observatory Crescent, Ottawa, Ontario K1A OY3, Canada

The expressions of the geomagnetically induced current in a pipeline and the voltage between the pipeline and the earth related to the current have a similar form whether they are derived from the Maxwell equations or from the transmission line analogy. This suggests that a pipeline can be represented as a transmission line, and geomagnetic effects can be calculated using the distributed source transmission line (DSTL) theory. The main advantage of the analogy is that we can use methods familiar from the circuit theory, e.g. the Thevenin theorem. Applying the Thevenin theorem we can model discontinuities of a pipeline which would be difficult if started directly from the basic electromagnetic theory. The latest achievements have been the modelling of branches of a pipeline network and inclusion of a non-uniform electric field. These new results make it possible to model the voltages and the currents produced in the entire pipeline network by realistic geomagnetically induced electric field.

150 YEARS OF GEOMAGNETIC EFFECTS ON TECHNOLOGY

D. H. Boteler1, H. Nevanlinna2, J. Allen3, L. Morris3, G. Jansen van Beek1, R. Pirjola2 1 Geomagnetic Laboratory, Geological Survey of Canada, 7 Observatory Crescent, Ottawa, Ontario K1A 0Y3, Canada. 2 Geophysical Research, Finnish Meteorological Institute, P.O. Box 503, FIN 00101 Helisinki, Finland. 3 National Geophysical Data Centre, NOAA, 325 Broadway, Boulder, Colorado 80303, USA.

Geomagnetic effects have been observed on electrical systems since the early days of the telegraph. As each new system involving long conductors was laid across the earth's surface the engineers involved found that they had to contend with the effects of geomagnetic disturbances. Geomagnetically induced voltages on submarine phone cables caused voice transmissions to alternate between shrieks and whispers. Telluric currents in pipelines interfere with the corrosion prevention systems. Geomagnetically induced currents in power systems cause transformer saturation and harmonic generation leading to misoperation of relays, equipment damage and power blackouts. The largest magnetic disturbances that cause the worst effects are infrequent events so to assess their frequency of occurrence it is necessary to examine a long period of geomagnetic data. Thanks to the efforts of Mayaud we have the aa index of magnetic activity extending back to 1868. Now, using early recordings from the Helsinki magnetic observatory, equivalent 3-hourly activity values have been produced and used to extend the aa sequence back to 1844. To obtain representative measures of the activity in a geomagnetic disturbance a 24-hour running mean of these values is taken. The resulting aa* index provides a record of geomagnetic disturbances throughout the whole period of electro-technological use on the earth.

EVALUATION OF TELLURIC CURRENT EFFECTS ON THE MARITIMES AND NORTHEAST PIPELINE

D. H. BOTELER (Geomagnetic Laboratory, Geological Survey of Canada, 7 Observatory Crescent, Ottawa, Ontario K1A 0Y3, Canada, email: Boteler@geolab.nrcan.gc.ca), R. Gummow (CORRENG Consulting Service Inc) B. Rix and R. Reid (Union Gas)

The Maritimes and Northeast Pipeline on the east coast of North America is being constructed through an area where large geomagnetic disturbances can be expected and where the electric fields produced will be amplified by the coast effect. In addition the water movement associated with the rise and fall of tides in the Bay of Fundy (the highest tides in the world) will produce significant tidal electric fields. Because of these factors it was decided to include consideration of telluric current effects in the design of the cathodic protection (CP) system for the new pipeline. An evaluation was made of the electric fields expected to be produced by geomagnetic disturbances and the tidal dynamo. A computer model was set up to examine the pipeline response to these electric fields. This allowed prediction of the pipe-to-soil potentials produced with different coating resistances and placement of insulating flanges and ground beds. The modelling capability allowed various cathodic protection schemes to be evaluated before construction and has resulted in a more efficient and cost effective CP design for the pipeline.

GEOMAGNETICALLY INDUCED ELECTRIC FIELDS AND CURRENTS IN PIPELINES

L. TRICHTCHENKO and D.H. Boteler (Geomagnetic Laboratory, Geological Survey of Canada, 7 Observatory Crescent, Ottawa, Ontario K1A 0Y3, Canada)

Variations of the Earth's magnetic field induce electric fields in pipelines. These induced electric fields drive currents along the pipeline that can interfere with the cathodic protection systems installed to prevent corrosion of the pipeline. For design of systems to counteract these effects it is necessary to be able to calculate the size of the currents that will be produced by different geomagnetic condictions.
In this study we present the results of numerical modelling of the induced electric fields and currents produced in a long coated pipeline buried in the Earth. The effects of changes of the pipe parameters (pipe dimensions, conductivities, magnetic permeability) are studied. Calculations are made for different frequencies and characteristics of the source fields.

PROJECT ON GEOMAGNETICALLY INDUCED CURRENTS IN THE FINNISH NATURAL GAS PIPELINE NETWORK

ANTTI PULKKINEN(1), Kari Pajunp‰‰(1), David Boteler(2), Ari Viljanen(1), Risto Pirjola(1) (1) Finnish Meteorological Institute, Geophysical Research Division, P.O. Box 503, FIN-00101 Helsinki, Finland (2) Geomagnetic Laboratory, Geological Survey of Canada, 7 Observatory Crescent, Ottawa, Ontario K1A OY3, Canada

This paper describes a study of geomagnetically induced currents (GIC) in the Finnish natural gas pipeline network being made by Gasum Inc., the pipeline owner, and the Finnish Meteorological Institute. The project involves theoretical studies and measurements of the currents and voltages produced in the pipelines during geomagnetic disturbances. The theoretical part of the project is performed by applying the distributed source transmission (DSTL) theory with new extensions developed in this study that make it possible to treat an entire pipeline network at the same time with a realistic non-uniform induced electric field. Profiles of GIC and voltage between the earth and the pipeline are calculated for different geomagnetic situations. Measurements are made of the voltage between the pipeline and the earth. The current along the pipeline is also measured by using two magnetometers: one near

the pipeline and the other is at the nearby Nurmij‰rvi Geophysical Observatory, so the difference of these two magnetic measurements is the magnetic field due to the current in the pipeline. The measured data will be combined with theoretical models to derive statistics of the GIC occurence on the pipeline system.

CHARACTERISTICS OF GEOMAGNETIC EVENTS CAUSING LARGE GEOMAGNETICALLY INDUCED CURRENTS

Ari VILJANEN, Olaf Amm and Risto Pirjola (Finnish Meteorological Institute, Geophysical Research, Division, P.O.B. 503, FIN-00101 Helsinki, Finland, email: ari.viljanen@fmi.fi)

Events of large geomagnetically induced currents (GIC) are studied by focusing emphasis on the relation between GIC and the local and global geomagnetic activity. From the local viewpoint, we especially attempt to describe the ionospheric currents which cause the largest GIC values. A global approach aims to clarify the possibilities of forecasting GIC. We present a rough classification of ionospheric currents associated with large GIC.

IMPACT AND OBSERVATIONS OF GEOMAGNETIC SUBSTORMS IN A WIDE AREA DIFFERENTIAL GPS NETWORK

Susan SKONE (Department of Geomatics Engineering, University of Calgary, 2500 University Dr. NW, Calgary, Alberta T2N 1N4, Canada, email: sskone@ensu.ucalgary.ca)

The Global Positioning System (GPS) is a satellite navigation system, in which 24 satellites currently provide worldwide positioning capabilities. Due to the dispersive nature of the ionosphere, GPS signals experience ranging errors dependent on both the given signal frequency and ionosphere electron content. Such range errors translate into a degradation of positioning accuracies.
Dual frequency GPS receivers enable the estimation of absolute ionospheric range delay and total electron content (TEC) along the signal path. By using a number of GPS reference stations, each equipped with a dual frequency receiver, it is possible to estimate values of the vertical ionospheric TEC (in latitude and longitude) on a spherical shell. This type of ionosphere delay modelling is employed in Wide Area Differential GPS (WADGPS) Networks. Features such as the main ionospheric trough, and enhancements/depletions of electron density, are observed in the TEC maps during periods of enhanced auroral ionospheric activity.
In this paper, ionosphere TEC variations are investigated in the auroral region during periods of geomagnetic substorms, and the impact on WADGPS applications assessed. GPS observations from reference stations in the Natural Resources Canada wide area network are used, providing extensive coverage of the high latitude Canadian sector. A spectral analysis of the ionosphere TEC variations is also conducted, demonstrating the potential of identifying auroral disturbances associated with substorms in real-time from the GPS data. Correlations with space weather parameters from ground-based and space-borne magnetometers and imagers are illustrated. The ability to track substorm development over a large region, using GPS measurements from the network of reference stations, is also investigated.

THE LARGE GEOMAGNETIC SUDDEN COMMENCEMENTS AT MOSCOW

Tamara KUZNETSOVA, Kharlampij Kanonidi (both at IZMIRAN, Troitsk, Moscow region, 142092, Russia, email: tvkuz@izmiran.rssi.ru)

A statistical study of geomagnetic sudden commencements (SCs) at observatory Moscow (geomagnetic latitude (g=51 o) since 1940 showed that the largest two SCs had amplitude in H-component equaled to 305 nT and 250 nT. These SCs are observed on 9 May, 1992, UT=19h59m and on 13 June, 1990, UT=14h16m respectively. A detail analysis of these events showed that the disturbances connected with the SCs had global character on the Earth. An analysis of the amplitude distribution showed that amplitude of the SCs observed at the close MLT are linear proportional to the L-shell of the observatory on the Earth in range of L=1.6-6. Vector diagrams of the disturbances show that the polarization vectors are in agreement with superficially wave passing from the dayside magnetopause in antisunward direction. The amplitudes show dependence on MLT of SC observations. The solar sources of the SCs could be interplanetary shock waves generated by the flares. An analysis shows that velocities of the shock waves should be greater than 1000km/sec. These high amplitude SCs at Moscow are unusual phenomena. The SCs form instantaneously a radiation belt that exists more than a half year and they are potentially-damaging space weather events. Time delays between the SCs and beginnings of strong geomagnetic storms are analyzed. The other peculiarities of the events are discussed.

SOLAR FLARE EFFECT CHANGES IN GEOMAGNETIC FIELD COMPONENTS AND IONOSPHERIC CHARACTERISTICS

I.M. VASILJEVIC (Geomagnetic Institute, 11306 Grocka, Belgrade, Yugoslavia, email: ivan@tehnicom.net) LJ.R. Cander (Rutherford Appleton Laboratory, Chilton, Didcot, Oxon, OX11 0QX, UK, email: l.cander@rl.ac.uk)

This paper describes the results of the analyses of two solar flare effects (SFEís) on the geomagnetic field components variations and the key ionospheric characteristics at Observatory Grocka. Two periods in September 1991 have been considered: 9-14 and 24-29 covering geomagnetically disturbed period and periods prior and after the storm. The SFEís were identified by A3 method of absorption measurements. The results have shown that SFEís could be directly correlated with the changes in the ionospheric parameters but the same is not valid for the variations in the geomagnetic field components.

TO EQUATORIAL SPREAD F USING MODELS OF THE LOW-LATITUDE IONOSPHERE AND ELECTRODYNAMICS

Dr Vince ECCLES

The fundamental processes of Equatorial Spread F (ESF) have been examined in detail for four decades. The gravitationally-driven Rayleigh-Taylor instability has long been identified as the initiating process. Likewise, controlling geophysical conditions of ESF have been identified: - large post-sunset vertical drift - conjugate sunsets - transequatorial winds - equatorial ionization anomaly conditioning However, forecasts of ESF occurrence and intensity of accompanying signal scintillation still are based on rough, but improving, probabilities from climatological models. A physics-based model of the low-latitude ionosphere and its resulting R-T growth rates are used to examine predictors of ESF occurrence. In particular, the model is used to examine afternoon precursor observations that might be used to forecast ESF occurrence.

GEOMAGNETIC SUBSTORM FORECASTING AT NETWORK OF HF RADIO PATHS

Donat V. BLAGOVESHCHENSKY (University of Aerospace Instrumentation, 67 Bolshaya , Morskaya Str., 190000, St. Petersburg, Russia, email:nataly@aari.nw.ru)

The emergence of active solar processes result in certain disturbances in the near-Earth environment. The disturbances manifest themselves first of all in the high-latitude ionosphere. Therefore the latter may serve as an object of studies in order to predict its state by means of radiophysical methods of investigation. Among them, one should specially single out the method of prediction with the help of a system of HF paths. The system represents a set of several paths of length up to 3000 km and of different directions but with one reception center located at a geomagnetic latitude ?L = 60-65?. The decameter waves pass through the ionosphere, hence they are an effective tool to predict its state. The network of HF paths makes it possible to obtain and carry out an analysis of a complex of statistical characteristics of the SW signal envelope at the receiver output. The envelope characteristics of the signal are evaluated by a computer in on-line mode and include: m - the Nakagami law parameter, ? - the time correlation radius, ?X - the signal average, L1, L2, L3 - parameters of the process non-stationarity and so on. Their variations at different phases of a substorm reveal certain regularities. By our studies, two-three hours before the start of the decrease of the H-component of the Earth magnetic field, there is observed the growth of absolute values of all parameters. At about one hour before the substorm intensification there begins a sharp decrease in magnitudes of the characteristics considered, which reach their minimum at the expansion phase of substorm. Hence the forecasting of the substorm onset my be made about two hours before the breakup begins. At the recovery phase there is a gradual growth of the parameters back to their original values. Thus the suggested method of forecasting the geomagnetic substorm by the characteristics of propagating radio waves is important for investigation of potentially-damaging space weather events.

AN IONOSPHERIC FORECASTING SERVICE BASED AROUND A NOVEL NONLINEAR TECHNIQUE CAPABLE OF USING BROKEN TIME SERIES

N M FRANCIS, P S Cannon *(Defence Evaluation and Research Agency,D705, St. Andrews Rd., Malvern, Worcs., WR14 3PS, UK.Tel: +44 (0) 1684 896484, Fax: +44 (0) 1684 895241, email: nmfrancis@dera.gov.uk *also at University Of Bath, UK.)

Recent advances in the fields of ionospheric and space weather forecasting have been possible due to the adoption of techniques derived from studies into artificial intelligence and non-linear dynamical systems theory. A common approach is that of using the Multi-Layer Perceptron (MLP) [1] to provide predictions based upon a time series input. However, we have adopted Radial Basis Function (RBF) Neural Networks (NN). The advantages of the latter over their MLP counterparts are outlined. This paper will describe an on-line WWW forecasting service of the ionospheric parameter foF2 for north western sub-auroral Europe. The forecast is based on data from the Chilton (UK) ionosonde. Scaled data can be routinely down-loaded from this ionosonde (and other Digisondes) and automatically processed by the forecasting algorithm. This algorithm produces hourly updated, nonlinear predictions for one to twenty four hours ahead, with data currently posted every 6 hours. In addition the pseudo-sunspot number derived from the forecast of foF2 is also posted. For algorithm evaluation purposes a wide complement of other algorithms are also available - although these are not available to the user. The paper will also review these and show comparative results. The user is, however, presented with a quantitative assessment of the efficacy of yesterdays forecast by reference to the measured values and the predicted monthly median values.
Of particular interest is the ability of this algorithm to deal with non-contiguous data sets, which are a recurrent problem in geophysical time series. Simple linear interpolation is undesirable because it can disrupt the delicate non-linear dynamics within the data, as well as degrading the performance of the nonlinear modelling process.

SEDAT: SPACE ENVIRONMENT DATABASE

Mike HAPGOOD, Matthew Wild and Richard Stamper (CLRC Rutherford Appleton Laboratory, Chilton, Didcot, Oxfordshire, OX11 0QX, UK, email: M.Hapgood@rl.ac.uk), Alain Hilgers, Hugh Evans and Norma Crosby (ESTEC, 2200 AG Noordwijk, The Netherlands,
email: ahilgers@estec.esa.nl)

SEDAT is a project, funded by European Space Agency, which aims to develop a new approach to the engineering analysis of the spacecraft charged-particle environment. This project will (a) assemble a database containing a comprehensive set of data about that environment as measured in-situ by a number of missions and (b) develop an extensible set of engineering analysis software tools that can operate on data retrieved from the database. Thus the user will be able to select space environment data appropriate to the engineering problem under study and then apply appropriate tools. An important aspect of SEDAT is that the database and tools will be seamlessly integrated so that the tools can be applied within queries, i.e. the user can construct queries that operate on the values of engineering functions derived from database parameters (and not just on the values of database parameters). This approach differs from traditional space environment engineering studies. I n the latter the space environment is characterised by a model that is a synthesis of previous observations. However, in SEDAT the environment is characterised directly by the observations. The poster will discuss the potential advantages of this new approach and describe the current state of the SEDAT project.

WWW SERVICE FOR SPACE WEATHER FORECAST PROGRAM IN KOREA

Seok-HEE BAE , Hwang-Jae. Rhee and Yoo Surn Pyo (Radio Research Laboratory, 901 Hogye-2 dong, Dongahn-gu, Anyang, Kyunggi-do, 431-082, R.O.Korea, email: shbae@cc.rrl.go.kr) , Kyung Seok. Cho and Guenho Lee (Ichon Branch of Radio Research Laboratory, 370-9, Shinpil-li Sulseong-meon, Ichon, Kyunggi-do 467-880, R.O.Korea, email: kscho@cc.rrl.go.kr)

Radio Research Laboratory(RRL) has developed a space weather forecast program from 1994. The final goal of this program is to build up a realtime space warning system for space communication and satellite operation.
RRL have three ground observation systems to accomplish the goal: a solar radio spectrograph, geomagnetometers in three stations and an digital ionosonde. In addition, several researches have been performed for developing items as a part of space weather

forecast program. Until now, RRL had several project for this program. That is a developed operational S/W for solar radio spectrograph, which obtained the information of solar activity in a near real time. And several research make it possible to observe 210 degree geomagnetic field, to model a numerical scheme of the geomagnetic substorms. Others calculate a sun transit outage prediction for communication satellites and study the spacecraft charging effect due to the space plasma.
RRL is trying to make an effort to systemise the use of the research results and observation data through internet. The main service on our www website (URL; http://spaceweather.rrl.go.kr) is to provide the ground based observation data for space environment research in a real time. That includes the solar radio spectrograph, 3 component geomagnetic field, and ionogram with ionospheric basic parameters. And another service contains current research area and contents as well as the results of some researches mentioned above. Others service has estimated 10.7 cm solar flux, dst index and so on for space researchers and satellite operators. For the public use, the home pages provide a monthly prediction of radiowaves propagation, weekly warning of radiowaves propagation disturbance and prediction of sun transit outage. Simple and interest topics on basic knowledge about space science are also described for the education.

SERVICES PROVIDED BY THE OTTAWA REGIONAL WARNING CENTRE OF ISES

Richard COLES, Hing-Lan Lam, Karen Harding, and David Boteler (all at Geological Survey of Canada, Geomagnetic Laboratory, 7 Observatory Crescent, Ottawa K1A 0Y3, Canada, email: coles@geolab.nrcan.gc.ca)

The Ottawa Regional Warning Centre of the International Space Environment Service (ISES) operates several services that provide forecasts, warnings, and reviews of geomagnetic activity in the Canadian region. Long-term (up to 27 day) forecasts are issued at three-week intervals. Short-term (up to 48 hours) forecasts are issued every hour, and include magnetic storm warnings as appropriate. Reviews of recent past activity are incorporated into the hourly short-term bulletins. Forecasts and information on past activity are available via a variety of media, including World Wide Web, Internet ftp, fax, e-mail, mail and, for the short-term forecasts, a fully-automated voice service.

THE AUSTRALIAN SPACE FORECASTING CENTER (ASFC)

G. Patterson, R. Thompson, D. Cole, J. Kennewell, R. Luckhurst, P.WILKINSON (IPS Radio and Space Services, P O Box 1386, Haymarket, NSW 1240, AUSTRALIA)

IPS Radio and Space Services (IPS) is a Government Program within the Australian Commonwealth Department of Industry, Science and Resources. IPS supplies the Australian radio and space environment services for the Australian region of interest to customers operating in the fields of radio communications; land, sea and air transport; broadcasting; defence applications; spacecraft operations and geophysical exploration. Services are delivered in a variety of ways from normal postage to advice on the internet and cover a range of time scales from diagnostic climatology advice to real-time Web and e-mail based services. The immediate, and real-time services are distributed from the Australian Space Forecasting Center (ASFC). This is staffed during extended normal working hours and during weekends in the mornings. Advice offered by the ASFC is based on a range of data collected at IPS observatories as well as from overseas groups. As part of the International Space Environment Services (ISES), all these data are shared with other groups. The Australian observatories include two solar observatories at Learmonth and Culgoora and 15 ionospheric observatories spanning low to polar latitudes. Nine currently report real time observations. IPS has recently started collecting real-time geomagnetic data from four of these observatories.
The ASFC services are mainly supplied from links to the IPS Homepage http://www.ips.gov.au/. These services include real time maps of the local ionosphere as well as services based on the maps. There are also services based on the real time geomagnetic data to assist with aeromagnetic surveys and TEC advice based on local GPS observations. A special aspect of the services is that many are grouped under customer headings making ready access to key services easier.

SOLAR AND GEOMAGNETIC ACTIVITY DURING CYCLE 23

Richard THOMPSON (IPS Radio and Space Services, PO Box 1386, Haymarket, NSW 1240, Australia, email: Richard@ips.gov.au) and the Solar Cycle Prediction Panel

Predictions of solar and geomagnetic activity are crucial for the planning of satellite operations, especially for those in low earth orbit where atmospheric drag varies in response to activity on the sun. In 1996, and again in 1997 and 1998, a panel of international scientists met to review forecasts of solar and geomagnetic activity to be expected in Solar Cycle 23. The panel was organised by the US Space Environment Center under a contract from NASA. The panel examined the techniques used to predict the cycle and considered the many individual predictions. A consensus prediction was reached for a cycle of amplitude of 160 in sunspot number (with extremes of 130 and 190) and for time of maximum as April 2000 (with extremes of June 1999 and January 2001). This will make the cycle one of the largest on record and comparable to the last two solar cycles. The panel felt it unlikely that it would reach the amplitude of Cycle 19, the largest observed solar cycle. Examination of the early rise of Cycle 23 suggested that the date of solar minimum - the start of the cycle according to the traditional measure of the sunspot number (May 1996) - may not be a good guide. For this reason, the panel recommended that October 1996 be used as the "effective onset" of the cycle for all predictions requiring this information. The panel has made a prediction for the shape of Cycle 23 based on the average of recent cycles of similar amplitude. This profile is being used as the basis of a new service providing medium to long term predictions of smoothed sunspot number. A novel feature of the panel discussion was a prediction of geomagnetic activity to be expected over the cycle. Predictions were made using two techniques and, whilst they give different profiles, both indicate high levels during the years 1999-2004.

JSA06/E/05-A1 Poster 1227-17

SOME PARTICULARITIES OF GEOMAGNETIC ACTIVITY TIME SCALES STATISTICS

V.G.VASILYEVA, N.S.Zaretsky, (Institute of Cosmophysical Reseach and Aeronomy, 677891 Yakutsk, Russia, email: v.g.vasilyeva@sci.yakutia.ru)

Statistical characteristics of global and local disturbances with most intense and fast geomagnetic field oscillations are considered. This is 4-dimentional consideration. It seems like it is possible to get some more information due to fractallic features of taken statistics either in space and time. And we have been trying to analyse power-like significance of disturbance duration scale what principally was stated earlier in Matsubara's analogy. Since the fundamental feature E~T~1/t has been understood as interaction intensification principle of ionospheric currents behaviour we could say the space weather forecasting makes deal with high "temperature", in its common sense.
Confirmation of existence of certain resonance fractals in magnetosphere the experimental data of geomagnetic activity indices are discussed.

FORECASTING THE MAGNETOSPHERIC AND IONOSPHERIC OF ENERGETIC ELECTRON FLUXES

MINEEV,Yu.V. (Skobeltsyn Institute of Nuclear Physics, Moscow State University, Moscow 119899, Vorobjevy Gory, Russia. email: mineev@srdlan.npi.msu.su)

The connection between solar wind velocity variations and the dynamics of energetic electrons (E=0.03-3.0 MeV) in magnetosheath, magnetopause, outer and inner radiation belts is considered. For the data on satellites "Prognoz", "Molnia", "Raduga" and "Sampex" analytical dependencies for electron flux density J on the magnetosheath, magnetopause and outer radiation belt were obtained for the solar wind V(t): J(t+d)=a+bV(t),where t-time, d-delay time; a,b-coefficients, depending on position of satellites region of space. The equation has been obtained which takes into account parameters of the solar wind and determines time for energetic electron transfer from the magnetospheric boundaries to ionospheric altitudes. The obtained electron flux dependencies, including the maximal flux dependencies, from a value of the maximal velocity of the solar wind, may be used for short-time prognoses (about two-three days) of radiation condition and safety. This method is compared with other methods of space weather forecasting. A new system for the forecasting of radiation condition in near cosmic space is proposed. The scheme takes into account the above stated effect and other data, including geophysical one. The role of energetic electrons in processes of D-layer_s ionisation, in an origin of the winter anomaly and in other phenomena in thermosphere and middle atmosphere is discussed.

JSA06/E/06-A1 Poster 1231-19

NOWCASTING CONVECTION VELOCITIES IN THE HIGH-LATITUDE IONOSPHERE - A COMPARISON OF STATISTICAL CONVECTION MODELS

P. L. DYSON(1), M. L. Parkinson(1), P. R. Smith(1),(2), and R. J. Morris(3) (1)Department of Physics, La Trobe University, Victoria 3083, Australia (2)Department of Electronic Engineering, La Trobe University, Victoria 3083, Australia (3)Australian Antarctic Division, Kingston, Tasmania 7050, Australia.

The Weimer and IZMEM statistical convection models are driven with a time series of interplanetary magnetic field (IMF) measurements made onboard the Wind spacecraft. The model outputs are used to infer convection velocity at Casey, Antarctica (80.8S geomagnetic latitude), and then compared with measurements of Doppler velocity made using a Digisonde, and measurements of convection ìvelocityî made using a collocated magnetometer. During a single, representative campaign interval, Feb. 13-17, the Weimer model explained 10% (27%) of the variation in Doppler speed (direction) observed by the Digisonde, and 18% (14%) of the equivalent convection components observed by the magnetometer. This compares with IZMEM, which explained 8% (37%) of the variation in Doppler speed (direction) observed by the Digisonde, and 31% (34%) of the equivalent convection components observed by the magnetometer. In general, there was better agreement between convection direction than convection speed. The results of this study show that measurements of ionospheric velocity using different experimental techniques need heavy averaging to identify a common component of velocity controlled by the IMF vector.

JSA06/L/09-A1 Poster 1233-20

AN ADJOINT METHOD OF CALCULATION OF ENERGETIC SOLAR-PARTICLE-EVENT EFFECTS ON THE EARTH'S ATMOSPHERE

K. O'BRIEN (Northern Arizona University, Flagstaff, AZ 86011 USA), Herbert H. Sauer (CIRES, University of Colorado, Boulder, CO 80303, USA; NOAA Space Environment Center, Boulder, CO 80303, USA)

High energy solar particles, produced in association with solar flares and coronal mass ejections, occasionally bombard the earth's atmosphere, resulting in radiation intensities additional to the already-present cosmic-ray dose rates. Access of these particles to the earth's vicinity during times of geomagnetic disturbance are not adaquately described by using static geomagnetic field models. These solar fluxes are also often distributed non-uniformly in space, so that fluxes measured by satellites obtained at great distances from the earth and which sample large volumes of space around the earth cannot be used to predict fluxes locally at the earth's surface. We present here a method which uses the ground-level neutron monitor counting rates as adjoint sources of the flux in the atmosphere immediately above them to obtain solar-particle dose rates as a function of position over the earth's surface. We have applied this approach to the large September 29-30, 1989 event (GLE 42) to obtain the magnitude and distribution of the dose rates from an atypically large event. This approach could easily be adapted to the calculation of other atmospheric quantities of interest, such as ionization and energetic primary and secondary particle fluxes.

ON THE FORECASTING OF GREAT FLARE ENERGETIC PARTICLE EVENTS TO SAVE ELECTRONICS ON SPACECRAFTS

Lev DORMAN (IZMIRAN, Technion and Israel Cosmic Ray Center, affiliated to Tel Aviv University; Current address: P.O.Box 2217, Qazrin 12900, ISRAEL; email: lid@physics.technion.ac.il)

The problem of influence of solar flare energetic particles (FEP) on micro-electronics code on spacecrafts is very important. Especially dangerous are single event phenomena (SEP)[1] which can destroy computer memories; according to [1] in the periods of great energetic particle fluxes is necessary to switch off some part of electronics to protect computer memories from SEP. How to predict this period of time? In principle it can be made by using high energy particles which came from the Sun much more early than main part of middle energy particles caused dangerous situation for electronics. The flux of these high energy particles is very small and can not be measured with enough accuracy on spacecrafts, but are measured continuously by ground based neutron monitors and muon telescopes with very small statistical errors. These predictions can be made exactly by the International Cosmic Ray Service[2], which could be organized in near future on the basis of world-wide network of cosmic ray observatories. For prediction of dangerous FEP events it is necessary to have 1-minute or 5-minute on-line data at least from several neutron monitors and muon telescopes. It is important that the accuracy of prediction increases with increasing of FEP event dangerous level. [1] J. Barak et al.,1995. Annual Report, Israel Atomic Energy Comission. [2] L.I. Dorman et al., 1993. Astrophys. and Space Sci., Vol. 208, p. 55.

COSMIC RAY FORBUSH-DECREASE AS A SIGNATURE OF SPACE DANGEROUS PHENOMENON AND POSSIBLE USE OF COSMIC RAY DATA FOR ITS FORECASTING

Lev DORMAN (IZMIRAN, Technion and Israel Cosmic Ray Center, affiliated to Tel Aviv University; Current address: P.O.Box 2217, Qazrin 12900, ISRAEL; email: lid@physics.technion.ac.il), N. Iucci (Terza Universita di Roma, Dipartimento di Fisica "E. Amaldi", Via della Vasca Navale 84, 00146 Rome, Italy), G. Villoresi (IFSI/CNR-Frascati c/o Terza Universita di Roma, Dipartimento di Fisica "E. Amaldi", Via della Vasca Navale 84,00146 Rome, Italy)

We consider the influence of space dangerous phenomenon as strong interplanetary shock waves caused a great cosmic ray Forbush-decrease on satellite electronics, as well as on people health and technology at ground level. The problem of influence of great magnetic storms accompanied by cosmic ray Forbush-effects was developed deeply by many authors (see review in [1] and references therein). The prediction of this dangerous phenomenon can be done by using cosmic ray data on preincrease effect and on the change of 3D cosmic ray anisotropy. We show that this prediction can be done accurately in the frame of International Cosmic Ray Service (ICRS) [2], which could be organize in near future. For prediction of dangerous Forbush-decreases it is necessary to have 1-hour on-line data. [1] .N.G. Ptitsyna, G. Villoresi, L.I. Dorman, N. Iucci, M. I. Tyasto. 1998. NONSTATIONARY PROBLEM OF COSMIC RAY PREINCREASE EFFECT AND FORBUSH-DECREASE: AUTO-MODEL SOLUTION FOR FORECASTING USING

Lev DORMAN (IZMIRAN, Technion and Israel Cosmic Ray Center, affiliated to Tel Aviv University; Current address: P.O.Box 2217, Qazrin 12900, ISRAEL; email: lid@physics.technion.ac.il), N. Iucci (Terza Universita di Roma, Dipartimento di Fisica "E. Amaldi", Via della Vasca Navale 84, 00146 Rome, Italy), G. Villoresi (IFSI/CNR-Frascati c/o Terza Universita di Roma, Dipartimento di Fisica "E. Amaldi", Via della Vasca Navale 84, 00146 Rome, Italy)

On the basis of Fokker-Plank equation with a boundary condition on the moving boundary (shock wave) we investigate nonstationary problem described the cosmic ray (CR) behavior beefore the interplanetary shock wave (CR preincrease effect) and after (CR Forbush-decrease). For this aim we transform the initial equation of partial derivatives from three variables (time, distance from the Sun and particle rigidity) to the ordinary differential equation of the second order from one auto-model variable. We found analytic solution for the auto-model problem with moving boundary (with conditions of continuity of CR density and equality of CR fluxes from both sides of the moving boundary) and describe the developing in time of the CR preincrease effect and Forbush-decrease in dependence of the shock wave speed and solar wind speed as well as values of diffusion coefficients before and after shock wave. Obtain analytic solution of CR preincrease effect in comparison with observation data can be used for forecasting of powerful shock waves caused a strong geomagnetic storms accompanied by great Forbush effects.

SUICIDE RISK DEPENDENCE ON HELIOGEOPHYSICAL ACTIVITY

S.CHERNOUSS, V.Roldugin (Polar Geophysical institute, Apatity, 184200, Russia, email: SergeyChernouss@hotmail.com), E.Vlassova (the Kola Science Centre Hospital with Clinic, Apatity, 184200, Russia, email: Vlassova@vita.kolasc.net.ru), A.Ronkko (Labour Protection District of Lapland, FIN-941000 Kemi, Finland, email: Ahti.Ronkko@tsp.stm.vn.fi)

Statistical studies of suicides in Finland, from 1920 to 1996 in depending on heliogeophysical activity, is under consideration. Statistics relating to commission of suicide by males correlate with Wolf Numbers statistics of the Solar activity. Eleven year period is clearly distinguished in the suicide statistical data estimated by spectral and correlation analysis including MEM. It is shown that about 20% of male suicide commissions are connected with geliogeophysical disturbances. The problem of mechanism of the impact including cosmic rays, weather conditions and electromagnetic disturbances are discussed. Hypothesis of interference of the human brain alfa-rhythm and Schuman resonance frequencies could be acceptable explanation of the observed effect. Some indirect evidences of the situation are demonstrated.

SPACE WEATHER AFFECTS HUMAN BEINGS. EXPERIMENTAL CONFIRMATIONS.

DMITRIEVA I.V., Khabarova O.V., Obridko V.N., Ragoulskaia M.V., Reznikov A.E. (The Institute of Terrestrial Magnetism and Radio Waves Propagation. Troitsk, Moscow region, email: bella@izmiran.troitsk.ru)

The results of experiment for determination of influence of geomagnetic field disturbances on a human organism are considered. We used method of electropuncture diagnostics by R.Voll for this aim. T he method is based on measurement of conductivity in acupuncture points and is convenient by that allows to estimate deviations from the norm in functioning of various organs in same units. Local A-index is used as an indicator of geomagnetic field disturbance. The daily measurements of group (27 persons) have shown presence of a synchronous mass response of inspected people on magnetic storm. At first it is exhibited as sharp (within 3-4 hours) increase of conductivity of the all acupuncture points from normal values, that corresponds to a maximum of adaptational capabilities of an organism. And then - long duration (about 4 day) falling of conductivity that describes depression of all organs and systems of an organism. The reaction of adaptation on three magnetic storms of identical intensity going with an interval per week was registered for a half inspected people. It was found out, that the duration of depression phase and disbalance of an organism, intrinsic to this phase, depends extremely on a wholeness of an organism (that is on a power of ties between organs and co-ordination of their activity), but not on a type of disease.

PEOPLE UNDER CONDITION OF ELECTROMAGNETIC CONTAMINATION OF MODERN MEGACITIES.

Maria RAGOUSKAIA, Olga Khabarova and Vladimir Lubimov (all at The Institute of Terrestrial Magnetism, Ionosphere and Radiowaves Propagation, 142092, Moscow region, Troitsk, Russia; email: MARY.L@izmiran.troitsk.ru), Yuri Gurfinkel (Central Clinical Hospital of Russia, 105203 Moscow, Russia)

The influence of space weather and high level of ambient electromagnetic noise of the modern megacities on a human health condition is considered. The method of electropuncture diagnostics based on measurement of electrical conductivity in acupunctural points (AP) of skin is used for this aim. The daily measurements of electrical conductivity of 22 AP of constant group inspected (30 persons) are carried out simultaneously in centre of Moscow and in 20 kms from Moscow since March 1998. The obtained data are compared with data of eomagnetic field disturbance level, atmospheric pressure, temperature, humidity and ambient noise. It was found out, ambient electromagnetic noise influences an average level of the indications, characteristic of each inspected, due to downturn of conductivity values for a long time (months) rather genetically established level. As result there are the reduction of immunity, increased tiredness and irritability of the large cities inhabitants. The people that engage intellectual activity and chiefs of collectives as a rule easier adapt for conditions of the modern megacities. The response on electromagnetic disturbance of technical nature that close to intensity and frequency band of geomagnetic storms is similar to a response on magnetic storms of a natural origin. At first it is exhibited as sharp (within 3-4 hours) increase of conductivity of the all AP from normal values, that corresponds to a maximum of adaptational capabilities of an organism. And then – long duration (about 4 day) falling of conductivity that describes depression of all organs and systems of an organism.

A PREDICTION METHOD OF GEOMAGNETIC DISTURBANCES BASED ON IPS OBSERVATIONS DYNAMICS FUZZY MATHEMATICS

F. XUESHANG

A prediction method for geomagnetic disturbances, based on a combined approach of interplanetary scintillation (IPS) observations, dynamics of disturbance propagation and fuzzy mathematics, is suggested. Prediction test for 37 geomagnetic disturbance events caused by the solar storm-associated interplanetary disturbances, which could be identified by IPS observations during the period of 1984-1985, are made based on the membership functions established by using observational data on the solar storm, interplanetary and geomagnetic disturbances in 1966-1982.

MAGNETOTAIL ANALYSIS DURING GEOMAGNETIC PERTURBATIONS

V. M. SILBERGLEIT

The auroral AE and the equatorial Dst indices with 1 minute time resolution were analized during three moderate geomagnetic storms. Different substorms periods are identified.

The distant Earth's magnetotail, using data from Geotail spacecraft are also studied. The existence of a Bz bipolar signature (a North then South turning of the magnetic field) and a pressure enhancement are observed. Those criteria indicate the existence of plasmoid events. In some cases, the plamosids appeared as multiple events, perhaps due to multiple onset substorms. The geomagnetic indices show changes some minutes before magnetotail events.

GEOMAGNETIC FORECASTING - STATE OF THE ART

BALCH, C (Space Environment Center, 325 Broadway, Boulder, CO 80303 USA. email:cbalch@sec.noaa.gov)

The prediction of geomagnetic conditions is an important part of the mission of the U.S. Space Weather Operations Center (SWO) in Boulder, Colorado. Geomagnetic activity is specified by means of the summary indices Kp and Ap (or real- time estimates thereof), and by probabilities for particular ranges of these indices (e.g. 'active', 'minor storm', and 'major storm' levels). These forecasts are based on available, timely observations of the Sun, the solar wind, and the magnetosphere. Solar observations include white-light, Helium 10830, and Hydrogen-Alpha images, x-ray images from Yohkoh/SXT. Images from SOHO were also quite useful when they were available. Solar wind conditions are monitored using real-time solar wind data from the ACE spacecraft. Magnetospheric conditions are evaluated primarily by means of a network of ground-based magnetometers.
Geomagnetic predictions produced by SWO consist of three types: daily forecasts, watches, and warnings. Daily forecasts and watches are predictions with lead times in excess of an hour; these products are necessarily restricted to inputs from observations of solar activity. Short term warnings, which can have a lead time of up to about forty minutes, are based on two additional inputs: 1) real-time solar wind measurements from the ACE spacecraft, and 2) an assessment of the current state of the magnetosphere.
In this talk I will give an overview of the observations and models that are available to the forecasters and I will discuss the various approaches used to synthesise the information into predictions. I will also review verification results as a means of measuring the success of current predictive techniques. Lastly I will identify what I perceive to be the key areas where significant progress can be made to advance the state of the art.

JSA06/W/20-A1 Invited **1420**

INTERPLANETARY MAGNETIC FLUX ROPES AS A TOOL FOR PREDICTING MAGNETIC STORMS

Katsuhide MARUBASHI (Communications Research Laboratory, Koganei, Tokyo 184-8795, Japan, email: kmaru@crl.go.jp)

It has become increasing evident that the coronal mass ejection (CME) produces the interplanetary magnetic flux rope (henceforth called flux rope for simplicity). Flux ropes sometimes carry strong southward magnetic fields in the solar wind, and cause intense magnetic storms. In this sense, the flux rope is literally a tie to connect CMEs on the Sun and magnetic storms on the Earth.
When a flux rope encounters the Earth's magnetosphere, the variation of interplanetary magnetic field (IMF) is determined by many conditions. They include (1) the field intensity; (2) the size and orientation of the flux rope; (3) the bulk speed and expansion of the flux rope; (4) and which part of the structure passed the magnetosphere. The ability to forecast magnetic storms based on the physics of flux ropes depends on how such conditions can be predicted based on solar observations. We review our present knowledge of flux ropes and examine the possibility of forecasting magnetic storms based on the flux rope model. It is seen that we have enough evidence for the fundamental relationship between the magnetic structures of flux ropes and large-scale magnetic fields in the solar source regions of CMEs. We have to admit, however, that more precise knowledge about the propagation of flux ropes is needed in order to predict magnetic storms. An attempt is made to estimate how our present knowledge of flux ropes can assist forecasting magnetic storms.

JSA06/W/23-A1 1440

FORECASTING HIGH LATITUDE SPACE WEATHER SOLELY FROM THE IMF/SW DATA

Vladimir PAPITASHVILI (Space Physics Research Laboratory, University of Michigan, Ann Arbor, MI 48109, USA, email: papita@umich.edu), Yohsuke Kamide (Solar-Terrestrial Environment Laboratory, Nagoya University, Honohara 3-13, Toyokawa, Aichi 442, Japan,
email: kamide@stelab.nagoya-u.ac.jp), Federica Marcucci (CNR- Instituto Fisica dello Spazio Interplanetario, Tor Vergata, Via Fosso del Cavaliere 100, Roma 00133, Italy,
email: federica@sunserv.ifsi.rm.cnr.it)

The World Wide Web access to existing science-based models of the solar wind-magnetosphere-ionosphere interaction facilitates their usability for a variety of space weather applications. The Linear Model of Ionospheric Electrodynamics (LiMIE, http://www.sprl.umich.edu/MIST) utilises the IMF/SW data measured at L1 point by the NASAís spacecraft ACE. The input data are available from the NOAA Space Environment Center http://sec.noaa.gov/ace/ACErtsw_home.html) in near-real time. The LiMIE specifies and then forecasts for ~1 hour ahead the ionospheric convection and field-aligned current distributions over both the Northern and Southern polar regions. The "snap-shot" maps are plotted in geographic co-ordinates or as the CGM Lat. - MLT polar dials. Other parameters (e.g., ion convection velocities, electric and magnetic fields, ionospheric currents, Joule heating and ground-induced current distributions) can also be plotted and statistical location of the auroral electrojets and pseudo-AE index can be estimated. The latter is important for electric and pipeline companies in northern Russia, Scandinavia, Canada, and United States. Forecasted ionospheric parameters over the Antarctic continent could be utilised for lanning of scientific experiments and for estimating the radio wave propagation conditions. The LiMIE is made accessible also from the Solar-Terrestrial Environment Laboratory (http://stesun8.stelab.nagoya-u.ac.jp) and from the AGONET Data Analysis Facility (http://sunserv.ifsi.rm.cnr.it/~adaf).

JSA06/W/01-A1 1500

A COMPARISON OF SOLAR WIND PLASMA AND MAGNETIC FIELD CORRELATIONS

K. I. PAULARENA, J. D. Richardson, (M.I.T., Center for Space Research, Cambridge, MA, USA, 02139, email: kip@space.mit.edu),G. N. Zastenker and P. A. Dalin (both at Space Research Institute, Russian Academy of Sciences, Moscow, Russia, email: gzastenk@iki.rssi.ru).

Recent work examining the degree of correlation between 6-hour periods of solar wind plasma data measured by different spacecraft (IMP 8, WIND, INTERBALL-1, and ISEE-3) has shown that the level of correlation can vary from good ($r > 0.8$) to quite poor ($r < 0.1$). The degree of correlation is fairly strongly related to the standard deviation of density during the 6- pour period, and somewhat to the distance between the spacecraft along the Sun-Earth line. For distances larger than 220 Earth radii there is a steep fall-off in the average correlation from that observed with smaller inter-spacecraft separations. Nevertheless, at all separations there are times of good and times of poor correlation, implying that the scale of solar wind plasma homogeneity is quite variable. In an effort to understand what really drives the degree of correlation seen, a comparison is made between the observed interplanetary magnetic field (IMF) and plasma correlation. Results using a limited set of data (133 periods) from the WIND and INTERBALL-1 spacecraft show that good plasma correlation are observed 65% of the time that IMF correlation are good, while good IMF correlation are seen during only 44% of good plasma correlation periods. This result is particularly surprising since it was expected that all or almost all periods with good IMF correlation would also show good plasma correlation. Therefore, this study has been extended to a larger data set to provide more statistically robust comparisons and to examine whether other factors affect these results.

JSA06/W/08-A1 1520

OPERATING AN AUTOMATED FORECASTING SERVICE - WHAT ARE THE PITFALLS?

Richard COLES (Geological Survey of Canada, Geomagnetic Laboratory, 7 Observatory Crescent, Ottawa K1A 0Y3, Canada, email: coles@geolab.nrcan.gc.ca)

In principle, an automated service of any kind has the promise of great efficiency and little human intervention. However, there are pitfalls. Canada has operated an automated magnetic forecasting and magnetic storm warning service since mid-1995. The Canadian service is committed to providing forecasts that are updated hourly every day of the year. To maintain such a service requires considerable effort, ingenuity, and expense. Any or all of the data streams (such as geomagnetic, solar wind, or solar) used by the forecasting process may fail or be interrupted. The forecasting process must be robust so that updates will continue to be issued. Backup systems or alternate paths for all stages in the process, including data telemetry and the provision of electrical power, are necessary. Current practice and future enhancements are presented.

JSA06/W/09-A1 Invited 1600

PROTON FLUENCE MODEL JPL1991: A REVEIW

Joan FEYNMAN (Jet Propulsion Laboratory, California Institute of Technology, 4800 Oak Grove Dr., Pasadena, CA 91109, USA, email: aruzmaikin@jplsp.jpl.nasa.gov)

The development of new technologies and the minimisation of sensors bring new requirements for our ability to predict and forecast hazardous space weather conditions. Of particular importance are protons of energies > 1 MeV which cause single event effects, displacement and ionization damage, and pose a hazard to biological systems in space and to personnel in polar orbit. Sporadic high energy solar particle events are a main contributor to the fluences and fluxes of such protons. A statistical model, JPL 1991, developed for use in spacecraft design is now widely used in the community. I will review the model and its use, including extensions to high energies higher than 60 MeV. Predictions of the model will be compared to observations of solar particle events that have occurred since model development.

JSA06/E/07-A1 Invited 1620

RADIATION BELT MODELLING IN THE FRAMEWORK OF SPACE WEATHER EFFECTS AND FORECASTING

D. HEYNDERICKX and M. Kruglanski (BIRA/IASB, Brussels, Belgium)

The Earth's trapped radiation belts were discovered at the beginning of the space age and were immediately recognised as a considerable hazard to space missions. Consequently, considerable effort was invested in building models of the trapped proton and electron populations, culminating in the NASA AP-8 and AE-8 models that have been de facto standards since the seventies. The CRRES mission has demonstrated that the trapped radiation environment is much more complex than the static environment described by the old models. Spatial and especially temporal variations were shown to be much more important than previously thought, and to require more complex models than those in use at that time. Such models are now becoming available, but they are as yet limited in spatial and temporal coverage. It is vital to co-ordinate future modelling efforts in order to develop new standard models. An overview of existing radiation belt models and future developments is presented.

JSA06/W/02-A1 1640

STORM-ASSOCIATED ELECTRON FLUX CHANGES IN THE OUTER RADIATION BELT

Takahiro OBARA (Hiraiso Solar Terrestrial Res. Ctr., 3601, Isozaki, Hitachinaka, Ibaraki, 311-1102 Japan, email: T.Obara@crl.go.jp)

To forecast a relativistic electron flux in the outer radiation belt is one of the important aspects from the Space Weather point of view. Once a magnetic storm takes place, the relativistic electron flux decreases at the Geostationary orbit. This reduction is found to be a sudden earthward shift of the relativistic particles due to an increased electric field. It was also found that in case of major storms the outer radiation belt disappears entirely. After a disappearance of the relativistic electrons which can last as much as one day, an increase in the flux occurs in low L-shells (3-4) which propagates to higher L shells. There is a systematic tendency in the energy spectrum from 300 keV to 2.5 MeV; i.e. both decay and growth are severer for higher energy and a time delay of the recover is apparent for higher energy, suggesting some acceleration processes take place within the radiation belt. The increase sometimes exceeds the pre-storm levels. Investigation has been made on the correlation of the electron flux increase and the IMF Bz polarity together with AL index during the storm recovery phase. Result demonstrates that a larger flux enhancement occurred when the IMF was southward and AL index was quite large. Source particles are effectively supplied due to the southward IMF together with high magnetic activity, and they further are accelerated up to MeV range by some processes within the outer radiation belt. One candidate is a wave-particle interaction there.

JSA06/W/14-A1 1700

SCOSTEP SPACE WEATHER WORKING GROUP AND SPACE WEATHER INFORMATION

HANNU KOSKINEN (Finnish Meteorological Institute, Geophysical Research, P.O.Box 503, FIN-00101 Helsinki, Finland, email: Hannu.Koskinen@fmi.fi, also at University of Helsinki), David Boteler (Geological Survey of Canada, Ottawa, Canada), Jih Kwin Chao (National Central University, Chung Li, Taiwan), Janet Kozyra (University of Michigan, Ann Arbor, Michigan, USA), Rainer Schwenn (Max-Planck- Institute fur Aeronomie, Katlenburg-Lindau, Germany), Howard Singer (NOAA Space Environment Center, Boulder, Colorado, USA), Takashi Tanaka (Communications Research Laboratory, Tokyo, Japan), Oleg Troshichev (Arctic and Antarctic Research Institute, St. Petersburg, Russia), Phil Wilkinson (IPS Radio and Space Services, Haymarket, NSW, Australia)

During the 1997 IAGA meeting in Uppsala the Scientific Committee on Solar-Terrestrial Physics (SCOSTEP) decided to form a working group on space weather under the SRAMP program. In the acronym SRAMP, R stands for Results, A for Applications, and M for Modelling. In the present rapid growth of space weather the results of solar-terrestrial physics form the scientific basis, applications are a central goal, and major efforts are put into further development of models. The space weather working group has taken information spreading as the central theme of its mission. While there is much information around, it is often scattered and relevant information may be difficult to find. This applies to the whole information chain, including availability of data and up-to-date models, schedules of various observation facilities, joint observation or data analysis efforts, etc. The first tasks of the working group have been to create a www server that contains updated information on the major space weather campaigns and is linked to space weather servers world-wide and promote a Space Weather Month for the autumn of 1999, (for more information, see http://aoss.engin.umich.edu/intl_space_weather/sramp/).

JSA06/W/22-A2 0930

SPACE WEATHER IMPACT ON HUMAN HEALTH IN THE NORTH

S.CHERNOUSS, M.Kuznetsova (Polar Geophysical institute, Apatity, 184200 Russia, email: SergeyChernouss@hotmail.com), Yu.Fedorenko (Institute of the North Ecological Problem, Apatity, 184200 Russia, email: yura@ifjf.uib.no), E.Vlassova (The Kola Science Centre Hospital and Clinic, Apatity, 184200 Russia, email: Vlassova@vita.kolasc.net.ru)

The Report consists of two parts. The first one is a review of famous results that show negative impact of magnetic disturbances and Solar activity factors on human health. The second one describes new approach to the problem of the heliogeophysical factors impact on human health. It is based on simultaneous measurements of geophysical and human organism parameters at Kola peninsula in the Polar Geophysical institute. It would be possible to remark that studies of heliogeophysical attack on human body was studied occasionally at the West, meanwhile the heliobiology took an advantage since 30-s after Chizhevsky works in Russia. The most of published before results on the problem are based on hardship events. Cardiac diseases statistics give us undoubted evidences of geomagnetic storm influence on human health. Statistics of myocardial infarction also confirm strong influence of geomagnetic storms on human health. It was pointed out that the strongest impact on human health is observed at the North where auroral and magnetic disturbances are permanent. In this work we try to base the method of measurements of some parameters characterizing adaptation function of human being to compare those data with geomagnetic disturbances i.e. to avoid any diseases, myocartial infarction and other hard events in the studies. The report consist of description of ideology, methods and equipment to measure the response of human being to some outdoor factors first of all heliogeophysical disturbances, weather and environment conditions. The main idea is to obtain information about adaptation function of human being by real time measurements of heart rate variation parameters. We have used for that purpose cardiac rhythmology method originally was proposed by R.Baevsky in 60-s to check health of Russian astronavts on board of the Salute space vehicle. The local centre of cardiac measurements.

JSA06/W/05-A2 0950

SPECIFICATION AND FORECASTING OF OUTAGES IN COMMUNICATION AND NAVIGATION SYSTEMS

SANTIMAY BASU and Keith M. Groves (Air Force Research Laboratory, VSBI, 29 Randolph Road, Hanscom AFB, MA 01731, U.S.A., email: santimay@aol.com) Sunanda Basu (National Science Foundation, Atmospheric Sciences Division, 4201 Wilson Boulevard, VA 22230, U.S.A., email: sbasu@nsf.gov)

The upper atmosphere above 100 km, called the ionosphere, is ionized and often becomes turbulent and develops electron density irregularities. These irregularities scatter radio waves to cause amplitude and phase scintillation and affect satellite communication and GPS

navigation systems. The effects are most intense in the equatorial region, moderate at high latitudes and minimum at middle latitudes. The thermosphere and the ionosphere internally control the generation of irregularities in the equatorial region and its forcing by solar transients is an additional modulating factor. On the other hand, the irregularity generation mechanism at high latitudes is driven by the magnetosphere and, therefore, high latitude scintillation can be tracked by following the trail of energy from the sun. The development of a global specification and forecast system for scintillation is needed in view of our increased reliance on space based communication and navigation systems, which are vulnerable to ionospheric scintillation. Such a system, called the Scintillation Network Decision Aid (SCINDA), has been developed for the South American sector. An international space weather initiative has been launched by SCOSTEP under the aegis of the S-RAMP group. It is hoped that during the proposed global campaign in September 1999, scintillation measurements will be performed at high and low latitudes and will contribute towards the development of a global scintillation specification and forecast system.

SHORT-TERM IONOSPHERIC AND TOTAL ELECTRON CONTENT FORECASTING OVER EUROPE

L.R. CANDER, M.F. Levy and M.I. Dick (CRLC Rutherford Appleton Laboratory Chilton, Didcot, Oxon OX11 0QX, UK, email: l.cander@rl.ac.uk), P. Muhtarov and I. Kutiev (Geophysical institute, Sofia, Bulgaria, email: ikutiev@geophys.bas.bg), S.M. Radicella and B. Nava (ICTP Abdus Salam, Trieste, Italy, email: rsandro@ictp.trieste.it) , R. Leitinger (University of Graz, Graz, Austria, email: leitinger@bkfug.kfunigraz.ac.at)

HF communications and GPS services can greatly benefit from accurate forecasts of ionospheric parameters (foF2, MUF(3000)F2 and FOT) and Total Electron Content (TEC) values in real-time mode. We describe an operational short-term forecasting tool for the European region based on continuous monitoring of the ionosphere. It is available on the World Wide Web for interactive use, at http://www.rcru.rl.ac.uk/iono/maps.htm. At any time, users may select a forecast map for 0 to 23 hours ahead, or browse through the archive of retrospective measurement maps. This paper outlines the basic principles of STIF (Short-Term Ionospheric Forecasting) and a technique to produce on-line forecast maps of vertical TEC over European region (100 W - 900 E, 300 - 700 N) and describes some of the on-line facilities. Statistical comparisons of maps obtained from forecast and measured values are discussed. European network of 23 ionospheric stations provide data every day as input parameters to an autoregressive extrapolation of foF2 and MUF(3000)F2 time series for each ionospheric station in the network. Kriging interpolation is used to get gridded values. TEC is obtained from a profiler based on a modified Di Giovanni - Radicella (DGR) model that has 5 semi-Epstein layers and uses ionospheric characteristics foE, foF1, foF2 and MUF3000(F2) as inputs. TEC maps are calculated with the last two characteristics given by STIF and simplified models for foF1 and foE values. The profiler has been adapted from the NeQuick model developed with ESA-ESTEC support.

INVESTIGATION AND FORECAST OF SPACE WEATHER EFFECTS ON SPACECRAFT SYSTEMS

Yury ROMANOVSKY and Sergey Tasenko (both at Fedorov Institute of Applied Geophysics, Rostokinskaya 9, Moscow, 129128, Russia, email: hciag@sunny.aha.ru)

Method to investigate Space Weather (SW) effects on geostationary (GEO) and low Earth orbit (LEO) spacecrafts is developed. This method was applied to clarify SW effects on malfunctions and failures of <Electro> GEO satellite systems. Database on LEO spacecraft failures for period 1981- 1995 years is prepared. It is revealed that for this time interval about 20% of failures could be raised by SW effects. Codes and operational (short-term) prognostic models are developed for prediction of possible SW effects on LEO and GEO spacecrafts with usage of real time information on SW parameters. On the base of this prediction recommendations and proposals on spacecraft control are being formulated using artificial intelligence methods.

FUTURE RADIATION DAMAGE IN SPACE DUE TO THE SOUTH ATLANTIC ANOMALY

J.R.HEIRTZLER (NASA Goddard Space Flight Center, Greenbelt, MD 20771, USA, email: jamesh@ltpmail.gsfc.nasa.gov)

Predictions of radiation damage for Low Earth Orbit (LEO) satellites now use semi-empirical models developed from prior satellite data. From these models it is clear that the low field strength of the South Atlantic Anomaly (SAA) controls where the maximum radiation damage occurs. One may make an estimate of future radiation damage to LEO spacecraft if one can predict the future of the SAA.
Although reliable maps of the geomagnetic field strength and its secular change have only been made in the last few decades, certain geomagnetic observatories in South America and Africa have recorded the geomagnetic field for a much longer time. These observatories show that the present geomagnetic field change has persisted for more than 100 years. In spite of the fact that a few observatories have shown sudden changes in secular variation, those around the SAA have shown a stable secular variation. Assuming that this will continue for the next 50 to 100 years one can show that the SAA will expand to cover most of the South Atlantic Ocean and will become much weaker. This will greatly intensify the radiation hazard in LEO, put significant new limitations on radiation-hardened hardware, severely restrict the length of time that humans can remain in orbit, and materially change the configuration of the radiation belts.

APPLICATION OF AI TO SPACE WEATHER FORECASTING

LUNDSTEDT, H (Swedish Institute of Space Physics, Space Weather and AI Division, Scheelevagen 17SE-223 70 Lund, Sweden. email: hlundstedt@solar.stanford.edu or Henrik@astro.lu.se)

Intelligent hybrid sytems (IHSs) represent not only the combination of different artificial intelligence techniques (neural networks, expert systems, fuzzy systems, genetic algorithms), but also the integration of intelligent techniques with mathematical and conventional statistical methods. Many of the physical processes, which cause the space weather, are complex, non-linear, highly dynamic and chaotic. The IHSs are therefore well suited for predicting and modelling the space weather.
The Lund Space Weather Model (LSWM) is based on such an intelligent hybrid system. The hybrid system predicts the space weather on time-scales from minutes to months. Real-time solar wind data from ACE has made real-time predictions possible. Several examples will be shown.
The goal of the LSWM is not only to predict the space weather conditions and the effects on power systems, satellites, radio propagation conditions and avionics, but also to explain the predictions and effects. For that a close collaboration with the user and industry is needed.
The review will also include AI applications to space weather forecasting developed by other groups.

JSA06/W/30-A2 **1150**

AUTOPREDICTION OF DST INDEX USING THE NEURAL NETWORKS AND THIER RELATIONSHIP WITH THE AURORAL ELECTROJET AND POLAR CAP INDICES

Marina STEPANOVA and P. Perez (Universidad de Santiago de Chile, Ecuador 3493, Casilla 307, Santiago, Chile, email: mstepano@lauca.usach.cl, pperez@lauca.usach.cl)

The possibility of prediction of Dst variations using previous Dst values has been studied using a feedforward multi-layer perceptron. It was found that the Dst index can be auto-predicted well a few hours ahead. Both main and recovery phases of geomagnetic storms are accurately predicted up to 3 hours in advance. But, for more advanced predictions, a time shift between observed and predicted Dst minima is observed. The use of auroral electrojet indices as input has shown that there exists a slight relationship between these indices and Dst 1 at least one hour ahead. Weak and moderate geomagnetic storms are predicted well, but the predicted Dst values for more intense storms are less negative than observed minima, which may be related to the known saturation of auroral electrojet indices due to intense storm development. Prediction based on the PC index shows better correlation with Dst. Although the amplitude of Dst variation is not reproduced correctly, there is no time shift between measured and predicted location of Dst minima.

JSA06/W/24-A2 **1210**

ADVANCES IN RING CURRENT INDEX FORECASTING

PAUL O'BRIEN, (IGPP/UCLA, Los Angeles, CA 90095-1567, USA, email: tpoiii@igpp.ucla.edu)
Robert McPherron, (IGPP/UCLA, Los Angeles, CA 90095-1567, USA,
email: rmcpherron@igpp.ucla.edu)

The Ring Current is the largest global feature of a geomagnetic storm. The Dst Index measures its intensity and is used as an input to many models of geomagnetic activity. In order to use such models in real time, it is necessary to have Dst in real time. However, official Dst data are typically 30 days behind real time. At present, the Kyoto World Data Center provides the most up to date Dst proxies, which are typically 12 to 24 hours behind real time. Using ACE Real-Time Solar Wind data and a modification of the well-known Burton Equation, we are able to advance Dst from the twelve-hour lag of Kyoto to an actual one-hour forecast. The primary modification of the Burton Equation consists of a solar wind parameterization of the decay time. Performance measures are provided for the operational Dst forecast. Improvement over existing models is indicated by typical skill scores of 30% to 50% for individual storms.

JSA06/W/26-A2 **1230**

MONITORING OF SPACE WEATHER WITH QUICK LOOK AE AND DST INDICES

Toyohisa KAMEI and Tohru Araki (WDC-C2 for Geomagnetism, Graduate School of Science, Kyoto University, Sakyo-ku, Kyoto 606-8502, Japan, email: toyo@kugi.kyoto-u.ac.jp), Masahisa Sugiura (Research Institute of Science and Technology, Tokai University, 2-28 Tomigaya, Shibuya-ku, Tokyo 151-0063, Japan, email: sugiura@jspan.kugi.kyoto-u.ac.jp).

Responding to the growing demands for quicker availability of the Dst index, we have begun derivation of a Near Real-time (QL-) Dst index. This index has been available on the WWW page of WDC-C2 for Geomagnetism Kyoto (URL http://swdcdb.kugi.kyoto-u.ac.jp) since October 1996. Through this page, the provisional Dst index and the Final Dst Index, to the extent that they are available, can also be accessed. Strong demands exist also for quicker derivation of the Auroral Electrojet (AE) indices. We are currently deriving Near Real-time (QL-) AE indices with eight of the twelve standard AE stations but with future plans on increasing the number of stations used for the derivation of these indices. However, regarding this program, we are facing serious problems with some of the stations. For instance, Cape Wellen, a Russian station, has been closed. Beginning January 1997, plots of the QL-AE indices are accessible through the same WWW page as the Dst index. These indices are updated frequently, with time delays typically from 3 hours to 3 days. Users are advised to use these QL indices for diagnostic purposes only, because the data used for the derivation of these quick-look indices are not adequately quality controlled. In particular, activity in QL-AE may often be underestimated due to insufficient station coverage. We recommend that for scientific analyses, the final Dst index which is usually published yearly with typically a 1.5 year delay, or the provisional Dst index which is normally made available within two months of the observation be used. Provisional AE indices have been published through 1994, and these data are accessible also through our WWW page.

ONE HUNDRED YEARS OF RESEARCH IN SEISMIC ANISOTROPY

Klaus HELBIG, Kiebitzrain 84, 30657 Hannover, Germany, e-mail: helbig@real-net.de, and Edward Szaraniec, Cracow University of Technology, ul. Warszawska 24, 31-155 Krakow, Poland, e-mail: edszar@usk.pk.edu.pl

The quest for geophysical knowledge is as old as mankind, but the first Geophysical Institute with a "Professor of Geophysics" as director was created as recently as November 1 1895,

when the Austrian Minister of Religion and Education appointed Maurycy Pius Rudzki as Distinguished Professor of Mathematical Geophysics and Meteorology to the newly established chair at the Philosophical Faculty of the Jagiellonian University of Cracow. Rudzki was 33 years old and had published 30 articles on a wide variety of subjects in mathematics, physics, geophysics, and geology.
Elastic anisotropy goes back at least to 1856, when William Thomson wrote his landmark paper, if not to 1837 and the treatises of Hamilton and McCullagh on optical rays in the (elastic) ether. Seismic anisotropy has started with Rudzki, who was interested in seismic wave types and in focal depths, both under the aspect of anisotropy of crust and mantle. The first publication we know is from 1898: "On the shape of elastic waves in rocks". The subject of this and several following articles is the description of the wave surface as a model for wavefronts in anisotropic media due to a point source (instead of the slowness surface). It took until 1911 until Rudzki solved the problem. In the absence of data, he assumed that the mantle had the properties of beryl (the five elastic constants were known by then). To construct the wave surface, he developed a parameter representation that is still in use today. In the course of his work he found what is known as the "fundamental inequality", and he was the first to point out that elastic waves in transversely isotropic media could have cusps, and thus there could be five direct arrivals at a single observation point.

JSS07/E/02-A2 1005

ANISOTROPIC PORO-ELASTICITY (APE): A NEW UNDERSTANDING OF PRE - FRACTURING DEFORMATION IN CRUST AND MANTLE

Stuart CRAMPIN (Department of Geology & Geophysics, University of Edinburgh, Edinburgh EH9 3JW, UK; email: scrampin@ed.ac.uk)

The fluid-saturated grain-boundary cracks and low aspect-ratio pores in almost all sedimentary, igneous, and metamorphic rocks in the Earth's crust are aligned by deviatoric stress. Sensitive to crack anisotropy, seismic shear-wave splitting polarised in the direction of maximum horizontal stress is seen in almost all rocks, with similar characteristics below about 1km-depth. The evolution of such microcracked rock can be modelled by anisotropic pore-elasticity (APE) where the driving force is fluid migration between neighbouring microcracks at different orientations to the stress field. APE modelling is tightly constrained yet matches a wide range of static and dynamic behaviour of shear-waves and cracks observed over several orders of magnitude in dimensions and frequencies, including the observed minimum of 1.5% and maximum of 4.5% shear-wave velocity-anisotropy of rocks in the crust. This means that pre-fracturing deformation of fluid-saturated crustal rock can be accurately modelled and the response to known changes calculated. (The success of the modelling is due to the critical non-linear behaviour of cracks in the crust which are always close to fracture criticality and fracturing.) The presence of water in mantle rocks is also well-established. In particular, small percentages of water lower the melting point of mantle rock so that pressure gradients in films of liquid melt are the preferred mechanisms for the turn-over in mantle convection currents. The mechanism for APE, flow of melt along pressure gradients between cracks at different orientations to the stress field, is a much more powerful mechanism than crystalline rotation. As a consequence, APE modelling applies to the upper mantle as well as to deformation of crustal rocks. The similar modelling explains the remarkable similarities between crustal and mantle shear-wave velocity anisotropy: approximately the same minimum velocity anisotropy, approximately the same maximum anisotropy and the same stress-aligned polarizations. These would not be expected for crystal-based anisotropy. The implications of APE-modelled upper mantle anisotropy is that shear-wave splitting is the result of current not paleo-stress effects.

JSS07/E/09-A2 1025

CRUSTAL FRACTURE ANISOTROPY REVEALED AT THE TRENCH OUTER WALLS

Kazuo KOBAYASHI (Japan Marine Science and Technology Center, 2-15 Natsushima, Yokosuka 237-0061 Japan, email: kobayashik@jamstec.go.jp) and Masao Nakanishi (Ocean Resaeach Institute, University of Tokyo, 1-15-1 Minamidai, Nakano 164-8639 Japan, email: nakanisi@ori.u-tokyo.ac.jp)

Mechanical anisotropy of the oceanic crust is manifested at the outer walls of the deep-sea trenches at which normal faults are formed under horizontal extensional force due to bending of the oceanic plate. We have examined its bathymetric evidence in the northwestern margin of the Pacific Ocean composed of a Pacific plate with magnetic lineaments trending in a direction of N70E. It is subducted along the Kuril, Japan, Izu-Bonin (Ogasawara) and Mariana Trenches, each having different trend of axis. At the western Kuril Trench with the trench axis trending N60E, a number of faulted_$B!!_(Bescarpments parallel to the magnetic lineaments (type 1) are identified. At the Japan and Mariana Trenches trending in directions quite oblique to the magnetic lineations, majority of faulted scarps are parallel to the trench axis (type 2). At rhe Izu-Bonin Trench trending nearly perpendicular to the magnetic fabrics the outer trench walls consist of faulted escarpments with two proximate directions, one perpendicular to the magnetic lineations (type 3) and the other parallel to the trench axis (type 2). Type 3 scarps appear to be rejuvenated non-transform offsets. Observed results seem to indicate that a direction of magnetic lineations is the weakest, the offset direction is the second weakest and directions quite oblique to them are the hardest for fault generation.

JSS07/P/01-A2 1105

THE FORWARD PROCEDURE OF CRUST ANISOTROPY FOR INTEGRATING RESEARCH BY SEISMIC WAVES AND ELECTRIC CONDUCTIVITY

LI Qinghe & Ruan Aiguo (Lanzhou Institute of Seismology, China Seismological Bureau, Lanzhou, Gansu, 730000, P. R. China. e-mail: liqh@lzu.edu.cn)

Through discriminate the polarisations of fast and slow shear waves and the time delay between their arrivals recorded on seismic diagram, the characteristics of anisotropy can be ascertained. However, shear wave splitting is the total effect of ray path so it is difficult to decide the location where anisotropy is produced. The electric anisotropic layers with low accuracy can be distinguished through MT inversion. It is expected that when the elastic parameters and electric ones both present strong anisotropy, the combining explanation of the two methods could provide more clear image of media conditions such as the direction of fluid filled cracks align, stress status, conductivity, the location of some special layers and so on; when only one kind of parameters presents obvious anisotropy combining explanation at least could determine the type of anisotropy easily. The forward procedure as a base of inversion is following. (1) Firstly, the rocks characteristics from various elastic experiments and also from electric ones were analysed and summarised, then to seek some important parameters which strongly affect rocks elastic and electric anisotropic features. (2). Establish elastic and electric eigenfunctions of earth media respectively, which are controlled by some parameters sensitive to anisotropy. (3) Simulate the time delay, polarization and attenuation of shear-wave splitting and the MT response ftmction at time for various models which consist of different parameters, layers structures and other factors. (4). Apply the combining explanation method to several practical examples to test above mentioned

MANTLE ANISOTROPY, DEEP GEOLOGY, AND MANTLE FLOW

P. G. SILVER (Carnegie Inst. of Washington, DTM, 5241 Broad Branch Rd. NW Washington DC 20015) R. Russo (Dept. of Geological Sciences, Northwestern University, Evanston IL 60208)

The study of upper mantle anisotropy can address two fundamental issues: the mantle's contribution to continental geology, and the convective flow regime associated with plate tectonics. Mantle anisotropy beneath the continents is best revealed by shear-wave splitting. The fast polarisation direction and delay time can be used to constrain orientation and depth extent of deformed regions. The proliferation of portable, broadband experiments over the last decade has enabled the sampling of the mantle on spatial scales appropriate for examining geological variations. A survey of the available splitting data for the continents, both from permanent stations and portable deployments lead to two basic conclusions. First, the crust and mantle deform coherently during orogenies with this deformation being preserved as fossil anisotropy as far back as the early Archean. Second, there is no evidence for an asthenospheric decoupling zone between continental plates and the mantle below, suggesting that these plates are strongly coupled to general mantle circulation. Another area that can be explored is the mantle flow field associated with plate tectonics. Shear-wave splitting observations from a variety of oceanic environments: spreading ridges, hotspots, and beneath subducting slabs suggest a surprising diversity of flow behaviour. This ranges from the classic two-dimensional flow beneath ridges to a more complex three-dimensional sub-slab flow field found at many convergent margins.

JSS07/E/11-A2 1155

LITHOSPHERIC ANISOTROPY CHANGE ACROSS THE EDGE OF THE CANADIAN SHIELD

Goetz HR BOKELMANN (Department of Geophysics, Stanford University, Stanford, CA 94305-2215, USA, email: goetz@stanford.edu) Paul G. Silver (Dept. of Terrestrial Magnetism, Carnegie Inst. of Washington, 5241 Broad Branch Rd., Washington, DC 20015, USA, email: silver@pss1.ciw.edu)

We report travel times and shear-wave splitting from the Archean-Proterozoic Transect 1989. This type of data set recorded by a transect of portable broadband instruments allows us to make inferences about mantle structure in the region between Wyoming Craton and Superior Province of the Canadian shield, i.p. to study the relation of velocity variation in the continental upper mantle with surface geology, tectonic features and age provinces. The values are corrected for crustal contribution and inverted for the vertical path upper mantle delay δt_{UM} under each station as well as azimuthal dependences of this quantity. The prominent feature in the upper mantle delays δt_{UM} is the variation by at least 1.5 seconds for S, much of which occurs over a narrow zone of just a few hundred kilometres width. This suggests a major lateral upper mantle transition, which does not coincide with the surface geological edge of the Canadian shield but is located within the shield. This same transition is also observed in shear-wave splitting delay times. Surprisingly, however, the P-delays do not exhibit a corresponding variation. We address this apparent contradiction and show how it may be explained in conjunction with anisotropy in the subcontinental lithosphere. simplified thermal model of the lithospheric transition zone, in which temperature controls the degree of alignment of crystal and thus seismic anisotropy, predicts this phenomenon.

JSS07/P/03-A2 1205

THE EVIDENCE OF SHEAR WAVE SPLITTING OBSERVED ON THE RECORDS OF THE 1997 ZIRKUH (GHAEN-BIRJAND, EAST-CENTERAL IRAN) AFTERSHOCKS

Z. ZARIFI (RAEESI) (Institute of Geophysics, University of Tehran, Tehran, Iran.
email: zarifi@ iman.ut.ac.ir); M. R. Gheitanchi and M. Raeesi (Both at the above address,
email: mrghchee@chamran.ut.ac.ir and mraeesi@iman.ut.ac.ir)

On 10 May 1997 at 7:57:26,9 GMT a destructive earthquake occurred in Zirkuh (Ghaen--Birjand) region, east of Iran with Ms=7.3, Geophysics Institute of Tehran University recorded aftershocks of this event from 31 May 1997 to 25 June 1997, with three component digital seismographs. We searched for shear wave splitting in the aftershocks with magnitude less than 3 and incident angles less than critical angle; arcsine(VsNp). We emphasized observation of particle motion of two horizontal components in a window including first arriving shear wave. Observation of no variety in particle motion in a range of time greater than sampling interval of recorded signal and less than about 200 ms was attributed to anisotropy. Then we used aspect ratio method to determine polarisation direction of fast shear wave and time delay between fast and slow shear waves. We found two directions for fast shear wave, including NE-SW and NW-SE. The dominant direction was NE-SW. This was compatible with direction of maximum regional stress that was mentioned by other researches in the region. As directions of fast shear wave suggest, here we have two sets of parallel cracks and we search about behaviour of shear wave in these two conjugate sets of cracks.

JSS07/E/07-A2 1225

ALONG-STRIKE VARIATIONS IN THE ANISOTROPIC STRUCTURE OF THE HIKURANGI SUBDUCTION ZONE, NEW ZEALAND.

Alex Brisbourne, Graham Stuart, J-Michael KENDALL. School of Earth Sciences, University of Leeds, LS2 9JT, UK.

A model of subduction-zone anisotropy for the North-Island, New Zealand based on observations of seismic anisotropy from a variety of seismic phases is presented. We have analysed anomalous surface-wave polarisations and shear-wave splitting in local S-phases and SKS phases. Anomalous particle motions of the equivalent to fundamental-mode Love-waves imply anisotropy in the New Zealand crust and the subducted Pacific slab. Shear-wave splitting analyses of regional phases in the northern North-Island show no increase in delay times between the fast and slow shear-waves (0.21+0.03s) with increasing source depth, unlike previous observations in the southern North-Island, which display an increase in delay time to about 0.5s over 250km. Polarisations of the fast shear-waves are approximately parallel to the strike of subduction. In contrast, the SKS-splitting parameters do not vary significantly across the North-Island. A mean fast-slow delay time of 1.5+0.3s and a fast polarisation direction of 25+7degs, sub-parallel to the strike of subduction, was determined for the SKS observations. Modelling using reflectivity and ray theory was used to guide the interpretations. Both the surface-wave polarisation and local shear-wave splitting observations require an anisotropic (4\%) New Zealand crust with a slow hexagonal-symmetry-axis dipping at 15-30$^\circ^$ and a fast symmetry plane parallel to the strike of the subduction. This is compatible with the structural trends of the regional geology. The variation of the splitting delay times with source depth across the North-Island implies a horizontal symmetry axis in the subducted slab to the south, but an axis dipping parallel to the plate interface beneath the northerly regions. This variation reflects the change in intra-plate stress towards the South Island where the India-Australian and Pacific plates are locked. Beneath the slab, trench-parallel mantle flow is inferred from interpretations of 4\% hexagonal anisotropy with a fast symmetry-plane parallel to the strike of subduction.

HOW TO RELATE BODY WAVE AND SURFACE WAVE ANISOTROPY?

Jean-Paul MONTAGNER (Dept. Seismology, Institut de Physique du Globe, 4 Place Jussieu, 75252 Paris cedex 05, France, email: jpm@ipgp.jussieu.fr), and Daphne-Anne Griot (Laboratoire de Sciences de la Terre, ENS-Lyon, 46 Allee d'Italie, 69364 - Lyon cedex 07, France)

The seismic anisotropy turned out to be one of the most efficient tool for structural geologists and geodynamicists developed during the last 30 years. Seismic anisotropy was evidenced in the upper mantle, primarily from two kinds of datasets, surface wave dispersion curves and body waves SKS data. First of all, the discrepancy between Rayleigh and Love wave dispersions makes it necessary to introduce transversely anisotropic medium with vertical symmetry axis characterized by 5 anisotropic parameters (A, C, F, L, N). Later on, the azimuthal dependence of Rayleigh wave and Love wave dispersion curves (at different periods) was largescale tectonic processes are taking place. We show that such is the case in Central Asia and Western USA.

JSS07/E/08-A2 Invited 1430

NEW PROBES OF THE DYNAMICS OF EARTH'S DEEP MANTLE

Lars STIXRUDE, Dept. of Geological Sciences, University of Michigan, Ann Arbor, MI 48109-1063, USA, email: stixrude@umich.edu

Seismological observations of elastic anisotropy in the deep mantle represent a potentially rich source of information on the dynamics and composition of this region of the interior. The anisotropy is determined by the elastic constants of the constituent minerals and their angular and spatial distribution. Our understanding of anisotropy in the deep mantle has been hindered by our ignorance of the relevant elasticity and deformation mechanisms at high pressure. We review recent results of first principle theory as applied to the prediction of elastic constants of important deep earth phases at high pressure. The foundation and implementation of the theoretical technique, the plane-wave pseudopotential method, is briefly discussed. The results show that predicted elastic constants are in good agreement with experiment: RMS deviations are typically a few percent, much of which can be accounted for by the difference in temperature between the athermal calculations and 300 K experiments. Predictions at high pressure show that anisotropy depends strongly on compression and that candidate deep mantle minerals are highly anisotropic. The theoretical predictions are discussed in terms seismological observations, paying particular attention to the properties of aggregates. The properties of anisotropic mono-phase aggregates are estimated based on 1) theoretical results for single crystals, 2) simple models of flow in D" and 3) mineralogical deformation mechanisms. We find that the SH/SV anisotropy may be large for aggregates of Mg-silicate perovskite, periclase, and silica (6-8 % in magnitude) compared with that observed in D". While mono-phase aggregates of silica exhibit fast SH velocity at pressures corresponding to D", perovskite and periclase aggregates have slow SH velocities. We discuss the implications of these results for the origin of anisotropy in D".

JSS07/L/03-A2 Invited 1500

DYNAMIC DISTRIBUTION OF MELT DUE TO DEFORMATION

Mark E. ZIMMERMAN, Shun-ichiro Karato and David L. Kohlstedt (University of Minnesota, Department of Geology and Geophysics, Minneapolis, MN 55455, U.S.A., Email: mark@olivine.geology.umn.edu)

Our shear experiments on partially molten peridotites demonstrate the importance of deformation in the development of a melt preferred orientation (MPO). Deformation redistributes melt from a random array of tubules and wetted grain boundaries to aligned planar melt pockets extending over the scale of several grains. The dynamic distribution of melt, such as that produced in our shear experiments, will dramatically influence the seismic and transport properties of the mantle within zones of partial melting such as beneath mid-ocean ridges and in mantle wedges above subducting lithospheric slabs. For example, vertically aligned planar melt pockets beneath a mid-ocean ridge induce shear-wave splitting with the fast polarization direction parallel to the ridge axis and strong Rayleigh wave anisotropy in the same orientation. Consequently, seismic observations of deforming partially molten regions of the upper mantle should observe anisotropy due to alignment of melt as well as crystallographic alignment of olivine, assuming that the direction of wave propagation is appropriate and that the resolution of the seismic technique is sufficient.
For our shear experiments, olivine-basalt aggregates with an average grain size of ~20 5m were deformed in a gas-medium apparatus at 1523 K and 300 MPa with shear stresses of 25 to 90JMPa to strains of 36 to 250J%. To preserve the microstructures formed during deformation samples were quenched under load at 1- 2JK/s. The non-coaxial shear deformation produces a strong lattice preferred orientation (LPO) with the (010) of olivine rotated sub-parallel to the shear boundary at high shear strains. Olivine grains also exhibit a shape preferred orientation (SPO) reflecting the finite strain of the sample. Under hydrostatic conditions, the anisotropic surface energy of olivine-melt interfaces causes preferential wetting of the (010) of olivine. However, during shear deformation the effect of surface energy on MPO is surpassed by the influence of the differential stress

JSS07/W/06-A2 1520

MANTLE MICROGEODYNAMICS AND SEISMIC ANISOTROPY

GEOFFREY E. LLOYD School of Earth Sciences, The University, Leeds LS2 9JT, UK
Email: g.lloyd@earth.leeds.ac.uk

The behaviour of the Earth's mantle remains a first order problem in the Earth Sciences. However, investigations are usually limited by restrictions imposed by scale. Mineral phase transformations, which are of primary significance in understanding mantle processes, can impact on all scales from the ionic to the geodynamic. A more comprehensive understanding of phase transformations, and hence mantle processes, can be achieved by combining investigations from different scales. Such an approach, referred to as 'microgeodynamics', is described here, in which crystal chemical modelling of phase transformations (ionic scale) and seismic anisotropy analysis of lithosphere structure (large scale) are combined via an interface provided by structural geology (intermediate scales). Significant recent advances in our understanding of mantle geodynamics have been gained from studies of seismic anisotropy. It is generally agreed that one major cause of seismic anisotropy is the preferred crystallographic alignment of anisotropic minerals during deformation or flow. Thus, understanding of seismic anisotropy requires knowledge of the deformation behaviour of rock-forming minerals and in particular their lattice preferred orientation (LPO) characteristics. In general, imposed environmental (i.e. pressure, temperature) and tectonic (i.e. stress, strain, strain-rate, etc.) conditions determine how an individual mineral phase behaves (e.g. dislocation or diffusional creep, fracture, etc.). These deformation mechanisms are ultimately responsible for the development of specific structures; they also may be associated with LPO development. By accurately measuring the complete LPO for all mineral phases present, it is possible to predict most of the petrophysical properties (including seismic characteristics) of a mineral, rock or structure, and hence to explain any seismic anisotropy observed in terms of geodynamic processes. Modern advances in scanning electron microscopy (SEM) technology (specifically, electron backscattered diffraction, EBSD) now make it possible to routinely determine LPO and derive petrophysical properties for a wide range of minerals and polymineralic rocks. The crystal chemical modelling approach used to assist the seismic and microstructural (LPO) investigations is based on defining characteristic…

JSS07/E/05-A2 1540

LATTICE PREFERRED ORIENTATION IN DEEP MANTLE MINERALS AND IMPLICATIONS FOR DEEP MANTLE ANISOTROPY

Shun-ichiro KARATO, Kyung-Ho Lee, Jeff Lawlis and Daisuke Yamazaki (University of Minnesota, Department of Geology and Geophysics, Minneapolis, MN 55455, U.S.A., Email: karato@tc.umn.edu) Dan Frost and Dave C. Rubie (Bayerisches Geoinstitut, Universitt Bayreuth, Bayreuth, Germany)

Previous experimental studies of anisotropic structure formation in Earth materials have been limited to those in upper mantle or crustal materials. However, most of the key questions in global geodynamics center around the processes in the deep mantle including transition zone and the lower mantle. We have developed a new experimental technique of large strain, shear deformation under deep mantle conditions and applied it to investigate the lattice preferred orientation in wadsleyite, ringwoodite and (Mg,X)O with X=Fe or Ni. High pressure, temperature deformation experiments were conducted on these materials to large strain, typically ~100%. The lattice preferred orientations (LPO) of deformed samples were determined by EBSP (electron backscattered pattern) analysis. We chose those samples that show evidence of dislocation creep (high density of dislocations and wavy grain-boundaries). Using the measured lattice preferred orientation, we calculated elastic constant tensors and calculated the seismic anisotropy. Together with the earlier works on analog materials, we draw the following conclusions: (i) anisotropy in wadsleyite and particularly ringwoodite is weak even in the dislocation creep regime, (ii) (Mg,X)O develops strong lattice preferred orientation in the dislocation creep regime: at high pressures for Fe or Ni-rich composition, the {100} plane tends to be parallel to the flow plane whereas the {110} plane is subparallel to the flow plane at low pressures and for low Fe or Ni content, (iii) (analog) perovskite (CaTiO3) shows strong LPO when deformed in the dislocation creep regime. Seismic anisotropy caused by LPO in these minerals is calculated and the following geodynamic conclusions are obtained: (i) Majority of the deep mantle appears to deform by diffusion creep, whereas the bottom boundary layer (the D" layer) is likely to deform by dislocation creep. (ii) The observed regional variation in anisotropy in the D" layer is likely to reflect the regional variation in stress level and the azimuthal anisotropy provides constraints on the flow direction. (iii) If the bottom transition zone is anisotropic (VSH>VSV), it implies a presence of laminated structure presumably caused by the delamination of paleo-oceanic crust.

JSS07/E/04-A2 Invited 1620

ANISOTROPY OF EARTH'S INNER CORE

K C CREAGER (Geophysics Program, Box 351650, University of Washington, Seattle, WA, 98195-1650; email: kcc@geophys.washington.edu)

Though the sampling is currently insufficient to obtain a robust image of the 3-D variations in anisotropy of the inner core, some robust conclusions can be inferred, and I speculate on a simple, but non-unique model, that is consistent with current observations. Thousands of differential travel times of the phases PKP (BC)-PKP(DF) and PKP(AB)-PKP(DF), picked by cross correlation by ourselves and other groups, provide compelling evidence that the inner core is strongly anisotropic with the fast direction parallel to the spin axis. Anisotropy is strong (2-4%) at depths from 100-400 km in the 240 deg longitude region from 160E to 360E to 40E (quasi-western hemisphere) and weak (0.5%) from 40E to 160E (quasi-eastern hemisphere). Below about 600 km depth into the inner core anisotropy appears strong (>2%) at all longitudes. The outer part (50-100 km) is not robustly imaged, but anisotropy appears weak here. The evidence for strong large-scale variation in anisotropy is compelling and must be incorporated in discussions of mechanisms for crystal alignment. On the other hand, the isotropic (Voigt averaged) velocities do not vary on this large scale, so there is no need to invoke lateral differences in temperature, chemistry, or density. I speculate on a new parameterization for the structure of the inner core, motivated by Song and Helmberger's [Science, 1998] inference from triplicated PKP (DF) arrivals that the inner core contains an internal discontinuity. Accordingly, I assume the inner core is divided into two regions, an upper inner core that is isotropic, and a lower inner core that is anisotropic. A model, characterized by velocity perturbations from model AK135 that are homogeneous within these two regions, can fit most of the features of my data set. The best fits are obtained when the discontinuity is less than 100 km from the inner core boundary beneath the Western Hemisphere, but more than 300 km deep in much of the Eastern Hemisphere.

JSS07/E/01-A2 Invited 1650

ORIGIN AND IMPLICATIONS OF ANISOTROPY IN THE INNER CORE

Bruce BUFFETT (Department of Earth and Ocean Sciences, University of British Columbia, Vancouver, BC, V6T 1Z4, Canada, email: buffett@eos.ubc.ca)

Accumulating evidence from the study of body waves and free oscillations provides compelling support for seismic anisotropy in the Earth's inner core. The origin of the anisotropy is generally attributed to a preferred orientation of the iron crystals, which comprise the inner core, but there is little consensus on the mechanism that produces this preferred orientation. Even the crystal structure of iron in the inner core is debated. Mechanisms that have been proposed to explain the alignment of iron crystals can be grouped into two categories. Those that produce alignment during solidification are not favoured because of the apparent absence of anisotropy in the top few hundred kilometres. More plausible explanations involve deformation of the inner core. Convection is possible at early times when the growth of the inner core was probably more rapid, but present-day estimates suggest that thermal and compositional stratifications are stable. An intriguing alternative can result from aspherical growth of the inner core. Viscous adjustment with strain-rates of order 10e-18 (1/s) can produce the observed crystal alignment by preferential growth of crystals in low energy orientations. However, low stresses cause the development of anisotropy by this mechanism to be prohibitively slow. Much larger stresses and strain-rates can be caused by rotation of the inner core through the aspherical gravitational field of the mantle. Total strains are small because the flow is periodic in time, but averaging over many revolutions can produce anisotropy with a cylindrical symmetry. Deformation of the inner core may also arise from Lorentz forces, depending on the strength of the magnetic field. In this talk I survey the relative importance of these various deformation processes and identify some of the difficulties that must be overcome to explain the origin of the anisotropy. Some

complications that arise in using the large-scale stress field to evaluate stresses at the scale of crystal grains are explored using analogous calculations for elastic inclusions.

JSS07/W/03-A2 **1720**

A LABORATORY MODEL FOR THE SOLIDIFICATION OF THE EARTH'S INNER CORE, AND THE INNER CORE'S SEISMIC ANISOTROPY

Michael BERGMAN (Physics Dept., Simon's Rock College, 84 Alford Road, Great Barrington, MA, 01230, USA, email: bergman@simons-rock.edu)

Although seismologists do not yet agree on the details of the depth dependence, the longitudinal variations, and perhaps the magnitude, to a first approximation the inner core has been inferred to be elastically anisotropic, with the direction parallel to the rotation axis fast. Many hypotheses have been suggested as a cause for the anisotropy, all involving a lattice preferred orientation, but the physical reality of many of them has not yet been demonstrated. Using ice as an analog material for high pressure, hexagonal closest packed iron, a series of laboratory experiments have been carried out in which salt-water is solidified from the center of a rotating, hemispherical shell. The experiments reveal more rapid growth of the solid nearer the pole than the equator, presumably because the Coriolis force inhibits convection within the tangent cylinder parallel to the rotation axis and circumscribing the inner core. Unlike in the Earth where pressure effects are important, in the experiments this leads to colder temperatures within the tangent cylinder. Because of the small length and time scales of the experiments it is not possible to study subsequent solid-state flow, but the experiments do demonstrate that the equilibrium solidification surface is not spherical. Using polarised light on thin sections of the ice, the columnar nature of the dendritic crystals is apparent, with the a-axes lying in the direction of growth. The laboratory model suggests how a solidification texture is frozen in, from which further textural changes might subsequently occur.

JSS07/E/03-A2 **1740**

ORIGIN OF SEISMIC ANISOTROPY IN THE INNER CORE: IMPLICATIONS FOR GEODYNAMO

Shun-ichiro KARATO (University of Minnesota, Department of Geology and Geophysics, Minneapolis, MN 55455, U.S.A., Email: karato@tc.umn.edu)

The strong interaction between inner and outer core of the Earth has been recognised in geodynamo modelling and the observed super-rotation of the inner core is considered to be a result of mechanical coupling through the stress caused by magnetic field (the Maxwell stress). Here I show that such a mechanical coupling through the Maxwell stress is also important in the large- scale, long-term deformation of the inner core that may be responsible for the observed nearly axi-symmetric seismic anisotropy. Toroidal magnetic field exerts large compressive stresses near the surface of the inner core that controls the geometry of flow. Inner core materials are squeezed from the regions of strong magnetic field to regions of weak magnetic field by the Maxwell stress, causing nearly axi-symmetric flow. The strain magnitude associated with this flow is significantly larger than those associated with other processes including the flow caused by gravitational interaction between the inner core and the mantle and the flow due to the anisotropic growth of the inner core. Therefore, the flow pattern and the resultant stress orientations in the inner core, which are likely to be related to the geometry of seismic anisotropy, should reflect the geometry of the magnetic field, particularly the toroidal field near the inner- outer core boundary. The flow causes melting and solidification at the inner- outer core boundary. This causes large release of latent heat that may affect convection pattern in the outer core and hence the geomagnetic field. The velocity of this flow is proportional to the Maxwell stress and inversely proportional to the viscosity of the inner core. For the reasonable range of parameters, the time scale of flow is estimated to be ~ 0.1-10 my, close to the time scale of geomagnetic field reversal (0.1-1 my). It is suggested that the feedback between the magnetic field and the flow-induced latent heat release may affect the geodynamo processes including reversal of the magnetic field. Thus the magneto-mechanical interaction between the inner and outer core may control a range of processes in the core including seismic anisotropy, super-rotation of the inner core and geodynamo. Seismic anisotropy of the inner core may provide a clue as to the generation of the geomagnetic field in the Earth.

MANTLE FLOW BENEATH ALTAI-SAYAN FOLDED BELT AND SURROUNDINGS (CENTRAL ASIA) FROM OBSERVATIONS OF SKS SPLITTING.

I. G. DRICKER, S. W. Roecker (both at E&ES, RPI, Troy, NY, 12180, USA, Email: ilya@geo.rpi.edu), L.P. Vinnik, Ye. A. Rogozhin, L. I. Makeyeva (all at IPE RAS, 10 B. Gruzinskaya, Moscow, 123810, Russia, Email: vinnik@synapse.ru).

We present measurements of anisotropy at 3 seismic stations (USK, AKT, TEL) in the Altai mountains, 3 stations in the Syan mountains (TDZ, ERN, TLY), ELT in the Salair range, VEN in the boundary region between Altai and the West-Siberian plate, and NVS in the West-Siberian plate. Altai and surroundings are believed to be formed by Palaeozoic accreation of microplates and island arcs and reactivated in the late Cenozoic. Fast axes of anisotropy in tectonically active areas of Altai and Sayan strike NE-SW, whereas N-W fast axis is detected beneath the West-Siberian plate station NVS. We rule out thE idea of frozen Palaeozoic anisotropy to be the cause of shear wave splitting, because detected fast axes are not parallel to the ancient tectonic trends not only in the area of active deformations, but also in the stable region to the North. In the active area fast directions of azimuthal anisotropy are oriented predominantly E-W, roughly parallel to the strikes of the mountain ranges. In addition, observed fast axes of anisotropy are parallel to the extensional axes of seismotectonic deformations obtained from fault plane solutions of local earthquakes. Delay times between fast and slow split waves vary from 1 to 1.5 s. This requires the anisotropic layer to be not less than 200 km thick, larger than the possible thickness of the subcrustal lithosphere. This is consistent with the observations in several other collisional belts, and can be interpreted as a passive reaction of the upper mantle to uniaxial compression or a flow parallel to the mountain belt

JSS07/W/05-A2 Poster **0930-02**

PN ANISOTROPY IN THE UPPERMOST MANTLE BENEATH THE ITALIAN AREA

Giuliana MELE, Istituto Nazionale di Geofisica, E-mail: meleg@marte.ingrm.it

Uppermost mantle anisotropy is imaged beneath the Italian area using Pn traveltime residuals inverted with the anisotropic tomography technique of Hearn (1996). The resulting pattern of anisotropy in the uppermost mantle is closely related with the regional tectonic trend and surface geology. The fastest Pn velocity is perpendicular to the direction of compression that originated the two major arc structures of Italy, i.e., the northern Apennines and the Calabrian Arc, deformed in Mio-Pliocene times. This suggests that the collisional processes that originated the two arcs have deformed a substantial portion of uppermost mantle. In the internal part of northern Apennines toward the Tyrrhenian Sea, presently dominated by normal faulting and graben tectonics, the direction of fastest Pn waves parallels the direction of extension. Low-velocity and high-attenuation zones in the uppermost mantle of Italy obtained both from tomography and shear wave attenuation are also shown.

THE ANISOTROPY OF THE EARTH'S INNER CORE AND THE GEOMAGNETIC FIELD

Vladimir V. KUZNETSOV, Vsevolod V. Botvinovsky (Institute of Geophysics SB RAS, Koptyug av., 3, Novosibirsk 630090, Russia; e-mail: kuz@uiggm.nsc.ru)

A model relating the cylindrical and the lateral anisotropy of the inner core to the circuit of the generation of the geomagnetic field is offered. The phenomenon of the anisotropy of the properties of the inner core consists in the fact that the time a seismic wave takes to traverse the core along the rotation axis is 1% less than the time taken in the equator plane. Another piece of evidence comes from the splitting of the Earth's eigen oscillation spectra. In addition to the velocity difference between traversing the core along and normal to the rotation axis, a lateral core anisotropy has been discovered both from function splitting and travel time data. The lateral anisotropy shows that the velocities of P- waves over the surface of the inner core at the regions, projected into the Earth surface at the Pacific and at the Atlantic oceans, are 0.2-0.4 % less than these at the poles and at the continents. The circuit of generation of the geomagnetic field is based on the model of current differencial loop looking like the double cylinder and taking place on the border of the inner core, at the F-layer, in the plane of equator. A model in which the cylindrical anisotropy of the core results from dissipative processes, accompanying the generation of the geomagnetic field. T he attempt to explain the interrelation of the lateral anisotropy of the core and the morphology of the geomagnetic field is made.

EXHUMATION HISTORY OF HP-HT ROCKS DEDUCED FROM PETROLOGICAL DATA IN A POLY-OROGENIC BELT: SOUTH CARPATHIANS, ROMANIA

IANCU VIORICA (Geological Institute of Romania, 1 Caransebes Street, Bucharest 32, Romania, RO-78344, Email: viancu@ns.igr.ro) Medaris Gordon Jr. (Dept. of Geology and Geophysics, Univ. of Wisconsin-Madison 1215 W., Dayton St., Madison, WI 53706, USA,
Email: medaris@geology.wisc.edu) Ghent D. Eduard (Dept. of Geology and Geophysics, Univ. of Calgary, email: Ghent@geo.Ucalgary.Ca) Maluski Henri (Lab.De Geochronologie, Geochimie et Petrologie, Univ. Montpellier 2, email: maluski@dstu.univ-montp2.fr)

The South Carpathians resulted from Alpine polystage collision characterised by: a double verging orientation of the crustal bodies, delimited by thrust/overthrust planes, in an assymetric, fan like, nape pile; a strong heterogeneity due to the alpine building and by the inheritence of a strong pre-Alpine anisotropy; important contrasts in the physical parameters of the metamorphic conditions correspond to the Alpine, Variscan and Pan-African cycles; the widespread occurences of the HP/HT rocks occur only in the Variscan units of the Getic-Supragetic basement. The aim of this presentation is to emphasise: the spatial distribution and position of the HP/UHP and medium-HT rocks in the uppermost alpine units, with a sub-orizontal crustal tectonic layering. The Variscan polystage crustal thickening and subsequent thinning due to collaps (recently 40Ar/39Ar ages are 354-331 Ma) produced the anisotropy of the pre-Alpine basement and exhumed the high grade rocks from the roots of the belt. Well constrained PT conditions for eclogites and granulites are 550-7000C and for peridotites are cca. 12000C/25-32 Kb, which are comparable to those for similar rocks in the Variscan Bohemian Massif. The paleozoic crustal anisotropy can be explained by a complex, polystage tectono-metamorphic evolution, involving a "tectonic collage" or "mixing" of the crustal bodies; the exhumation processes of the HP rocks can be understand only by descifering of the whole pre-Alpine history. The pre-331 Ma effects of thickening-thinning processes were followed by further uplift and erosion (cooling ages of 309-320 Ma, Dallmeyer et al., 1986). The presence of scarce allohtonous Carboniferous granites, large migmatitic areas, and "in situ" anatectic granitoids suggest the exhumation of magmatic root crustal domains at least in some units.

OVERVIEW OF THE MESOSCALE ALPINE PROGRAM

Philippe Bougeault, Meteo-France/CNRM, 42 Avenue G. Coriolis, TOULOUSE 31057, France.
E-mail:phillipe.bougeault@meteo.fr Telephone No: 33-56107-9358 Fax No: 33-56107-9626)

The Mesoscale Alpine Program is an international initiative to improve understanding of atmospheric and hydrological processes over the Alps and their prediction by numerical models. There are about 200 participants from 15 different countries. The main focus of the program are:
1) An extensive program of intercomparison of numerical models
2) The concentation of all existing measurements in a single data center
3) The realization of a major field campaign, featuring special atmospheric and hydrological measurements by a variety of platforms (research aircraft, doppler radars, airborne lidars and radiometers, profilers, etc...). This field experiment will take place from 7 September to 15 November 1999.

The talk will illustrate the general strategy and organization of the program, present a variety on-going work, and highlight the plans for the upcoming field campaign.

JWM08/W/04-A2 1020

OROGRAPHIC PRECIPITATION: RESULTS FROM SALPEX (THE SOUTHERN ALPS EXPERIMENT).

Jeff Copeland, David Wratt, Warren Gray, Howard Larsen and Michael Revell (NIWA. Wellington, New Zealand, email: j.copeland@niwa.cri.nz). Geoff Austin (Physics Department, Auckland University, New Zealand, email: g.austin@auckland.ac.nz). Roddy Henderson and Richard Ibbitt (NIWA Christchurch, New Zealand, email: r.henderson@niwa.cri.nz). Jorgen Jensen and Sunhee Lee (CSIRO Atmospheric Research, Aspendale, Australia, email: jbj@atmos.dar.csiro.au). Niels Bormann, (Research School of Earth Sciences, Victoria University Wellington, Wellington, New Zealand, email: n.bormann@niwa.cri.nz).

This paper summarises orographic precipitation and river flow research results from New Zealand's Southern Alps. Important microphysical and dynamical processes influencing precipitation distribution have been identified through a synergy of SALPEX surface, radar and aircraft observations. The structure of air flow approaching the Southern Alps has been established, including blocking and formation of the barrier jet. Relationships between air mass properties and spillover (leeward precipitation intensity) have been determined. Observations and model studies are being used to test theories of mountain influence on frontal structure. Validation studies using SALPEX field campaign data show the RAMS mesoscale model has improved skill at predicting orographic rainfall over the global model in which it is nested. River flows predicted by the TOPMODEL hydrologic model driven by RAMS precipitation forecasts compare well with observations.

JWM08/E/07-A2 1040

GPS PRECIPITABLE WATER MEASUREMENTS MADE DURING THE SALPEX'96 EXPERIMENT

MARK FALVEY (School of Earth Sciences, Victoria University of Wellington, PO Box 600, Wellington, New Zealand, Email: mfalvey@gamma.gns.cri.nz) John Beavan (Institute of Geological and Nuclear Sciences, PO Box 30368 Lower Hutt, Wellington, New Zealand, Email: J.Beavan@gns.cri.nz) Niels Bormann (School of Earth Sciences, Victoria University of Wellington, PO Box 600, Wellington, New Zealand, Email: bormann@thor.niwa.cri.nz) Jeff Copeland (National Institute of Water and Atmosphere, PO Box 14-901 Kilbirnie, Wellington, New Zealand, Email: j.copeland@niwa.cri.nz) James McGregor (School of Earth Sciences, Victoria University of Wellington, PO Box 600, Wellington, New Zealand, Email: mcgregor@geo.vuw.ac.nz) David Wratt (National Institute of Water and Atmosphere, PO Box 14-901 Kilbirnie, Wellington, New Zealand, Email: j.copeland@niwa.cri.nz)

SALPEX'96 (Southern Alps EXPeriment) was a three week long field experiment conducted in the South Island of New Zealand during October - November of 1996. A primary goal of the experiment was to examine the processes occurring during periods of high orographic rainfall, induced by north-westerly flow over the Southern Alps. The equipment deployed during SALPEX'96 included a set of eight GPS (Global Positioning System) receivers arranged in a transect across the mountains. The high quality GPS data collected has since been used to make hourly measurements of total precipitable water (PW) above each receiver site. We present here a validation of the GPS measurements by comparing with PW derived from radiosonde data collected at two of the GPS sites. We also investigate the correlation between PW and rainfall during selected storm events that occurred during the SALPEX'96 period. Finally we compare the GPS PW measurements with PW derived from RAMS (Regional Atmospheric Modeling System) mesoscale simulations of the SALPEX events. We examine the ability of the model to correctly capture the temporal evolution of the vapour fields and also to resolve the sharp PW gradients observed across the mountains during the storm events.

JWM08/E/06-A2 1120

REAL-TIME FINESCALE NUMERICAL WEATHER PREDICTION DURING THE MAP FIELD EXPERIMENT

R. Benoit (1), P. Binder (2), S. Chamberland (1), H.C. Davies (3), M. Desgangè (1), D. Lüthi (3), J. Schmidli (3), M. Sprenger (3), C. SCHÄR (3) schaer@geo.umnw.ethz.ch, S. Thomas (1) and E. Zala (2) (1 = Recherche en Prevision Numerique (RPN), Env. Canada, Dorval, Canada) (2 = Swiss Meteorological Institute (SMI), Zürich, Switzerland) (3 = Swiss Federal Institute of Technology (ETH), Zürich, Switzerland)

Further developments in numerical modelling and computer technology will soon allow for limited-area numerical weather prediction at a resolution of 1-2 kilometers. This advance opens exciting prospects for the prediction of orographic precipitation over complex terrain. The increase in resolution will allow for (i) a substantially improved representation of the underlying topography, (ii) the explicit (rather than parameterized) simulation of convective precipitation events, and (iii) the coupling with hydrological run-off models operating at the scale of individual catchments.
Within the Mesoscale Alpine Programme (MAP) attempts are underway to run the Canadian MC2 model in real time at a resolution of 2-3 km during the MAP field phase (August - November 1999). The MC2 model will be driven by a model chain consisting of a global model and a 14 km resolution mesoscale models in a one-way nesting mode. Current plans foresee a resolution of 2-3 km, a computational grid of ~300x300x60 gridpoints, and a computational domain covering the whole of the Alpine region.
Initial testing of such configurations is already well underway. An overview of the model configuration will be presented along with results from test cases of orographic precipitation events. Critical aspects that require particular attention in future research will also be discussed.

JWM08/E/02-A2 1140

RAINFALL FORECASTS OVER THE NEW ZEALAND SOUTHERN ALPS FOR SALPEX'96: CHARACTERISATION AND THE IMPORTANCE OF ICE-SPECIES

NIELS BORMANN NIWA/VUW Centre of Excellence, PO Box 14 901, Kilbirnie, Wellington, New Zealand/Aotearoa, email: n.bormann@niwa.cri.nz Crispin J. Marks NIWA Wellington, PO Box 14 901, Kilbirnie, Wellington, New Zealand/Aotearoa

Mesoscale and global-scale precipitation forecasts over the New Zealand Southern Alps are characterised and validated for the October/ November 1996 field campaign period of the Southern Alps Experiment (SALPEX) using rain gauge observations. SALPEX is a collaborative mountain meteorology project initiated to study processes through which the Southern Alps affect New Zealand weather and hydrology. The mesoscale forecasts are gained from a 48h, 20km configuration of the Regional Atmospheric Modeling System (RAMS). The contribution of the hydrometeor species snow, graupel, and aggregates on model precipitation in these forecasts is investigated by performing parallel month-long series of model experiments with and without these ice-species.
The rainfall predictions are satisfactory in general and the RAMS setup shows better skill in resolving heavy orographic precipitation than the global model, particularly when the full RAMS microphysics scheme is used. The mesoscale model allows a better representation of the fine-scale orography of the Southern Alps. The results from RAMS show that heavy precipitation is strongly sensitive to the configuration of the microphysics scheme. It is essential to include processes related to snow, graupel, and aggregates in the model in order to reproduce the strong orographic enhancement observed and to improve rainfall forecasts in the lee of the Southern Alps. This suggests that these hydrometeor species play a key-role in determining the distribution of rainfall over the Southern Alps and affect the occurence of spill-over across the alpine divide.

JWM08/E/05-A2 1200

OROGRAPHIC RAINFALL AS SIMULATED BY THE NONHYDROSTATIC MODEL LM OF DWD

J. Steppeler, (Deutscher Wetterdienst, Frankfurterstr 135, 63067 Offenbach, Germany),
e-mail: jsteppeler@dwd.d400.de

Orographiccally induced rain simulated by the nonhydrostatic model LM of DWD is compared to observations. Model versions using horizontal meshes of dx=7 km and dx=2.4 km are used. For verification SYNOPS and the climatological observations as well as a dense network over the country of Baden-Wuertemberg are used.The cases simulated comprise:
• The Rhine flooding case
• The Odra flooding
• The Brig case of MAP
For the Rhine flooding precipitation output of LM was used as input for a flood simulation runoff model in a cooperation with the country of Baden-Wuertemberg. For the pegel of Karlsruhe the use of precipitation forecasts leads to an increase of useful flooding forecast time by 24 hrs. A selection of cases is presented where an increased model resolution produced improved orographic precipitation forecast.

JWM08/W/02-A2 1220

MODELLING INTENSE OROGRAPHIC PRECIPITATION OVER THE TEVERE VALLEY: A CASE STUDY

G. Pisacane, N. Tartaglione, P.M. Ruti - ENEA Roma A. Speranza - Un. di Camerino.
E-mail: giovanna@mantegna.casaccia.enea.it Telephone No: +39 06 304 83570 Fax No: +39 06 304 83591)

Orography has been demonstrated to play a fundamental role in determining both the intensity and distribution of precipitation. The Italian Peninsula is characterized by the presence of mountains along its whole length, in addition to the Alpine Chain, so that interaction between weather systems (fronts, cyclones, MCS) and orography may frequently take place. In the present work, a case study of heavy precipitation over the Tevere basin has been conducted, using the limited area model BOLAM to predict the meteorological fields of interest. An elongated front coming from the North-West crossed Italy on 5-6 December 1992. The associated pre-frontal low level jet, directed towards the North-East, impinged the Apennines over Central Italy, causing precipitation up to 40 mm/day over the whole basin. The event was characterized by two rainfall peaks, which in turn saturated the soil and caused saturation overland flow, in addition to large runoff volumes. We show the results of a high resolution (10 km) control run and some sensitivity experiments.
A comparison between rainfall data and simulated precipitation is presented. Future developments concern the application of rainfall forecast to a hydrological model in order to obtain flood prediction, whose skill dramatically depends on our ability to determine the correct relationship between precipitation and runoff.

RAINFALL ANALYSIS AND RUNOFF FORECASTING

JWM08/E/01-A2 Invited 1400

STUDY ON THE USE OF OROGRAPHICAL DATA WITH SPATIAL ANALYSIS OF MONTHLY PRECIPITATION ON GLOBAL SCALE

Bruno RUDOLF (Deutscher Wetterdienst, 63004 Offenbach a.M., Germany, Tel.: +49-69-8062-2765, email: brudolf@dwd.d400.de) and Franz M. Albrecht (Programm-und Gutachtenservice, Frankfurt)

The measurement and mapping of precipitation is fundamental to meteorology, hydrology and to a number of other sciences. Precipitation data measured locally using raingauges need to be transferred to area-means in order to calculate water budgets or to compare the results from raingauge-measurements with satellite-based observations or numerical model results. Geometric spatial interpolation scheme are commonly used with global analyses. In order to reduce the interpolation error the use of precipitation-orography relationships was recommended. In order to find out the effect, a multivariate regression method has been established and tested with various orographical variables (elevation, slope, orientation, exposure, latitude, longitude, distance to coast).
First results of the tests have been: Application areas should not be larger than 250,000 km2, preferably smaller. The test analyses show remarkable variations of the regression fit. Correlations for longterm mean precipitation and orography are clearly higher than for individual monthly precipitation. The quality of the regression fit depends highly on the conditions in the individual regions and months, and varies between acceptable values and values near zero. For individal months, a fraction of the total variance of 5% to 50% only is described by regressions. In some regions the orographical variables are of nearly no importance. Most problems with the regression method occured for the tropics and for Europe. North America with its large and significant north to south oriented structures shows the best evaluable relationships, the SALPEX'96 period. Finally we compare the GPS PW measurements with PW derived from RAMS (Regional Atmospheric Modeling System) mesoscale simulations of the SALPEX events. We examine the ability of the model to correctly capture the temporal evolution of the vapour fields and also to resolve the sharp PW gradients observed across the mountains during the storm events.

JWM08/E/03-A2 1440

THE BIASED ASSESSMENT OF TOPOGRAPHY EFFECTS ON PRECIPITATION

Boris Sevruk (Swiss Federal Institute of Technology, ETHZ, CH-8092 Zurich, Switzerland,
email: sevruk@geo.umnw.ethz.ch)

The results of studies of the effects of topography on precipitation in the mountains are sometimes contradictory and confusing. In addition to the complex matter of precipitation processes and their regional character this is partly caused by different and/or subjective definitions and modifications and even combinations and number of topographic variables as used by individual authors to obtain the best results. A further bias is due to the systematic error of point precipitation measurement, particularly the wind-induced error and the prevailing

positioning of gauge sites in the high mountains in the valleys. Consequently, a valley gauge network must not be adequate for other topography elements (e. g. slopes) where other conditions could prevail. Moreover gauges situated on exposed slopes and in high altitude show larger wind induced error.
Problems exist also on the interrelation of topographic variables used as precipitation predictors in multiple regression analysis (e.g. altitude and distance to the mountainous ridge or altitude and slope). This indicates that results of studies of topography effects on precipitation are hardly transferable from one scale or region to others. Beside the region and weather situation they appear to depend on the general strategy of network design, the scale, the range of altitude and the method of selection and estimation of topographic variables. Principally, the relationships derived for large areas or valleys are scarcely adequate to be used for smaller areas or slopes. Examples from Switzerland will be presented.

JWM08/W/13-A2 1500

ABOUT THE NECESSITY OF TOTALIZER MEASUREMENTS IN HIGH ALPINE REGIONS FOR CLIMATOLOGICAL PURPOSES

INGEBORG AUER (Central Institute for Meteorology and Geodynamics, Hohe Warte 38, 1190 Vienna, AUSTRIA, Email: ingeborg.auer@zamg.ac.at)

More than 120 totalizer gauges complete the Austrian precipitation network, especially in the high alpine regions. The majority of totalizers are installed at locations where it seems to be impossible to make daily gauge readings, however there are some places where parallel reading of rain gauges (tipping buckets or weighing gauges) and totalizers have been done since many years.
For financial reasons and often insufficient results there are tendencies to reduce the number of totalizer gauges. The paper intends to demonstrate that the advantages of totalizer measurements outweigh the disadvantages, that well done totalizer readings provide more reliable results than rain gauges and that totalizers are an indispensable component of the Austrian climatological network.

TOPOGRAPHIC EFFECTS IN PRECIPITATION CLIMATE AND VARIABILITY: ANALYSIS FROM HIGH-RESOLUTION RAIN-GAUGE OBSERVATIONS IN THE ALPINE REGION

Christoph FREI and Manfred Schwarb (Swiss Federal Institute of Technology (GI-ETH), Winterthurerstr. 190, CH-8057 Zurich, Switzerland, email: christoph.frei@geo.umnw.ethz.ch)

Topographic effects on precipitation processes operate on a broad range of spatial scales. This study examines, for the region of the European Alps, the topographic influence as revealed in surface rain-gauge observations. Special consideration will be given to the organisation of the precipitation climate and frequency distribution in relation to the various scales of the ridge topography. The analysis is based on a comprehensive dataset of high-resolution observations (more than 6000 stations) with a typical inter-station distance of 10 kilometers covering the entire ridge and surrounding foreland regions. The dataset includes daily precipitation totals for a period of 20 years. The results of the statistical analyses reveal, on the ridge-scale, a pronounced upstream enhancement, shading of inner mountain areas and features of topographic channelling. On more local scales (a few kilometers) the relation to the underlying topography becomes weaker.

JWM08/W/05-A2 1540

PRECIPITATION CLIMATE MAPS FOR THE ALPINE REGION. EVALUATION OF A HIGH-RESOLUTION ANALYSIS SCHEME USING COMPREHENSIVE RAIN-GAUGE DATA

Manfred SCHWARB (Swiss Federal Institute of Technology, Institute of Geography, Winterthurerstrasse 190, CH-8057 Zurich, Switzerland, email: schwarb@geo.umnw.ethz.ch) Christopher Daly (Oregon State University, Department of Geosciences, 326 Strand Agricultural Hall, Corvallis, OR 97331-2204, U.S.A., email: daly@oce.orst.edu) Christoph Frei (Swiss Federal Institute of Technology, Institute of Geography, Winterthurerstrasse 190, CH-8057 Zurich, Switzerland, email: christoph.frei@geo.umnw.ethz.ch)

Mapping of precipitation climate fields at spacial resolutions close to or finer than the resolution of observational networks requires the use of analysis schemes capable of representing local terrain effects upon precipitation. This study assesses the performance of a sophisticated statistical-geographical analysis approach for the entire region of the European Alps. A specific challenge of the region is the existence of pronounced and regionally variable topography-precipitation relationships, requiring special flexibility of the analysis scheme.
The analysis procedure being considered is the regression based model PRISM (Parameter-elevation Regressions on Independent Slopes Model), specifically developed for climate mapping over complex topography. The model applies linear regressions with elevation as a predictor. Variable weights are assigned to the point observations depending on topographic attributes of the stations' environment. The model is operated on a regular grid of 1.25 minutes resolution and makes use of a comprehensive dataset consisting of observations at more than 6000 rain-gauge stations. The model performance is quantified using cross validation results. The analysis method reproduces stable and realistic precipitation-height gradients and successfully reproduces regional variations of these gradients between the Alpine lowlands, the rim and the inner region of the ridge.

JWM08/W/01-A2 1630

FLOW FORECASTING USING MESOSCALE PRECIPITATION PREDICTION

Roddy Henderson, Jeffrey Copeland, Richard Ibbitt, and David Wratt (National Institute of Water & Atmospheric Research Ltd. - NIWA, PO Box 14 901, Wellington, New Zealand, email: r.henderson@niwa.cri.nz)

The extreme nature of New Zealandís topography and precipitation, and lack of upstream information have made it difficult to forecast river flows beyond the nowcast (6-12 hour) time period. Mesoscale models nested within global forecasts can produce quantitative precipitation predictions of high spatial and temporal resolution and have the potential to provide forecasts up to two days ahead. A significant difficulty is validating these forecasts against rain gauges in regions of complex terrain.
One solution is to use observed riverflows as a measure of catchment integrated precipitation. This is particularly valid in catchments that have high runoff with little loss and short response times. We have applied this technique to 36 catchments in the Southern Alps for the SALPEX (Southern Alps Experiment) 1994 period using RAMS (Regional Atmospheric Modeling System) precipitation. The mean catchment integrated model rainfall was 65% of observed runoff with an R2 of 0.87.
The next step is to use the mesoscale model precipitation as input to a distributed hydrologic rainfall-runoff model (TOPMODEL). This approach has been tested on a range of New Zealand mountain catchments for several different events and the intensity and timing of the forecast riverflow compares favourably with observed flows. A linked system holds the potential for use as an operational flow forecasting tool.

JWM08/W/10-A2 1650

ON THE MODELING OF OROGRAPHIC PRECIPITATION AND ITS HYDROLOGICAL IMPLICATIONS

L.R. LEUNG, M.S. Wigmosta, and S.J. Ghan Pacific Northwest National Laboratory Richland, WA 99352, U.S.A. E-mail: ruby.leung@pnl.gov Telephone No: 1-509-372-6182 Fax No: 1-509-372-6168)

Surface topography explains a high percentage of spatial variability in precipitation over mountainous regions. The prediction of orographic precipitation has important implications to the prediction of surface hydrology such as snow cover and streamflow. An efficient way of modeling orographic precipitation is through subgrid parameterization. An example of such schemes has been developed and implemented in a regional climate model. The method aggregates subgrid variations in surface elevation to a limited number of elevation bands. An airflow model is used to determine the height rise or descent of air parcels as they encounter mountain barriers or valleys. A thermodynamic model is used to determine the temperature, humidity, and cloud water of the air parcels. Cloud, radiation, and surface processes are all calculated for each elevation band of each model grid cell. The prediction of surface variables such as temperature and precipitation is mapped from elevation bands to geographical locations during postprocessing to yield high resolution spatial distributions. This method has been evaluated by driving the regional climate model with large scale analyses for simulating precipitation over the U.S. Pacific Northwest. The model is found to correctly capture the surface temperature and precipitation variations as functions of surface topography over different mountain ranges, and under different climate regimes. The simulation has been used to drive a distributed hydrology model at two mountain watersheds in the Pacific Northwest. Simulation of snow cover and streamflow in these remote watersheds requires different degrees of accuracy and spatial resolutions in surface temperature and precipitation fields, which are neither widely observed nor easily predicted by models. A detailed case study using observed and simulated meteorology to simulate surface hydrology in those two watersheds will be described. Also will be discussed are the implications for assessing the impacts of climate variability and change on water resources in mountainous regions.

SOME QUESTIONS REGARDING OROGRAPHIC PRECIPITATION

Ronald B. Smith (Yale Department of Geology, P.O.Box 208109, New Haven, CT, 06520-8109, USA, email: ronald.smith@yale.edu)

A number of physical processes combine to make the phenomena of orographic precipitation rather varied and complex. This brief review will discuss only four of these processes: 1)the effect of latent heat on airflow splitting and/or focussing, 2)hydrometeor drift and spillover, 3)upstream effects and 4)seeding from higher clouds and cloud top processes. Results of some previous field projects around the world will be reviewed, including stable isotope data from surface precipitation. The influence of the scale, shape and latitude of various mountain ranges will be discussed.

JWM08/W/16-A3 1020

NUMERICAL STUDY OF MOIST FLOW OVER AN ISOLATED 3-D TOPOGRAPHY

Mario MIGLIETTA (Institute for the Study of Atmospheric pollution and Agrometeorology, CNR-ISIAtA, Strada Provinciale Lecce-Monteroni, 73100 Lecce, Italy, Email: miglietta@axple.le.infn.it) and Andrea Buzzi (Institute of Atmospheric and Oceanic Sciences, ISAO-CNR, Via Gobetti 101 - 40129 Bologna, Italy, Email: buzzi@ocean.fisbat.bo.cnr.it)

Orographic precipitation is intimately connected with the properties of flow regimes over orography in the presence of saturated atmospheric layers. The complexities related with the flow over mesoscale obstacles, even of idealised shape, in a moist atmosphere has limited the number of contributions on this subject to a few analytical and model simulation studies, mainly related to two-dimensional topography. On the other hand, analysis of numerical simulations of real events of heavy orographic precipitation have emphasised important dynamical effects of humid processes over flow patterns and precipitation. The present study is aimed at investigating moist effects in relation with orographic precipitation, as a function of different flow regimes, with particular attention devoted to upstream features. The effect of moisture is analysed with a systematic simulation approach, by estimating the role of different parameters like static stability, relative humidity, height and shape of the obstacle, in cases of highly idealised stratified flow over an isolated obstacle. A channel version of a meteorological model (BOLAM3), that includes a simplified treatment of microphysical processes, is employed. The simplest obstacle shape considered is that of a Gaussian mountain of circular horizontal section. Dry and moist flows are contrasted in different parameter regimes. The presence of humidity in the atmosphere, when saturated regions appear, can effectively modify the flow pattern in comparison with the dry case, given the same upstream values of wind and temperature profiles. In general, "flow over" is enhanced with respect to "flow around" in the moist case. This result can be interpreted, but only to some extent, in terms of variations of the local Froude number, which changes strongly from the dry case to the moist one. For example, in the moist case, nonlinear effects as the formation of stagnation regions upstream or of vortices downstream are confined to higher mountain cases than in the corresponding dry case. A decrease of the Froude number has the effect of increasing the volume of saturated air and the amount of precipitation. However, a complication arises because the volume of saturated air, where the decrease of the local Froude number takes place, is in itself a function of the flow regime that establishes near the obstacle. In this respect, the effects of variations of the shape of the mountain and of the humidity content in the upstream profile are examined.

JWM08/W/09-A3 1030

OROGRAPHIC PRECIPITATION

A V COALS and S D Mobbs (The Environment Center, The University of Leeds, Leeds LS2 9JT, UK. E-mail: alison@lec.leeds.ac.uk Telephone No: 0113 233 1596 Fax No: 0113 233 6716)

Precipitation rates can be greatly enhanced by orographically-generated flows, but practical predictive models to date have been limited by the use of simple airflow models which are essentially dry. Airflow models for the flow of dry air over orography recently developed at The Environment Centre at the University of Leeds have been adapted in order to include moisture, thus allowing the prediction of the humidity field over complex terrain. Data obtained from experimental field work has been used as input. Verification of the moist flow model has been achieved by comparing the vertical velocities and humidity associated with gravity waves with actual measurements made by aircraft.

JWM08/W/07-A3 **1120**

LEE INTERNAL WAVES AND VORTICES IN A SLOPING INCIDENT FLOW

Yuli D.Chashechkin (Laboratory of Fluid Mechanics of the Institute for Problems in Mechanics of the RAS, Moscow, prospect Vernadskogo, 101-1, 117526, Russia, E-mail: chakin@ipmnet.ru)

Pattern of three dimensional lee internal waves past a 3D body is calculated in linear approximation in the case when an arbitrary oriented uniform flow of a viscous stratified fluid with constant buoyancy frequency is incident upon an obstacle. Amplitude and phase characteristics and loci of caustic limited an area of wave propagation are found. Laboratory investigations of the pattern of flow past a sphere towing with constant velocity under an arbitrary angle to horizontal in a stratified brine are carried out using electrolytic precipitation, schlieren visualization and probe sounding techniques. Calculation results for the form of crests and troughs and for location of the boundary of the wave domain are in good agreement with experiment, whereas the calculated values of amplitude are underestimated. Distortion of the wave shape is used for calculation of a horizontal velocity profile in the vertical centreplane. Deformation of a shape of a pair bottom vortices with variations of an angle of the trajectory to horizon and internal Froude number are studied. Sharpening of an initial gradient inside a separating boundary current is measured by a narrow beam schlieren device. Flow regime diagram on the plane Froude number-Reynolds number is presented.

JWM08/W/14-A3 **1140**

STAGNATION POINTS IN 3-D MOIST MOUNTAIN FLOW

QINGFANG JIANG and Ronald Smith Department of Geology, Yale University

The formation of stagnation points in airflow over mountains determines the onset of gravity wavebreaking and low level flow splitting. In this study, flow with uniform wind speed, a constant dry buoyancy frequency, and a deep moist layer, over a bell-shape mountain is investigated using a non-hydrostatic mesoscale model (ARPS). The control parameters of such a system are surface temperature, windspeed, and non dimensional mountain height. Two cases are considered here: a deep moist layer adjacent to the topography and a deep moist layer aloft above a shallow (2km) dry layer. It is demonstrated that in the absence of condensation or limited condensation, the speed extrema values collapse onto the `universal curves' (Smith andGronas 1993). However, with increasing condensation, the wet curves depart from the dry `universal curves'. This departure is caused by latent heating/cooling related to the condensation/evaporation process. The results question the idea that the wet dynamics can be predicted quantitatively by replacing the dry buoyancy frequency with a wet buoyancy frequency. With the moist layer adjacent to the topography, condensation occurs mainly over the windward slope and the peak. The release of latent heat helps flow to climb over a higher mountain and effectively delays the onset of both wave breaking and flow splitting. The maximum lee slope wind is also reduced significantly. It is found that the critical mountain height for windward stagnation is also approximately the mountain height to produce maximum precipitation. Beyond this height, lower level moist flow starts to split and less precipitation can be expected.With a moist layer aloft, condensation occurs mainly over the lee slope. It is found that the related latent heat release promotes wave breaking aloft and enhances the downslope wind maxima. However, it has little influence on windward stagnation. The steady precipitation rate is compared to a `slab thermodynamic' model. The implications and applications to real situations are discussed.

THE EFFECT OF OROGRAPHIC RESOLUTION ON EXTREME PRECIPITATION EVENTS: IMPLICATIONS FOR CLIMATE MODELS

Deborah J. ABBS (CSIRO Atmospheric Research, Private Bag No. 1, Aspendale, Vic. 3195, Australia. Email: debbie.abbs@dar.csiro.au) Brian F. Ryan (CSIRO Atmospheric Research, Private Bag No. 1, Aspendale, Vic. 3195, Australia. Email: brian.ryan@dar.csiro.au)

The CSU Regional Atmospheric Modeling System (RAMS) has been used to model extreme precipitation events that have occurred along the steep, coastal escarpment of the Sydney-Illawarra region of south-eastern Australia. Results have been obtained at a horizontal resolution of 7 km. The synoptic-scale system considered in this presentation is of an east-coast low that was associated with 24-hr rainfall in excess of 300 mm. East-coast lows have been identified as the major cause of flood-producing rains on the east coast of Australia, and are characterized by heavy rainfall and strong winds.
For this study, simulations with high-resolution orography, GCM scale orography and no orography have been performed. In this presentation we will analyse the statistics of the 7 km RAMS simulations at horizontal scales of 300 km and 50 km. Parameters to be analysed will include cloud `optical properties, cloud-top height, cloud cover, precipitation and phase. These statistics will be compared with observations.

JWM08/W/11-A3 **1220**

HIGH RESOLUTION ENSEMBLE PREDICITON WITH A LIMITED AREA MODEL

Chiara Marsigli, ANDREA MONTANI, Fabrizio Nerozzi, Tiziana Paccagnella, Paolo Patruno (ARPA-SMR, Viale Silvani, 6, 40122 Bologna, Italy, Email: eps@metgranew.arpamet.regione.emilia-romagna.it), Roberto Buizza (ECMWF, Shinfield Park, Reading, UK) and Franco Molteni (CINECA, Via Magnanelli 6/3, 40033 Casalecchio di Reno, Bologna, Italy)

The aim of this work is to provide a contribution to the definition of a flood risk alarm system. The SMR-ARPA operational Limited Area Model (LAMBO) is nested on the ECMWF Ensemble Prediction System (EPS) and its capability to predict at the medium range (5 days ahead) and at high horizontal resolution (about 20 km) heavy rainfall events is investigated. Four case studies of flooding, selected from MAP case list, are examined. The clustering algorithm, using the 700 hPa geostrophic wind vector field as discriminant variable, allows to find, after 5 forecast days, different evolution scenarios, the most likely one being relative to the most populated cluster. For each case study, 5 different members of the EPS are selected and used as boundary and initial conditions for LAMBO integrations. In 2 case studies, the LAMBO-integrations, which correspond to the members of the most populated clusters, predict, to a very good degree of spatial accuracy, the heavy rainfall occurred. In the other cases, the LAMBO-spread of the ensemble is large enough so that the extreme events are predicted by at least one of the other members. The sensitivity to the choice of the variable for clustering the EPS members is also discussed.

THE PROCESSES INVOLVED IN THE OROGRAPHIC ENHANCEMENT OF PRECIPITATION AND THEIR DETECTION BY RADAR

G.L. AUSTIN, J.Purdy, A.W Seed (Atmospheric Physics Group, University of Auckland, New Zealand, g.austin@auckland.ac.nz) and I Cluckie (Water Resources Group, University of Bristol)

In many parts of the world, including New Zealand, the annual distribution of rainfall is clearly intimately related to topography and wind direction. Climate change scenarios for New Zealand involve systematic changes in wind direction probabilities rather than direct surface heating. It thus becomes an important issue to discover quantitative relationships between topography and wind to predict climate and operational impacts on important activities such as agriculture and hydro-electric power generation. Two sets of high resolution radar and raingauge data from the SALPEX experiment are presented in the context of the other relavent meteorology. They represent the normal highwind speed Nor'wester which produces most of the rain in the South Island of New Zealand and a more unusual low wind speed event. Techniques for the determination of the detailed evolution of the precipitation processes involved are illustrated.

JWM08/W/12-A3 **1440**

OBSERVATIONS OF CONVECTION TRIGGERED BY WINDFLOW OVER HILLS

Warren Gray (National Institute of Water and Atmosphere, PO Box 14 - 901,Wellington New Zealand, Email: w.gray@niwa.cri.nz)

The upmotion resulting from windflow over hills can lead to the triggering of convection in a potentially unstable flow. This can lead to an increase in rainfall over the hills compared to upwind regions. Two observational campaigns have been carried out in New Zealand, on two different scales of hills, to increase our understanding of the processes involved in the enhancement of rainfall over hills. The OPERA campaign studied rain over hills up to 1500m high and SALPEX studied rain over the Southern Alps, which have peaks in excess of 2500m.
High-resolution scanning radar data from OPERA show that convection tends to develop over the hills in conjunction with the passage of pre- existing showers. That is, showers pass over the hills from areas upwind, and as they pass more convective showers develop over the hills. This is commensurate with the concept that the pre- existing showers are marking areas of enhanced instability, which is then released by the upmotion of the flow over the hill. High- resolution rain gauge data show that, in general, that character of the showers over the hills is similar to those upwind, but the showers are more frequent over the hills.
Vertically pointing radar data and RHI scanning radar data from SALPEX show that the pre-frontal convection triggered by the windflow over the hill has echo top heights of only around 3 km, yet surface rainfall intensities can reach up to 100 mm h-1. Rain gauge data also shows that the rainfall becomes more variable as the flow moves towards the hill, but decreases nearer the crest. Numerical solutions to the windflow over the hill shows that, for stable flow, there is down motion aloft which would "cap" any rainfall formed at lower levels. This "capping" becomes stronger further towards the crest, and this could explain the more stratiform nature of the rainfall there.

JWM08/W/06-A3 **1500**

OROGRAPHIC INFLUENCES DURING WINTER PRECIPITATION EVENTS ON THE AVALON PENINSULA, NEWFOUNDLAND

COLIN E. BANFIELD, David R.Hudak and Alan Thomson (Memorial University of New Foundland, Elizabeth Aveenue, ST. Johnís, New Foundland A1B 3X9. E-mail:colinb@morgan.ucs.mun.ca Telephone No: 709-737-8981 Fax No: 709-737-3119)

Precipitation enhancement over a low coastal hill in winter is demonstrated for particular associations of synoptically determined onshore airflow and local geography encountered over southeastern Newfoundland. Four such cases are analysed, in which various sequences and combinations of precipitation types occurred at surface temperatures just below freezing during pre-warm front situations. Comparative surface gauge records from sites at the coast and hill summit, together with detailed volume scan data from a nearby Doppler radar, are employed to substantiate the interaction of local orography and meteorological factors. Although precipitation at the hill summit and upwind coast was of similar overall duration in each case, the observed surface rates on the hilltop exceeded those at the coast by approximately 1.0-4.0 mm hr-1 during different stages of the events. Analysis of representative vertical cross sections of Doppler reflectivity patterns reveals that intensities are especially enhanced near the windward hill crest; this supports the observed association of periods of greatest enhancement with a local upslope wind component exceeding 20 m s-1. In the majority of these cases the enhancement is maintained primarily by the seeder feeder mechanism, which appears to be accelerated during transitions between precipitation types and when the surface warm front is 120-150 km distant. However, a preliminary phase of snowfall enhancement in advance of the main warm frontal clouds, due to the topographically-induced uplift of stable onshore airflow, was also observed.

ACTIVE VOLCANOES OF THE ANTARCTIC PLATE

Wesley E. LE MASURIER (Department of Geology, University of Colorado, Denver, Colorado, 80217-3364, USA, email: wlemasurier@carbon.cudenver.edu)

It has been estimated that there are 41 active volcanoes on the Antarctic plate, but there are only eight for which Holocene activity is unquestioned. This large uncertainty exists because direct observation is difficult, and because documenting Holocene activity by ^14C dating is not possible where no life forms exist. Fifteen of the 41 "active" volcanoes are in the West Antarctic rift system, including a recently discovered sub-glacial volcano inferred from

geophysical data. Twelve others are oceanic islands, 9 are in the South Sandwich arc, and 5 are on the Antarctic Peninsula. The Antarctic plate is almost completely encircled by mid-ocean ridges and has hardly moved since 85 Ma. This environment limits the mechanisms available to sustain volcanic activity on the continent. Thus, mantle plume activity and the interaction of transform faults with the rift system are the main mechanisms that have been invoked to explain volcanism in the rift.
The great enigma of Antarctic volcanism is the extent to which Cenozoic activity has occurred beneath thick ice cover, and the potential it, and associated high heat flow, may have to destabilize the West Antarctic ice sheet. Aeromagnetic surveys suggest the existence of 10^6 km^3 of subglacial volcanic rock, and it has been suggested that the aseismicity of the rift system may be related to magma overpressure. These portend significant subglacial volcanic activity (and high heat flow) in the future, but glaciologists are skeptical that these could be factors in the instability of the ice sheet. Until the potential effects of these factors are modeled, and the causes of the aeromagnetic anomalies verified, the question of how serious this threat might be will remain a matter of speculation.

JSA09/W/14-A2 1000

ICE-VOLCANO INTERACTION DURING SUBGLACIAL ERUPTIONS IN TEMPERATE ICE CAPS IN ICELAND

Magnus T. GUDMUNDSSON (Science Institute, University of Iceland, Hofsvallagata 53, 107 Reykjavik, Iceland, email: mtg@raunvis.hi.is)

Subglacial eruptions occur in volcanic regions at high latitudes and at some large strato-volcanoes in other areas. About 11% of Iceland is ice covered and eruptions within ice caps have been frequent. Some of the most active volcanoes in Iceland are ice covered, notably the Grimsvotn volcano in the Vatnajokull ice cap and the Myrdalsjokull volcano. Jokulhlaups associated with volcanic eruptions in Iceland may drain several cubic kilometers of water and discharge rates of order 100,000 m3/s have been reported. Landscape in the volcanically active zones is dominated by hyaloclastite ridges and tuyas, formed under the Pleistocene ice sheets. The first eruption within a large ice cap that could be monitored was the Gjalp eruption in Vatnajokull in 1996. About 0.4 km3 of magma erupted in 13 days. Melting rates were very fast, 0.5-0.8 km3/day for the first four days when the rate of eruption was highest. This high rate of melting suggests fragmentation of the magma and formation of hyaloclastites. Comparison of the Gjalp eruption with eruptions in the nearby Grimsvotn caldera, illustrates the effect of ice thickness on the response of the surrounding glacier. When the ice is thick, as in Gjalp (500-750 m), the ice deforms and flows into the depression created by melting and drainage. In Gjalp the depressions had a width of several kilometers but the glacier around the depressions was not affected. At known eruption sites in Grimsvotn, ice thickness is about 100 m. Openings are quickly melted in the ice, leading to explosive eruptions that disperse tephra over the ice cap. The ice surrounding the craters is mainly passive and suffers little deformation. Ice-volcano interaction, similar to that observed in Grimsvotn, occurs on ice covered strato-volcanoes in many parts of the world

JSA09/W/08-A2 1045

ARCTIC GRAVITY PROJECT

Rene FORSBERG (Geodynamics Dept., KMS, Rentemestervej 8, DK-2400, Copenhagen NV, Denmark, email: rf@kms.dk)Steve KENYON (NIMA, 3200 S 2nd St, St. Louis, Mo., USA, 63118-3399, email: kenyons@nima.mil)

The gravity field of the Arctic Ocean region is of prime importance for global gravity field and geoid models, for providing information on the geology and tectonics of the Arctic Basin, and for navigation and orbit determination. Planned satellite gravity field missions such as CHAMP, GRACE and GOCE will all to a varying degree be strongly affected by the gravity field of the polar areas, especially for the satellites launched with a non-polar orbit, where a polar gap will remain in the coverage.
Ongoing gravity activities over many years have resulted in a nearly complete coverage of the Arctic with gravity field data. In recent years major airborne and surface survey activities have been carried out in the High Arctic and Greenland, US nuclear submarines have criss-crossed under the ice on scientific cruises, and Russia has continued adecade-long program of surface and airborne gravity measurements. Recently an international initiative, involving a.o. scientists from all circumarctic countries, has been taken to compile all available and releasable gravity data into a 5' uniform, public-domain gravity grid in year 2000. The paper will report on the progress of the project, and showexamples from some recent airborne gravity survey activities.

JSA09/E/02-A2 1115

POLAR GRAVITY MAPPING FROM FUTURE SATELLITE MISSIONS

C.K. SHUM (Department of Civil and Environmental Engineering and Geodetic Science, The Ohio State University, 470 Hitchcock Hall, 2070 Neil Avenue, Columbus, OH 43210-1275, USA, Email: ckshum@osu.edu) and Andy Trupin (School of Natural Science, Oregon Institute of Techology, Klamath, Oregon, USA, email: trupina@oit.edu)

By the beginning of the next Millennium, GRACE and CHAMP gravity mapping missions are expected to provide a three-fold improvement in our knowledge of the Earth's static gravity field to 1 cm accuracy in geoid at a wavelength of 300 km or longer, and to measure time-varying mass variations of the Earth system with a temporal resolution of days to weeks. With applications to the mass balances of the polar ice sheets, GRACE with a five-year mission is anticipated to provide a measurement accuracy corresponding to better than 0.01 mm/yr of sea level rise for each of Antarctica and Greenland ice sheets, over a spatial scale of 1600 km or longer. The orbital inclinations of GRACE/CHAMP would however limit the coverage of the polar ice caps to within +/- 87 degrees. In 2001, NASA will also launch IceSat, whose instrument Geocience Laser Altimeter System (GLAS) will provide accurate measurements of ice elevation change. Radar altimeters are providing measurements of ice elevation change for interior of Antarctica and Greenland ice sheets. GPS measurements are providing crustal uplift information. In addition, cannon-satellites with satellite laser ranging are enabling determination of long wavelength gravity changes. In this paper, we will discuss the results of pilot studies for the anticipated improvement in the static and temporal gravity fields of the polar regions, and the ability of future satellite missions with combined use of in situ observations to potentially separate ice sheet mass balance, isostatic uplift, and changes in snow accumulation at the surface.

JSA09/W/01-A2 1145

A HIGH RESOLUTION ARCTIC MARINE GRAVITY FIELD FROM ERS ALTIMETRY

Seymour LAXON, Neil Peacock (both at University College London, MSSL, Holmbury St. Mary, Dorking, RH5 6NT, email: swl@mssl.ucl.ac.uk) David McAdoo and Anahita Tikku, (both at U.S. National Oceanic and Atmospheric Administration, NODC/Lab for Satellite Altimetry, SSMC3, Silver Spring, MD, 20910, US, email: dave@comet.grdl.noaa.gov)

A new, detailed, high-accuracy gravity field has been derived from ERS-1 and ERS-2 satellite radar altimeter data over all Arctic seas south of 82 degrees north including permanently ice-covered seas. The entire ERS-1 Geodetic Mission and 22 cycles from the ERS-2 mission have been used in generating this field. In addition to using this larger data set, we have employed enhanced processing techniques, to retrack and reduce these ERS waveform data. Comparisons with airborne measurements show that this new Arctic gravity field resolves features down to crustal scales (i.e., spatial wavelengths as short as 20 km) representing a significant improvement over the 75 km resolution limit of our 1994 Science field (Laxon and McAdoo, Science, vol. 265, 621-624, 1994).
This gravity field should prove a particular help in unravelling the tectonic history and structure of the Canada Basin and Chukchi Borderland. For example, the gravity field clearly shows the anomalies associated with the Alaskan and Canadian continental shelf edges bordering the Canada Basin, shelf edge anomalies bordering the Eurasian Basin as well as a lineated low coincident with the Northwind Ridge. Anomalies and lineations arising from tectonic details imprinted in the seafloor can also be seen including: a north-south trending, negative lineation locating an apparent extinct spreading ridge in the middle of the Canada Basin. Other distinctive anomalies include those due to structures associated with crustal extension in the Chukchi Continental Borderland as well as on the Siberian continental margin and those overlying the active spreading ridge in the Eurasian Basin north of the Laptev Sea. At the other - or Atlantic end - of the Eurasian Basin, anomalies coincident with the Spitsbergen FZ and Lena trough can be seen.

JSA 09/E/04-A2 1200

EARTH TIDES AND OCEAN TIDAL LOADING ON GREENLAND: CORRECTION OF SURFACE DEFORMATIONS BY TIDAL GRAVITY MEASUREMENTS

Gerhard JENTZSCH and Markus Ramatschi (both at Institute for Geosciences, FSU Jena, Burgweg 11, D-07749 Jena, email: jentzsch@geo.uni-jena.de), Per Knudsen (Geodetic Institute, National Survey and Cadastre, DK-2400 Copenhagen, email: pk@kms.dk)

Space and air borne observations of the earth concerning the changes of the Greenland ice cap are related to kinematic GPS measurements connected to fiducial sites. With regard to the accuracy of these measurements the time variation of the coordinates of the reference stations must be determined. Since most of the reference stations are close to the coast the correction applying standard ocean load models is not sufficient: Due to incomplete ocean tidal charts especially north of 60° and in shelf areas the computed loading signal does not explain the observation.
With our L & R tidal gravimeter ET 18 we performed gravity tidal measurements from 1993 to 1997 at four sites covering about one year each. The determination of the vertical deformation requires the separation of the Newtonian attraction from the observed load signal by model computations applying a local crust / mantle structure and a local distribution of the ocean tides derived from different models. The vertical deformations obtained for the main tidal waves of up to 35 mm explain about half of the observed effect in gravity only. Thus, the ocean tide models need improvement.

JSA09/W/13-A2 1215

ANALYSIS OF GPS DATA OBSERVED BETWEEN 1997-99 ON PERMANENT STATIONS IN ANTARCTICA AND ITS VICINITY

Xin CHEN (1), Falko Menge (2), Hans Werner SCHENKE (1), Tilo Schoene (1), Guenter Seeber (2), Christ of Voelksen (2) ((1)Alfred Wegener Institute for Polar- and Marine Research, Columbusstrasse, D-27568 Bremerhaven, Germany, e-mail: Schenke@AWI-Bremerhaven.DE, (2) Institut fuer Erdmessung, Universitaet Hannover, Schneiderberg 50, D-30167 Hannover, Germany, e-mail: menge@mbox.ife.uni-hannover.de)

Under the scientific program GIANT (Geodetic Infrastructure of Antarctica, coordinated under the auspices of the SCAR Working Group on Geodesy and Geographic Information) several new permanent GPS stations were established in Antarctica and its vicinity during 1997 and 1998. The resulting network has enhanced our capability in monitoring crustal deformation in Antarctica. The new stations include: Jubany /Dallmann (DALL), Gough Island (GOUG), Sanae IV (VESL), General Belgrano II (BELG), Mawson (MAW1), Palmer (PALM), Syowa (SYO1), and Dumont d'Urville (DUM1).
The data were processed together with other existing permanent GPS-stations in Antarctica and several permanent IGS-stations in the southern hemisphere, using the GAMIT/GLOBK (Alfred Wegener Institute) and GIPSY-OASIS II (Institut fuer Erdmessung) software packages. Site position time series and site velocities were determined in the ITRF reference frame, and were then compared and analyzed with estimates from other sources.

JSA09/L/02-A2 1230

PLATE DEFORMATIONS AND PLATE KINEMATICS OF ANTARCTICA DERIVED BY GPS

R. DIETRICH, R. Dach, J. Perlt (TU Dresden, Institut für Planetare Geodäsie, D-01062 Dresden), H.-W. Schenke, T. Schöne, M. Pohl (Alfred-Wegener-Institut für Polar- und Meeresforschung, Columbusstraße, D-27568 Bremerhaven), J. Ihde, G. Engelhardt (Bundesamt für Kartographie und Geodäsie, Außenstelle Leipzig, Karl-Rothe-Straße 10, D-04105 Leipzig), G. Seeber, F. Menge, Ch. Völksen (Universität Hannover, Institut für Erdmessung, Schneiderberg 50, D-30167 Hannover), W. Niemeier, H. Salbach (TU Braunschweig, Institut für Geodäsie und Photogrammetrie, Gaußstraße 22, D-38106 Braunschweig), K. Lindner, H.-J. Kutterer, M. Mayer (Universität Karlsruhe, Geodätisches Institut, Englerstr. 7, D-76128 Karlsruhe), H. Miller, A. Veit (Universität München, Institut für Allgemeine und Angewandte Geologie, Luisenstraße 37, D-80333 München)

Repeated GPS observations are an efficient and accurate tool to study crustal deformations in polar regions. The results presented here are based on data obtained from 1995 until 1998 in the frame of the SCAR GPS Campaigns. A joint German research group contributed substantially to the field activities as well as analyzed the data with different software packages (BERNESE, GAMIT/GLOBK, GIPSY, GEONAP). The resulting network deformations can be used to relate the kinematics of the Antarctic plate to other major tectonic plates. Furthermore, regional deformation patterns, e.g. in the area of the Antarctic Peninsula, are obtained.

THE GEOPHYSICS OF ARCTIC SEA ICE

Donald K. Perovich (USA CRREL, 72 Lyme Road, Hanover NH 03755, email: perovich@crrel.usace.army.mil)

Perennial sea ice covers much of the Arctic Ocean. The presence of the ice cover profoundly affects energy exchange between the atmosphere and the ocean. The energy exchange process is complicated by the considerable seasonal and spatial variability exhibited in the properties of the ice cover. For instance, due to a combination of thermodynamic and dynamic processes, ice thicknesses can ranges from open water to ridges tens of meters thick. Albedos decrease from peak values of 0.9 in the spring to minima of 0.4 at the height of the summer melt season. General circulation models indicate that Arctic sea ice may be a sensitive indicator of climate change. The sensitivity of the ice pack to climate changes is due in part to the ice-albedo and cloud-radiation feedbacks. This presentation will describe the key geophysical properties of the Arctic sea ice cover and summarize recent sea ice studies. Particular attention will be paid to sea ice feedback processes and the surface heat budget of the Arctic Ocean.

JSA09/L/03-A2 1445

GEOPHYSICS OF THE ANTARCTIC ICE SHEET

CHARLES R. BENTLEY, Geophysical and Polar Research Center, University of Wisconsin, 1215 W. Dayton St., Madison, WI 53706, USA; email: bentley@geology.wisc.edu

The Antarctic ice sheet contains sufficient ice to raise world-wide sea level by more than 60 m if melted completely; the amount of snow deposited annually on its surface is itself equivalent to over 5 mm of global sea level. Thus, the ice sheet could be a major agent of change for the present-day sea level, but it is still not known whether the ice sheet is growing or shrinking and the snow accumulation rate may be changing. The ice sheet is potentially subject to alteration in a modified climate; in fact, it may be shrinking now in response to the end of the last ice age. The West Antarctic ice sheet, which rests on a bed far below sea level, may be particularly capable of rapid retreat. Rates of discharge from some of the major ice streams have changed markedly in recent decades and the grounding line of one of them may be retreating rapidly. Measurements from satellites early in the 21st century are expected to settle the question of current growth or shrinkage, but prediction of the future will remain problematic for many years. Critical to improving our understanding of ice-sheet behavior is to learn more about the key physical processes that govern ice-stream dynamics. These include the interaction between an ice stream and its bed, which may vary with scale; complex temperature-dependent processes at lateral shear margins; interaction with ice shelves; and the spatial and temporal initiation of stream-like flow.

JSA09/L/04-A2 1515

ARCTIC METEOROLOGY AND CLIMATOLOGY : CURRENT UNDERSTANDING AND FUTUREDIRECTIONS

Amanda H. Lynch, University of Colorado, USA

The circulation and surface energy and mass balance of the Arctic atmosphere, land surface, sea ice and ocean system combine to have direct impacts on global climate. For example, the freshwater inputs via runoff and precipitation less evaporation (P-E) play a key role in maintaining the halocline, thereby influencing global ocean circulation as well as regional sea ice cover. The processes determining runoff and P-E include a complex series of feedbacks involving clouds, permafrost, atmospheric circulation, sea ice cover, and many other factors. In addition, the most recent IPCC assessment shows that the largest disagreement between coupled climate model simulations of present day climate remains the polar regions. The disagreement reflects the sensitivity of this interconnected system as well as our limited understanding.
Recent analyses of observations have identified interesting variations in the North Atlantic and Arctic Oscillations, the North Atlantic thermohaline regime, the sea ice distribution, precipitation, permafrost distribution and many other climate variables. It remains to be determined whether these variations are consistent with, or indicators of, the type of polar amplification predicted by global climate model experiments. This presentation will provide an overview of some current findings in the Arctic, and discuss future research directions.

JSA09/E/06-A2 1600

ANTARCTIC METEOROLOGY AND CLIMATOLOGY: RECENT DEVELOPMENTS AND OUTSTANDING PROBLEMS

J.C. KING (British Antarctic Survey, Cambridge CB3 0ET, UK, email: j.c.king@bas.ac.uk)

Over the past two decades, considerable progress has been made in understanding the processes that control the climate of Antarctica and couple this region with the rest of the global climate system. Technological developments have made it feasible to deploy automated measuring systems in previously inacessible areas, while the wealth of data now available from satellite sensors permit continent-wide monitoring of key climatological variables. These advances in measurement technology have been paralelled by improvements in global and regional scale models that, for the first time, provide a synthesis of the workings of the Antarctic climate system. In this talk I will review the advances of the last two decades and will look at some problems that are still outstanding. These include identifying the causes of the recent warming seen in the Antarctic Peninsula and correctly parametrising the processes that control katabatic flow.

In the frame of the "Airborne Polar Experiment" (APE) a Russian military plane M55 has been converted in a high flying research platform for investigations of the polar lower stratosphere and upper troposphere. A first campaign, carried out in the Arctic during the winter 1996-97 has proved the capability of M55-Geophysica aircraft to access altitude and geographical locations, which are difficult to reach with other platforms.
A new mission of the M55, supported by the Italian National Program for Antarctic Research (PNRA), is now planned over the Antarctic Peninsula for the study of the chemical processes responsible for stratospheric ozone losses, its subsequent recovery and its interaction with mid-latitude air. The campaign, named APE-GAIA (Geophysica Aircraft In Antarctica), will based in airport of Ushuaia, Argentina (Lat. 54°S, Long. 68°W) from 15 September to 15 October 1999 and will represent the first major mission with a scientific payload of both in-situ and remote sensing instruments conducted on board of a high altitude aircraft in the southern polar region.

JSA09/E/07-A2 1645

SIMULATED VARIABILITY AND TRENDS OF THE ARCTIC SEA-ICE COVER PROPERTIES

Michael Hilmer, Markus HARDER, Peter Lemke

The polar sea-ice caps have received special attention in the context of Global Warming. Especially focussing on detecting trends of the Arctic ice cover as an indication of Climate Change, it is essential to determine its natural variability. The tempora l variations of the Arctic sea-ice cover properties, such as ice thickness and ice extent, are investigated with the dynamic-thermodynamic Kiel Sea-Ice Simulation (KISS). The model is integrated over 40 years (1958 to 1997) with a daily time step. Daily fields of surface wind and air temperature derived from the NCEP/NCAR.
Reanalysis Project provide the atmospheric forcing. The simulation yields both strong inter-annual variability and a statistically significant, decreasing trend in ice thickness. Largest inter-annual variations of the ice thickness occur in the Beaufort Sea and near the Siberian shelves. Statistically significant negative trends of the ice thickness mainly occur near the North Pole and in the Kara and Barent Seas where the inter-annual vari ability is small.

JSA09/E/01-A2 1700

GEOPHYSICAL METHOD OF DETERMINATION OF THE BASE PERMAFROST BOUNDARY IN HOLES

Boris SEDOV (North-East Interdisciplinary Research Institute, the Russian Academy of Sciences, Magadan, Russia)

During the development of deposits in criolithic zone (production of coal, diamonds, placers etc.) there is a need to know the position of the base permafrost boundary (BPB) that in case of mineralized waters, does not coincide with 0_ isotherm. To determine the position of the base permafrost boundary in the hole, geophysical method was used. This method makes possible to carry out the determinations with any possible precision. For this, multicore cable is installed into the hole after drilling. Every line of such a cable ends with electrode. The distance among the electrodes is chosen according to prescribed precision for (BPB) depth determination. During the recovery of rock temperature in frozen stratum, solution freezes in the hole. Ice is not formed under the BPB. Freezing- in of electrode into the ice increases the earth resistance.

JSA09/W/17-A2 1715

ANTARCTIC PHYSICAL OCEANOGRAPHY: INTERACTIONS WITH SEA ICE, ICE SHELVES AND ICE SHEETS

S.F. ACKLEY, (111 Villa Ann, San Antonio TX 78213, USA, email: jlongbotham@pol.net)

Within the world ocean, a significant fraction of the total water mass has had "contact" with the cold atmosphere in the Antarctic region, and is defined as Antarctic Bottom Water (T< 2°C). Sea ice affects significantly this water mass formation and its circulation in the polar oceans. The seasonal cycle of the ice cover modifies the large-scale density gradients due to the different locations of freezing and melting areas. Circulation beneath ice shelves results in cooling and freshening of water masses, while topography of ice shelves serves to steer water mass circulation, with consequences on their dynamics and thermodynamics. Investigations over the last two decades, when the few (but first) oceanographic expeditions to Antarctica during winter conditions have taken place have shown complex and sensitive interactions between the ocean circulation and sea ice and glacial processes. Event-driven processes originating in the sea ice and glacial ice account for significant variability in water mass modification. Sea ice-atmosphere interaction in the eastern Weddell Sea may, for example, account for the interdecadal variability in the occurrence of the deep water Weddell Polynya (1974-1976). When the Weddell Polynya occurred, total deep water formation of Antarctic Bottom Water was increased substantially, exceeding that occurring from interactions on the continental shelves alone. Ice Shelf Water, a constituent of Antarctic Bottom Water, is formed by modification of inward flowing waters from the continental shelves, that melt a portion of the ice shelves during their transit beneath them. The intensity of the circulation, and seasonal and interannual fluctuations, appear to be linked to the topography of the ice shelves, driven by glacial processess, and the properties of the continental shelf source waters, driven by sea ice formation in front of the ice shelves. Coastal polynyas, (found extensively around East Antarctica) can occur where glacial tongues from the ice sheet block the flow of sea ice.

JSA09/W/02-A2 1745

MODELLING OF THE ANTARCTIC CIRCUMPOLAR CURRENT: A COMPARISON OF FRAM AND EQUIVALENT BAROTROPIC MODEL RESULTS

Vladimir IVCHENKO (Jet Propulsion Laboratory/NASA, 300-323, 4800 Oak Grove Drive, Pasadena, CA 91109, USA, Email: voi@sundog.jpl.nasa.gov) Alexander Krupitsky (Lehman Brothers Holdings, Inc 3 World Financial Center, New York, NY 10285, USA, Email: akrupits@lehman.com); Vladimir Kamenkovich (Dept. of Marine Science, Institute of Marine Sciences, The University of Southern Mississippi, Stennis Sp.C., MS 39529, USA, Email:kamenkov@sunfish.ssc.usm.edu); Neil Wells (Scool of Ocean and Earth Sciences, Southampton Oceanography Centre, European Way, Southampton SO14 3ZH,UK, Email:n.c.wells@soc.soton.ac.uk)

Analyzing the Fine Resolution Antarctic Model (FRAM) simulations, Killworth (1992) noticed a strong tendency for self-similarity in the vertical structure of the velocity field of the Antarctic Circumpolar Current (ACC). Based on the self-similarity hypothesis, Krupitsky et al.(1996) developed an equivalent barotropic (EB) model of the ACC capable of describing the horizontal structure of the ACC. Compared to the multi-level-primitive-equation GCM, the EB model appeared substantially simpler and therefore useful in process-oriented and sensitivity studies. To assess the applicability of the EB model to the analysis of the horizontal structure of the ACC we performed the comparison of the EB model results with the time-mean depth-averaged results of the FRAM model. The horizontal structure of the ACC transport stream function appears reasonably similar in both models. The more detailed regional analysis shows a rather satisfactorily agreement in the regions with pronounced topographic features (Crozet-Kerquelen area, Macquarie-Ridge Complex and near Pacific-Antarctic Ridge, and to the east from the Drake Passage). In the regions with a more quiet topography (eastern part of the Indian Sector of the Southern Ocean, and in the Southeast Pacific Basin) the agreement is worse but still meaningful. It seems that the EB model satisfactorily describes the influence of the bottom topography on the ACC. It is known (Stevens and Ivchenko 1997) that the

averaged (over time, depth and a latitude circle) FRAM zonal momentum equation provides the balance essentially between the wind stress and the bottom pressure drag. The same averaged momentum balance is given by the EB model.

TECTONICS AND SEISMICITY OF THE ANTARCTIC PENINSULA REGION

Stacey D. ROBERTSON, Douglas A. Wiens, and Gideon P. Smith (Department of Earth & Planetary Sciences, Washington University, St. Louis, MO, email: stacey@izu.wustl.edu), Emilio Vera (Universidad de Chile, Santiago, Chile), George Helffrich (University of Bristol, UK)

The purpose of the Seismic Experiment in Patagonia and Antarctica (SEPA) is to learn more about the seismic and tectonic characteristics of the South Shetland trench and Antarctic peninsula, which are largely unknown. It has been unclear whether subduction is still occurring in the South Shetland trench, and the level of tectonic activity in the backarc Bransfield Strait is also uncertain. Major changes in plate motions over the past 4 million years suggest that this region may provide important insights into several important processes, including very slow subduction, the initiation of rifting, and how plate tectonic systems change through time. The Antarctic portion of the SEPA deployment consists of seven broadband seismic instruments located in the Antarctic Peninsula - South Shetland Islands region. Three of these stations are at inhabited sites and receive occasional support throughout the year, and four are located at field sites which can only be reached during the Antarctic summer and which must receive all their power through solar power and banks of Carbonaire batteries. Fourteen ocean bottom seismographs were recently deployed in the South Shetland trench and Bransfield Strait in conjunction with Leroy Dorman of Scripps Institute of Oceanography.
Although the South Shetland Island area displays a low level of seismicity in global catalogs, the data which we obtained from 1997 and 1998 indicates a high level of local seismicity (mb 2-4). Preliminary locations of these events indicate that the seismicity is concentrated in the South Shetland trench with a few earthquakes located in the Bransfield Strait. The seismicity of the South Shetland trench extends to depths of about 70 km, indicating that subduction is currently occurring. Some earthquakes are concentrated near large seafloor volcanoes along the central rift of the Bransfield Strait, suggesting current eruptive activity. We are also investigating mantle seismic anisotropy from shear wave splitting to provide constraints on the pattern of possible mantle flow through Drake Passage.

JSA09/E/05-A3 0900

SURFACE WAVE TOMOGRAPHY OF THE ARCTIC REGION

Michael Barmin, Anatoli LEVSHIN, Michael Ritzwoller, Alex Padgett (all at Department of Physics, University of Colorado at Boulder, Campus Box 390, Boulder, CO 80309, U.S.A,
e-mail: levshin@lemond.colorado.edu)

Because of the station and earthquake distributions at high northern latitudes, the large-scale structure of the Arctic crust and uppermost mantle is best explored with surface waves. We report on the results of a study of surface wave dispersion at high northern latitudes. We have extended earlier studies of surface wave dispersion across Eurasia in three ways.
(1) Data processing. We have obtained new Rayleigh and Love wave dispersion measurements at GSN, USNSN, and CNSN stations following about 300 earthquakes which occurred around the northern hemisphere from 1995 through 1997.
(2) Isotropic dispersion maps. We have estimated broadband (20 s - 150 s) isotropic group velocity maps across the entire eastern hemisphere north of the equator and for the western hemisphere north of about 50 degree N latitude.
(3) Azimuthally anisotropic dispersion maps. We have simultaneously estimated 2*psi azimuthally anisotropic group velocity maps for the same region at the same periods. We report on the features that appear in the estimated isotropic group velocity maps and on the relation of these features to those apparent in other large-scale dispersion studies. The observed maps display the signatures of sedimentary and oceanic basins, crustal thickness variations, and upper mantle anomalies under both continents and oceans. For example, there are two significant Arctic oceanic low velocity anomalies at long periods. The first and more prominent is associated with the Iceland hotspot and the northward continuation of this anomaly adjacent to the Mohns Ridge toward the Fram Strait between Greenland and Svalbard. The second anomaly runs from the Laptev Sea to the Mendeleev Ridge. The latter anomaly is not obviously coincident with the sismically active Arctic Mid-Oceanic Ridge. At 150 s the low velocities are more nearly coincident with the aseismic Mendeleev Ridge. Finally, we report on the importance of the estimated azimuthal anisotropy in fitting the dispersion data and how its inclusion in the tomographic inversions affects the isotropic maps.

JSA09/W/05-A3 0930

AEROMAGNETICS IN ANTARCTICA.

Massimo CHIAPPINI (Istituto nazionale di Geofisica, Vigna Murata 605, 00143 Roma, Italy; Email: chiappini@ingrm.it) Fausto Ferraccioli (Dipteris Univ. Genova, Italy,
email: magne@dister.unige.it)John Behrendt (INSTAAR - University of Colorado Boulder, CO 80309-0450 USA, Email: behrendj@stripe.colorado.edu) Julie Ferris (British Antarctic Survey High Cross, Madingley Road Cambridge CB3 OET United Kingdom, Email: JKF@pcmail.nerc-bas.ac.uk).

The Antarctic continent is 99% covered with ice and is the most poorly understood region of the planet. International interest of Earth Sciences in the Antarctic is considerable because of the central role of its tectonics and geology in both Gondwana and Rodinia evolution. Remotely-sensed data, such as magnetic anomaly data provide one of the few ways to obtain geological information over much of the continent, helping to delineate major structural components of the continent, such as cratons, , mobile belts, terranes and rifts. Consequently, numerous near-surface magnetic surveys have been carried out by the international community for site-specific geologic objectives.
Individual magnetic surveys are being combined into regional and ultimately continental scale magnetic synthesis for the Antarctic. In 1995, an international Working Group was established, and initiated efforts to develop an inventory of all magnetic data sources for the Antarctic region south of 60 degrees S, by means of a multinational cooperation called ADMAP, the Antarctic Digital Magnetic Anomaly Project. A number of Antarctic aeromagnetic surveys are reviewed, as a contribution to ADMAP's activities.

JSA09/E/11-A3 1000

A REVIEW OF MAGNETIC ANOMALY FIELD DATA FOR THE ARCTIC REGION: GEOLOGICAL IMPLICATIONS

Patrick T. TAYLOR (Geodynamics Branch, NASA/GSFC, Greenbelt, MD 20771, USA, email: ptaylor@ltpmail.gsfc.nasa.gov); Ralph von Frese and Daniel R. Roman (both at Department of Geological Sciences, The Ohio State University, Columbus, OH 43210, USA, email: vonfrese@geology.ohio-state.edu); James J. Frawley (Herring Bay Geophysics, Dunkirk, MD 20754, USA, email: hbgjjf@ltpmail.gsfc.nasa.gov)

Due to its inaccessibility and hostile physical environment remote sensing data, both airborne and satellite measurements, have been the main source of geopotential data over the entire Arctic region. Ubiquitous and significant external fields, however, hinder crustal magnetic field studies. These potential field data have been used to derive tectonic models for the two major tectonic sectors of this region, the Amerasian and Eurasian Basins. The latter is dominated by the Nansen-Gakkel or Mid-Arctic Ocean Ridge and is relatively well known. The origin and nature of the Alpha and Mendeleev Ridges, Chukchi Borderland and Canada Basin of the former are less well known and subject to controversy. The Lomonosov Ridge divides these large provinces. In this report we will present a summary of the Arctic geopotential anomaly data derived from various sources by various groups in North America and Europe and show how these data help us unravel the last remaining major puzzle of the global plate tectonic framework. While magnetic anomaly data represent the main focus of this study recently derived satellite gravity data (Laxon and cAdoo, 1998) are playing a major role in Arctic studies.

JSA09/E/09-A3 1015

MAGNETIC AND GRAVITY COMPILATION OVER VICTORIA LAND (ANTARCTICA): SOME TECTONIC IMPLICATIONS AND PROBLEMS

Fausto FERRACCIOLI, Emanuele Bozzo, Massimo Spano (all at DIP.TE.RIS., Univ. Genova, Italy, email: magne@dister.unige.it) Massimo Chiappini (Istituto Nazionale di Geofisica, Rome, Italy, email: chiappini@marte.ingrm.it)

Victoria Land (VL) is a key area to study the geology of Antarctica and at a broader scale for the reconstruction of Gondwana assembly, evolution and dispersal. As a first step towards geophysically consistent models for the tectonodynamical evolution of the region we compare magnetic and gravity patterns/trends with geologic and seismic constraints. After hypothized rifting in Precambrian times at the East Antarctic Craton margin, the Early Cambrian to Carboniferous history features subduction, accretion and collision of terranes. Jurassic tholeiitic magmatism at the site of the later Transantarctic Mountains (TAM) was followed by amagmatic(?) crustal extension in the Cretaceous. Finally Cenozoic transtensional and transpressional reactivation of Paleozoic and Mesozoic faults was accompanied by rift-related alkaline magmatism and major uplift of the TAM. Prominent magnetic anomalies have previously been recognized to be associated to Cenozoic plutonism and volcanism. Now it is clear that the pre-existing lower Paleozoic architecture controls its location. New gravity and magnetic data leads to an improved imaging of the Mesozoic to Cenozoic Rennick pull-apart basin and its relationship to VL terrane boundaries. A major magnetic and gravity anomaly break is recognized to correspond to the western boundary of the Wilson Terrane. Extensive Jurassic magmatism focussed in this boundary zone. Open questions regard the nature of the Bowers/Wilson Terrane and the docking mechanisms to the East Antarctic Craton. Unravelling the late-Proterozoic to lower Paleozoic history of VL is still particulary intriguing.

JSA09/W/21-A3 1045

INTERPRETATION OF 'RECONSTRUCTED' MAGNETIC ANOMALY DATA FROM THE BARENTS SEA-EAST GREENLAND SHELF REGION

Jan R. Skilbrei (Geological Survey of Norway, po box 3006, N-7002, Trondheim, Norway, email: jan.skilbrei@ngu.no)

Potential field anomalies from the Barents shelf and the East-Greenland shelf is interpreted in a pre 'break-up' reconstruction. The geology of the Barents Sea and the Greenland margin is interpreted using the magnetic anomaly in this pre-Eocene context. The magnetic data has been compared with the seismic profiles and the gravity data in order to identify the structural highs and the sedimentary basins, and constrain the interpretation.
The Precambrian and Caledonian geology of Scandinavia and East Greenland is compared with the geophysical data in order to differentiate between intrabasenent and suprabasement sources of the anomalies on the shelves. Long-linear anomalies are related to rift structures of the East Greenland shelf and the Barents Sea. A comparison with the Basin and Range Province of the western U.S. will be made, and the implications of the interpretations for the petroleum industry will be discussed. The lineament patterns as they are illustrated by the potential field images of shelves of the North-Atlantic region will be commented on.

JSA09/W/18-A3 1100

POLAR CRUSTAL ANOMALIES IN SATELLITE MAGNETIC AND GRAVITY OBSERVATIONS

Ralph R.B. VON FRESE, Hyung Rae Kim (both at Dept. of Geological Sciences, The Ohio State University, Columbus, OH 432120, USA, email: vonfrese@osu.edu, kim@geology.ohio-state.edu) Patrick T. Taylor (NASA Code 921, Goddard Space Flight Center, Greenbelt, MD 20771, USA, email: ptaylor@ltpmail.gsfc.nasa.gov)

Comparing satellite gravity data with terrain gravity effects can help sort crustal from subcrustal components. Crustal thickness variations may be estimated from the spectral correlation between the two data sets. Satellite gravity observations in combination with terrain gravity data may also be used to help estimate crustal components in satellite magnetic measurements. Here the first radial derivative of the terrain gravity effect may be used via Poisson's theorem for correlative potentials to sort crustal from noncrustal components in magnetic observations. Estimates crustal thickness variations and crustal components in satellite gravity and magnetic observations for the Arctic and Antarctic are presented.

JSA09/W/10-A3 1115

POLAR IONOSPHERES

Ted ROSENBERG (Institute for Physical Science and Technology, University of Maryland, College Park, MD 20742-2431 USA, email: rosenberg@uarc.umd.edu)

Quite recently, Newell [Eos, 79(51), 625, 1998] summarized evidence of the importance, even perhaps the controlling influence, of the ionosphere on magnetospheric dynamics, as manifested by the behavior of the aurora and other aspects of magnetosphere-ionosphere coupling. Changes in the background ionospheric conductivity affected by the amount of sunlight is thought to play the crucial role, with the flux of ionizing charged particles perhaps also having some significance. The two polar ionospheres are linked by the extension of the geomagnetic field into space which also provides a path for moving charged particles between hemispheres. Hence the importance of understanding the similarities and differences of the polar ionospheres. New facilities established in both polar regions in recent years have enabled extensive and simultaneous coverage of the polar ionospheres. The distributed high-latitude ground-based observations provide a valuable complement to the measurements being made in space. This has created new opportunities for global (including conjugate) studies of particle

precipitation, magnetic pulsations, ionospheric currents, radiowave emissions, and the structure and dynamics of the ionospheric plasma, as will be reported on here.

JSA09/W/20-A3 1130

WHERE ARE THE MAGNETIC POLES ?

Wallace H. CAMPBELL (World Data Center A for Solar Terrestrial Physics, NGDC / NOAA, 325 Broadway, Boulder, CO 80303-3328, USA, email: whc@ngdc.noaa.gov

Cartographers indicate a specific location in the Northern and Southern Hemisphere of the Earth as the place of a "Magnetic Pole." To geomagnetic scientists, it is unclear what is the meaning or value of such map locations. "Magnetic" poles of differing location can be defined by the dip of the International Geomagnetic Reference Field, by a geomagnetic co-ordinate system, by the eccentric geomagnetic field axis or surface dip, by paleomagnetic evidence, or by local (induction anomaly and external disturbance sensitive) determinations of a vertical field. These differing pole locations can be tens of degrees apart. The locations are slowly varying in poisition over the years, although cartographers never attach dates to their "exact" poles. Contrary to some popular beliefs, the mapped spot is, most certainly, not the average global location toward which a compass points.

PECULIAR DECREASE IN THE MAGNITUDE OF VERTICAL GEOMAGNETIC FIELD NEAR THE MAGNETIC POLES IN SUMMER SEASON

Naoshi FUKUSHIMA (Dept. of Earth and Planetary Physics, University of Tokyo, Tokyo 113-0033 Japan. email: fukusima@nipr.ac.jp)

This paper points out a remarkable decrease in the magnitude of vertical geomagnetic field Z (amounting to several tens of nT) observable only in the summer in the polar regions centering the northern or southern magnetic poles. This peculiar phenomenon was known since the Second International Polar Year 1932-1933, through an extensive analysis of world data by Vestine et al. compiled in the Carnegie Institution of Washington Publication No. 580 (1947). Later with the aid of the data during IGY 1957-58 and following years, Mansurov and Mansurova (1971) showed that the same kind of Z-decrease were also observed at Vostok, magnetic south pole station in the Antarctica. It is worth noting here that the geomagnetic anomaly maps published by Langel and Estes (Figs. lb and 2b on pages 2497-8 in JGR 90 [1985] showing the calculated difference of Z-values at 500 km level from their model based on the Magsat data) show the greatest negative anomaly over Vostok, because the Magsat was operative during the austral summer.
The peculiar decrease in geomagnetic Z-field near the magnetic poles in summer seasons has been discussed at present even in connection with the earth's interaction with the solar wind, including the effect of IMF (Interplanetary Magnetic Field) Bz and By. However, it will be more essential for us to study a possible influence of ionized plasma produced in the sunlit polar ionosphere. We must bear in mind that the daily-mean energy received from the sun in the polar area at the summer solstice is even greater than at the equatorial region.

JSA/09/C/GA5.01/W/20-A3 1200

DETERMINATION OF THE MAGNETIC POLES LOCATION

Vladimir V. KUZNETSOV, Vsevolod V. Botvinovsky (Institute of Geophysics SB RAS, Koptyug av., 3, Novosibirsk 630090, Russia; e-mail: kuz@uiggm.nsc.ru)

The idea of this model is that the magnetic pole drift is caused by change of the intensity of the main dipole field and the field of the global magnetic anomalies which are considered as sources that are quasi-independent from the main geomagnetic dipole field source. We have verified this hypothesis using the data of the geophysical magnetic observatories for the modern drift of the North magnetic pole (NMP) and the South magnetic pole (SMP). In particular, the NMP-1994 location was predicted by us. The observations of this location have confirmed our prediction with high accuracy. Based on the analysis of the magnetic observatories data, we have introduced a correction into the location of the NMP-1831 and the location of the SMP-1909. The application of our hypothesis has permitted us to explain the character of the magnetic pole motion during the reversal. The observations of the magnetic observatories and the hypothesis permit to interpret paleomagnetic data in a new way.

JSA09/E/03-A3 1215

SUB-GLACIAL IMAGING IN SCHIRMACHER OASIS-WOHLTHAT MOUNTAINS REGION IN ANTARCTICA EMPLOYING HELI-MAGNETIC AND SURFACE GRAVITY SURVEYS

Saurabh K. VERMA, H.V. Rambabu, and G.S. Mital (National Geophysical Research Institute, Uppal Road, Hyderabad-500 007, India, email: postmast@csngri.ren.nic.in)

Helicopter-borne magnetic survey was carried out over an area measuring approximately 100 km x 85 km between the Schirmacher Oasis (SO) and Wohlthat Mountains (WM) during the Seventh Indian Antarctic Expedition. Two-dimensional spectral inversion of the data revealed gross features of the topography of the base of the glacier between SO and WM. Subsequently, during the Ninth Indian Antarctic Expedition, Helicopter-supported surface gravity measurements were done along five profiles over the glacial region. Modeling of these profiles provided additional information on the glacial depths, first order structural features, and moho thickness in the region.
Combined interpretation of the magnetic and gravity data has resulted in a more coherent model of the subglacial structure. Imaging of the magnetic map of the region highlights the prominent subglacial features including a graben like structure between SO and WM. Gravity modeling reveals the presence of faults in the subglacial basement that could be correlated with the known faults and structural trends observed in SO.

RESTORATION OF SPACE PARTICLE DATA COLLECTIONS

Nickolay N. Kontor, Nickolay N. PAVLOV, and Elmar N. Sosnovets (Skobeltsyn Institute of Nuclear Physics, Moscow State University, Moscow, 119899, Russia, email: nnpavlov@taspd.npi.msu.su).

Since 1965, Theoretical and Applied Space Physics Division, Institute of Nuclear Physics, Moscow State University carries out monitoring of charged particles in space with use of Russian far spacecraft and satellites. Significant part of the data from old missions is stored only on paper, many data sets have been saved due to special issues published by the WDC-B. The data sets from both paper and old tapes needed to be restored and transferred to the modern computer media. This work has been supported by NASA, grant NAG5-4656. Useful collaboration with NSSDC has also made this project realizable.
Assuming that similar projects are being currently launched by many research groups for the sake of utilization of the benefits of the new Internet era we would like to share our experience in typical problems, common approaches and software tools used in our work. The main goal is to make the collection living and publicly accessible via Internet. Such issues as data input, data formats, file structure, use of database system, IDL, Java are concerned here. Interactive graphic rectification of raw data sets and creation of the proper documentation are highlighted as the most important for the solving of a key problem of data quality. A simple method of improving the ability of navigation within a multi-spacecraft data collection based on a plain ftp is discussed as well as our approaches to the effective graphic access to the data. Attaching of some simple tools for remote data analysis to the user interface is also considered as a way to make the services more attractive and useful.

FIRST ABSOLUTE GRAVITY MEASUREMENTS AT THE FRENCH STATION DUMONT D'URVILLE (ANTARCTICA)

Martine Amalvict, Jacques HINDERER (both at Ecole et Observatoire des Sciences de la Terre, 5 rue Descartes, 67084 Strasbourg Cedex, France, e-mail: mamalvict@eost.u-strasbg.fr).

We present the first series of absolute gravity measurements at the French station Dumont d'Urville in Antarctica. These measurements will be performed with a FG-5 (Micro-g Solutions Inc.) absolute gravimeter in a continuous way during a week in March 1999. We will report the conditions of the experiment for which a thermally regulated shelter has been built and discuss the quality of the results. A special attention will be paid to the influence of tidal ocean loading and different corrections according to existing models will be tested. We will also take this opportunity to establish a gravimetric link with a Scintrex CG3-M relative gravimeter to the tide gauge of Dumont d'Urville belonging to the ROSAME network in order to provide a geodetic reference. It is essential to be able to distinguish in the long term any vertical motion of tectonic origin from true sea level changes. A further use of our determination of the gravity field is to allow the establishment of a precise gravimetric calibration line between Hobart (Tasmania) and Dumont d'Urville which should be useful for the marine geophysics campaigns in this region.

JSA09/W/07-A2 Poster 0930-02

INTRAMAP - INTEGRATED TRANSANTARCTIC MOUNTAINS AND ROSS SEA AREA MAGNETIC ANOMALY PROJECT: STATUS & PROGRESS

Massimo CHIAPPINI (Istituto nazionale di Geofisica, Vigna Murata 605, 00143 Roma, Italy; Email: chiappini@ingrm.it) Fausto Ferraccioli, Emanuele Bozzo (DISTER, Univ. Genova, Italy, email: magne@dister.unige.it) Detlef Damaske (Bundesanstalt für Geowissenschaften und Rohstoffe Stilleweg 2, 30655 Hannover Germany, Email: d.damaske@bgr.de) John Behrendt (INSTAAR - University of Colorado Boulder, CO 80309-0450 USA, Email: behrendj@stripe.colorado.edu)

Within the framework of the evolving Antarctic Digital Magnetic Anomaly Project (ADMAP), an international consortium called INTRAMAP was initiated in 1997. The aim of INTRAMAP is to compile the aeromagnetic, ground and marine magnetic data acquired throughout the "Ross Sea Antarctic sector" (60 degrees south and 135-255 E) including: the Transantarctic Mountains (TAM), the Ross Sea, Marie Byrd Land, the Pacific Coast, and also to begin the compilation effort to new data over the Wilkes Basin to be collected along the "backside of the TAM" which is the site of proposed future activities within joint Italian, US and German cooperations. Finally the integration of satellite and near-surface magnetic data will result in a compilation that accurately portrays the fullest possible spectrum of magnetic anomalies from the Antarctic lithosphere in the "Ross Sea sector". The final compilation will contribute both in delineating and in studying the major structural and geologic components of the Ross Sea Area. From the geodynamical point of view, the merged magnetic data will permit assessment of different tectonothermal provinces within the West Antarctic Rift System leading to regions of differential uplift along the TAM and in Marie Byrd Land. The status and progress of the project will be presented.

JSA09/W/06-A2 Poster 0930-03

THE HYDROTHERMAL STRUCTURE OF POLYTHERMAL GLACIERS IN SVALBARD USING GROUND PENETRATING RADAR

Anja PÄLLI (Department of Geophysics, University of Oulu, BOX 400, 90571 Oulu, Finland, E-mail: anjapa@paju.oulu.fi); John Moore (Arctic Centre, University of Lapland, BOX 122, 96101 Rovaniemi, Finland, E-mail: jmoore@levi.urova.fi)

A Ramac (Malå Geosience) Ground Penetrating Radar (GPR) working at 25, 50 and 200 MHz frequencies has been used to map the hydrothermal structure of two polythermal glaciers Hansbreen and Werenskjoldbreen and their tributaries in southeast Spitsbergen. The GPR data was compared with the data from several temperature boreholes instrumented with thermistors and with heights of water tables in moulines. The data collected is of high resolution and the cold ice temperate ice interface was easily detected in all the measured profiles.The bedrock reflection was detected almost everywhere. Many moulins and smaller water channels (probably of metre scale) seen as point reflectors were mapped. The GPR data shows that the hydrothermal structure of Hansbreen is highly variable both along the centre line and on transverse profiles. The temperate firn/cold ice transition appears to show a more gradual transition than observed on other glaciers in northern Svalbard. Water contents in cold and temperate ice were investigated by fitting hyperbolic model reflections to point reflectors. The water content in temperate ice varied from 0 to 2% but water contents up to 5% were calculated from areas associated with surface crevassing and moulins. Isolated point reflectors within the cold ice indicate large water filled bodies that are probably related to the regular drainage structure of the glacier.

DETERMINATION OF PLATE TECTONIC MOTION RATES IN THE REGION OF THE ANTARCTIC PENINSULA

MICHAEL MAYER, Klaus Lindner, Hansjoerg Kutterer and Bernhard Heck (all at Geodetic Institute, University of Karlsruhe, Englerstr.7, D-76128 Karlsruhe, Germany,
email: mmayer@gik.uni-karlsruhe.de)

The Geodetic Institute of the University of Karlsruhe (GIK) takes part in a bundle project called "Reference Network Antarctica II" which is sponsored by the Ministry of Science, Research, Education, and Technology of Germany (BMBF). Within this bundle project seven German institutions are co-operating in order to create a three-dimensional velocity field of the atlantic part of Antarctica. The basis and the motivation of this bundle project lays in the previous bundle project "Reference Network Antarctica" which was sponsored by the BMBF, too. The main goal of this bundle project was the creation of a highly precise three-dimensional reference network for the whole Antarctic continent. In the Antarctic summer 1994/95 simultaneous GPS observations (24 h per day, 21 days) were carried out at GPS stations situated on Antarctica

and on neighbouring tectonic plates to fulfill the main goal of the first bundle project. This work was done within the framework of the SCAR Epoch 95 Campaign (SCAR95). The GIK working group was responsible for preparatory investigations of the achievable point positioning accuracy by means of spectral analysis, and processing of the GPS observations based on the Bernese GPS Software Version 4.0 (BS). Furthermore several investigations were carried out concerning the accuracy of point positions (influence of atmospheric disturbances, ambiguity resolution strategies, effect of the selection of the ITRF-fiducials). Using the experiences gained from processing a network covering the complete southern hemisphere (SCAR95-data plus IGS-data) - characterized by inhomogeneous baseline lengths (from 1 km up to 4400 km) as well as by an irregular distribution of the sites showing high density in the area of the Antarctic Peninsula and the closeness of some network points to the geomagnetic pole in East Antarctica - the above mentioned second bundleproject was initiated.

HOW GEODETIC OBSERVATIONS CAN CONTRIBUTE TO THE DETERMINATION OF VERTICAL CRUSTAL DEFORMATIONS IN WEST GREENLAND INDUCED BY CHANGING ICE LOADS

Mirko SCHEINERT (Reinhard Dietrich Technische Universität Dresden, Institut für Planetare Geodäsie, D-01062 Dresden, Germany, e-mail:mikro@ipg.geo.tu-dresden.de)

Mass changes of ice sheets induce loading effects on the earth crust. These vertical deformations occur on different time scales. Viscous effects are due to the glaciation history, while elastic effects are mainly caused by recent ice mass changes. These different effects will be reviewed especially for West Greenland.
West Greenland provides a unique research field: large regions along the west coast are ice-free. This allows a comparably easy access to carry out geodetic field measurements in the immediate vicinity of the proceeding ice mass changes, which are the largest at the ice edge. In order to observe the ice-induced vertical deformations a special GPS network between the 61st and 69th parallel was set up. The first epoch observation of this network was carried out in 1995. These GPS observations were densified along the 67th parallel, from the coast up to the ice edge, in the subsequent years. Additional relative gravimetric observations in the region of Kangerlussuaq supplemented the GPS observations. The set-up of the investigations will be reported. The results of the regional observations obtained so far will be presented and discussed.

MORPHOMETRIC PATTERNS AND GEODYNAMICS OF THE LOMONOSOV RIDGE AND ADJUSENT BASINS

Elena DANIEL (All-Russia Research Institute for Geology and Mineral Resources of the World Ocean, 1, Angliysky pr., St.-Peterburg, 190121, Russia, email: dani@vniio.nw.ru)

The new computer bathymetry model reveals essential features of the ocean floor in more detail than in previously published small-scale bathymetric maps. The patterns of the ocean relief forms characterize the deep Arctic basin structures dynamic. Been situated between the Eurasian and Amerasian basins the Lomonosov Ridge has several bends through its extension. These bends coordinate with the such of the Gakkal Ridge and surrounded it basins. These bends are also accompanied by transverse extend line zones. These zones cross the Eurasian and Amerasian basins. The zones characterize ancient tectonic frame to with geometry of temporary spreading is submitted. In the seafloor relief these zones are presented by various forms having the same rout of extension and increased gradient in bathymetry. The escarpments with height of 500-600 m between plains are display of these zones. The plains are characterized by isobaths of 1,600; 2,200 m and of 2,700; 3,200; 3,800 m on the ridges and in the basins, respectively, with is the truth both from the Eurasia and North America point of view. The seismosounding data according the geotransect "De Long islands - Makarov Basin" (Krjukov et al., 1993) show that escarpments are the reflection of the earth crust flexures with accompany its rejuvenation. Probably the formation of the ocean in the Amerasian basin was together with long formation of the surrounded steps, relict of which are saved in temporary seafloor relief.

AEROMAGNETIC FEATURES OF ENDERBY LAND AND EASTERN DRONNING MAUD LAND: IMPLICATIONS FOR GONDWANA ASSEMBLY

Alexander V. GOLYNSKY (VNII Okeangeologia, 1 Angliysky Ave., 190121, St. Petersburg, Russia, email: sasha@gus1.vniio.nw.ru)

In the shield areas of East Antarctica (EA) interpretation of aeromagnetic data allowed to better define the boundaries between the Archean stable blocks and the Proterozoic mobile belts, and to trace these boundaries beneath the ice sheet. Four main boundaries of the EA Shield terranes are distinguished within Enderby Land and eastern Dronning Maud Land from the change of magnetic anomaly pattern. The boundary between the Napier terrane and the Rayner terrane is delineated by the oval band of high-intensity magnetic anomalies. The Napier terrane displays a complex magnetic grain which tends to reflect the lithology of granulites. Metasedimentary rocks and granitoids are associated with magnetic lows, whereas orthogneisses correlate with highs. A broad magnetic low, at least 100 km in width, is associated with the structural grain of the Rayner Complex originated during 1000 Ma event. The boundary between the Rayner - Lützow-Holm Bay (LHB) terranes is clearly visible on the map by distinction of trends. The elongated, fragmented magnetic highs and intervening lows of the LHB terrane is associated with the rocks metamorphosed under granulite facies conditions. Character of distribution and structural pattern of magnetic anomalies do not allow us to accept models of Gondwana reconstruction in which the LHB Complex in EA and Highland Group of Sri Lanka developed in the suture zone at the last phase the Pan-African orogeny and the Late Proterozoic supercontinent was separated by a missing ocean at the position of the LHB Complex. The absence of any well-defined anomalies coherently running in direction of proposed Cambrian orogenic belt allow us to joint to more appropriate conclusion of many authors that the 500 Ma event in East Antarctica was an intraplate phenomenon of Gondwana and restricted to minor though widespread activity.

THE GLENNY ANOMALIES OF ANTARCTICA AND SURROUNDING SEAS

Andrej N.Grushinsky (United Institute of Physics of Earth, Russian Academy of Science, B. Gruzinskaya, 10, Moscow 123810, e-mail: grush@uipe-ras.scgis.ru, Pavel A.Stroev (Sternberg State Astronomical Institute, Moscow State University, Universitesky pr., 13, Moscow 117899, e-mail: pstroev@sai.msu.su) and Eugenij D.Koryakin (Sternberg State Astronomical Institute, Moscow State University, Universitesky pr., 13, Moscow 117899, e-mail: koryakin@sai.msu.su)

The gravitational effect of far zones and Glenny anomalies for Antarctica has calculated. This calculations take into account the thickness of sediments and their mean densities. The structure of the total correction for middle and far zones was analysed. The main features of this correction is determined by the middle zone one. West Antarctica has a poorly effect on the form of middle zone correction isolines. This fact allows to suppose, that West Antarctica is an active continental margin. The field structure of the far zone gravitational effect connect with the distribution of continents and ocean on the Earth and have clearly expressed long-waved character. The influence of far zones manifests in the total correction by asymmetry: the values of correction for Pacific ocean sector some less, than for Indian ocean one. The structure of Glenny anomalies clearly enough indicates the main geological structures of Antarctica and allows to do some conclusions about the structure of its lithospere. The Glenny anomalies correlation with heat flow was found for South ocean. The preliminary conclusions about isostatical models for different regions of Antarctica may be made from the considerable analysis. Authors are grateful to Russian Fundamental Investigations Foundation, which provided financial support (grant 98-05-64446).

SUBGLACIAL ERUPTION PILLOW LAVA BRECCIAS IN FUMAROLE BAY, DECEPTION ISLAND, ANTARCTICA:

CORINA RISSO, Alfredo Aparicio Yague, Antonio Delgado

The pillow lava breccia have a central part of massive columnar jointing pahoehoe lava with basaltic-andesite Composition. The external zone are compossed by pillow lobes and fragments derived directly from the lobes during their development from the breaking up of the lava flow. The size of the pillows and lobes range from 0.10 to 4 m. Their shape varys from nearly spherical to elongate. The central zone, light brown, has porphyritic to cluster texture with plagioclase and clynopyroxene phenocrysts and glassy groundmass with plagioclase and clynopyroxene partialy palagonitized. The external zone (0.5 to 0.8 cm) is chraracterized by a black obsidiane rim. The small outcrop in Fumarole Bay, belongs to the "Conjunto Superior" and begins with base-surge deposits, poorly consolidated with reverse gradding laminated bedding sets, deposited maybe during an explosive activity in a cupola of steam. To the top the participation of pillows and lobe fragments increase, followed by a massive lava flow and ending with strombolian deposits similar to others presents in others localities of the island. This sequence indicates the independence of water/snow/ice in the last stages of the eruption. High negative deuterium rates (d2H=-66,7/-61,4) indicates meteoric water contribution. The pillow lava outcrop is 50 m up to the actual sea level and in his original eruption position. According with this observations the eruption begun under a thin and shallow ice/snow cover.

NETLANDER : THE FIRST GEOSCIENCE NETWORK ON MARS

P.LOGNONNE (1), A.M. Harri (2), O. Marsal (3), F. Angrilli (4), B. Banerdt (5), J.P. Barriot (6), J.L. Bertaux (7), J.J. Berthelier (8), S. Calcutt (9), J.C. Cerisier (8), D. Crisp (5), V. Dehant (10), D. Giardini (11), R. Jaumann (12), Y. Langevin (13), M. Menvielle (8), G. Musmann (14), J.P. Pommereau (7), T. Spohn (15) and the Netlander team. 1) IPGP, 4 Avenue de Neptune, 94107 Saint Maur des Fosses Cedex, France, 2) FMI, Finland, 3) CNES, France, 4) Un. of Padova, Italy 5) JPL, USA, 6) OMP-GRGS, France, 7) SA, France, 8) CETP, France, 9) Oxford Uni., UK, 10) Royal Observatory of Belgium, Belgique, 11) Institut of Geophysics, Switzerland, 12) DLR/IPE, Germany, 13) IAS, France, 14) IGM, Germany, 15) IfP, Germany

The fundamental scientific objectives of the Netlander mission are to return the geophysical and atmospheric data necessary to perform a comparative study between Mars and the Earth. It will deploy in 2006 a network of 4 stations on the surface of Mars and will perform network science and multi-site observations.
The first objective will be the determination of the deep internal structure of the planet, especially the state and size of the core, the structure of the mantle and shape of discontinuities. It will be addressed by a package of VBB seismometer, magnetometer, and a geodetic experiment. A second specific objective will be the determination of the crustal and subsurface structure below all landing sites. It will use a package of a short period seismometer and a ground penetrating radar, in addition to the radar. A third objective will address the surface mineralogy and the geological context of the landing sites with a multi-spectral camera. A fourth objective will be performed by a package of multiple atmospheric sensors and finally, the planet ionised atmosphere will be studied jointly by the magnetometer and the measurement of the total ionospheric content.
The Netlanders, launched in 2005 with the Mars Sample Return mission on an Ariane 5, will be developed by CNES, FMI, DLR with significant contribution from NASA and possibly from new partners. The surface operations are expected to last over one Martian year, from August 2006 to July 2008, with an orbital support of the ESA Mars Express orbiter.

THE NETLANDER MAGNETIC EXPERIMENT

M. MENVIELLE (CETP, 4 Avenue de Neptune, F-94107 SAINT MAUR CEDEX, FRANCE), G.Musmann (IGM/TU-BS, Braunschweig, GERMANY), M. Alexandrescu (IPG, Paris, FRANCE), J.J. Berthelier (CETP, FRANCE), K.H. Glassmeier (TU-BS, GERMANY), J.M.Knudsen (Copenhagen Univ., DENMARK), F. Kuhnke (TU-BS, GERMANY), U. Motschmann (TU-BS, GERMANY), K. Pajunpaa (FMI, Helsinki, FINLAND), J.L. Pincon (LPCE, Orléans, FRANCE), F. Primdahl (DTU, Lyngby, DENMARK, K. Schwingenschuh (IWF, Graz, AUSTRIA), L. Szarka (GGKI, Sopron, HUNGARY)

The transient variations of the Mars magnetic field result from both the interaction between the planetary environment and the solar wind plasma (primary source) and induction in the conductive planet (secondary source). The main objective of the NetLander magnetic experiment is to make continuous recordings of the transient variations of the magnetic field at a the Mars surface. It will therefore allow one to obtain a first description of the transient magnetic field of Mars, and then provide information on both the inner structure and the electrodynamics of the ionised environment of Mars: - the depth of penetration of an electromagnetic wave in a conductive medium increases with decreasing frequencies:

the higher part of the frequency spectrum enables one to probe the uppermost kilometres of the crust, and the lower part enables one to probe the mantle down to a few hundreds of kilometres in depth. - as is the case for the Earth, different controlling plasma processes will lead to different current patterns inside the magnetosphere and therefore different magnetic signatures at the planetary surface. Continuous recordings of the transient variations of the magnetic field onboard landers will then provide constraints on the electrodynamics within an ionosphere-magnetosphere system in which the ionosphere lies at great heights relative to the dimensions of the magnetospheric cavity. Another objective of the NetLander magnetic experiment could be the investigation of the magnetic properties of the Martian surface rocks an/or dust and the search for and analysis of possible paleomagnetic signatures in the rocks. This would need to have the magnetometer sensor embedded in a magnetizing field coil and placed on the Mars surface: the field coil magnetizes the Martian surface while the fluxgate afterwards measures its magnetic response.

JSA10/W/11-A2 1000

NETLANDER IONOSPHERIC AND GEODETIC EXPERIMENT

Jean-Pierre BARRIOT (Observatoire Midi-Pyrénées, 14, Av. E. Belin, Toulouse, France, email: Jean-Pierre.Barriot@cnes.fr) Veronique Dehant (Observatoire Royal de Belgique, Brussells, Belgium, email: veroniq@oma.be) Jean-Claude Cerisier (Centre d'Etudes des Environnements Terrestres et Planétaires, St-Maur des Fossés, France, email: cerisier@cetp.ipsl.fr) André Ribes (Centre National d'Etudes Spatiales, 18, Av. E. Belin, Toulouse, France, email: Andre.Ribes@cnes.fr)

The objectives of the NEtlander Ionospheric and Geodetic Experiment (NEIGE) of the Mars Sample Return mission (MSR) is to obtain new information about the interior of Mars, surface/atmosphere interactions (e.g the seasonal cycling of CO2), and about the total electron content (TEC) of the Mars ionosphere. This information would be obtained from measurements of the Doppler shifts of the radio links between an orbiter and a network of four landers, and between the Earth and this orbiter. We detail both the technical and scientific aspects of this important experiment.

JSA10/W/08-A2 1045

PYROCLASTIC FLOWS AND POSTERUPTIVE LAHARS AS THE RELIEF-FORMING FACTOR OF A MARS SURFACE

Alexander I. MALYSHEV (Institute of Geology and Geochemistry, Urals Branch of RAS, Pochtovy per 7, Ekaterinburg, SU-620151, Russia, email: root@igg.e-burg.su) Lidiya K. Malysheva (Kourovskaja astronomical observatory, Urals University, Lenina street 51, Ekaterinburg, SU-620083, Russia, email: lidiya.malysheva@usu.ru)

In the report the problem of an origin of channel-shaped valleys on the Mars surface is considered. Nowadays in the given area the concept of catastrophic freshet water flows dominates. The main reason for the benefit of the concept of Mars channels formation at the expense of catastrophic freshet water flows is the circumstance, that the researchers could not find any other substation except water capable to production so powerful eroding influence and creation characteristic inner valley deposits. A serious drawback of the given concept is the fact, that the representations about the formation of Mars's channels under the influence of powerful current of large volumes of liquid water are incompatible with domination of low temperatures on the Mars surface. However alternative substations capable to make similar or even more powerful eroding effect, - pyroclastic flows and especially posteruptive lahars are well known for the researchers specializing on study of volcanic processes on the Earth. The pyroclastic flows are being formed during eruptions of large volumes of the heated fragmental material and have high mobility at the expense of the presence of the heated volcanic gases. Most powerful lahars, are being formed after the eruptions of pyroclastic or lava material in cases when at the area of eruption there is a plenty of frozen water. The presence on a Mars of very large volcanic structures, such as Nix Olimpica, and, possibly, a wide circulation of frozen water as rockforming mineral require more attentive attitude to an opportunity of large relief forms formation under the influence of pyroclastic flows and post eruptive lahars.

JSA10/C/GA4.15/P/01-A2 1100

SAHARA CAMPAIGN FOR FIELD TESTING MARS EXPLORATION INSTRUMENTS FOR 2001-2005 MISSION ROVERS

M.A. Mosalam SHALTOUT (National Research Institute of Astronomy and Geophysics, Helwan, Cairo, Egypt. Tel: (202) 2630833; Fax: (202) 5548020 Email: mamshaltout@frcu.eun.eg

On July 4, 1997, NASA's Mars Pathfinder landed safely on the surface of the red planet, the first spacecraft to do so in 21 years. After this success, Mars exploration is a high priority program in the United States. There is a plan for testing instruments for a Mars Rover to be launched in the time period 2001-2005 in the Western Desert of Egypt. It is the driest Sahara in the world, and contains a variety of rocks and soil deposited by catastrophic floods early in the history as that occurred in the past history of Mars. Beside, dust storms for 50 scattered days during the year "El- Kamassen" similar in the dust storms in Mars. With The Planetary Society (TPS) in Pasadena, USA, currently, we are considering bringing a group of about 12 scientists, 5 from the United States (NASA-J PL), 3 from Russia (IKI), 1 from European Space Agency (ESA) and 3 from Egypt, to do Mars instruments testing in the very dry region of the Western Desert, at three different sites chosen by their analog with Martian Desert – like conditions, and contain subsurface water at different depths. The instruments to be tested will be electromagnetic sounder, magnetic coil, infra-red spectrometer, radiometer, co-ordination and GPS Navigation. The exception duration for testing is the Autumn of 1998.

JSA10/L/01-A2 1115

EFFECT OF MARS' ATMOSPHERE ON NUTATION AND ROTATION

O.DE VIRON

Models of the atmospheric circulation of Mars will be used in order to compute the atmospheric torque acting on the planet, as well as the angular moment changes. This effect can either perturb the rotation of Mars, or, if the diurnal time scale is considered in a frame tied to the planet, perturb the nutations (long periods in space). These computationsare rather important in the frame of the NEtlander Geodesy Experiment consisting of observing Mars' orientation in space during one Martian year. This experiment will give us information about the parameters of the interior of Mars that appear in the models. Mars' elasticity or inelasticity parameters are studied in the frame of long term effects. The amplitudes of the effects of the atmosphere on the Mars' rotation will be evaluated.Parameters related to the Free Core Nutation are considered at diurnal time scale. At that time scale, it is possible to compute an order of magnitude of the effects of the atmosphere on the nutations.

JSA10/L/02-A2 1130

EFFECT OF MARS ICE CAP LOADING ON MARS' ROTATION.

O.DE VIRON

Models of Mars' ice cap are used in order to compute the changes in the loading effects (due to CO2 sublimation and condensation) on Mars'rotation and polar motion. The response of the planet involves parameters of the interior as mantle inelasticity, core rheology. We have examined the response of Mars to the ice cap loading in order to compute the sensitivity of the potential observations to the these parameters. Observing the effects of the sublimation and condensation of the ice cap on Mars' rotation would in principle give us the amount of ice changeswith time and would also give information on Mars rheology. We examine the potentiality of the geodesy experiment of Netlander to detect these effects.

JSA10/L/03-A2 1145

MARS' INTERIOR FROM NEIGE GEODESY

V. DEHANT, T.Van Hoolst, J.-P. Barriot et al.

The NEtlander Ionospheric and Geodesy Experiment (NEIGE) consists in observing Mars' orientation in space by considering Doppler counting measurements. These measurements will give us the possibility to observethe polar motion, the rotation and the precession/nutations of Mars. Wegive here the objectives of NEIGE geodesy part and the order of magnitude ofthe expected motions. We show how this experiment will enable us to obtainimportant parameters on Mars' interior. In particular, we show how itwould be possible to answer the question whether the core is liquid orsolid. That question is in fact related to the existence or not of one important normal mode called the Free Core Nutation which only exists if the core is liquid.

MERCURY, VENUS, MOON AND PLANETARY GEOPHYSICS

JSA10/W/05-A2 1400

CORRELATION OF SURFACE FEATURES WITH GEOID IN THE APHRODITE-THEMIS-BETA REGION OF VENUS

Paul STODDARD (Dept. of Geology, Northern Illinois University, DeKalb, IL, USA, email: prs@geol.niu.edu) Donna Jurdy (Dept. of Geological Sciences, Northwestern University, Evanston, IL, USA, email: donna@earth.nwu.edu)

The recent Magellan mapping mission to Venus has returned a wealth of data. The apparently random distribution of impact craters indicates that the entire planet has been resurfaced over the last ca. 300-700 m.y. Studies of stratigraphic relationships show that certain Venusian terrain types tend to be older than others. Crater counts by terrain type also support a global terrain- based stratigraphy. In this vein, we look at distribution of coronae, craters, and chasmata in relation to the geoid and topography of Venus. The vast majority of chasmata fall along five great circle arcs with a combined length equivalent to that of the ridge spreading system on Earth. Furthermore, the gross similarity in morphology between these two suggests that chasmata may indeed be tectonically active regions. One unique region, bounded by Themis Regio, Beta Regio, and the eastern part of Aphrodite Terra, contains two major geoid highs at the intersection of three of these great circle arcs. One arc, extending 15000 km from Aphrodite to Themis, lies within 500 km of a line of 10 domal coronae (20% of the Venusian total). These coronae, distinguished by central uplift with no surrounding moat, may be the youngest of the coronal features, possibly even still active. In addition, craters near this arc are disproportionately embayed (30% compared to 6% planet-wide), and a first look at coronae in this region shows them to be linked morphologically to the location of chasmata. Alternatively, the arc extending 6000 km from Beta to Themis is heavily cratered with few coronae of any kind.

JSA10/W/07-A2 1415

TECTONISM ON VENUS; AN EXPERIMENTAL AND IMAGE BASED STUDY

M.R.BALME (1,2), P. Sammonds (1) and C.Vita-Finzi (2) (1) Rock and Ice Physics Laboratory. University College London. email: m.balme@ucl.ac.uk (2) Centre for Planetary Studies. Department of Geological Sciences, University College London, London, England.

Enigmatic tectonic deformation has been observed in several regions of the volcanic plains of Venus. The 'Gridded-plains' of Guinevere Planitia, for example, are peculiar in that the fracture sets are orthogonal, but it is the close spacing (1-3km) of one of these sets that is most striking. Geophysical models of deformation are constrained by the physical properties of the plains material, which are currently only orders of magnitude estimates. To understand fully the tectonic setting, laboratory measurement of 'fracture-toughness' (an intrinsic material property) at Venusian surface conditions (90 bar of CO2 at 450˚C) are used to provide the data necessary to constrain fracturing models. We describe here the testing apparatus used in this investigation and the methodology for applying the results to Magellan imagery of tectonic features. Results at different temperatures and pressures are presented using Iceland basalt as the sample rock. Although the eruption of flood basalts is the preferred model for plains formation, some recent volcanic models suggest that large areas may have compositions that are more exotic. A programme of fracture toughness experiments using different candidate rocks coupled with image analysis is proposed. This will be used to constrain the choice of candidate plains material and therefore lead to refined models of formation and deformation.

JSA10/W/06-A2 1430

ESA ADVANCED PLANETARY MISSION STUDIES: VENUS SAMPLE RETURN AND MERCURY SAMPLE RETURN

Lebreton J.-P. (1), Scoon G. (2), Lognonné Ph. (3), Masson Ph. (4), TAYLOR F. W. (5), Wänke H., (6), Coradini M. (7), and the VSR and MeSR Study Teams (1) Space Science Dept. of ESA, Solar System Division, ESTEC, P. O. Box 299, 2200 AG Noordwijk, The Netherlands (2) Scientific Project Dept, Future Project Office, ESA/ESTEC, P. O. Box 299, 2200 AG Noordwijk, The Netherlands(3) IPG, Paris (4) Univ. Paris-Sud (5) Oxford University (6) MPI Mainz (7) ESA/HQ, Science Directorate, 8-10 Rue Mario Nikis, F-75738 Paris Cedex 15.

Looking into the next decade, the Mercury Orbiter mission is the only future Planetary Exploration mission which has been identified as a potential element of ESA's Horizons 2000 Science programme. In order to prepare for the next steps in planetary exploration beyond the Mercury Orbiter mission, ESA is carrying out advanced studies of Planetary Sample Return Missions. The Venus Sample Return mission was first studied in early 1998 and was

completed in June 1998 with the publication of the study report ESA SCI(98) 3. A similar study is being undertaken for a Mercury Sample Return. The study was initiated in September 98 and is expected to be completed in February 1999. In this presentation we describe the scientific objectives of both missions and give an overview of the two baseline mission scenarios that have been identified. Although there are technical challenges that have to be worked before undertaking such ambitious missions, those initial studies demonstrate that such very exciting missions are within Europe's technical capabilities.

JSA10/E/04-A2 1500

SPECTROPOLARIMETRIC INDEX OF THE LUNAR SOIL MATURITY

V.V.SHEVCHENKO, T.P.Skobeleva (Sternberg State Astronomical Institute, Moscow University, Universitetskii pr. 13, Moscow 119899, Russia, email: shev@sai.msu.su)

It was used a new calculations to obtain a number of spectropolarimetric ratio of the maximum degree of polarization values in blue and red parts of spectrum (Pmax (419 nm)/ Pmax (641 nm)) for relief formations on the lunar surface. A new catalog contains 90 values of the ratio which characterize different features of the near side of the Moon (crater, mare and highland types). Distribution of the values has bimodal shape. The second mode of the distribution corresponds bright new formations (crater Proclus, swirl Reiner-gamma and others). The spectropolarimetric parameter has not any correlation with chemical composition of the regolith surface layer. The values of FeO content for Apollo and Luna landing sites were used to compare these characteristics. The values of Is/FeO (magnetometric index of the soil maturity) for Apollo landing sites were used for comparison of the spectropolarimetric index with average degree of the soil maturity. The corresponding diagram of dependance of the spectropolarimetric index from soil maturity shows a slight correlation between them. The values of average sized particles in the surface layer, which were obtained by remote method, were used to plot diagram of dependance of the spectropolarimetric index from granulometric characteristics of the local soil. The diagram shows an evident correlation between both parameters. The 2 last diagrams show dependance of the spectropolarimetric index from exposure age of the lunar surface layer. So, the spectropolarimetric ratio mentioned above can be used as synonymous parameter of soil maturity which is obtained by means of remote method from Earth or from lunar orbit.

JSA10/E/01-A2 1515

LUNAR CRUST PETROLOGY AND STRATIGRAPHY FROM CLEMENTINE MULTISPECTRAL DATA

P. C. PINET, S. Chevrel, P. Martin, Y. Daydou; UMR 5562 /OMP/GRGS/CNRS, 14 Av. E. Belin, Toulouse, 31400 France.

Detailed remote sensing surveys have been conducted in the Humorum and Imbrium impact basin regions. Based on multivariate statistics and spectral mixture analyses, these studies deal with the characterization of the regional chemical composition (Fe and Ti content) and establish a first estimation of both the mineralogy and optical maturity state of the surface, on the basis of the spectroscopic properties. For Humorum basin, the combination of the results issued from the spectral mixture modelling with the regional geomorphologic and topographic information puts constraints on the emplacement of the different types of mare and highlands units, as well as on the stratigraphic and petrological crustal variations related to the basin formation, with for instance the detection of exposed anorthositic units as possible remnants of the primordial crust. For the Imbrium/Procellarum region, the Gruithuisen domes region is recognized as a candidate for an extended nonmare volcanism unit, suggesting that this style of volcanism (viscous flow of possible more silicic composition) might have occurred prior to the Iridum event (3.8 Ga ago) and could have been more widespread in the early part of lunar history than previously thought. Also the regional spectral variability of the Aristarchus volcanic Plateau is characterized and the spectroscopic mapping within Aristarchus crater reflects a petrological change with depth. The deepest material exposed in the uplifted central peak indicates an anorthositic horizon, overlain by an olivine/pyroxene-rich horizon, with a progressive change in the pyroxene/olivine ratio, the pyroxene abundance increasing as the depth decreases. These new results arise from the recent revival in lunar space exploration and will both benefit from (in terms of interpretation) and contribute (preparation and scientific goals) to the ongoing and soon-to-come missions to the Moon, such as Lunar Prospector, Lunar-A, Smart-1 and Selene.

JSA10/W/10-A2 1600

USING THE MAGNETIC DATA FOR PROBING THE ELECTRICAL STRUCTURE OF A PLANET

P. TARITS, N. Grammatika (IUEM/UBO, Place Nicolas Copernic, F-29280, Plouzané, France, email: tarits@univ-brest.fr); M. Menvielle (CETP - 4 Avenue de Neptune, F-94107 Saint Maur cedex - France)

The magnetic field of a planet may result from two primary sources, convection in a conductive liquid core and the interaction between the planet and solar wind plasma, and from two secondary sources, the local magnetisation and electric currents induced in the planet by the transient magnetic fields of external origin. The external natural fluctuations (the primary source) of the magnetic field induce an internal response (the secondary source) that can be used to infer the electrical conductivity structure of the planet. The maximum depth resolved by the technique is a function of the longest period of variations of the external magnetic sources that may be recovered from the data. The external transient variations result from both the interactions between the planetary environment and the solar wind plasma. Traditionally, induction studies on Earth make use of magnetic data recorded continuously at stations set up at the Earth surface transitionally or permanently (the geomagnetic observatories). The upcoming of several magnetic satellite missions in the next years has triggered the interest of the electromagnetic induction community to use satellite data to investigate the electrical conductivity of the Earth. The satellite provides a complete coverage of the planet. Several studies both theoretical and with the 15 years old MAGSAT data have shown that the secondary induced field may be recovered from the satellite magnetic data and that electrical conductivity may be derived from them. There is therefore a great interest to apply a similar approach for the planetary exploration. Measuring the vector magnetic field in a satellite surveying the planet offers the unique opportunity to investigate at planetary scale the deep electrical conductivity structure. This parameter depends strongly on the temperature, partial melting, fluid phase as well as on the mineralogy and may provide strong constraints upon the mantle structure. One of the difficulties is the limited data about the primary field.

JSA10/W/12-A2 1615

ELLIPSOIDAL HARMONIC EXPANSIONS OF THE GRAVITATIONAL POTENTIAL OF SMALL BODIES OF THE SOLAR SYSTEM: THEORY AND APPLICATION

Romain GARMIER (OMP, UMR5562, 14 avenue E. Belin 31400 TOULOUSE FRANCE, Email: garmier@boreal-ci.cst.cnes.fr) Jean-Pierre Barriot (OMP, UMR5562, 14 avenue E. Belin 31400 TOULOUSE FRANCE, Email: jean-pierre.barriot@cnes.fr)

Small bodies of the solar system are now the targets of space exploration. Many of these bodies have elongated, non spherical shapes. Usual spherical harmonic expansions are not well suited for the modelling of spacecraft orbits around these bodies, as they can show strong divergence properties inside the smallest sphere enclosing the body.
An elegant remedy is to use ellipsoidal harmonics instead of the usual spherical ones, as the divergence is restricted to the smallest triaxial ellipsoid enclosing the body. We summarize mathematical properties of the ellipsoidal harmonics, and demonstrate their use with a simulation of the landing of the Rosetta module on the surface of comet Wirtanen.

JSA10/C/GA4.15/P/02-A2 1630

SPACECRAFT'S ANOMALOUS ACCELERATION TOWARDS THE SUN

Probhas RAYCHAUDHURI (Departmend of Applied Mathematics, Calcutta University, Calcutta 700 009, India. Email: prc@cucc.ernet.in

Anderson et al. detected a mysterious phenomena that appears to slow down the spacecrafts and drag them off course (e.g., Pioneer 10, Pioneer 11, Galileo, and Ulysses etc.). The space probes appear to be experiencing an unexplained extra pull from the sun suggesting that an unknown force not known to the accepted laws of physics. In this paper I wish to point out that the unexplained extra pull is due to the contraction of solar core during the sunspot minimum period (about 4.6 years) in the solar activity cycle. During this period the solar core has extra tug throughout the solar system than the effects of gravity exerted by the sun in other times of the solar cycle. We show that the acceleration acting on the spacecraft with a magnitude of approximately 8.16 x 10-8sec/cm2 directed towards the sun. This suggests that the anomalous acceleration towards the sun is the effect of solar core pulsation.

COSMOCHEMISTRY AND THE OUTER SOLAR SYSTEM

JSA10/E/02-A3 Invited 0830

COSMOCHEMISTRY FROM THE BEGINNING TO THE YEAR 2000

Jonathan I. LUNINE (Lunar and Planetary Laboratory, The University of Arizona, Tucson AZ 85721 USA, email: jlunine@lpl.arizona.edu)

Cosmochemistry--the study of the origin of the planets from chemical clues in samples and in remotely observed planetary environments is a field with a rich and convoluted history. The time available for this presentation does not permit a comprehensive and balanced historical treatment. To avoid the inevitable pitfalls of highlighting the work of a few at the expense of many other contributors, I focus on the overall development of ideas in the context of observational advances in the laboratory, at the telescope and in space. In the mid-twentieth century, increasingly detailed analyses of meteorite samples provided constraints on the solar nebula environment in the realm of the terrestrial planets. Simulations of nucleosynthetic processes in main sequence stars, supernovae and other stellar environments combined with meteorite analyses to provide a detailed picture, by the 1980's, of the timing and environment of solar system formation within a nascent molecular cloud. This picture was refined and bolstered by astronomical observations of cloud-forming regions, in which by the 1990's processes in planet-forming disks could be analyzed. Despite the fact that the vast majority of the solar system's mass lies in the outer planets, understanding of the cosmochemistry of the outer solar system lagged behind that of the inner because of the vast distances, which limited both remote observations and the capability to field spacecraft experiments in the region. A watershed event of 1995 was the direct sampling of Jupiter's atmosphere by the Galileo Probe, allowing noble gases and other spectroscopically inaccessible species to be measured. The start of the new millenium sees prospects for in situ measurements of comets and Titan, which along with more powerful telescopic studies will enable development of a cosmochemistry of the outer solar system commensurate with that of the inner.

JSA10/L/01-A3 Invited 0900

THE CASSININ/HUYGENS MISSION TO THE STURNIAN SYSTEM

D.L.MATSON (1) and J.P. Lebreton (2). (1) Jet Propulsion Laboratory, California Institute of Technology, Passedena, CA 91106 USA. (2) Space Science Dept., ESTEC, Noordwijk, The Netherlands.

Cassinin/ Huygens will carry out and in-depth expoloration of the Saturnam system. On October 15, 1997 the spacecraft was launched in its interplanetary journey. On the way to saturn, Cassini/Huygens flybys Venus, twice (April 26, 1998; June 24, 1999), the Earth once (August 18, 1999), and Jupiter (December 30, 2000). On approach to Saturn a small satellite Phoebe will be encountered on June 11, 2004. Upon arrival at Saturn on July 1, 2004, Cassini/Huygens will fire its main engine and go into orbit about the planet. Huygens will be delivered to Titan on November 27, 2004. After deceleration in the upper atmosphere, Huygens will deploy a parachute system and its six instruments will make scientific measurements and observations as it descends to the surface. These data then will be transmitted to the Orbiter, which, in turn, will relay them to the Earth. The Orbiter will then commence a four year long tour of the Saturnian system. With its complement of 12 instruments, Cassini is capable of making a wide range of in situ and remote sensing observations. There will be repeated close flybys of Titan both to make measurements and for gravity assisted orbit changes that will enable Cassini to visit other satellites, various parts of the magnetosphere, and obtain occultations of the rings and atmospheres of Saturn and Titan. During the span of the mission, Cassini will also record temporal changes in many of the properties that it can observe. The presentation will emphasize current status and plans for the mission. (The Cassini mission is a joint undertaking by NASA and ESA. This work was carried out at Jet Propulsion Laboratory, California Institute of Technology, under contract to NASA

JSA10/W/01-A3 Invited 0930

EXPLORATION OF THE SATURNIAN SYSTEM WITH CASSINI RADIO SCIENCE

Arvydas J. KLIORE (Jet Propulsion Laboratory, California Institute of Technology, Pasadena, CA 91109, USA, E-mail: akliore@jpl.nasa.gov)

The ongoing Galileo mission has provided many new insights into the Jovian system. Among them are new discoveries from the Radio Science investigations , including multiple measurements of the Jovian ionosphere, the ionospheres and plasma environments of Io, Europa, Ganymede, and Callisto, and the internal structure of the Galilean satellites.
The Cassini spacecraft, which will be placed in orbit about Saturn in 2004, will conduct Radio Science investigations of many aspects of the Saturnian system with a radio instrument of unprecedented stability and versatility. It will use radio links at three wavelengths: S-band (13 cm), X-band (3.5 cm), and Ka-band (1 cm) to probe the atmospheres and ionospheres of Saturn and Titan and Saturn's rings by means of radio occultations, and to measure the masses and gravity fields of Saturn, Titan, and selected icy satellites by precision tracking. In addition, the stability of the radio instrument will be utilized to conduct a search for gravitational

waves during solar oppositions, and to precisely measure general relativistic effects during solar conjunctions during the interplanetary cruise prior to arrival at Saturn.

JSA10/W/13-A3 Invited **1000**

NITROGEN ISOTOPE FRACTIONATION AND THE CONSEQUENCES FOR TITAN'S ATMOSPHERIC EVOLUTION

Helmut LAMMER (Institute for Space Research, Austrian Academy of Sciences, Elisabethstrasse 20, A-8010 Graz, Austria, EMail: helmut.lammer@oeaw.ac.at) Willibald Stumptner and Siegfried J. Bauer (both at Institute for Space Research, Austrian Academy of Sciences, and Institute of Meteorology and Geophysics, University of Graz, Halbaerthgasse 1, A-8010 Graz, Austria, E-Mail: willibald.stumptner@oeaw.ac.at, siegfried.bauer@kfunigraz.ac.at), Tobias Owen (Institute for Astronomy, University of Hawaii, 2680 Woodlawn Drive, Honolulu, Hawaii 96822, USA, E-Mail: owen@hubble.ifa.hawaii.edu)

A nitrogen isotope anomaly on Mars has been established as the consequence of dissociative recombination in the Martian ionosphere. We have investigated the possible sources of nitrogen isotope fractionation in the Titan atmosphere where this molecule is the principle constituent. As on Mars, electron dissociative recombination of N2+ ions is one possible source, however, electron impact dissociation and atmospheric sputtering due to Titans location within Saturns magnetosphere also represent possible sources of isotope fractionation. Using a Monte Carlo method we have shown that electron impact dissociation of molecular nitrogen could lead to an isotope fractionation since the released energy of the newly born 14N isotope is slightly smaller than the necessary escape energy. The 14N isotope can therefore only escape from altitudes above the exobase level (1450 km) while the lighter 14N isotope can also escape from lower altitudes. This process may therefore be responsible for the observed enrichment of 14N on Titan, enabling us to estimate the total nitrogen reservoir required to produce the present atmosphere.

JSA10/W/02-A3 Invited **1045**

THE JOVIAN MAGNETOSPHERIC ENGINE

C T RUSSELL (University of California, Los Angeles, CA, USA)

The energetics of the jovian magnetosphere are unlike those of any other magnetosphere in the solar system. The fuel for this gigantic engine is the mass loading deep in the planetary magnetosphere from the volcanic moon, Io. The energy gained by this fuel is drawn from the rotational energy of the planet extracted through the ionospheric currents that keep the magnetospheric plasma in rapid rotation. The magnetospheric plasma in turn accelerates the newly born ions erected from Io's neutral gas cloud. Once in the torus surrounding Io these circulating ions slowly but ever more rapidly drift outward. Once the dipolar magnetic field becomes too weak to confine this dense, rapidly rotating plasma, the configuration of the field becomes more disk-like and the field lines become much longer. Eventually the stretched out field lines "reconnect" across the current sheet producing magnetized islands that shed the mass down the tail that was long ago scavenged from Io. Empty flux tubes now make their way back into the interior of the jovian magnetosphere much as a conveyor belt returns to its loading point to pick-up another package but unlike most conveyor belts, the jovian magnetospheric circulation appears to be quite unsteady.

JSA10/W/09-A3 **1115**

THREE-DIMENSIONAL SPHERICAL SIMULATIONS OF MANTLE CONVECTION IN IO

PAUL J. TACKLEY (Earth and Space Sciences Department, University of California, Los Angeles, CA 90095, USA), Gerald Schubert (Earth and Space Sciences Department and Institute of Geophysics and Planetary Physics, University of California, Los Angeles, CA 90095, USA), Gary A. Glatzmaier (Earth Sciences Department, University of California, Santa Cruz, CA 95064, USA), and J.Todd Ratcliff (Jet Propulsion Laboratory, Pasadena, CA, USA)

The Galilean moon Io has a very high heat flow of ~10^14 W, much greater than Earth's, and should thus be undergoing very vigorous convection in its silicate mantle. Recent Galileo measurements suggest that Io may have an internally-generated magnetic field, indicating vigorous circulation in a liquid iron core. The pattern and dynamics of core convection are expected to be strongly influenced by the heat flow pattern at the core- mantle boundary imposed by mantle convection. Thus, we are performing simulations of Io mantle convection both to determine the heat flux variation at the CMB and to understand the distribution of surface heat flux and features. The heat source for Io's mantle convection is quite different from that of previously-simulated planetary mantles, being dominated by non-uniform internal (volumetric) heating due to tidal dissipation, rather than uniform volumetric heating from the decay of radiogenic isotopes. The distribution of tidal heating in Io's mantle is uncertain, with two end-member scenarios [Ross and Schubert, 1985] being dissipation in the entire mantle, or dissipation in a thin (~100 km thick) asthenosphere. We consider both end-members plus the 'prefered' distribution of [Ross et al., 1990] comprising 1/3 mantle and 2/3 asthenosphere heating. The amount of tidal heat generation is extremely large and the associated (internally-heated) Rayleigh number is O(10^12), orders of magnitude larger than that of Earth, Venus or Mars, and larger than anything which can presently be simulated in 3-D. Results at Ra of O(10^6-10^8) indicate a large-scale flow pattern which is dominated by the pattern of tidal heating, with superimposed small-scale asthenospheric instabilities which become more pronounced as Ra is increased.

JSA10/W/16-A3 Invited **1130**

GALACTIC DUST MEASUREMENTS NEAR EARTH

EBERHARD GRUEN, (MPI-Kernphysik, Heidelberg, Germany,
Email: eberhard.gruen@mpi-hd.mpg.de) M. Landgraf (NASA JSC, Houston, TX., U.S.A.), H. Svedhem (ESA-ESTEC, Noordwijk, The Netherlands) and M. Horanyi (LASP, Boulder, CO., U.S.A.)

Galactic interstellar dust (ISD) is the major ingredient in planetary formation. However, information on this important material has been extremely limited. Recently the Ulysses dust detector has identified and measured interstellar dust outside 1.8 AU from the Sun at ecliptic latitudes above 50 deg. Inside this distance it could not reliably distinguish interstellar from interplanetary dust. From the Hiten satellite in high eccentric orbit about the Earth there are indications that ISD indeed reaches the Earth's orbit. The Stardust mission intents to analyze by an in-situ detector and to collect ISD between 2 and 3 AU from the Sun. Modeling the Ulysses data suggests that up to 30 % of dust flux with masses above 10^-13 g at 1 AU is of interstellar origin. In order to identify the ISD flux levels at 1 AU a mission is proposed that can identify and quantify interstellar dust flux in high-Earth orbit (outside the debris belts) and can provide chemical composition information of galactic dust. A mission scenario is described that allows us by in-situ dust measurements to distinguish interplanetary from interstellar dust and provide important physical and chemical information on ISD. In addition, crucial information is provided for follow-up missions to collect galactic dust in Earth orbit for sample return.

JSA10/W/04-A3 Invited **1145**

FUTURE EXPLORATION OF THE JOVIAN SYSTEM

Torrence V. JOHNSON, Jet Propulsion Lab, Pasadena, CA 91109, USA.
email: tjohnson@jpltvj.jpl.nasa.gov

Exploration of Jupiter's system began in 1610 with Galileo's first telescopic observations. The telescope remained the principle tool for Jupiter studies for more than 350 years before the first spacecraft missions to the giant planet were planned. Pioneers 10 and 11 opened the spacecraft era with flybys in 1973 and 1974 followed by Voyager 1 and 2 in 1979. Since December 1995 the Galileo spacecraft has orbited Jupiter sending back information about the planet, its moons and rings, and the magnetosphere. As we enter the next century, plans are being laid to continue Jupiter system exploration with a further extension of the Galileo mission, possibly allowing joint observations with the Cassini mission as it flies by in December 2000. Beyond that, a Europa orbiter mission is planned for launch in 2003, to study this fascinating moon and search for proof of a liquid ocean under its icy shell. Objectives, status and plans for these future explorations will be discussed in the context of what we have already learned about the system. This work was done at Caltech's Jet Propulsion Laboratory under a contract from NASA.

SPACE EXPLORATION

JSA10/C/GA4.15/P/03-A3 Poster **1400-01**

THE MARTIAN EGYPTIAN DRILL PROJECT

M.A. Mosalam SHALTOUT (National Research Institute of Astronomy and Geophysics, Helwan, Cairo, Egypt. Tel: (202) 2630833; Fax: (202) 5548020 Email: mamshaltout@frcu.eun.eg

During the fourth UN/ESA Workshop on Basic Space Science, held in Cairo, July 1994, the possible participation of Egypt in future Mars Rover mission was discussed. One concept suggested was that Egypt participate in these missions through involvement in the design, building and testing of a drill for obtaining sub-surface samples.
The Planetary Society (TPS), Sponsor of the UN/ESA Basic Space Science Workshop, is following up this suggestion. Society representatives Adriana Ocampo and Chris McKay, together with Egyptian Scientist Farouk El-Baz, and Society Executive Director Louis Friedman have begun organising a study of the concept. They informed the Space Research Institute (IKL) of the Russian Academy of Sciences about the idea, and they, in turn, formally invited the Egyptian ministry of scientific research to study the concept for potential use on the Russian Mars 2001 Mission. That study has now begun, under the direction of Dr. Farouk El-Baz and Prof M.A Mosalam Shaltout. Of the many important scientific objectives of the Marsokhod mission, among the most interesting, is the analysis of sub-surface samples. Inclusion of same sort of drilling mechanism in the payload of such a mission would assist scientists in the investigation of volatile organic materials and mineralogy.
Twenty years ago, the arm on the Viking Mars lander was to obtain samples from depths up to 10cm. Today, a drill with the capacity of boring at least an order of magnitude deeper (more than one metre) would be essential to further research and investigation.
Egypt has expertise in drill development. A few years ago, as part of the archaeological exploration of the Pyramids, a sophisticated drilling system was developed to drill into and deploy a Camera into a sub-surface chamber without allowing air into the chamber. The drill perforated the limestone to a depth of 2m without the use of lubricants or cooling fluids that might have contaminated the Pit's environment, and successfully collected (six) samples.
This experience as well as more common terrestrial applications suggests that the necessary technology base for a drill development can be brought together. In the proposed application for the Mars 2001 Mission. A study team of Egyptian scientists, collaborating with American, Russian, AND European scientists, is now being organized.

JSA10/W/14-A3 Poster **1430-02**

A TWO DIMENSIONAL SIMULATION OF THE CONSERT EXPERIMENT (RADIO TOMOGRAPHY OF COMET WIRTANEN)

Jean-Pierre BARRIOT (Observatoire Midi-Pyrénées, 14, Av E. Belin, Toulouse, France, email: Jean-Pierre.Barriot@cnes.fr), Wlodek Kofman (Laboratoire Images et Signaux, BP 46, St Martin d'Heres, France, email: wlodek.kofman@lis.inpg.fr)

We make in this poster two dimensional simulations of the mapping of the comet Wirtanen internal permittivity from CONSERT (COmet Nucleus Sounding Experiment by Radiwave Transmission) phase and amplitude measurements. We study the influence of a priori covariance matrices on the mapping process through Tikhonov or linear regression inverse formulas. We show that this a priori information permits a smooth imaging of the internal permittivity, sometimes affected by ghosts (false anomalies). We demonstrate that taking into account indirect propagation paths into the comet material (rays totally reflected by the comet surface) can alleviate this problem.

JSA10/E/05-A3 Poster **1500-03**

ON THE COMETARY ORIGIN OF THE LUNAR AND MERCURIAN POLAR ICE

V.V.SHEVCHENKO (Sternberg State Astronomical Institute, Moscow University, Universitetskii pr. 13, Moscow 119899, Russia, email: shev@sai.msu.su)

The most convincing model for the "swirls" (lunar and mercurian albedo anomalies) origin seems to be surface contact with the gas/dust coma of comets passing by or falling onto the bodies. It is possible to show that the most probable scenario for the water ice polar deposit origin is the falls of young comets onto the Moon (and possible onto Mercury) during comet showers. In particular the comet Hale-Bopp has become a sufficiently convincing confirmation of the existence of bodies with gigantic nuclei. Thus its parameters can serve as the first interaction data for the quantitative assessment of the lunar ice with a comet origin. The Hale-Bopp comet nucleus diameter was estimated to be about 40 km. Consequently after a similar body with a density of 0.1 g/cm3 falls on the lunar surface a vapour cloud with a mass of about 3.4x10E+18 g is formed. The water melting, surface, and crush-up energies are neglected. According to the above given assessment the mass of the volatile compounds which stay in the lunar environment will be 3.4x10E+17 g. Assuming that these substances, distributed equally above the lunar surface, will further cool and deposit in the regolith upper layer, the assessed mass will be about 10E+10 g per a square kilometre. It is obvious that the subsequent preservation of the deposit is only possible in cold traps located near to the poles. Thus for the given assessments of the total area for both the southern and northern poles where the neutron spectrometer of the Lunar Prospector fixed the ice presence (3700 km2), the calculated mass of the volatile deposits of comet origin can be up to 10E+13-10E+14 g for each giant comet fall. These estimates fit the data obtained by the Lunar Prospector in the first approximation.

SEA SURFACE HEIGHT VARIABILITY DERIVED FROM ERS-2 ALTIMETER DATA NEAR CHINA SEA

HANJIANG WEN, H.Suenkel, Institute of Theoretical Geodesy, Steyrergasse 30, TU-Graz A-8010 Graz, Austria

A small area near China sea was used to study the sea surface height variability using one-year ERS-2 altimeter data. A local cross-over adjustment was carried out to reduce the residual radial orbit error, and the influence of the earth's geopotential model was also studied. Collinear analysis was then used to derive the RMS sea surface height variability, and seasonal variation of the sea surface was also compared.

JSG11/E/04-A3 0910

GLOBAL SEA LEVEL CHANGES FROM SATELLITE ALTIMETRY AND TIDE GAUGES

A. Cazenave, J.F. CRETAUX, K. Dominh and L. Soudarin (LEGOS-GRGS/CNES, 18, Avenue Edouard Belin, 31401 Toulouse Cedex 4, France, e-mail: anny.cazenave@cnes.fr)

Since late 1992, the global mean sea level variations are precisely monitored from space by the Topex-Poseidon (T/P) altimeter satellite. A mean sea level rise of 1.8 + 0.2 mm/yr is recorded between January 1993 and October 1998.
Excluding data since early 1997 which evidence the large rise and fall of the sea level associated with the 1997 El Ni=F1o, the global mean sea level rise measured by T/P. Poseidon reduces to ~ 1.0 + mm/yr. There is indication however that T/P underestimates the mean sea level rise by ~ 1-1.5 mm/yr due to an instrumental drift of the onboard radiometer. By comparing sea level changes measured by T/P and tide gauges of the GLOSS network since early 1993, we confirm the presence of a sea level drift of ~ -1.8 mm/yr between T/P and tide gauge measurements in agreement with independent estimates of the T/P radiometer drift. As a consequence, the global mean sea level monitored from space shows a rate of change of ~ 2.5 mm/yr since early 1993. Attempt to understand this global sea level change in terms of thermal expansion and mass exchange with continental waters is also presented.

JSG11/E/09-A3 0930

FOURIER AND WAVELET ANALYSES OF TOPEX/POSEIDON-DERVIED SEA LEVEL ANOMALIES OVER THE SOUTH CHINA SEA - A CONTRIBUTION TO SCSMEX

Cheinway Hwang and Sung-An Chen (both at Department of Civil Engineering, National Chiao Tung University, 1001 Ta Hsueh Road, Hsinchu 300, Taiwan. email: hwang@geodesy.cv.nctu.edu.tw)

We process 5.6 years of TOPEX/POSEIDON altimeter data and obtain time series of sea level anomalies (SLA) over the South China Sea (SCS). Fourier analysis shows that sea level variability of SCS contain major components with periods larger than 180 days. Tidal aliasing create 30 to 180-day components which can be misinterpreted as wind-induced variabilities. Continuous and multiresolution wavelet analyses of SLA show that sea level variability of SCS has monthly to interannual components, but with time-varying amplitudes. The sea level slope is 8 mm/year, possibly caused by decadal climate variation. Coherences of sea level with wind and sea surface temperature are significant only at frequencies lower than 2 cycles/year, and wavelet coefficients show high coherences at the interannual scales. Zero-crossing of SLA is highly correlated with the onset of the summer monsoon. The interannual variabilities of SCS sea level are correlated with ENSO, and most important is that when the El Nino-like wavelet coefficients change curvatures, an El Nino starts to develop, suggesting that real-time SLA over SCS or the western Pacific warm pool can provide a warning to the occurrence of an EL Nino. This a contribution to SCSMEX.

JSG11/E/12-A3 0950

SEALEVEL VARIATION DATA EVALUATION IN INDONESIAN WATERS

Sobar SUTISNA (Center for Basicdata Survey, National Coordination Agency for Surveying and Mapping, P.O.Box 46/CBI, Cibinong 16911, INDONESIA, email: sobar@cbn.net.id) Mujiana and Bambang S. Pratomosunu (both at Center for Marine Mapping and Aerocharting, Bakosurtanal, P.O. Box 46/CBI, Cibinong 16911, INDONESIA)

Bakosurtanal (the National Coordination Agency for Surveying and Mapping of Indonesia) has today 28 tide stations in operation. The sealevel observation in the country are essential and are used for different purposes in both local and regional level as well as on a global scale. Tidal analysis were carried out using harmonic analysis method by treating the sum of a finite number of harmonic constituents whose angular speeds and phases are determined from the astronomical arguments.
This paper presents the results of analysis have been carried out at Bakosurtanal for all of the 28 tidal station data in order to determine mean sea level (MSL) position, to calculate low astronomical tide (LAT) and high astronomical tide (HAT) at each tide station locations. The possibility to define sealevel baseline data for sealevel rise monitoring in relation to climate change in Indonesia will also be discussed.

JSG11/W/03-A3 1010

A COMPREHENSIVE ANALYSIS OF THE TIDAL AND OCEANIC SIGNALS FROM THE WOCE SEA LEVEL OBSERVATIONS AND PRELIMINAR APPLICATIONS.

F. Ponchaut (email: ponchaut@cnes.fr), F. Lyard (email: Florent.Lyard@cnes.fr) and C. Le Provost (email: Christian.Le-Provost@cnes.fr) (all at LEGOS/GRGS, UMR5566 CNES- CNRS-UPS, 14 Avenue E. Belin, 31400 Toulouse, France)

A new sea level observation network initiated by the WOCE program is delivering hourly data from 150 ocean stations worldwide. A complete analysis of these data, the WSLA 98 data set (standing for WOCE Sea Level Analysis, 1998) was performed using a least-squares method allowing better accuracy over time series virtually unlimited in time (up to 13 years in this case). In addition to the classical tidal constants, the power density spectrum of the de-tided signal was computed and the 95% confidence intervals have been systematically estimated. Beyond the need for high accuracy de-tided sea level data, like in vertical ground movements applications, or for mean sea level monitoring purposes, the analysis outputs are a highly valuable material in the studies of the ocean waves, and in particular for the tidal modelling. The availability of confidence intervals allows to investigate more precisely the tidal waves of low amplitude, like long period or non-linear tides. For instance, the oceanic residual energy spectrum is used to select the tidal constant set needed to validate and compare the long period tide models. This selection is performed by eliminating stations where the oceanic continuum spectrum magnitude (around a given tidal frequency) is more than 25% of the corresponding tidal peak amplitude. It also gives the opportunity to prescribe realistic data error bars in the data assimilation models. This analysis intends to lead to a better exploitation of sea level observations, which contain highly valuable information in the tidal and non tidal domains. The authors emphasise the need for the WOCE Sea Level network to be maintained.

JSG11/W/04-A3 1030

SEPARATION OF THERMAL AND MASS SIGNALS IN SEA LEVEL VARIABILITY BY COMBINING SATELLITE ALTIMETRY AND XBT DATA

Don CHAMBERS, Jianli Chen, and Byron D. Tapley (University of Texas at Austin, Center for Space Research, R1000, Austin, TX, 78712, USA, Email: chambers@csr.utexas.edu)

Sea level variability can be measured quite accurately on regional and global scales with satellite altimetry. However, the altimeter measures the combination of changes caused by thermal and mass variations. In order to study the relative effect of mass or thermal variations, other measurements must be combined with altimetry. Expenable Bathythermagraphs (XBTs) dropped from ships measure temperature at depth, and can be integrated to compute the sea level variations due to thermal changes. However, the XBT casts are limited in both time and space. In this study, we interpolate XBT data for the period 1993 to 1997 to a uniform grid by using Empirical Orthogonal Functions computed from TOPEX/POSEIDON (T/P) altimeter data. The T/P and XBT sea level measurements are then compared on regional and global scales to determine the relative size of thermal to mass variability to the total signal. Interannual and annual variations in the global water mass balance are also studied by comparing the T/P and XBT measurements with output from various atmospheric and hydrological models.

JSG11/W/18-A3 1110

SEA-LEVEL CHANGES AND VERTICAL CRUSTAL MOVEMENTS IN THE SOUTHERN CARIBBEAN FROM SATELLITE ALTIMETRY, TIDE GAUGE RECORDS AND GPS HEIGHT DETERMINATIONS

Wolfgang BOSCH, Hermann Drewes, Klaus Kaniuth (all at Deutsches Geodaetisches Forschungsinstitut, Marstallplatz 8, D-80539 Muenchen, Germany,
email: bosch@dgfi.badw-muenchen.de) , Hans Kahle (Institut fuer Geodaesie und Photogrammetrie, ETH Hoenggerberg, HPV G 52, Zuerich, Switzerland, email: kahle@geod.ethz.ch) , Napoleon Hernandez (Servicio Autonomo de Geografia y Cartografia Nacional, Av, Este 6, C.S.B., Edif. Camejo, Piso 2, Caracas 1010, Venezuela, email: hernandez.sagecan@conicit.ve)

The sea surface variability derived from four years of Topex/Poseidon altimeter data shows a heterogeneous feature in the southern Caribbean. The variations are analyzed and compared with records of tide gauges along the northern South American coast of the corresponding epoch. Long-term tidal records present a non-uniform behaviour ranging from -2 mm/a decrease to +2 mm/a increase of sea-level. To separate in the tidal records the sea-level changes from the vertical crustal movements, the tide gauges with extreme observed variations (Carupano, La Guaira, and Amuay, all at the Venezuelan coast) have been precisely determined in height by GPS measurements in three campaigns from 1993 to 1999. The results are analyzed together with the satellite altimetry data.

JSG11/W/19-A3 1130

THE INTEGRATION OF SEA-LEVEL MEASUREMENTS FROM SATELLITE ALTIMETRY SPANNING TWENTY-FIVE YEARS

Timothy J. URBAN, John C. Ries, Byron D. Tapley (all at University of Texas at Austin, Center for Space Research, 3925 W. Braker Lane, Suite 200, Austin, TX, 78759-5321, USA, e-mail: urban@csr.utexas.edu, ries@csr.utexas.edu, tapley@csr.utexas.edu), C.K. Shum (Ohio State University, 2070 Neil Ave., Columbus, OH 43210, USA, e-mail: ckshum@osu.edu)

Satellite altimeter data from the two and a half decades of data collection has been integrated into one data set for the purpose of monitoring long-term sea level. The satellites included are GEOS-3 (1975-1978), SEASAT (1978), GEOSAT (1985-1989), ERS-1 (1991-1996), TOPEX/POSEIDON (1992-present), and ERS-2 (1995-present). The historic data are improved with the most modern satellite orbits, media and geophysical correction models, yielding data sets as homogenous as currently achievable. Crossover and other analyses are performed to validate the correction models and resulting sea-level data. An accuracy assessment of the combined data is given, including orbit error and long-term analysis of altimeter corrections. Relative sea-level biases between satellite missions are determined through tide gauge and other analyses. Including gaps in the time series, a twenty-five year estimate of satellite-measured sea-level rise is produced.

JSG11/W/22-A3 1150

A GENERALIZED APPROACH TO THE CROSSOVER ANALYSIS OF ALTIMETRY DATA

Q.W. LIU and Y.Q. Chen (both at Department of Land Surveying & Geo-Informatics, The Hong Kong Polytechnic University, Hunghom, Kowloon, Hong Kong, email: lsqwliu@polyu.edu.hk)

The crossover adjustment has been extensively employed to correct altimetry data for the radial orbit error. The traditional procedure for the crossover adjustment is to use the difference of the sea surface height at crossover points to form the system equation and solve it by least squares. It is shown that the method is not effective in small ocean basins due to the few crossovers per track and to the relatively short tracks. An alternative approach is to make direct use of altimetry measurements at crossover points without differencing and to estimate simultaneously orbit parameters and mean sea surface heights in a single, unified adjustment. The rank defect inherent in the crossover estimation problem is overcome by introducing

additional constraints, as fixing certain number of parameters of non intersecting tracks (Schrama 1989), or adding an appropriate set of new constraints (van Gysen et al., 1997), or by combing the altimetry data with tide gauge station data (Fenoglio and Groten 1995). The purposes of our research are twofold. One is to theoretically generalize the existing crossover methods in order to provide a convenient theory for crossover analysis. It is shown that all the existing methods are special cases of our generalized approach developed by considering a weight for the estimated parameters of orbit error and mean sea surface height. Another is to practically compute a realistic estimate of the total radial orbit error and the mean sea surface. The detailed formula of the generalized approach is derived. Formulation and numerical example demonstrate its application.

JSG11/W/21-A3 1210

LOCAL SEA LEVEL CAN BE MONITORED...

Kyra VAN ONSELEN, Delft University of Technology, Email: onselen@geo.tudelft.nl

Local sea level can be monitored using a tide gauge, which relates sea level height variations to a local bench mark. In order to combine sea level height series for a number of tide gauges, the heights of these local tide gauge bench marks have to be determined in a common reference system. The geodetic measuring techniques used to perform these height connections will introduce measuring and systematic errors in the collection of sea level height series. The purpose of this work is to investigate how the detectability of a common pattern in sea level height series is influenced by the limited accuracy of the geodetic measuring techniques used to connect the tide gauges in height. Time series used are a combination of simulated patterns with periodic fluctuations obtained from actual tide gauge data. The effect of connecting the tide gauge bench marks is simulated based both on knowledge of error characteristics of geodetic measuring techniques and (differences) between actual sea level height series. Sea level height variation patterns under consideration are one common variation curve for all tide gauges, and a linear variation in this pattern for tide gauges situated along a specific coast.

JSG11/E/10-A3 1400

DETERMINATION AND CHARACTERIZATION OF LONG-TERM MEAN SEA LEVEL CHANGE

C. K. SHUM (Department of Civil and Environmental Engineering and Geodetic Science, The Ohio State University, 470 Hitchcock Hall, 2070 Neil Avenue, Columbus, OH 43210-1275, USA, Email: ckshum@osu.edu), Hong-Zeng Tseng (Ohio State University) Tim Urban and Byron Tapley (Both at University of Texas), Michael Anzenhofer GeoForschungs Zentrum Potsdam, Germany), and Philip Woodworth (Proudman Oceanographic Laboratory, Bidston, UK)

Recent studies of global sea level change have concluded that the global eustatic rate of sea level rise during the last century has been 1-2 mm/yr [Warrick et al., 1993]. Although there is no firm evidence of an acceleration in the rate of sea level rise over this time period [Woodworth, 1990], the projected future sea level rise is 13 +/- 4 cm during the next 40 years (1987-2027), and 61 cm over the next 100 years (1987-2087) [Woodworth, 1995]. Sea level change represents consequences of complicated interactions of the solid Earth-atmosphere-hydrosphere-ocean- cryosphere system and in part forced by human-originated greenhouse effect. Current long-term (40-100 years) sea level change estimates (e.g., IPCC studies) are primarily provided by long-term tide gauges located near coastal regions and continental margins. The estimate has deficiencies from local land movements (e.g., due to postglacial rebound and subsidence) and vertical datum knowledge, and the fact that the data only covers less than 5% of the global ocean. Satellite radar altimetry missions, both historic and current (Geos-3, Seasat, Geosat, ERS-1, TOPEX/POSEIDON, ERS-2, GFO-1, and future (Envisat, Jason-1, NPOESS), would provide global coverage but is deficiency both in data span (less than 10 years of continuous data), and the difficult in the knowledge of instrument biases. In this study, we attempt to use the available, improved processing of multiple mission altimeter measurements [Urban et al., abstract submitted to this session] and long-term tide gauges, to provide a combined analysis to examine the current rate of mean sea level rise. Second part of the study is intended to provide a characterization of the sea level change by using modern observations, including global sea surface temperature (spaceborne and in situ), ice extents [M. Anzenhofer et al., abstract submitted to session JSH12], postglacial rebound models, glacier and ice sheet mass balance data. Specific examples such as the sea level change in the China Sea region during the last decade will be discussed in the presentation.

JSG11/P/01-A3 1420

INTERANNUAL AND ANNUAL SEA LEVELS IN THE SEISMIC AND TECTONIC ACTIVE ZONE IN THE NORTHWESTERN PACIFIC

Shigehisa NAKAMURA(Famille Villa-A104,Tanabe 646-0031,Japan)

Interannual and annual sea levels in the seismic active zone is studied in order to realize what effects are seen just neoghbour the tectonic boundary. A special reference is that in the north-west Pacific. As for the problem of the tectonic effect to the apparent sea level at a tide station, a typical example of the 1995 seismic event can be introduced. The tide station of Kobe was strongly affected at the event, so that the marigram showed the patterns of the seismic motions and the successive upheaval as the vertical ground motion.This effect can be seen in the sea level variations of monthly mean or annual mean after processing the hourly read tide data. The interannual sea levels for about 100 years in the 20 century suggests the effect of under-ground waters and the effects of the crustal upheaval and the Kuroshio as an ocean curent intensified in the western boundary of the Pacific. Spectral analyses are undertaken to demonstrate what specific variations of the spe(--trat patterns at several tide stations located just south of the tide station Kobe neighbour the boundary of the Eurasian tectonic plate. At the three tide stations located on the coast facing the Pacific, the spectral patterns are suggesting a signifcant effect of the Kuroshio meandering just off the tide stations. Successive studies should be followed after the year of 1999.

JSG11/W/05-A3 1440

BIFROST PROJECT: FENNOSCANDIAN NETWORKS FOR CRUSTAL DEFORMATION AND SEA-LEVEL CHANGES

J.M. JOHANSSON, H-G, Scherneck, G. Elgered (all at Onsala Space Observatory, Chalmers University of Technology, SE-43992 Onsala, Sweden, email: jmj@oso.chalmers.se) J.L. Davis, R.A. Bennett (both at Harvard-Smithsonian Center for Astrophysics, Cambridge, MA, USA,
email: jdavis@cfa.harvard.edu); H. Koivula, M. Poutanen (both at Finnish Geodetic Institute, PL 15, FI-02431 Masala, Finland, email: hannu.koivula@fgi.fi) ; G. Hedling and B. Jonsson (both at National Land Survey of Sweden, SE-80182 G‰vle, Sweden, email: gunnar.hedling@lm.se)

Project BIFROST (Baseline Inferences for Fennoscandian Rebound Observations, Sea level, and Tectonics) uses the continuous GPS observations in northern Europe to determine the 3-D motion associated with glacial isostatic adjustment. The backbone in this project is the permanent networks in Finland (FinnRef) and Sweden (SWEPOS). These networks has also proven to be an excellent tool for studying various effects of the environment near to the permanent sites.
In total, GPS-data from about 2000 days, have been acquired and analyzed. We have used different software packages and strategies. The entire data set has been analyzed with the GIPSY software package, both in a network solution as well as with the Precise Point Position method. Data from 1996 an onwards have also been analyzed using the Bernese software, partly as a contribution to the EUREF permanent network and the IGS. Furthermore, periods of data have been analyzed with the GAMIT software package. The BIFROST project, the networks and their purposes are presented. We discuss the error budgets in an inter-comparison of analysis procedures. We discuss antenna and site related perturbations and methods for their reduction.

JSG11/W/09-A3 1500

BIFROST PROJECT: 3-D CRUSTAL RATES INFERRED FROM GPS IN APPLICATION TO THE POSTGLACIAL REBOUND AND SEA-LEVEL IN FENNOSCANDIA.

H-G. SCHERNECK, J.M. Johansson (both at Chalmers, Onsala Space Observatory, SE-439 92 ONSALA, Sweden, e-mail: hgs@oso.chalmers.se, jmj@oso.chalmers.se) M. Vermeer (Finnish Geodetic Institute, PL 15, FI-02431 Masala, Finland, e-mail: mv@fgi.fi) J.L. Davis, R.A. Bennett, G.A. Milne (Harvard-Smithsonian Center for Astrophysics, Cambridge, MA 02133, USA, e-mail: jdavis@cfa.harvard.edu, gmilne@cfa.harvard.edu, rbennett@cfa.harvard.edu) J.X. Mitrovica (Dept. Physics, University of Toronto, Toronto, Ontario, Canada M5S 1A7)

Since autumn 1993, the BIFROST project has provided daily GPS solutions of geodetic positions from a network of more than 40 stations covering a large area of the Baltic shield. This area is supposed to show large vertical motion due to glacial isostatic rebound after the deglaciation at the end of the pleistocene. This presentation will discuss the inference of three-dimensional rates of crustal motion at the GPS stations with respect to (1) a plate-fixed average as regards the horizontal components; (2) a geocentric reference in order to infer absolute changes of sea level from vertical crustal motion and models of geoidal rebound. We show that the horizontal strain rate pattern is largely dominated by unilateral extension and low in horizontal shear. As regards vertical motion a crucial issue is the stability of the geocentre in the GPS frame. We show results from Precise Point Positioning analysis which exhibits the problem more clearly than network solutions. We also show the importance to systematically reduce regional and local problems related to a number of surface loading problems.

JSG11/E/05-A3 1520

BIFROST PROJECT: APPLYING 3-D CRUSTAL DEFORMATION DATA TO CONSTRAIN MODELS OF GLACIAL ISOSTASY IN FENNOSCANDIA

Glenn MILNE, Jim Davis (Harvard-Smithsonian Center for Astrophysics, Cambridge, USA; e-mail gmilne@cfa.harvard.edu), Jerry Mitrovica (University of Toronto, Toronto, Canada), Hans-Georg Scherneck, Jan Johansson (Chalmers Institute of Technology, Onsala Space Observatory, Onsala, Sweden) and Martin Vermeer (Finnish Geodetic Institute, Masala, Finland)

The most recent solutions of BIFROST (Baseline Inferences for Fennoscandian Rebound, Sea-Level and Tectonics) project data for 3-D crustal-motion rates show a coherent picture that is clearly related to the glacial isostatic adjustment process. In this contribution, we shall present results from a series of both forward and inverse modeling calculations that adopt a spherically symmetric earth model with a compressible Maxwell viscoelastic rheology, a suite of different ice models and a sea-load model that is calculated by solving the sea-level equation in a gravitationally self-consistent manner. Our forward modeling analysis shows, in particular, that the data provide good constraints on the location of the center of mass and the large-scale geometry of the ancient Fennoscandian ice sheet. Also, the data are highly sensitive to viscosity variations within the upper mantle and, given the results of a simple sensitivity analysis, should provide a relatively firm lower bound on this parameter. An inverse analysis, based on ICE-1 [Peltier and Andrews, Geophys. J. R. astr. Soc., vol. 46, 1976] and an earth model with a 120 km elastic lithosphere and upper/lower mantle viscosities of 1/2 x 10**21 Pa s, indicates that the data prefer a relatively `soft' upper mantle (< 10**21 Pa s) with a substantial increase in viscosity into the shallow lower mantle (viscosity within the deep mantle is not well constrained by the data). These general characteristics are consistent with a number of recently published viscosity profiles. We hope to present results from a new inverse analysis based on a viscosity profile that exhibits these general features and a recently published Fennoscandian ice model [Lambeck, Smither and Johnson, Geophys. J. Int., vol. 134, 1998].

JSG11/W/02-A3 1540

MODELLING OF THE MULTIPLE PROCESSES AFFECTING SEA LEVEL RISE IN THE CENTRAL MEDITERRANEAN

G. Di Donato, A.M. Negredo, R. SABADINI, L.L.A. Vermeersen, J.X. Mitrovica (Dipartimento Scienze Terra, Sezione di Geofisica, Universita di Milano, Via L. Cicognara 7, I-20129 Italy, Email: stud1@sabadini.geofisica.unimi.it)

Geophysical modelling of tectonic mechanisms active in the central Mediterranean and of post-glacial rebound allows us to establish their relative contributions to sea-level changes. For a mantle stratified in viscosity, we obtain that the peak value of sea-level increase due to the two processes are comparable in magnitude, while its spatial variability portrays a different pattern. In the Adriatic sea, along the eastern part of the Italian peninsula, the effects of tectonic subsidence and post-glacial rebound sum up to a total sea-level increase that can be as high as 1 mm/yr. Both the amplitude of sea level rise and its spatial variability along the eastern coasts of Italy agree with secular sea-level changes inferred from archeological data, from Aquileia in the northern sector of the Adriatic sea to Egnatie in the southern part. Also in the historical cities of Venice and Ravenna model predictions agree with the data. The effects of a weak layer in the crust on the whole set of observables associated with glacial isostatic adjustment are also analyzed.

JSG11/W/10-A3 1620

MANTLE VISCOSITY INFERRED FROM FENNOSCANDIAN STRAND LINE DATA

Karin WIECZERKOWSKI (Institute of Planetology, University of Münster, Wilhelm-Klemm-Str. 10, D-48149 Münster, Germany) Jerry X. Mitrovica (Department of Physics, University of Toronto, 60 St. George Street, Toronto, Ontario M5S 1A7, Canada) Detlef Wolf (GeoForschungsZentrum Potsdam, Telegrafenberg, D-14473 Potsdam, Germany)

The postglacial rebound of the Fennoscandian shield has raised Holocene strandlines up to 200 m above the present sea level. The space-time distribution of these strandlines was used previously (e.g. McConnell 1968, JGR 73, 7089) to calculate the relaxation spectrum of rebound, i.e. the decay time of the uplift versus the wavelength of the deformation. Since it is unbiased by assumptions regarding the space-time history of the load, this spectrum has played a significant role in the inference of mantle viscosity. Previous relaxation spectra were derived on the basis of highly contentious hypotheses on strandline evolution (see Wolf 1996, GJI 127, 801). In this study we use strandlines based on more reasonable assumptions. Accounting also for the results of synthetic strandline calculations, we derive a new relaxation spectrum. Following Mitrovica & Peltier (1993, GJI 114, 45), we apply formal inverse theory to the new relaxation spectrum. In particular, we present estimates of the resolving power of the data as well as revised constraints, including uncertainties, on mantle viscosity. We find (5 +- 1) x 10^20 Pa s in the depth range 100 to 500 km and (2 +- 1) x 10^21 Pa s in the depth range 300 to 800 km.

JSG11/E/08-A3 1640

MICROFOSSIL EVIDENCE OF LAND SUBSIDENCE OF THE 1964 EARTHQUAKE IN ALASKA

YONGQIANG ZONG and Ian Shennan Department of Geography, University of Durham, Durham, UK

Diatom and pollen assemblages from a number of outcrops and cores at Girdwood Flats and Kenai River, in the Cook Inlet, record four phases of relative land and sea-level movements. The first phase is the development of freshwater swamp above high marsh sediments during relative land uplift, caused by strain accumulation along the locked portion of the Alaska-Aleutian subduction zone. In phase two, diatom and pollen groups from the top few centimetres of the peat reveal relative sea-level rise (or relative land subsidence) prior the main shock of the earthquake of March 1964. The third phase is rapid land subsidence, 1.7m at Girwood Flats and 0.5m at Kenai River, during the main shock that initiated intertidal silt sedimentation above the peat. The final phase is the colonisation of mudflat by saltmarsh communities during the post-seismic land uplift.
The concentrations of radionuclide 137Cs were measured to determine the time span of the second phase. The results suggest that the small land subsidence occurred about twenty years before the main shock in 1964, and was possibly a result of a major pre-shock.
The microfossil data compare favourably with sequences from Washington, Oregon and British Columbia that record late Holocene submergence events caused by large earthquakes. The results from Alaska raise the question whether pre-seismic sea-level rise (or land subsidence) represents any kind of warning of large earthquakes.
Co-workers include Dr. R. Combellick, Alaska Division of Geological & Geophysical Surveys, Fairbanks, Alaska, USA; Miss S. Hamilton and Ms M. Rutherford, Department of Geography, University of Durham, Durham, UK.

JSG11/E/17-A3 1700

TECTONIC-HYDRO-CLIMATIC MECHANISM OF THE LEVEL FLUCTUATIONS IN THE INTRACONTINENTAL SEAS: THE CASPIAN

Dmitri A. LILIENBERG (Institute of Geography, Russian Academy of Science, 29, Staromonetny per., 109017 Moscow, Russia, e-mail: geography@glas.apc.org)

A climatic concept has failed to predict a sudden and disastrous rise of the Caspian Sea level in 1978-95. As our recent studies show, the major impact to the Caspian Sea bath volume is caused by the lateral crustal motions in the Caucasian-Caspian nappe-overthrust domain. The lateral motions are parented by compression and tension produced by the Arabian Plate collision and are in complicated relations with hydro-climatic variations. The concurrent action of the tectonic and hydro-climatic mechanisms has also resulted in disagreement between Caspian transgressions and glaciation events. In the second half of the 20th century the Circum-Caspian was covered by repeated geodetic, sea-level, and seismic surveys with involvement of 10 geodynamic test areas. The resultant set of maps and profiles show the high mobility of the Circum-Caspian area, the reciprocal and variable contemporary motions, their dependence on the general morphostructure. Phases of the crustal extension and subsidence of the Caspian bath correlate with the sea-level drops in 1905-15 and 1929-40; the compression and uplifting correlate with the sea-level rise in 1978-95; but all level changes are independent of the actual sea water volume. The fluctuations of the sea level are in connection with the large-scale geodynamic processes, such as seismic activation in the Carpathians, Caucasia, and Asia Minor. The vertical motion rates make up few millimetres per tens of years, but can attain 5-7 cm/y. As recorded by trilateration and GPS surveys the lateral displacements are in the range of centimetres per year. The crustal motions, seismicity, mud volcanism, dynamics of subsurface fluids have a quasi-recurrence of 100-120, 80, 50-60, 35-40, 25-30, 10-20, 5-7, 2-3, and 1 year, which correlate with the hydro-climatic variations. Thus the Caspian Sea level fluctuations are caused by the integral tectonic-hydro-climatic mechanisms governed by the global processes.

HOLOCENE SEA-LEVEL CHANGES ALONG THE MEDITERRANEAN COAST OF ISRAEL - ARCHAEOLOGICAL OBSERVATIONS VERSUS ISOSTATIC MODEL

DORIT SIVAN and Avner Raban (both at the Center for Marine Studies, .University of Haifa, Haifa, 31905 Israel, Email: Dsivan@research.Haifa.ac.il). Shimon Wdowinski (Department of Geophysics and Planetary Sciences, Tel Aviv University, Ramat Aviv, 69978, Israel, Email: Shimon@geol.tau.ac.il). Kurt Lambeck (Research School of Earth Sciences, The Australian National University,Canberra, ACT 0200, Australia, Email: Kurt.Lambeck@anu.edu.au) Ehud Galili (Marine Archaeology branch, Israel Antiquities Authority, P.O.B. box 180, Atlit 30350, Israel, email: Udi@israntique.org.il)

Underwater and coastal archaeological research conducted along the Mediterranean coast of Israel reveals significant sea-level changes during the Holocene. We consider the archaeological observations as upper and lower constraints of paleo sea-level. High resolution numerical models of sea-level change during the Holocene have been developed for the Mediterranean coast of Israel, and the predicted curves have been compared with field observations. The archaeological observations and the model curve are generally consistent indicating that sea-level rising rates along the Israeli coast were high and reached values of 7.5-9.0 mm/yr between 8,000-6,000 BP. The rate decreased to less than 1 mm/yr from 6000 BP. The close agreement between the modeled and the inferred curves also suggest that the local vertical crustal movements were low: less that 0.25 mm/yr, for the past 8 000 years.

SEA LEVEL CHANGES AND GEODYNAMICS

Nils-Axel Morner Paleogeophysics & Geodynamics, S-10691 Stockholm, Sweden,
email: morner@pog.su.se

Sea level can only change within the limits set by the physical processes involved. Sea level changes is a multi-facetted problem, however, that calls for deep knowledge in a number of different subjects and interacting processes. Sea level changes as a function of several different processes and by that it is, at the same time a remarkable measure of a number of different geodynamic processes. On the Ma-time scale, we are primarily dealing with long-term deformations of the ocean basin volume, the mass distribution and the rate of rotation. On the Ka-time scale, we are dealing with glacial eustasy and related effects on isostasy, rotation and geoid shape. On the Cy-time scale, we seem - though much debated - to be dealing primarily with changes in the distribution of ocean masses via changes in the oceanic circulation in a feed-back coupling with the Earth's rate of rotation. On the Yr-time scale, we are dealing with local dynamic factors, and in some places ENSO-effects, too. For different reasons and aspects, both geophysesists and geologists tend to oversimplify the picture, however. This is especially true when it concerns the changes during the last centuries and the expected future changes. Glacial eustatic changes virtually finished in Mid-Holocene time. The most powerful Late Holocene process of rapid changes in regional sea level refers to the variability in the main oceanic circulation system as a function of interchange of angular momentum between the solid Earth and the hydrosphere. The steric expansion of the water column is limited to individual oceanic layers with quite different recycling times. Only the surface layer can experience rapid changes in the order of are less than 10 cm in a century. If, on the whole, there was a global rise in sea level in the last 150 years, it cannot have exceeded 1.1 mm/yr. Evaluating the past and present changes in sea level, the expected changes in the near-future are estimated at "some 10 cm - at the most 20 cm - per century".

SCHEME OF THE CIRCUM-PACIFIC HIGH PRECISION SEA LEVEL GPS MONITORING NETWORK

Hu Jianguo, Chinese Academy of Surveying and Mapping

The circum-pacific high precision sea level GPS monitoring network(i.e. a net work combing GPS points with tide gauging)is proposed to establish according to this scheme. And at the same time, the satellite altimeter data is used to monitor the absolute changes of sea level in this area, to study the el niÒo, the movements of geological plates and other geodynamical matters, and to unify the vertical datum in the circum-pacific area. The network is composed of 41 points which lie in Asia, Australia, South America, North America, Antarctica and some islands around the Pacific Ocean. After all those points are Surveyed during the same period through GPS. This network will be put into the ITRF96 Reference Frame. It is supposed the horizontal precision of those points will be 5-8mm, the vertical precision 10-16mm.

JSG11/E/15-A4 1010

GPS MONITORING OF VERTICAL GROUND MOVEMENTS AT UK TIDE GAUGE SITES SINCE 1990

Richard BINGLEY, Nigel Penna, Alan Dodson and Vidal Ashkenazi (IESSG, University of Nottingham, Nottingham, NG7 2RD, UK, Email: richard.bingley@nottingham.ac.uk), Trevor Baker (Proudman Oceanographic Laboratory (POL), Bidston Observatory, Birkenhead, Merseyside L43 7RA, UK, Email: tfb@pol.ac.uk)

Long term changes in mean sea level recorded by tide gauges are corrupted by vertical ground movements, which can be of a similar order of magnitude. Hence, to properly monitor changes in mean sea level, the rates of any vertical ground movements at tide gauge sites must be determined. The application of GPS to monitoring vertical ground movements at selected sites of the UK National Tide Gauge Network has been on-going at the IESSG and POL since 1990.
This work has closely followed the recommendations of the "Carter Reports" of 1989 and 1994, plus the more recent IGS/PSMSL workshop in 1997. Nine episodic GPS campaigns were carried out between 1991 and 1996, incorporating sixteen UK tide gauge sites. Since 1997, five of these sites have now been equipped with continuously operating GPS receivers (COGRs), which were some of the first to become operational at tide gauges in Europe.
This presentation charts the developments in using GPS at tide gauge sites, presents the results obtained in the UK from episodic GPS campaigns and COGRs, and discusses the contribution of these COGRs to a future European Sea Level Observing System (EOSS).

JSG11/E/16-A4 1030

GROUND MOVEMENTS OF THE DORIS STATIONS DUE TO THE SEASONAL LOADING

LAURENT SOUDARIN, Anny Cazenave, and Jean-Francois Cretaux (Laboratoire d'Etudes en Geophysique et Oceanographie Spatiales, 18 avenue Edouard Belin, 31401 Toulouse cedex 4, France, email: Laurent.Soudarin@cnes.fr)

The ground positioning performances of the DORIS space system are at present at the centimeter level for the horizontal and vertical components (even subcentimetric for high-latitude stations), thanks to the combination of the data collected by the satellites carrying a DORIS receiver. Spot2, Spot3, and Topex/Poseidon data have been analysed over 1993-1997, and monthly positions computed for the about 50 stations of the permanent tracking network. Periodic variations are detected in the time series of the coordinate stations. In particular, a few mm annual signal is observed for a quarter of the sites. We investigate the atmospheric pressure loading effects which could cause the earth deformation signals observed. From the gridded surface pressure of the NCEP/NCAR reanalysis project, and the load Love numbers, we compute the crustal deformation by the atmosphere. We also investigate the loading deformation of snow and Continental hydrology.

JSG11/W/01-A4 1050

MONITORING THE SEA-LEVEL AND VERTICAL CRUSTAL MOVEMENTSIN THE SOUTH ATLANTIC ALONG THE COAST OF ARGENTINA

Hermann DREWES, Wolfgang Bosch, Klaus Kaniuth (all at Deutsches Geodaetisches Forschungsinstitut, Marstallplatz 8, D-80539 Muenchen, Germany,
email: drewes@dgfi.badw-muenchen.de); Claudio Brunini, Juan Moirano, Francisco Azpilicueta (all at Facultad de Ciencias Astronomicas y Geofisicas, Universidad La Plata, La Plata, Argentina, email: claudio@fcaglp.fcaglp.edu.ar)

Long-term tide-gauge records along the South Atlantic coast of Argentina show aquite heterogeneous behaviour of sea-level variations ranging from -3.5 mm/a decrease to +5 mm/a increase. These signals are analyzed and compared with time series derived from six years Topex/Poseidon satellite altimetry data. Since December 1998, a selected number of representative tide gauges is monitored by repeated precise height determinations using the Global Positioning System (GPS). The ellipsoidal height of the sea surface at the tide gauges is compared with the sea surface height from satellite altimetry in order to detect systematic

effects. The repeated height determinations of the tide gauges will provide information about vertical crustal movements.

JSG11/W/08-A4 1130

TECTONIC MOTION OF NY-ALESUND VLBI OBSERVATORY

Oleg TITOV (Astronomical Institute of Saint-Petersburg University, Bibliotechnaya sq., 2, Petrodvorets, Saint-Petersburg, 198904, Russia, email: oleg_titov@usa.net)

Ny-Alesund VLBI observatory has been operated since October, 1994. It is located on Svalbard archipelago which is an active tectonic area near edge of Eurasian plate. Therefore motion of the Ny-Alesund observatory is very complex. Natural deformation processes at the region could cause an unexpected shift of the site position. The previous estimates by GPS and VLBI technique sometimes show a disagreement between each other. About 150 single VLBI experiments has been processed by special software OCCAM to provide a detailed picture of the Ny-Alesund velocity drift in relation to conventional NNR-NUVEL-1A model. The five-years time series for vertical and horizontal components are presented. Generally, Ny-Alesund observatory moves in a good accordance with considered model. But it is suspected that seasonal effects in vertical component are able to distort the estimates of linear velocity. Origination of the seasonal effects is not clear up to now. Slow variations of longitude component are observed after removing of linear trend.

JSG11/W/17-A4 1150

SEA LEVEL FROM GPS BUOYS

Authors: M. PARKE, C.K. Shum, K. Snow, K. Cheng (all at The Ohio State Univ., Columbus, OH) G. Mader and D. Martin (both at NOAA/NOS, Silver Spring, MD) F. Kelly and N. Guinasso (both at Texas A&M, College Station, Tx); G. Jeffress (Texas A&M, Corpus Christi, Tx) R. Gutierrez and B. Schutz (both at Univ. of Texas, Austin, TX) and J. Blaha (NRL, Stennis Space Center, MS)

Sea level measured from buoys can satisfy a wide range of oceanographic and geodetic requirements. In this talk we will address their roles in calibrating altimetric satellites, as "GPS tide guages", spatial mapping of the sea surface for oceanographic and geodetic purposes, and in coastline mapping (in conjunction with other remote sensing techniques). Two experiments will be used for examples.
Between 19 April 1998 and 3 May 1998 a gps equipped buoy was taken on a Texas A&M hydrographic cruise. Data were taken using a gps buoy at 53 stations in conjunction with CTD measurements. All but one station were taken along altimeter ground tracks either for Topex/Poseidon or ERS-2. Two stations encompassed T/P overflights while one station encompassed an ERS-2 overflight. Other measurements along ground tracks were never more than about two days separated in time from the corresponding altimeter measurements. Data were taken in the El Dorado Eddy and the Fourchon Eddy with dynamic sea level signatures expected to be up to 20 cm and 60 cm respectively relative to the position of the mean sea surface. One station was taken near the center of the Fourchon Eddy (away from altimeter tracks) with an expected dynamic signal of about 80 cm.
A GPS buoy is being developed for deployment near a triple crossover point (a location where the three major altimetric satellite orbits cross: ERS, T/P, and GFO) as part of a plan for long term altimeter calibration and cross calibration.

JSG11/W/23-A4 1210

LOCAL TIDE AND GEOID DETERMINATION FROM AIRBORNE GPS KINEMATIC POSITIONING AND LADS SURVEY

Shaowei Han, Chris Rizos and A. H. W. Kearsley (at School of Geomatic Engineering, The University of New South Wales, Sydney NSW 2052, Australia, email: s.han@unsw.edu.au, c.rizos@unsw.edu.au, w.kearsley@unsw.edu.au)

Airborne GPS kinematic positioning provides the geodetic height of the aircraft, and the Laser Airborne Depth Sounder (LADS) system can provide the distance between the aircraft and the sea surface. The height of the sea surface above the ellipsoidal model can then be determined, and this includes the local tide, local geoid, sea swell and noise. The local tide and local geoid can then be identified based the specific spectral features of the different components. In this paper, an experiment to test the utility of this concept using the Australian LADS system, together with state-of-the-art, geodetic GPS receivers, was carried out. The combination of an ambiguity recovery technique and a linear bias correction procedure has been used for this application to overcome the technical challenges of ambiguity resolution and cycle slip repair over distances many hundreds of kilometres. Finite Impulse Response filters are used to eliminate the measurement noise and sea swell distortion so that the local tide and geoid can be extracted. From a data analysis of this experiment, the accuracy of the local tide and geoid has been confirmed to be at the centimetre level from the comparison of four different sets of data in which three kinds of GPS receivers were involved. The comparison between the experimental results and theoretical computations of the local tide and geoid is attempted and commented upon.

THE SEA LEVEL CHANGES AND VERTICAL GROUND MOVEMENTS IN THE SEA OF OKHOTSK

Olga Poezzhalova and George SHEVCHENKO (both at Institute of Marine Geology & Geophysics, Russian Academy of Sciences, 693002, Nauki street, Yuzhno-Sakhalinsk, Russia,
E-mail: tsunami@sakhmail.sakhalin.ru)

We examined the tendencies of changes of annual mean levels for different stations of the Okhotsk Sea. Parameters of linear trend were determined by least square method. The most expressed trends occurred at the stations of Kuril Islands. Annual mean levels in Severo-Kurilsk (Paramushir Is.), Matua (Matua Is.) and Malokurilsk (Shikotan Is.) decreased quickly (velocities is about 5 - 6 mm/year). That it speaks about uplifting of islands. However, Shikotan subsided at 50 cm after strong earthquake in October, 1994.The land subsidence looks in area of Kurilsk (Iturup Is.) andYuzhno-Kurilsk (Kunashir Is.), particularly intensively this process proceed from 1955 to 1975. Analogous tendency observed in south-eastern coast of Sakhalin Island (Poronaysk, Vzmorye, Starodubskoe, Korsakov). That it speaks about subsiding of southern part of the Okhotsk Sea. The similar tendencies are not expressed at continental stations (Nagaeva bay, Okhotsk, Litke cape, Baydukov Island).

JSG11/E/03-A4 Poster 1400-02

INTERDISCIPLINARY APPLICATIONS OF THE GPS ARRAY "CRETE"

Erricos C PAVLIS (JCET/UMBC, NASA Goddard, Code 926, Greenbelt, MD 20771, USA, email: epavlis@Helmert.gsfc.nasa.gov) and Stelios Mertikas (Tech. Univ. of Crete, Chania, Greece)

A regional GPS array (CRETE) is being deployed over the past two years on the western side of the island of Crete, Greece. When complete, the array will consist of a continuously operating permanent site at the Technical University of Crete (TUC), Chania, Greece, and a number of other sites some of which will be permanent, continuously tracking while others will be visited periodically in "campaign style". We present here results from the expanded utility of this multipurpose GPS array. The Eastern Mediterranean area is one of great interest for its intense tectonic activity as well as for its regional oceanography. The contribution of the array to tectonics is the deformation field that can be inferred from the daily position time series. Another component of the project is the occupation the two tide-gauge sites at Souda Bay and Heraklion. We show here the so-far available position time series from Souda Bay. Tide-gauge monitoring has gained importance lately since tectonics contaminate the inferred sea level variations, and a global network of tide-gauges with long historical records can be used as satellite altimeter calibration sites for current and future missions (e.g. TOPEX/POSEIDON, GFO, JASON-1), a common IOC-GLOSS-IGS effort, already underway. Crete hosts these two tide-gauges, the oldest in the area, and our plans are to further expand the array to the south of the island with a new site on the isle of Gavdos. Gavdos is situated under a groundtrack crossing point of the T/P and JASON-1 orbits. It can be an ideal calibration site if the tectonic motions are monitored precisely. Our future plans include the deployment of additional instrumentation at this site (transponders, etc.) to ensure the best possible and most reliable results.

VERTICAL SITE MOTIONS FROM EUROPEAN VLBI CAMPAIGNS

James CAMPBELL, Axel Nothnagel, Klaus Boerger (Geodetic Institute, University of Bonn, D-53115 Bonn, Germany, email: campbell@picasso.geod.uni-bonn.de) Ruediger Haas (Onsala Space Observatory, Chalmers technical University, S-43900 Onsala, Sweden, email: haas@oso.chalmers.se) Paolo Tomasi, Istituto di Radioastronomia, CNR, I-40129 Bologna, Italy,
email: tomasi@boira6.ira.bo.cnr.it) Dirk Behrend, Institut d'Estudis Espacials de Catalunya, Edif. Nexus, Gran Capita, 2-4, E-08034 Barcelona, Spain, email: behrend@ieec.fcr.es)

The European geodetic VLBI observations started in the late eighties and have been continuing through 1997 and 1998 at a rate of six experiments per year with six to nine stations in slightly different station configurations. The core network is formed by the stations of Onsala, Wettzell, Medicina, Matera, Noto and Madrid. More recently, the network has been consid-erably extended nothward with the station of Ny Alesund on Spitsbergen and eastward with Simeis on Crimea, Ukraine. For those stations with a long enough observing record we present the results for the vertical site motions from the most recent analyses. Due to the high sensitivity of the vertical component to mismodelling of the atmospheric path delays, the level of significance of the vertical rates has been marginal up to now. Special attention has been given to the local effects at the sites such as telecope deformation due to temperature variations. At three stations repair works on the wheels and tracks have lead to defined height changes which can be seen in the time evolution of the vertical components. Local geodetic measurements have been carried out to establish these discrete vertical changes with high accuracy. The size of the vertical site velocities has been shrinking over the years to become more realistic with increasing length of the data set. The most apparent vertical change with respect to Wettzell, a site in Central Europe, happens at Medicina where we see significant and sustained subsidence of several mm/year. It is sure that the results derived from the VLBI campaigns will constitute a much needed basis for the geophysical interpretation of sea level changes and other vertical motion applications.

JSG11/E/07-A4 Poster 1400-04

VERTICAL GROUND MOVEMENTS IN THE LOWER RHENISH EMBAYEMENT

Barbara GOERRES, James Campbell, Holger Kotthoff (all at Geodetic Institute, University of Bonn, D-53115 Bonn, Germany, email: goerres@picasso.geod.uni-bonn.de)

The Lower Renish Embayment is known for both its present-day seismo-tectonic activity and the extensive brown coal mining. The ground water withdrawal associated with the mining activities has produced widespread subsidence of several meters over a time span of 40 years. In parallel to the regular levellings in this area, a series of annual GPS-campaigns covering 13 simultaneously observed points has been started in 1993 in order to obtain vertical change by an an independent technique. The size of the GPS network is about 100 km x 100 km. The initial goal of the project was to develop strategies to improve the accuracy (repeatability) of the vertical component measured by GPS. Apart from taking into account troposperic refraction the observation sessions were extended to cover three entire days (3*24h) and to go down to low elevations. In addition, all antennas were calibrated for phase center variations. Extensive tests revealed that the best repeatabilities are obtained with an elevation cutoff of 10 degrees. The data from six annual campaigns show significant height changes of up to 22 mm/y at three points. For all GPS points connected to the levelling network, the vertical velocities from GPS were in excellent agreement with the levelling results. In terms of wrms repeatability the vertical GPS results are at the level of 3 to 4 mm for each epoch and the velocities are at 1 to 2 mm/y. This confirms the validity of the chosen strategy and demonstrates the potential of GPS as a high precision tool for monitoring vertical change.

JSG11/E/13-A4 Poster 1400-05

MODALISATION STOCHASTIQUE DES VARIATIONS DU NIVEAU D'EAU DANS L'ESTUAIRE DU SAINT-LAURENT, CANADA

MOHAMMED EL-SABH (email: mohammed_el-sabh@uqar.uquebec.ca), Karim Hilmi et J.P. Chanut (all at Département d'océanographie, Université du Québec á Rimouski, Rimouski, Québec, G5L 3A1, Canada)

Les enregistrements du niveau d'eau horaire á la station Québec Lauzon située á la tête de l'estuaire du Saint-Laurent, Canada, sont analysés á la fois dans le domaine fréquentiel (de 1970 á 1979) et dans le domaine temporel (durant l'année 1973). Les variations tidales expliquent 90 á 95% de la variabilité initiale de niveau d'eau observé entre 1970 et 1979. Les variations résiduelles (non tidales), de nature stochastique, peuvent contenir des valeurs irrégulières responsable des seiches et ondes de tempête. Bien que limitées á moins de 10% des variations initiales du niveau d'eau, ces variations résiduelles sont analysées et modélisées selon la méthodologie de Box et Jenkins afin d'identifier les facteurs environnementaux qui agissent de façon complémentaire sur le milieu marin. La réponse du niveau d'eau résiduel au forçage météorologique (pression atmosphérique et vents) se situe á une échelle de 2 á 28 jours; elle est de quelques heures á un jour pour les variations attribuables aux seiches longitudinales, aux cycles semi-diurne et diurne de la marée atmosphérique et aux périodes inertielles. Le débit d'eau douce contribue pour 29% á la

variabilité mensuelle du niveau d'eau résiduel, tandis que les vents et la pression atmosphérique y contribuent pour 8,9% et 8,1% respectivement. La composante U du vent, parallèle á la cÛte, agit davantage sur les variations du niveau d'eau résiduel que la composante V, perpendiculaire au rivage, avec une contribution approximative de 7%.

SUBSIDENCE PHENOMENON IN THE MONITORING OF SEA LEVEL RISE ALONG THE NIGERIAN COAST

DR. P.C. NWILO, Department of Surveying, University of Lagos, Yaba - Lagos, Nigeria, Tel + 234 1 821114 ext. 1865, fax + 234 1 2691315, Email: Library@rcl.nig.com

The Nigerian coast is low lying; the rocks are of sedimentary origin and recent. The coast is still undergoing natural compaction due to the weight of the sediments. This zone is the home to oil and gas exploitation in Nigeria. A number of highly populated cities such as Lagos, Port Harcourt, Bonny and Calabar obtain a large portion of water for industrial and domestic use from the bore holes that dot the coastal environment. There is, therefore, subsidence due to fluid extraction such as water, gas and crude oil.
Analysis of tidal data from Bonny for 19 years shows that the sea level is rising at about 1mm per annum. This rate of sea level rise does not take into account the subsidence phenomenon. Also, using over 40 years of tidal data for Takoradi, Ghana, it was obtained that the sea level was rising at the rate of 3.9mm per annum. This may represent the regional situation for the Gulf of Guinea coastal environment. The impact of sea level would be more devastating than currently envisaged due to subsidence.
Efforts to monitor subsidence along the Nigerian Coast using geodetic levelling methods have not been successful due to the difficult nature of the environment and lack of funding. There is, therefore, an urgent need for Federal Government, coastal states, the oil companies prospecting in the environment and the international community to show interest in subsidence monitoring along the Nigerian Coast. This can be done through the provision of funds for subsidence monitoring. Subsidence along the Nigerian Coast can be accomplished using the Global Positioning Methods. A clear indication of the rate of subsidence will help in the design of a national policy on managing the impacts of climate change along the coast of Nigeria.

TIDAL CHANGE IN THE YELLOW/EAST CHINA DURING THE LATE HOLOCENE

Katsuto Uehara (Research Institute for Applied Mechanics, Kyushu University, 6-1 Kasuga Koen, Kasuga, Fukuoka 816-8580 Japan, email: uehara@riam.kyushu-u.ac.jp)

One of the prominent features found in the present Yellow/East China Sea (YECS) is its large tidal influence. Maximum range exceeds 10m at the Korean coast and the vertical mixing effect of the tide is considered to be a significant factor to determine the circulation in the YECS (Lee, 1997). However, the tides in the past are expected to have different natures from today because the sea-level change is estimated to be more than 100m during the last 20000years. In particular, zonal asymmetry of the bottom topography become less evident in the lower sea- level stages because the present continental shelf extended in the western part of the YECS is mostly less than 60m deep.
In this study, two-dimensional tidal simulations are carried out for the ages of 0, 6, 9, 12 and 20 ka BP, in order to investigate the effect of the topographic change since the last glacial maximum. Several changes, including the reduction of the tidal range and the shift of the amphidrome points, are observed. Analyzing the results will not only provide a first scope to reproduce the paleotides of the Yellow/East China Sea, but also help us to understand the effect of the topography on the present tidal environment.

LONG-TERM SEA-LEVEL VARIABILITY IN THE BALTIC SEA AND ITS RELATION TO CLIMATE PHENOMENA

Dietrich, R. and LIEBSCH, G. Institut fuer Planetare Geodaesie Technische Universitaet Dresden D-01062 Dresden Germany

Investigations concerning long-term sea-level variations require sea-level records of a high quality and reliability. Over the past years records with a homogenous local height reference were generated at several stations in the southern Baltic Sea. The measurements at these stations were initiated in the middle of the last century and are among the longest records in the Baltic Sea. Beside monthly mean sea-level records, which are in common use, records of monthly extreme sea-level values were created. On the basis of these records we will outline different aspects of the sea-level variability. This implies the analysis of - the mean sea-level records in the time domain as well as in the spectral domain and - potential changes of the extreme sea level with respect to the mean sea level. Furthermore, we will discuss possible relations between the sea-level heights in the Baltic Sea and the North Atlantic Oscillation (NAO), which is a large-scale alternation of atmospheric masses in the North Atlantic Sector.

CONTINUOUS GPS MONITORING AT BREST AND MARSEILLE GLOSS TIDE GAUGES

Serge Allain (1: SHOM, 13, rue du Chatellier BP 426, 29275 Brest, France), Claude Boucher (2: IGN/LAREG, 6-8, Avenue Blaise Pascal, 77455 Marne-la-Vallee, France), Serge Lannuzel (1), Didier Maillard (2), Bernard Simon (1) and Guy WOPPELMANN (*)

Brest and Marseille are among the longest tide gauge time series available in the world, beginning in the early (1807) and late (1885) 19th century respectively. Time series spanning over at least 40 years are actually required to filter out the interannual and interdecadal sea level variability and to derive sea level trends which might be related to recent climatic changes. However, the long term signal inferred from tide gauge records is ambiguous : it includes eustatic sea level change as well as land movements. Space geodetic techniques like GPS can measure these components and have already been recommended by several international group of experts to monitor crustal vertical movements at tide gauge sites in a well defined and maintained geocentric reference system.
Brest and Marseille tide gauges are committed to the Global Sea-level Observing System (GLOSS). The French agencies, SHOM (Service Hydrographique et Océanographique de la Marine) and IGN (Institut Gèographique National), are undertaking a close cooperation work to upgrade and fulfill GLOSS quality station requirements, especially the geodetic monitoring of the tide gauge zero. Both tide gauge stations have been equipped with continuous GPS receivers, since july 1998 in Marseille and since november 1998 in Brest. The hundred-year-old tide gauge in Marseille was repaired mid-1998 after the failure due to vandalism occurred in 1997. An acoustic one was purchased and installed in june 1998. This new tide gauge can provide numerical high frequency data.
The presentation will give a brief description of both coastal sea level observing stations : the local environmental conditions and the instrumentation. GPS and tide gauge data analyses will be presented. A more comprehensive sea level picture will be addressed at both sites by the synergetic tide gauge GPS approach.

SPECTRAL ANALYSIS AND FILTERING BY TWO DIMENSIONAL FOURIER TRANSFORM OF SEA SURFACE TOPOGRAPHY OBSERVED BY TOPEX/POSEIDON ALTIMETRY.

Waldemar Popinski Department of Standards, Central Statistical Office, Al. Niepodleglosci 208, 00-925 Warsaw, Poland, Email: w.popinski@stat.gov.pl Wieslaw KOSEK Space Research Centre, Polish Academy of Sciences, Bartycka 18A, 00-716 Warsaw, Poland, Email: kosek@cbk.waw.pl

A method of spectral analysis and filtering of sea level anomalies obtained from Topex/Poseidon altimetric measurements is presented. Such sea level anomalies at a particular time moment create sea surface topography which can be analysed using the two dimentional discrete Fourier transform (DFT).
The original data called 'cycles' are defined on a rectangular grid in latitude-longitude domain and are transformed using the two dimensional DFT to corresponding wave-number domain. Filtering of the sea surface topography is achieved by multiplying the transformed data by a bivariate filter transfer function and next inverting the DFT.
These analyses enable detection of the most energetic waves in sea surface topography and estimating how much the sea level anomalies corresoponding to different time moments are correlated along the meridian and parallel directions. It has been found that the correlation and coherence of the sea surface topography along the parallel direction is higher than along the meridian direction for the whole wave-number range and independently of time.

CHANGES IN SEA LEVEL, SEA SURFACE TEMPERATURE AND ATMOSPHERIC PRESSURE FROM SATELLITES.

Per Knudsen and Ole Baltazar Andersen (both at National Survey and Cadastre, Copenhagen NV, Denmark, email: pk@kms.dk, oa@kms.dk)

In studies of Global Change, sea surface temperature data may provide valuable information. Global sea surface temperature data may indicate changes in the heat budget of the oceans. Five years of sea surface temperature data and sea level height for the same period is analysed. Altimetry from the TOPEX/POSEIDON satellite will be used along with pressure observations provided in the T/P records and low resolution averaged sea surface temperature data from the ATSR 1 and 2 sensor onboard the ERS satellites and AVHRR data from the NOAA satellites.
The global and regional characteristics of the sea level trends and the trends in the sea surface temperature as well as trends in the atmospheric pressure during 1992-1997 are investigated. The changes in the sea level are compared with changes in sea surface temperature to decide whether the changes in sea level are related to changes in the heat content of the ocean. Spatial and temporal correlation between the signals are investigated, and a bivariate coherency analysis of the sea level together with the sea surface temperature is carried out at different spatial scales.

APPLICATION OF SAR INTERFEROMETRY TO DEM GENERATION OF ANTARCTICA

Taku Ozawa (The Graduate University for Advanced Studies, 1-9-10, Kaga, Itabashi-ku, Tokyo 173-8515, email: ozawa@nipr.ac.jp); Koichiro DOI, Kazuo Shibuya (both at National Institute of Polar Research, 1-9-10, Kaga, Itabashi-ku, Tokyo 173-8515, email: doi@nipr.ac.jp and shibuya@nipr.ac.jp)

SAR interferometry is an effective tool for estimating ice sheet motion as well as generating a digital elevation model (DEM). There are few precise DEMs in Antarctica except for some restricted regions, because of logistic difficulties to make dense ground surveys. It is true that satellite radar altimetry provides us data to generate DEM in Antarctica, but more precise DEM is required for monitoring ice sheet motion by SAR interferometry. As a first step to estimate the ice sheet motion, we tried to generate DEM by SAR interferometry technique. We employed the 3-pass method to separate the topographic fringe and the displacement fringe which are mixed in a SAR interferogram obtained on the Antarctic ice sheet. As a test site, we selected the ice sheet and outcropped area in the vicinity of Syowa Station (69.0degS, 39.5degE), which is the wintering base for the Japanese Antarctic Research Expedition, and analysed three serial JERS-1 SAR images acquired on June 16, July 30, and September 12 in 1996. We successfully extracted the topographic fringe on a large part of the ice sheet in the image.

GEODETIC INDICATIONS ON RECENT ICE MASS CHANGES IN AN EAST ANTARCTIC REGION

Dietrich R. KORTH, W., Metzig, R., Perlt, J. (Institut fur Planetare Geoddasie Technische Universität Dresden, D-01062 Dresden, Germany)

During the last decade geodetic-glaciological investigations were carried out in Dronning Maud Land, Antarctica. The working area of about 300 by 300 square kilometres is located in the region of the Schirmacher Oasis (B=71° S, L=12° E). Different techniques were used to carry out observations, e.g. terrestrial geodetic measurements, static and kinematic GPS, tide gauge and SAR interferometry. As a result the flow of the inland and ice shelf glaciers has been completely studied. Detailed knowledge has been obtained on the ocean tide induced vertical motions of the ice shelf. Particular attention was paid to local rates of ice-sheet thickening or thinning. Such specific mass balances were derived from measurements along traverses crossing an ice stream. For one traverse running through an accumulation area the

results are disturbed by short-term fluctuations in snowfall and snow densification. Measurements in ablation areas with blue ice at the surface are not affected by these influence. A thinning of the glacier of about 10 centimetres per year was determined for a large blue ice region. A significant lowering of the level of lake Untersee about 100 kilometres inland confirms this observed trend.

COUPLED MARINE ICE-SHEET/EARTH DYNAMICS

Emmanuel LE MEUR, Richard Hindmarsh (both at British Antarctic Survey, Madingley Road, CB30ET Cambridge, U.K. Email: lemeur@nerc-bas.ac.uk; rcah@nerc-bas.ac.uk)

The West Antarctic ice sheet represents the only large marine icesheet on Earth. With most of the underlying bedrock below sea level, it strongly interacts with the sea which leads to specific ice dynamics and make these marine ice sheets potentially unstable. West Antarctica is believed to have substantially fluctuated during the last glacial/interglacial transition with a global sea level contribution of about 6 m. The question of its response to present-day conditions or to future environnemental changes is therefore of major concern. Previous studies have shown the key effect on the ice dynamics from the free water depth at the grounding line. Like sea level change, by modifying this water depth, bedrock displacements make the grounding line migrate and can significantly modify the ice sheet configuration. This presentation describes a simple 1-D axisymmetric marine ice sheet model which couples with a spherical visco-elastic earth model. By incorporating a kinematic grounding line migration formula, the ice model is able to generate the ice sheet span in response to the sea Level forcing, the ice flow and the bedrock characteristics. After testing the model response to some basic forcings we focus on the different effects resulting from including or excluding the bedrock response. The main effect of bedrock coupling consists of stabilizing the system by substantially reducing the grounding line migration. The overall time-dependent response of the system partly controlled by the delayed viscous mantle confirms the existence of specific ice/Earth dynamics and justifies the importance of realistic isostatics in ice sheet models.

SPACEBORNE LASER ALTIMETRY OF THE POLAR ICE SHEETS

B. E. Schutz (University of Texas at Austin); C. R. Bentley (University of Wisconsin); R. Thomas (EG&G, NASA Wallops); J. Zwally (NASA Goddard)

In July 2001, NASA will launch a laser altimeter on ICES at into a near-circular, near-polar orbit to measure changes in polar ice-sheet topography. The ice sheet measurements will address fundamental questions about the growth or shrinkage of the polar ice sheets and their contribution to current and future global sea level change. The orbit inclination was chosen to provide coverage with the nominally nadir-looking altimeter, the Geoscience Laser Altimeter System, to a latitude of about 86 degrees. Exceptionally dense nadir tracks will occur at the high latitudes because of the orbit characteristics, thereby providing dense coverage of, for example, most West Antarctic features. The altimeter and related measurement systems have been designed to measure a secular height change with an accuracy of 15 mm/yr and over an area of 100 km x 100 km. This accuracy requirement was based on the analysis of van der Veen (1993) of the probability that a particular dh/dt is due to a real secular change in the ice sheet rather than arising from normal interannual variations in the snowfall. In the analysis of the results advantage will be taken of the synergy with the gravitational satellite GRACE to remove from the surface elevation changes any isostatic rebound signal that may exist. This paper will further describe the science requirements and the design considerations to meet the requirements, as well as the procedures planned for verification of the measurements and validation of the data products.

CRUSTAL UPLIFT AND SEA LEVEL CHANGE AROUND SYOWA STATION, ANTARCTICA

K. KAMINUMA

There is a great deal of evidence concerning crustal uplift, after deglaciation, in the vicinity of Syowa Station (69.0S, 39.6E), East Antarctica, from geomorphological data as elevated beaches, marine terraces etc. The uplift of about 20 M was recognized during the last 600 years. Therefore the rate of uplift is estimated to be 3-6mm/y from geomorphological data. A tide guage was installed at Syowa Station in 1966, and the observation has been continued currently. Sea level falling of 4.5mm/y was found using data 1975-1992. The falling rate is consistent with geomorphological data. Both data show that the crustal uplift is going on around Syowa Station at present. Micro seismic activity around Syowa Station are inferred to be caused by the tectonic stresses which are accumulated by the crustal uplift after deglaciation, as the location of the earthquakes are in the costal and offshore areas. Local earthquake activity corroborates the crustal uplift, and it is an intermittent phenomenon with 10-20 year interval. A trend of the falling sea level at Syowa Station at the rate of about 10mm/y was found by the detailed data processing using the well-controlled sea level data from1981-1987. More than ten micro- and small- earthquakes were recorded a Syowa Station in1987-1990. These earthquakes correspond well with the inferred crustal uplift of 10mm/y. Only one/two small/micro earthquakes per year were recorded at Syowa Station since 1990. A superconducting gravimeter (SG) was installed at Syowa Station since 1993. It is expected to detect the crustal uplift by SG. If the crustal uplift ata rate of 5 mm/y continues ten years, the total uplift obtained will be 5 cm, 15Gal in gravity change. Thisuplift is detectable by SG.

SIX YEARS OF DUAL FREQUENCY TOPEX ALTIMETER DATA OVER SOUTH GREENLAND

Benoit LEGRESY (1), Frederique Remy (1), Patrick Vincent (2) (1: UMR5566/GRGS (CNES-CNRS-UPS) 18 Av. E. Belin, 31401 Toulouse cedex 4 FRANCE) (2: CNES DGA/T/ED/AL/MA 18 Av. E. Belin, 31401 Toulouse cedex 4 FRANCE E-mail: benoit.legresy@cnes.fr)

Since Topex/Poseidon was launched in 1991, it regularly releases altimetric data in C and Ku band every 10 days. As the satellite inclination only allows observations below 66 degree North latitude, only the southern part of the Greenland ice sheet is covered by a few tracks. The dual frequency altimetric information has been found useful for ice sheet surface properties investigation and for snow penetration induced error on the height measurement control. 6 years of data are now available. We have reprocessed the sensor level data of the time series for 8 tracks that cross Greenland. It allows us to analyse the seasonal cycle of the measurement and its relation to the ice sheet surface conditions in the accumulation area.
The C-Band radar waves penetrate deep into the snowpack, of the order of 10 to 30 m for dry snow, while Ku-Band radar waves penetrate 5 to 15 m. Ku-Band measurements are more sensitive to surface snow metamorphism. The difference of penetration between the two frequencies is linked to snow grain size and stratification. We also used radiometer brightness temperature data at 18, 21 and 37 Ghz which are simultaneously acquired on-board Topex/Poseidon. We find that brightness temperatures are complementary to the altimetric measurement in order to characterise snow surface metamorphism. Finally the 6 year long measurements provided by Topex/Poseidon are well controlled and can be accurately interpreted despite the sparse coverage of the satellite.

ELEVATION CHANGES OF THE GREENLAND ICE SHEET FROM REPEATED GPS AND SAR INTERFEROMETRY

K. KELLER, R. Forsberg, C. S. Nielsen (KMS, Rentemestervej 8, DK-2400 Copenhagen NV, Denmark, email: kk@kms.dk) N. Gundestrup, C. C. Tscherning (Niels Bohr Institute, Univ. of Copenhagen, Juliane Maries Vej 30, DK-2100 Copenhagen O, Denmark, email: ng@gfy.ku.dk) S. N. Madsen, J. Mohr, J. Dall (Institute of Electromagnetic Systems, DTU, DK-2800 Lyngby, email: snm@emi.dtu.dk)

Elevations of the Greenland ice sheet has been measured repeatedly over several years at two sites at the centre of the Ice Sheet (at the GRIP drilling sites), and at a marginal ice cap in central East Greenland (Geikie Plateau). Repeated GPS measurements at the GRIP site since 1992 shows the ice sheet in this region to be essentially stable, with measured elevation changes and strain rates in good accordance with accumulation and ice flow models. Satellite and airborne SAR interferometry, and airborne laser altimetry, has additionally been used to study the coastal ice cap, primarily in order to evaluate accuracy of methods, as well as detect possible large yearly elevation changes in a region of high and variable yearly snow accumulation. The paper will present the project activities, methods and some recent results.

ICE-3G RETREAT INCONSISTENT WITH GREENLAND OBSERVATIONS

R THOMAS and S Manizade(EG&G, NASA/WFF, Wallops Island, VA 23337, USA,
email: thomas@osb.wff.nasa.gov; manizade@osb.wff.nasa.gov); W Krabill (Lab for Hydrospheric Processes, NASA/WFF, Wallops Island, VA 23337, email: krabill@osb.wff.nasa.gov); J Wahr, K. Larson, and S Gross (U. Colorado, Boulder, CO 80309, USA, email: wahr@lemond.colorado.edu; kristine@lemond.colorado.edu; sjg@quake.colorado.edu); T van Dam (Obs. Royal de Belgique, B-1180 Bruxelles, Belgium, email: tonie@oma.be); X Wu (JPL, Pasadena, CA 91109, USA,
email: xpw@cobra.jpl.nasa.gov)

ICE-3G representation of Holocene retreat implies present-day isostatic uplift of the east and west coasts of southern Greenland by about 3-4 mm/yr if the present-day ice sheet is in balance. Satellite radar and aircraft laser altimeter surveys indicate overall balance for higher-elevation regions since 1978, with significant recent thinning nearer the east coast and areas of both thickening and thinning near the west coast. We would expect the areas of thinning to cause increased uplift rates, but continuous GPS measurements at Kangerlussuaq on the west coast, since 1995, and at Kulusuk on the east coast, since 1996, show subsidence of 7.7 +- 2.6 mm/yr in the west and 6.1 +- 5.1 mm/yr in the east. Kangerlussuaq is near to areas of ice that are approximately in balance and Kulusuk is close to ice that is rapidly thinning.
These observations suggest that either the Holocene retreat of the Greenland ice sheet differed significantly from that described by ICE-3G, and/or there was substantial thickening sometime between about 5000 BP and a few decades ago. We have used our observations of ice-surface elevation change and coastal subsidence to infer a range of ice-sheet histories and mantle-viscosity profiles that are consistent with those data, and these suggest that the southern part of the ice sheet may have been substantially thinner than at present at some time during the past few thousand years.

A RE-EVALUATION OF THE MASS BALANCE OF GREENLAND

Atsumu Ohmura and Pierluigi CALANCA (both at Deptartment of Geography, Swiss Federal Institute of Technology, Winterthurerstr. 190, CH-8057 Zurich, Switzerland, e-mail: calanca@geo.umnw.ethz.ch)

The present mass balance of the two major ice sheets, Antarctica and Greenland, is not known with sufficient accuracy. A re-evaluation of the mass balance of Greenland and its spatial distribution are presented. The accumulation is derived from direct observations. Compared to previous estimates, additional data for some 48 pits and 5 meteorological stations are included in the analysis. Moreover, care is taken to correct the precipitation measurements for the wind-induced defect, separately for the liquid and solid phases. The ablation is derived from the three-summer-months mean temperature. Finally, the calving rates are estimated from remote sensed data and the geometry of the outlet glaciers.

JSH12/E/02-A5 **1100**

ICE CAP VOLUME CHANGE ON FRANZ JOSEF LAND DURING LAST 40 YEARS

Yuri Macheret, Andrey GLAZOVSKY (bouth at Institute of Geography, Russian Academy of Sciences, Staromonetny per., 29, 109017 Moscow, Russia, email: andrey@glazov.msk.ru); Julian Dowdeswell (Bristol Glaciology Centre, School of Geographical Sciences, University of Bristol, Bristol BS8 1SS, UK, email: j.a.dowdeswell@bristol.ac.uk); Michael Gorman (Scott Polar Research Institute, University of Cambridge, Lensfield Road, CB2 1ER Cambridge, U.K)

Airborne radio-echo sounding of 26 ice caps of various morphology and area (26 to 1.892 km2) was carried out on Franz Josef Land archipelago in 1994. Ice thickness data were obtained on 12 ice caps as maps and on 14 other ice caps as profiles. These data allowed to find the close empirical relationships between ice cap area and volume as well as between average and maximum ice thickness. These yield exponents for the power-law relations between volume-area of 1.312 and 1.228 and between maximum ice thickness-area of 0.295 and 0.245 for ice caps with and without outlet glaciers, and coefficients for the linear average-maximum ice thickness relation of 0.504 and 0.510, respectively. Relations between volume and area parametrized by maximum ice thickness provide exponents equal to 1.295 and 1.245, respectively. Using these empirical relations the ice volume of all ice caps on archipelago is estimated.
Total ice cap volume is estimated as 2105.9 km3 in 1993 and as 2147.8 km3 in 1953 with volume decrease during this period by 41.9 km3 and area reduction by 209 km2. The volume decrease is equal to mean net specific mass balance -7.0 cm per year in water equivalent. Comparison of this value with mass-balance data of other authors suggests that the negative mass balance rate in the last 40 years has been approximately 3.3 times less than in 1930-

1960 which in turn agrees well with data on decrease of mean summer air temperature in compared periods on Franz Josef Land.

JSH12/W/06-A5 1130

SEA LEVEL CHANGE AND SEA-ICE VARIATIONS – A LINK?

ANZENHOFER, M (GeoForschungsZentrum Potsdam (GFZ), c/0 DLR, Postfach 1116, D-82230 Oberpfaffenhofen, Germany. E-mail:anzenhof@gfz-potsdam.de)

Model runs simulating future climate conditions assuming a further increase of atmospheric greenhouse gases show various asymmetries. Especially for the sea-ice extension, a decrease is expected for the North pole and an increase for the South pole. Time series of sea- ice extensions of both poles exist from passive microwave satellite observations from 1978 till now. Accurate sea level time series, however, only exist from 1992 on (the problem of linking Geosat and ERS or TOPEX data is still unsolved). Recent investigations have shown a surprisingly high correlation between sea level variations and sea-ice extension anomalies around Antarctica. The correlation time period was only 3 years long. The presentation will focus on an enhanced study of the correlation between vertical sea level and anomalies in spatial sea-ice distribution by the extension of the altimeter derived sea level data base, the analysis of North pole sea-ice, and the inclusion of sea surface temperature data.

JSH12/W/01-A5 1200

THE GLACIAL-INTERGLACIAL PARADOX

John A.T. BYE, (Flinders University, GPO Box 2100, Adelaide, Australia, 5001, email: John.Bye@flinders.edu.au)

Sea level variability during the Quaternary is simulated using a stochastic climate model and a sensitivity relation for the change in net oceanic evaporation due to a change in sea surface temperature, on the assumption that the greater part of the change in net oceanic evaporation causes changes in the land ice volumes, rather than being directly returned to the ocean by rivers. The analysis suggests that the observed sea level changes can be interpreted as due to the transfer of heat to the deep ocean from the surface mixed layer, arising from random radiation perturbations of the same variance as would give rise to the interannual variability of the global temperature series.

SCANDINAVIAN ISOSTATIC REBOUND: CONSTRAINTS ON THE LATE WEICHSELIAN ICE MODEL

Kurt LAMBECK (Research School of Earth Sciences, The Australian National University, Canberra, ACT 0200, Australia, email: Kurt.Lambeck@anu.edu.au)

Sea-level information from three different data sources have been combined to develop a comprehensive model of the isostatic rebound for Scandinavia in which it has been possible to separate effectively those parameters describing the earth response and those describing the ice sheet. The data sources used are: geological estimates of shoreline age-height relationships, the alternating marine freshwater stages of the Baltic Sea, and the recent tide-gauge and lake-tilt measurements. The essential glaciological result is an ice sheet that is distinctly asymetrical over Scandinavia, with the ice over the southeastern and southern areas being relatively thin when compared with the ice over the north and west. Maximum ice thickness at about 18,000 years ago is unlikely to have exceeded 2000 m with the maximum ice cover occurring over northern Sweden rather than Finland. Earth model results include a well defined stratification in the mantle viscosity, consistent with analyses from other parts of the world.
The paradox is that glacial conditions (increase in ice volume) are favoured by positive (temperate) sea surface temperature anomalies, and interglacial conditions (decrease in ice volume) by negative (temperate) sea surface temperature anomalies. The evolution of both these regimes, which are inherently unstable, appears to be controlled by the deep water formation process, while albedo feedback is of minor importance.

JSH12/W/13-A5 1430

GRAVITATIONAL-VISCOELASTIC PERTURBATIONS OF A SPHERICAL EARTH WITH COMPRESSIONAL DENSITY STRATIFICATION

G. Li, D. WOLF (both at GeoForschungsZentrum Potsdam, Telegrafenberg, D-14473 Potsdam, Germany, email: dasca@gfz-potsdam.de)

We derive the analytic solution for the deformation and gravity change caused by the loading of a self-gravitating spherical earth model consisting of a viscoelastic mantle with compressional density stratification and a homogeneous inviscid core. The fundamental characteristics of the solution are evident in the Legendre-transform domain, where we show relaxation-time and amplitude spectra for the mantle and core modes that constitute the time-dependent part of the response. Following this, we predict in the space-time domain the radial displacement, the free-air gravity anomaly and the geoid height for an axisymmetric load model with parabolic cross-section and dimensions similar to those of the Laurentide ice sheet. A comparison with the corresponding predictions for an earth with homogeneous density in the mantle underlines the importance of allowing for the compressional density stratification when modelling load-induced gravitational-viscoelastic perturbations of the earth.

JSH12/E/03-A5 1500

THERMALLY INDUCED LATERAL VISCOSITY VARIATIONS AND POSTGLACIAL REBOUND: IMPLICATIONS FOR RELATIVE SEA LEVELS IN LAURENTIA

Patrick WU (Dept. of Geology & Geophysics, University of Calgary, Calgary, Alberta T2N-1N4, Canada , Email: ppwu@ucalgary.ca), John Wahr (Department of Physics, University of Colorado, Boulder, Colorado 80309 USA, Email: wahr@longo.colorado.edu); W.R. Peltier (Dept. of Physics, University of Toronto,Toronto, Ontario M5S-1A7, Canada, Email: peltier@atmosp.physics.utoronto.ca)

Quantifying lateral viscosity variations in the mantle is useful in understanding mantle dynamics. From seismic tomography, which maps the three dimensional structures in the mantle, one can convert lateral velocity variations to viscosity variations by simple scaling since both are affected by the same thermal structure. The assumption in doing so is that the contribution of lateral variations in chemical composition can be neglected. In reality, the viscosity variations obtained this way are only upper bound estimates. Let the ratio of the actual viscosity variation over this upper bound estimate be given by the factor Beta, the aim of this work is to estimate the value of Beta from the postglacial sea level data in Laurentia. The finite element method is used to calculate the deformation and relative sea levels in a laterally and vertically heterogeneous flat Earth. The loading history is given by the realistic ICE4G model and its eustatic sea level loads. Several cycles of loading before the last glacial maximum are also included. The radial viscosity profile is assumed to be given by the VM1 or VM2 models of Peltier. The lateral viscosity variations are obtained by applying the simple scaling relation of Ivins & Sammis (1995) to Beta multiplied by the shear-wave velocity fluctuations in the S20A model of Ekstrom & Dziewonski (1998). A range of laterally heterogeneous viscosity models are constructed - each characterized by a different value of Beta. These viscosity models are tested to see which is consistent with the sea level data in North America. The maximum value of Beta that can explain the sealevel data simultaneously will give the maximum contribution of thermal effects on lateral viscosity variation.

GLOBAL GLACIAL ISOSTASY, SEA LEVEL AND GLACIOLOGY

Richard PELTIER (Department of Physics, Universityof Toronto, Toronto,Ontario, Canada M5S-1A7, email: peltier@atmosp.physics.utoronto.ca)

The global viscoelastic and gravitationally self consistent theory of the glacial isostatic adjustment process has recently been refined considerably so as to incorporate the influence of both time dependent coastlines and the feedback onto sea level of the earth's changing rotational state. Although the primary focus of the analyses that have been performed with this theory has been on the inverse problem for mantle viscosity, it has other, equally interesting, applications. For example it may be invoked to provide important constraints on both the origins of the global rise in sea level that is apparent on modern tide gauge recordings and on fundamental questions in glaciology. In the former area the strength of the rotational feedback on sea level turns out to be interesting, especially from the perspective of space geodesy(eg GRACE), whereas in the latter area its application has led to important constraints upon ice rheology.

JSH12/W/14-A5 1630

ANTARCTIC REBOUND AND THE TIME-DEPENDENCE OF THE EARTH'S SHAPE

Erik R. IVINS (JPL, Caltech, Pasadena, CA 91109-8099 USA, email: eri@scn1.jpl.nasa.gov); Thomas S. James (Geol. Survey of Canada, Sidney, BC, Canada, email: james@pgc.nrcan.gc.ca)

Great strides have been made during the past 30 years in refining models of the last global glaciation. The refinements draw upon a vastly expanded relative sea level and sedimentary core record. Furthermore, we now possess a sharpened understanding of the mechanisms that drive climate changes associated with deglaciation. Some 15 years ago, using only 5.5 years of ranging data, analyses of the acceleration in LAGEOS I nodal drift was used to infer that postglacial rebound was responsible for a secular change in the Earth's ellipsoidal shape [Yoder et al., 1983]. Today there exists a wealth of geodynamics satellite orbit data that constrain the secular time-dependence of the Earth's shape and low order gravity field, which includes mass redistribution from present-day glacier and great ice sheet imbalance and from postglacial rebound. We have shown that an unambiguous determination of the secular variation in the Earth's pear shaped harmonic (l = 3, m = 0) might provide information that bears on the present-day mass balance of Antarctica. This issue is revisited in light of new constraints on glacial loading during the late-Pleistocene and Holocene. An especially critical issue for the interpretation of secular odd degree zonal harmonics, l = 3 to 7, is the timing and magnitude of the deglaciation of Antarctica from Last Glacial Maximum. We explore ways in which the recovery of secular variation In both zonal and non-zonal harmonics for l = 2 through 7 can improve constraints on both rebound and present-day ice sheet balance.

JSH12/W/11-A5 1700

SURFACE TEXTURE AND ICE-STREAM BASAL DRAGRICHARD

C.A. HINDMARSH, (British Antarctic Survey, High Cross, Madingley Road, Cambridge, CB3 0ET. E-mail:rcah@bas.ac.uk)

Ice streams are restrained by a combination of lateral drag and basal drag. Borehole observations from Ice-Stream B indicate little basal coupling, but the problem of whether ice-stream surface texture originates from internal rheological variations, basal topography or coupling of ice, till and water flows remains unresolved. If it is from such coupling, we conclude (i) that significant basal drag is present and (ii) this is dynamic and can change, implying that the basal resistance can change very fast, changing the rate of ice export to the sea.
This paper addresses the coupling of flows of ice, till and water, and the issue of whether such coupling provides mechanisms for meso-scale (kilometres to tens of kilometres) variability in ice-sheet flow and texture. The question of whether effective pressures at the ice-bed interface are statically or hydraulically controlled is examined in this paper. The answer is scale dependent, and has a significant effect on the relationship between ice surface and basal topography.
Linear stability analyses indicate that there appears to be sufficient variability in the ice-till-water system to potentially explain texture in ice stream surfaces, variations in ice stream thickness of tens of metres not directly relatable to topography, and waves moving upstream or downstream. Most importantly, the ice-stream/bed system is shown to exhibit meso-scale variability simply by coupling ice-flow according to the shallow ice approximation, till flow according to the hydrostatic thin-till approximation and water flow according to an effective pressure-dependent hydraulics.

MANTLE LAYERING WITHIN THE LOWER MANTLE

Stephen GRAND (Dept of Geological Sciences, University of Texas, Austin, TX 78712; steveg@maestro.geo.utexas.edu)

Recent tomographic images of the mantle clearly show that most slab enters the lower mantle below 700 km depth. Our most recent model of mantle shear wave speeds, based on the travel

times of multiply reflected S phases as well as ScS, SKS, and SKKS travel times, shows higher than average velocities beneath all subduction zones from 700 to about 1000 km depth. Above 700 km depth, high velocity anomalies are also seen but their volume is not large enough to account for the volume of slabs that have subducted during the last 40 Ma. We therefore conclude that the seismic anomalies seen from 700 to 1000 km depth are subducted slab remnants. Deeper than 1000 km, however, the pattern of fast anomalies is quite different. In several subduction regions, for example beneath South America, Indonesia, the Kuriles, the Mariannas, and Tonga-Kermadec, the high wave speed anomalies associated with subduction appear to terminate above about 1200 km depth. Other regions, particularly beneath Central and North America, Japan, and southern Eurasia show fast seismic velocities to much greater depths in the lower mantle, in some cases even reaching the core-mantle boundary. In these regions, however, the anomalies have their highest amplitudes and greatest widths in the range 1000 to 1500 kmdepth. In some cases there also appears to be a lateral offset of high wave speed anomalies above about 1300 km depth and below. Slow anomalies in the deepest mantle are very prominent beneath Southern Africa and the Cape Verde region. In both areas, however, the strong slow anomalies seen at depths below 1000 km or so, are not seen at shallower depths. An exception to this is beneath the East African Rift. The tomographic results seem to be most compatible with a barrier or impediment to flow at depths between 1000 and 1200 km depth. This is consistent with some other recent geophysical studies including the observation of a reflector near 1000 km depth beneath Indonesia by Kawakatsu and Niu (1994), a jump in viscosity near 1000 km depth inferred by Mitrovica and Forte (1997) and the study of the geoid and dynamic topography by Wen and Anderson (1998) who concluded that a barrier to flow is needed near 1000 km depth in order to fit both observables. The cause of such a boundary may be a chemical contrast or due to a phase change or viscosity change.

JSS13/W/06-A4 Invited 1430

GLOBAL TOMOGRAPHY IMAGES OF (PAST) SUBDUCTIONS AND UPWELLINGS

Harmen BIJWAARD and Wim Spakman (both at the Vening Meinesz School of Geodynamics, Institute of Earth Sciences, Utrecht University, Budapestlaan 4, 3584 CD, Utrecht, the Netherlands, email: bijwaard@geo.uu.nl)

Recent tomographic imaging of the Earth's mantle (Bijwaard et al, 1998) has provided detailed observations of (past) subduction zones as well as some prominent hotspot regions. This high-resolution tomography model was obtained through the application of nearly 8 million accurately processed P and pP phases and the implementation of an irregular model parameterization in which cell sizes were adapted to the amount of ray sampling. Observations in the upper mantle include thin zones of high P wavespeed associated with subduction. These 100-150 km thick anomalies generally continue into the transition zone where they may flatten on top of the upper-to-lower mantle discontinuity (660 km). Many of these anomalies (eventually) continue into the lower mantle as substantially thicker high velocity structures. In several instances, notably below the Aegean, the Sunda arc, South America, and Central America, these structures connect (at 1000-1300 km) with large-scale anomalies that have been associated with past subduction of the Tethys ocean and the Farallon plate. Below eastern Asia and Central America subduction-related anomalies seem to be continuing even further to the core-mantle boundary (CMB). Apart from subduction-related anomalies we find in several places deeply rooted low-velocity structures below prominent hotspots. Low velocities beneath the Africa rift, the Society Islands, Yellowstone, and Iceland can be traced to the lower mantle. Below Iceland estimates of the vertical resolution indicate that the observed structure is probably continuous from the CMB to the surface.

JSS13/W/15-A4 1500

MANTLE CIRCULATION AS REVEALED FROM SEISMIC ANISOTROPY

Jean-Paul Montagner, Eleonore Stutzmann, Sebastien Chevrot (all in Dept. Seismology, Institut de Physique du Globe, 4 Place Jussieu, 75252 Paris cedex 05, France, email: jpm@ipgp.jussieu.fr), Goran Ekstrom (DEPS, Harvard University, Cambridge MA02138, USA), Lev Vinnik (IPE, Bolshaya Gruzinskaya 10, Moscow, Russia)

Whereas isotropic tomography only provides the location of seismic velocity heterogeneities, the anisotropic tomography is opening a new dimension by enabling to map the convective flow itself. So far, there are some good evidences of seismic anisotropy in the top 300km of the upper mantle and the bottom D"-layer, by using either the fundamental mode of surface waves or body waves. We present some new evidences of seismic anisotropy in the upper (410-660km) and lower (660-1000km) transition zones, obtained by different seismic waves. The normal mode dataset and converted P->S phases at 660km below the Grafenberg array and the GEOSCOPE station BNG, made it necessary the presence of seismic anisotropy on both sides of 660km discontinuity. Another way to get deep seismic anisotropy is to use overtones of surface waves. We will show how to map it by generalizing the technique developped by Stutzmann and Montagner.
All these investigations show that the presence of anisotropy is related to boundary layers and flow circulation in convective systems. In this framework, the transition zone turns out to be a secondary boundary layer in the mantle.

JSS13/W/11-A4 1520

FINE DETAILS OF THE WADATI-BENIOFF ZONE UNDER INDONESIA: DIRECT EVIDENCE FOR MANTLE FLOW

H.-J. SCHOEFFEL and S. Das Department of Earth Sciences, University of Oxford, Parks Road, Oxford OX1 3PR, UK, email: hanss@earth.ox.ac.uk

The Indonesian subduction zone shows normal subduction under Java and Flores and very complex subduction beneath the Banda Sea. This region is the eastward extension of the Java subduction zone with an almost 180 degrees bend of the seismic zone, at depths down to 600km. Reliable hypocentral locations, especially depth, are essential to understanding this highly contorted zone and, thus, we use the procedure of Schoeffel and Das (1999) to achieve this. We use the JHD method, and handpicked arrival times for P, S, pP, sP, PcP and ScP phases from digitally recorded seismograms, together with agency reported times. Under Java and Flores, we find that (i) the portion of the arc between (110E-123E), and deeper than 500km, is dipping southwards at an angle of approximately 75 degrees, that is, in a direction opposite to the upper part of the north-dipping slab, (ii) east of about 108E, the seismic zone is wider near 670km than at 500km depth, with a thickness as wide as 100km below 600km. (i) suggests southward lateral flow in the mantle, relative to the plate motion vector here. P- and T-axes follow the general trend of downdip orientation for deep and intermediate events, respectively. From the contortion of the seismic zone along the eastern portion of the Indonesian arc, we can estimate the average lateral shear strain rate in the 300-670km depth range to be of the order of 10e-16s, over the last 10-20 million years. Previous studies of the Banda arc show that it consists of 2 subducting plates. We suggest the plate underneath the Seram Trough subducts with a shallow angle to the SW down to 650km.

JSS13/W/16-A4 1540

THREE-DIMENSIONAL MANTLE DENSITY STRUCTURE OBTAINED BY NORMAL MODE SPECTRAL MEASUREMENTS

Chaincy KUO and Barbara Romanowicz (both at UC Berkeley Seismological Laboratory and Department of Geology and Geophysics, University of California, Berkeley, California, 94720, USA, email: chaincy@seismo.berkeley.edu)

We present models of Vs, Vp, and density perturbations in the mantle, derived from spectra of the Earth's free oscillation spheroidal modes. Mantle heterogeneity from normal mode studies has been generally derived from "splitting coefficients", which represent an integration, over depth, of the lateral heterogeneity weighted in depth by the mode's sensitivity. The splitting coefficients, measured from individual mantle modes from observed spectra, are then inverted for mantle structure from this linear relationship. In contrast, we forego this intermediate stage of solving for splitting coefficients and invert directly for mantle structure from the spectral data for a sweep of mantle modes. In this manner, the inverse problem for structure becomes more constrained than the dual-stage inversion approach. Previous models determined from normal mode data were parameterized in terms of dln Vs, where aspherical structure in Vp and density were scaled to Vs structure, based on proportionality constants from studies by Li et al, 1991, for example. We demonstrate that this assumption is inadequate, and by preserving it, the final S-wave velocity model is contaminated by P-wave velocity and density structure. By setting the scaling relationships free, the model solutions resulting from independently and jointly inverting for dln Vs, dln Vp, and dln rho improves the correlation of S-wave velocity models with the existing Berkeley model derived from surface wave and body wave studies (SAW12D, Li and Romanowicz, 1996). We show that the Vp and density models elicited from these separate parameter inversions are valid.
In agreement with the study of Robertson and Woodhouse 1996, the Vs and Vp structure is found to correlate down to the mid-lower mantle, beyond which decorrelation of Vs and Vp dominates. Furthermore, in regard to the depths of correlation, the ratio of Vs to Vp root-mean-square amplitudes which we find are in concurrence with the determinations of the Robertson and Woodhouse 1996 paper. The density model is consistently robust, and presents high density features which coincide with the location of slabs in the upper mantle in the circum-Pacific region. A 3D mantle density model could provide a significant contribution to our understanding of mantle convection.

JSS13/W/19-A4 1620

PKP PRECURSORS: FURTHER EVIDENCE FOR WIDESPREAD, WHOLE MANTLE CONVECTION

Michael A.H. HEDLIN and Peter M. Shearer (University of California, San Diego, La Jolla, CA, USA, 92093-0225, email: hedlin@ucsd.edu)

The recent global tomographic images of Grand, van der Hilst and their colleagues have revealed, with unprecedented clarity, large scale velocity variations in the mantle. In the mid-mantle, continuous, high-velocity trends are unmistakeable and clearly correlate with known subduction zones such as the Tethys and Aegean trends in southern Eurasia and the Farallon trend in central America. These trends are believed to reveal subduction of slab material beneath the 660 km discontinuity into the mid-mantle. Beneath mid-mantle depths however the Eurasian trends become discontinuous and the question of whether the slabs remain intact and continue to subduct into the deepest mantle in these areas remains open for debate.
Precursors to the inner core phase PKPdf, which are due to scattering from velocity heterogeneity at the CMB and in the mantle, might provide further constraints on mantle convection. A recent analysis of GSN recordings by Hedlin et al. (1997) indicates the scattering that gives rise to the precursors occurs with equal strength at all mantle depths. Subsequent studies (Vidale & Hedlin, 1998; Hedlin et al., 1998) have used this model of global average scattering to identify regions that can be associated with anomalously strong or weak scattering. With ray-tracing it is possible to back-track precursors from the recording station into the mantle. Although vertical resolution is poor, it is possible to unambiguously associate early precursors recorded at all ranges, and all precursors that are recorded at ranges ranges < 137 deg. with scatteringbeneath the mid-mantle. Precursors are subject toambiguity as to which end of the propagation paththe scattering occurred but it is possible tolimit this ambiguity with processing recordings that sample the same volumes of the Earth but byusing dissimilar, i.e. crossing, paths. A global image of scattering strength which usesGSN recordings of precursors shows a possiblecorrelation between mid-mantle velocity anomalies, such as the Aegean and Tethys trends, andunusually strong scattering beneath the mid-mantle. The precursors may be inferring indirectly the existance of these subductingtrends by detecting small fragments that areentrained with the slabs or the fragmentaryremains of the slabs which are decimatedby passage into the deepest mantle. Although thisfinding requires further study, this suggests that material from the Eurasian trends has subductedinto the deepest mantle.

JSS13/E/05-A4 1640

THE CAPABILITIES AND LIMITATIONS OF EXISTING NORMAL MODE CONSTRAINTS ON LONG-WAVELENGTH 3-D DENSITY STRUCTURE

Joseph Resovsky and Michael Ritzwoller (Department of Physics, University of Colorado, Boulder, Campus Box 390, Boulder, CO, 80301, email: resovsky@abdu.colorado.edu)

Descriptions of long-wavelength density heterogeneity are essential to modelling mantle dynamics, and new constraints on density provided y the latest catalogues of normal mode structure coefficients have been employed in several recent inversions for this structure. We demonstrate the capabilities and limitations of such inversions using set of more than 500 different inversions of normal mode data. First, e confirm the existence of a coherent signal from 3-D density structure and show that density models from normal mode inversions are robust with respect to the specification of other mantle structures. Second, we show that existing normal mode data do not yield density models that are robust with respect to the parameterization and damping of density heterogeneity. In particular, although normal modes clearly imply some decorrelation of shear velocity and density heterogeneity, the depth of such decorrelation is indeterminate. Finally, we demonstrate that this ambiguity may be reduced by applying emerging new normal model constraints on mantle structure and through using improved models of mantle discontinuity topography and 3-D velocity heterogeneity.

JSS13/E/04-A4 1700

A TELESEISMIC SHEAR WAVE SPLITTING STUDY TO DETECT MANTLE FLOW AROUND SOUTH AMERICA THROUGH THE DRAKE PASSAGE

G. HELFFRICH (Earth Sciences, U. Bristol, Bristol, UK), D. Wiens (Earth & Planetary Sci., Washington U., St. Louis, MO USA) S. Barrientos, E. Vera (Dept. de Geofisica, U. Chile, Santiago, Chile)

Alvarez proposed the idea of mantle flow around South America to reconcile the demands of mantle mass conservation with the plate tectonically observed closing of the Pacific Ocean basin. Building on this notion, Russo and Silver (1994) studied South American shear wave

splitting and reported a pattern of fast polarization directions paralleling the western and northern coasts of South America. They interpreted the pattern as arising from anisotropy generated by olivine aligned by lateral flow. In this model, the flow is north-south around the buttress of the subducted lithospheric slab under South America's western coast, and east-west where the mantle material flows into the sub-Atlantic region around South America's cratonic roots through the Caribbean.
In the southerly reaches of South America's western subduction margin, the slab appears to be shorter and there are no cratonic roots. Thus, if mantle flow in fact occurs, it should flow under the Patagonian part of South America and through the Drake Passage. To test this prediction, in 1996-1998 we deployed broadband seismometers in Patagonia and Antarctica (the SEPA experiment) to look for the analogous pattern of shear wave splitting observed by Russo and Silver in northern South America. Preliminary results from stations around the Drake Passage/Scotia Plate yield splitting results typical of ~1 second continental splitting times except for PMSA, which is among the largest recorded (> 2 seconds). Drake Passage directions are mostly oblique to the E-W directions observed in Venezuela (Russo et al., 1996) and splitting times not as large (0.95 s average vs. 1.8 s). These observations suggest that a coherent, symmetric mantle flow structure is not present around South America like Alvarez envisaged, and that elimination of the shrinking volume of the sub-Pacific mantle must be achieved by a more diffuse circulation.

JSS13/W/01-A4 1720

TOMOGRAPHIC IMAGES OF ANCIENT SUBDUCTED SLABS UNDER ASIA

Rob Van der Voo (Department of Geological Sciences, University of Michigan, Ann Arbor, MI. 48109-1063, U.S.A., email: voo@umich.edu); Wim Spakman and Harmen Bijwaard (both at Vening Meinesz School of Geodynamics, Institute of Earth Sciences, Utrecht University, Budapestlaan 4, 3584 CD Utrecht, the Netherlands, email: wims@geo.uu.nl)

The mantle under Siberia, the Indian subcontinent and the adjacent Indian Ocean reveals several zones of relatively high P-wave velocities at various depths, which can all be interpreted as remnants of subducted lithosphere ("slabs"). In the upper 600 km of the mantle under the Himalayas a slab appears to represent delaminated sub-continental mantle lithosphere that went down when Greater India continued to converge northward with Asia after about 45 Ma. High-velocity anomalies under Siberia occur at depths between 1500 km and the core-mantle boundary and are inferred to be remnants of Jurassic oceanic lithosphere, subducted when the Mongol-Okhotsk Ocean closed between Mongolia and Siberia by earliest Cretaceous time. This slab appears to join a "graveyard" (Wysession, 1996) of slab remnants at the bottom of the mantle. Deep slabs under India and the Indian Ocean occur between 1000 and 2300 km and form three parallel WNW-ESE striking zones. We interpret these three zones as remnants of Paleo-and Neo-Tethys oceanic lithosphere, subducted between Late Jurassic and earliest Tertiary times, as southern Tibet, and later, India collided with Asia. Our interpretation implies (1) that most significant fast seismic anomalies in the lower mantle can be connected to past subduction, (2) that slab remnants in the mantle can still be recognized and interpreted some 150 million years or more after subduction ceased, and (3) that the mantle under Asia, which can be thought of as a growing "supercontinent", is characterized by dominant mantle downwelling.

JSS13/C/ST2/W/25-A4 1740

REMNANT SLAB DYNAMICS FOLLOWING CONTINENTAL COLLISION

G.T. JARVIS (Department of Earth and Atmospheric Science, York University, Ontario, Canada M3J 1P3, email: jarvis@mantle.eats.yorku.ca) and J.P. Lowman (Institute of Geophysics and Planetary Physics, Los Alamos National Laboratory MS C305, Los Alamos, NM 87545, USA, email: lowman@lanl.gov)

A 2D numerical model of mantle convection, which incorporates rigidly moving surface plates, is used to study the effects of the accretion of a 2000 km wide block of continental crust, such as the Indian sub-continent, to the margin of a large stationary continent. This continental block is carried along with an oceanic plate towards a subduction zone at the leading edge of a much larger stationary continent, such as Asia. Prior to continental collision, subducted oceanic plate material under-rides the margin of the larger continent for several hundred kilometers before peeling away from the surface boundary layer and descending into the mantle as a cold narrow slab. Consequently, once the moving continental block arrives at the continental margin and closes over the original subduction zone the surface location of the continental suture lies several hundred kilometers away from the location of the cold remnant of the sinking slab. Convective flow in the subcontinental mantle adjusts to accommodate the change in mechanical boundary condition at the upper surface. We find that once the upper surface is immobilized, there may be a final pulse of vigorous subduction after which the continued descent of the cold slab is inhibited, and the cold remnant remains below the collision zone longer than expected based on 'normal' rates of subduction. Evolution of temperature and flow fields in the former subduction zone result in a relaxation of normal stresses at the upper surface and a consequent slow regional topographic uplift. Although the model is limited to two-dimensions, the observed time scales and orders of magnitude the observed variations are expected to be reasonably accurate.

DYNAMICS OF CRETACEOUS VERTICAL MOTION OF AUSTRALIA AND THE ORIGIN OF THE AUSTRALIAN-ANTARCTIC DISCORDANCE

Michael GURNIS (Seismological Laboratory, California Institute of Technology, Pasadena, CA 91125 USA, email: gurnis@caltech.edu); Louis Moresi (Australian Geodynamics Cooperative Research Centre, CSIRO Exploration and Mining, Nedlands, WA 6009Australia, e-mail: louis@ned.dem.csiro.au); R. Dietmar Mueller (Department of Geology and Geophysics, University of Sydney, Sydney, NSW 2006, Australia, e-mail: dietmar@es.su.oz.au)

We propose that the anomalous Cretaceous vertical motion of Australia and distinctive geochemistry and geophysics of the Australian-Antarctic Discordance (AAD) were caused by a subducted slab which migrated beneath the continent during the Cretaceous, stalled within the mantle transition zone, and is presently being drawn up by the South East Indian Ridge (SEIR). Using a three-dimensional model of mantle convection with imposed plate tectonics, we show that both the vertical motion of Australia and the distinct geochemistry and geophysics of the SEIR are related. The models start with slabs dipping toward the continent, but ~1,400 km from the present eastern margin. As Australia moves east in a hot-spot reference frame from 130-90 Ma, a broad dynamic topography depression of decreasing amplitude migrates west over the continent causing the continent to subside and then uplift. During this period most of the slab descends into the deeper mantle, but part of the cooler mantle becomes trapped within the transition zone above a viscosity jump and phase transition at 670 km depth. From 40 Ma to the present, wisps of this cool mantle are drawn up by the northwardly migrating ridge between Australia and Antarctica. This causes a circular dynamic topography depression to develop at the present position of the AAD. In addition, the cool mantle leads to thinner oceanic crust. The method demonstrates the predictive power of mantle convection models when they incorporate plate tectonics.

JSS13/W/17-A5 0930

LITHOSPHERIC STRESS FIELD AS A CONSTRAINT ON GLOBAL MANTLE CIRCULATION

Bernhard STEINBERGER and Harro Schmeling, (both at Inst. f. Meteorology and Geophysics, University Frankfurt, Feldbergstr. 47, 60323 Frankfurt, Germany, e-mail: steinber@geophysik.uni-frankfurt.de)

Lithospheric stresses have so far not been widely used as indicators of flow in the mantle beneath: It has been difficult to extract a large-scale stress field from stress measurements; the causes of lithospheric stresses have mostly been assumed inside the lithosphere; due to large uncertainties no good agreement between stresses predicted from mantle flow and observations could be achieved. The situation has however improved considerably during recent years: Seismic tomography can now give much better constraints on the driving forces of large-scale mantle flow, and an interpolated global stress map has been published.
Here we present a model of global mantle flow that gives a good agreement with an interpolated global stress distribution. The flow field is calculated with the method of Hager and O'Connell; driving forces are inferred from seismic tomography; for the surface boundary condition, the two limiting cases are a rigid lid, and the lithospheric plates moving freely in response to the forces acting on them. The model is similar to one that has been used to explain Africa's long-wavelength topography as dynamic topography, i.e. supported by internal flow. The agreement between predicted and observed stresses is particularly good in regions where lithospheric stresses and mantle tomography are well constrained (e.g. North America, Europe, East Asia). Our results clearly show that there is a long-wavelength lithospheric stress field that is due to flow in the underlying mantle. Except in regions of large continental topography (especially around Tibet) mantle flow is the dominant cause of this long-wavelength stress field.To further support our model we consider thedistribution of hotspots and intraplateearthquakes: our model shows that most hotspots are located in regions of extensional stress and no hotspots are in regions of strong compression. A likely explanation for this observed distribution is that deep mantle plumes may not be able to penetrate a lithosphere that is strongly under compression. Our model also predicts high lithospheric shear stresses mostly in regions where the hazard due to intraplate earthquakesis considered high. We anticipate that it will be possible to use the large-scale stress field as a constraint to mantle flow. As a practical application, a model of mantle flow and induced lithospheric stresses will be able to better assess earthquake risk in intraplate settings.

JSS13/W/09-A5 0950

THE HEAT FLOW CONSTRAINT ON RADIAL MIXING IN NUMERICAL MODELS OF MANTLE EVOLUTION

S. L. Butler and W. R. Peltier (both at Department of Physics, University of Toronto, Toronto, Canada, M5S 1A5, email: sam@atmosp.physics.utoronto.ca, peltier@atmosp.physics.utoronto.ca)

We demonstrate that when CMB temperature is fixed by the results of high pressure experiments in a spherical axisymmetric model of the thermal convection process then the total surface heat flow is considerably greater than that which is observed if the mantle rheology is Newtonian. In these analyses the radial variation of mantle viscosity is taken to be fixed by formal inversion of the constraints of glacial isostatic adjustment. The convection model then reconciles the observed heat flow if the degree of layering induced by the 660 km endothermic phase transition in our model is sufficiently strong. We present a suite of numerical simulations in which we characterize the effects of layered convection on surface heat flow. In particular, we determine that in order for the surface heat flow in our model to match that of the real Earth, the radial mass flux transiting the 660 km depth horizon must be only slightly greater than the extremely small values for this quantity that have been inferred on the basis of geochemical observations. The magnitude of the Clapeyron slope of the endothermic phase transition that is required to induce such strong layering is somewhat greater than high pressure experiments would suggest. We further demonstrate, however, that a decrease in viscosity in the region of the phase transition of the type that one would expect due to transformational superplasticity can significantly increase the ability of a phase transition to induce a layered style of flow. The strong layering required to reconcile the surface heat flow may then be compatible with the Clapeyron slope of the endothermic phase transition based on high pressure experiments.

JSS13/W/14-A5 1010

MANTLE CIRCULATION MODELS AND TRUE POLAR WANDER

GREFF-LEFFTZ Marianne (Institut de Physique du Globe de Paris, Geomagnetism Department, 4 place Jussieu, 75252 Paris cedex 05, France) Bunge Hans-Peter (Department of Geosciences, Guyot Hall, Princeton University, Princeton, NJ 08544, United States)

Relative motion between hotspot and paleomagnetic reference frames is called true polar wander, to distinguish it from apparent polar wander, which is related to continental drift. Few studies have tried to link paleomagnetic constraints to a reference frame tied to vigorous mantle convection. Here we use a 3D spherical mantle circulation model to study the sensitivity and general character of true polar wander events during the past 100 million years, testing their dependence on a high viscosity lower mantle, the amount of core heat flux excavated by mantle plumes, or the buoyancy effects of mantle phase changes in the upper/lower mantle transition zone. The degree two geoid and the inertia tensor perturbations associated with these mantle density heterogeneities are computed and the Euler equations for conservation of angular momentum subject to the visco-elastic adjustment of the rotational bulge are solved at each time step. We find that the reorientation of pacific plate motion from its formerly northward to a northwestward trend at 43 Ma, which initiated a system of new subduction zones in the western pacific, produces a marked shift in the direction of predicted true polar wander at about 30 Ma, if the anomalous buoyancy effects from an endothermic phase change at 670 at depth are excluded. Otherwise, no cusp is produced, due to the dynamic compensation of newly subducted slabs in the transition zone. We also find that increasing the plume flux reduces the amount and rate of of true polar wander, resulting in greater overall stability. These results indicate the potential of using mantle circulation models and observations from paleomagnetic and geochronological data to constraint the dynamic cause of true polar wander.

JSS13/W/10-A5 Invited 1000

THE TECTONIC RECORD IN THE DEEP MANTLE

CAROLINA LITHGOW-BERTELLONI (Department of Geological Sciences, University of Michigan, Ann Arbor, MI 48019, USA, Email: crlb@umich.edu)

An important goal of the solid Earth sciences must be to understand how processes in the Earth's deep interior might be reflected in the surface geological record. Global tectonic

reconstructions used in connection with mantle flow models and the most recent images of the mantle from seismic tomography have allowed us to connect the tectonic record with structures in the deep mantle [e.g. Richards & Engebretson, 1992; Lithgow-Bertelloni & Richards, 1998; Bunge et al., 1998; Voo et al., 1998]. Moreover, simple dynamical flow models based on subduction over the last 200 My have successfully explained a variety of observations: the geoid [Ricard et al., 1993], present and past plate motions [Lithgow-Bertelloni & Richards, 1998], the Cenozoic true polar wander record [Richards et al., 1997], and continental flooding history [Lithgow-Bertelloni & Gurnis, 1997]. I will present a summary of the efforts to model global mantle circulation and related dynamical processes using the past 200 My of tectonics. I will also compare in detail to existing seismic tomographic models in an effort to interpret the observed seismic heterogeneity in relation to the tectonic record. I will examine the implications for global mantle circulation and address the question of whether dynamical barriers to flow are required by the observations, and therefore if the observed seismic heterogeneity is thermal or chemical in origin. Finally, I will show how the existing high-resolution tomographic models can provide important constraints to tectonic reconstructions when coupled with simple models of subduction history and mantle flow. I will look in particular at the evidence for changes in subduction polarity and cessation of subduction of the Phoenix plate under South America in the Mesozoic and whether the current tectonic reconstructions can be reconciled with the gaps in fast seismic heterogeneity seen in the tomography.

JSS13/W/03-A5 1130

ABOUT THE SURVIVAL OF VISCOUS BLOBS IN THE MANTLE

Nicolas MERVEILLEUX DU VIGNAUX and Luce Fleitout (both at Laboratoire de Geologie de l'ENS, 24 rue Lhomond, 75005 Paris, France, email:nmerveil@jadeite.ens.fr)

The survival of blobs more viscous than the surrounding mantle is an important issue : the degassed harzburgite might be more viscous than the primordial mantle and this may affect its properties as a geochemical reservoir and also its gravitational segregation. It has been shown (Spence et al., Geophys. J., 1988) that the deformation of a viscous blob is in first approximation proportional to its aspect ratio divided by its relative viscosity. Once submitted to a large strain, all blobs may have acquired a large aspect ratio so become easily deformed and mixed.
We study in a time-dependent laminar convective regime the deformation of blobs as functions of their viscosity and aspect ratios. The deformation is measured by small markers within the blobs. The deformation of the blobs is indeed inversely proportional to its relative viscosity but the aspect ratio has a moderate impact. The elongated blobs tend to buckle so that their effective aspect ratio becomes of the order of 1, or they separate in blobs of aspect ratio close to 1 rather than forming very elongated blobs. These results are analyzed with the help of numerical experiments where the blobs are submitted to pure and simple shears.

JSS13/W/13-A5 1150

AN ULTRAFAST PLUME UNDER GREENLAND?

Tine B. LARSEN (National Survey and Cadastre, Geodynamics Dept., Rentemestervej 8, DK-2400 Copenhagen NV, Denmark, e-mail: tbl@kms.dk), David A. Yuen (Dept. of Geology and Geophysics and Minnesota Supercomputer Inst., 1200 Washington Ave. S, Minneapolis, MN 55415, USA, e-mail: davey@krissy.msi.umn.edu), and Michael Storey (Danish Lithosphere Centre, ýster Voldgade 10, DK-1350 Copenhagen K, Denmark, e-mail: ms@dlc.ku.dk)

Recent geochemical and geochronological data from the N. Atlantic region have placed strong constraints that copious amounts of hot magmatic material have been transported to the surface on a timescale of a few million years or less. A small, fast moving plume appears to be a more viable mechanism from these new observational findings than the traditional idea of a giant plume head with a diameter equal to or larger than the thickness of the entire upper mantle. In order to reconcile the idea of an ultrafast plume with the observed plate velocities, a physical mechanism is needed for inducing a separation of timescales between the plume speed and the surrounding mantle circulation. Thermal convection with a non-Newtonian temperature- and depth-dependent rheology has been found to provide such a mechanism wherein extremely fast plumes ascending at velocities between one to tens of meters per year can be produced in an otherwise slowly convecting mantle at cm/yr. This transport mechanism is capable of bring up very hot matter from the transition zone to the lithosphere, where considerable melting would take place. Basalts of nearly the same age have been found in West Greenland, East Greenland, the Faeroe Islands and Scotland. It is thus possible to explain these semi-contemporaneous igneous events by a fast moving mantle plume spreading out below, upon surficial impact, with a horizontal velocity of around 0.5 m/yr. We discuss also the relationship of the upper-mantle plume under Iceland to the recent findings by seismic tomography of a deep mantle plume under Iceland and the presence of an ultra-low velocity zone at the very base of the mantle.

THREE DIMENSIONAL SPHERICAL EFFECT OF THE CIRCUM-PACIFIC LITHOSPHERE SUBDUCTION ON THE LARGE-SCALE MANTLE PLUME ACTIVITY

Takao EGUCHI (National Research Institute for Earth Science and Disaster Prevention, 3-1, Ten-nodai, Tsukuba, Ibaraki 305-0006, JAPAN, email: eguchi@geo.bosai.go.jp)

To make clear the basic and fundamental nature of mantle convection dynamics including unsteady large-scale plume activity, we must carry out numerical simulation with various initial and boundary conditions as well as constraints for rheology parameters such as viscosity and temperature, etc. Recently, Eguchi (1994) proposed a concept of _$B%a_(Jcool mantle doughnut_$B%b_(J (CMD) with the great circle dimension surrounding the Pacific ocean, inferred from recent studies of the global seismic tomography and plate subduction history, etc. The CMD may involve the zone of major energy dissipation associated not only with the plate convergence but also with the global mantle downgoing flow.
To investigate unsteady recent mantle dynamics possibly influenced by the CMD, we developed a new code for 3-D numerical simulations of the spherical mantle convection. The basic three equations are for the continuity, the motion with the Boussinesq (incompressible) approximation, and the (thermal) energy conservation. The simulation code developed newly incorporates the spherical mantle layer with the temperature-dependent viscosity, etc. Our program is based on the finite difference method (Newton method) with the control volume technique. During the calculation, as for one of the initial condition, we inserted the relatively lower temperature material throughout at the equatorial zone, in addition to the horizontally uniform thermal field. We start the calculation with the zero initial velocity and displacement within the mantle layer. Thus, in our model, the equatorial zone is the centroid of the lithosphere downgoing and successive large-scale downwelling flow. The result shows that large-scale upwelling flows are exited at the latitude of 30-40 deg., after a certain period, as a response of the equatorial lithosphere subduction. North-south wider zone of equatorial subduction can shift the upwelling sites to the higher latitude to some extent. Our simulation result, however, constrains that the sites of the large-scale upwelling cannot reach the North and South poles.

MANTLE CONVECTION AND THE GENERATION OF THE PRINCIPAL GEOCHEMICAL RESERVOIRS

Uwe WALZER and Roland Hendel (both at Institut f. Geowissenschaften, Universitaet Jena, Burgweg 11, 07749 Jena, Germany, email: walzer@geo.uni-jena.de)

We investigate the evolution of the principal geochemical reservoirs of the mantle, the oceanic plateaus, the continents etc using new 2D-FD Oberbeck-Boussinesq convection models plus a fractionation mechanism. In one model a constant core-to-mantle heat flow is assumed, in the other model the CMB temperature is assumed to be constant. The fractionation generates the chemical diversity and an inhomogeneous mantle heat-source distribution, whereas the solid-state convection works toward homogenization. The deformation of the 410- and 660-km mineral phase change interfaces produces additional positive and negative buoyancy forces. A minor planar heat source at CMB creates the D" layer and thermal plumes. The pressure- and temperature-dependence of the viscosity is an essential feature of the models. Segregation takes place if the asthenospheric viscosity falls below a certain threshold. Oceanic plateaus, enriched in incompatible elements, develop leaving behind depleted parts of the mantle. A laterally moving continent grows by the accretion of oceanic plateaus. For the Phanerozoic we arrive at a mainly depleted upper half of the mantle and a predominantly pristine lower half of the mantle.

JSS13/W/18-A5 1420

WHOLE MANTLE CONVECTION AND GEOCHEMICAL RESERVOIRS

Nicolas Coltice, Yanick Ricard and Philippe Gillet (Laboratoire de Sciences de la Terre; Ecole Normale Superieure de Lyon; 46, allee d'Italie; 69364 Lyon cedex 07)

A wide range of geophysical observations suggests that slabs sink into the deep mantle. The injection of crustal and depleted material is of fundamental importance in understanding geochemical signature of oceanic basalts. In this study, we try to interpret the geochemical data (He, Sr and Pb) with a whole-mantle convection point of view. To propose a model of geochemical evolution of the mantle,we (a) try to understand the physical relationship between geochemical box models and fluid dynamic models in terms of mixing, (b) use geophysical observations and perform geochemical mass balance and geodynamical calculations to constrain mantle reservoirs and the fluxes between them. Using an inversion of a geochemical box model, we show that the geochemical features of hotspots can be related to recycled material, a mixture of oceanic crust and a high 3He/4He component: ancient lithospheric mantle.

JSS13/W/08-A5 1440

HELIUM ISOTOPE RATIO IN OCEANIC ISLAND BASALT: ITS ORIGIN AND CONSTRAINT ON MANTLE CIRCULATION

Yang WANG (Lab. for Geothermics, Institute of Geology, Chinese Academy of Sciences, P.O.Box 9825, Beijing 100029, China, email: thalassa@263.net)

The helium isotope ratio (He3/He4) in mid ocean ridge basalt (MORB) is ~8 RA (atmospheric He3/He4 ratio); but He3/He4 ratio in oceanic island basalt (OIB) exhibits geographic diversity, it is ~5-6 RA in the OIB which are mainly located in southern hemisphere, and ~10-35 RA in the OIB (i.e. Hawaiian, Loihi and Iceland) of northern hemisphere. This feature was previously explained by two layer steady state mantle model which requires a volatile degassed upper mantle, and a more volatile and high viscosity lower mantle. Nowadays, high resolution seismic tomography indicates the lithospheric plate penetrate the 670 km discontinuity, this should destroy the primitive isotopic composition of helium in the lower mantle. Numerical experiments on mantle convection by van Keken and Ballentine(1998) suggest that, He3/He4 ratio remains relative homogeneous through the entire mantle over 4.6 Ga evolution, furthermore, degassing is more rapid in the case of high viscosity lower mantle. We consider a new model to explain the characters of He3/He4 ratio in OIB. It is well known that the OIB of southern hemisphere has a lithosphile-rich source which is the mixture of oceanic mantle and subducted continental material from Gondwanaland. Enriched U, Th in this source will product more radiogenic He4 than normal oceanic mantle after ~300 Ma (the time since the break-up of Gondwanaland), and result in low He3/He4 ratio in southern OIB. The high He3/He4 ratio of the OIB in northern hemisphere needs a source in which uranium and thorium is much depleted than normal oceanic mantle; and the ancient subducted oceanic lithosphere, which lose U and Th during subduction, is a possible candidate. After long period (e.g. 1-2 Ga), the source will have much less radiogenic He4 and high He3/He4 ratio. The calculation of van Keken and Ballentine (1998) also indicated that preservation time of chemical heterogeneity in mantle is 1-2 Ga. The geographic diversity in He3/He4 ratio of OIB should be due to spherical harmonic degree l=2 pattern of mantle convection, which has hemispheric scale dimension. D.L. Anderson (1998) points out that the hotspots correspond to spherical harmonic degree l=6 pattern of convection, which means convection cell is of 6000 km dimension and its lower boundary is 670 discontinuity. Integrated his viewpoint and isotopic characters of He, Nd, Sr and Pb, we deduce that OIB in southern hemisphere is originated from the source stored in 670 discontinuity, and OIB in northern hemisphere from lower mantle; then the dominant circulation patterns in northern and southern hemisphere is very different.

JSS13/E/03-A5 1500

HELIUM ISOTOPE CONSTRAINTS ON THE STRUCTURE AND EVOLUTION OF THE ICELANDIC MANTLE PLUME

HILTON, D.R., Scripps Inst. Oceanography, La Jolla, CA 92093 USA (email: drhilton@ucsd.edu)
Gronvold, K., Nordic Volcanological Inst., Reykjavik, Iceland Macpherson, C.G., Royal Holloway, Univ. London, Egham, Surrey, UK

High and variable 3He/4He ratios (> MORB He) throughout Iceland point to both a deep-seated origin of the Icelandic mantle plume - consistent with recent seismic studies which place its origin in the lower mantle or at the core-mantle boundary (Wolfe et al., 1997; Helmberger et al., 1998; Shen et al., 1998) - and to a complex history of mantle mixing and/or crustal interaction. To elucidate further details of the structure and evolution of the plume, we report new helium isotope data from two key areas in Iceland: (a) Vestfirdir, the oldest region of the Icelandic crust (~15 Myr) and the location of the highest geothermal 3He/4He ratios observed to date (30RA; Hilton et al., 1998), and (b) Central Iceland, at the juncture of the western and northern rift zones and the hypothesised center of the Icelandic plume. Vesfirdir phenocrysts have 3He/4He ratios up to 37RA - the highest ratio ever reported for Iceland. Central Iceland basalts have values up to 33RA and show a sharp discontinuity with lavas erupted ~100 km into the northern rift zone which have 3He/4He ratios equal to MORB (~8RA). The new results, when combined with earlier studies (e.g. Polak et al., 1976; Condomines et al., 1983; Kurz et al., 1985; Hilton et al., 1990; Poreda et al., 1992), allow a detailed picture to be constructed of helium isotope variations throughout Iceland. This

distribution will be discussed in terms of the past and present-day history of impingement of the plume against the Icelandic crust, and the nature and spatial variability of mantle sources contributing to Icelandic volcanism.

JSS13/W/12-A5 1520

BUFFERING THE DEPLETED MANTLE WITH CRUST: AN INTERPRETATION FROM THE TRACE ELEMENT AND ND-HF- PB ISOTOPIC COMPOSITION OF MORB

A.D. SMITH (Dept. Earth Sciences, Cheng Kung University, Taiwan;
email: mochinm@mail.ncku.edu.tw)

The rate of isotopic evolution of the mantle of 2.2 epsilon Nd units per Ga through the Phanerozoic and Proterozoic and the shape of the modern MORB Nd-Hf isotopic array can be reproduced by subducted basaltic crust and sediment comprising 5-6% and 0.1-0.5%, respectively, by volume of the depleted mantle. Basalt and pelagic sediment generates the high 176Hf/177Hf-low 143Nd/144Nd part of the MORB array while basalt and turbidite generates the low 176Hf/177Hf -high 143Nd/144Nd signatures. In contrast, the rate of isotopic evolution of the Early Archean mantle as deduced from alumina- depleted komatiites corresponds to a scenario in which there is only limited crustal recycling into the depleted mantle, and is consistent with models for a voluminous early crust ~8% greater in volume than today. Depleted mantle Pb isotopic ratios are not correlated with Hf isotopes because of modifications to the U/Pb ratio on seafloor alteration and removal of these elements into the mantle wedge at subduction zones. However, variations in the efficiency of these mechanisms allows the buffering process to account for both the elongation of the MORB field toward HIMU and its tilt toward EM2 in Pb-Pb diagrams. The common argument that Ce/Pb-Nb/U ratios in MORB precludes buffering of the depleted mantle by crust is valid only for modern slab dehydration regimes. Melting of an ancient primitive mantle reservoir generates a depleted residue with higher Nb/U than the modern MORB- source. Remixing crust into this very-depleted reservoir produces the trend from high Nb/U-low Ce/Pb to low Nb/U-high Ce/Pb seen in MORB as tectonic regimes change from slab-melting to slab- dehydration regimes, with the greater retention of Pb in the slab under the former conditions accounting for elevated 207,208Pb/204Pb signatures in Precambrian mantle-derived rocks.

JSS13/E/02-A5 1610

EVIDENCE FOR A SMALL, GEOCHEMICALLY DISTINCT BODY IN THE MID-LOWER MANTLE

SATOSHI KANESHIMA (Department of Earth and Planetary Sciences, Tokyo Institute of Technology, Meguro-ku, Oookayama, Tokyo 152, JAPAN, Email: kane@geo.titech.ac.jp) and George Helffrich (Geology Department, University of Bristol, Queens Road, Bristol UK,
Email: george@geology.bristol.ac.uk)

We report observations which clearly show the presence of small-scale, geochemically distinct bodies in the mid-lower mantle. Our analyses of array data from western United States short period seismic networks detect S-to-P converted waves at a thin low seismic velocity sheet (with a velocity decrease from the surrounding mantle larger than 4%, and nearly 8 km thick) in the mid-lower mantle (1400 to 1600 km depth) east of the Mariana and Izu-Bonin subduction zones. The low velocity sheet dips nearly 40 degrees southward and is at least 500 km by 300 km. Its steep dip clearly rejects an origin as a pressure-driven phase transition, and its intensity and sharpness further imply a chemical rather than a purely thermal origin. Ancient oceanic crust subducted into the lower mantle would be the most plausible candidate for the low velocity sheet given its broad, thin extent. Previous seismic tomography studies do not predict significant velocity anomalies there.
Plate reconstructions suggest the Indonesia slab may have been located above the site at 160 to 170 Ma. Laboratory estimates of thermoelastic properties currently available do not predict seismic velocity anomalies as large as the observation, but large uncertainties of shear velocity do not permit conclusive arguments. Undistorted sheets imply minor resistance to lower mantle slab penetration and may provide long-term geochemical reservoirs whose mixing into the mantle is not effective.

JSS13/W/04-A5 1630

GEODYNAMICAL IMPLICATIONS OF THE HETEROGENEOUS ELECTRICAL CONDUCTIVITY STRUCTURE OF THE MID-MANTLE

Pascal TARITS (UBO/IUEM, UMR CNRS ' Domaines Oceaniques' Place Nicolas Copernic, Brest F-29280, France, E-mail: tarits@univ-brest.fr, Mioara Alexandrescu (IPGP, Observatoire Magnétique de Chambon La Foret, Beaune la Rolande F-45340, France, E-mail: mioara@ipgp.jussieu.fr

In this study monthly mean values of the geomagnetic field from about 100 observatories have been analyzed. We selected time windows of 30-35 years which was appropriate for most of the available observatory data. The main field and the secular variation was removed using the model provided by Bloxham and Jackson (1992). A robust simultaneous spectral analysis in the time domain and in the spatial domain was carried out on the 3 components X, Y and Z at each observatory to obtain the internal and external magnetic potential coefficients. The transfer function between the internal and the external spectral components of the field was calculated robustly for periods between 2 months and 1 year. 3D conductivity models of the Earth were obtained from the non-linear minimisation of a penalty function between the data and the theoretical reponse of the model. The earth was parameterised with an homogeneous upper mantle down to 400 km and two heterogeneous layers each 250 km thick. Below these layers the Earth is assumed homogeneous. The heterogeneous conductivity is given on a grid 10 (north-south) by 20 (east-west) corresponding roughly to maximum wave numbers l=6-8. We compare the geodynamical implication of the models to other geophysical data.

JSS13/W/07-A5 1650

MAGNETIC FABRICS OF TROODOS OPHIOLITE REVEAL LOCALIZED FLOW PATTERNS

Dr Graham Borradaile, Lakehead University, email: borradaile@lakeheadu.ca

Harzburgites exposed in the Troodos complex of Cyprus provide clear magnetic fabric patterns both from anisotropy of low field susceptibility (AMS) and anisotropy of anhysteretic remanence (AARM). AARM isolates the orientation distribution of ferromagnetic accessory minerals whereas AMS combines this with the contribution from paramagnetic mafic silicates. The two subfabrics differ somewhat due to differing ages of crystallization in noncoaxial flow. The magnetic fabrics define spatially varying flow patterns that indicate a general sense of regional tectonic flow. This helps to position the exposed rocks with respect to the spreading axis, a result that would be difficult to achieve by conventional petrofabrics, or other means.

JSS13/L/01-A5 1710

TOMOGRAPHIC CONSTRAINTS ON PAST PLATE MOTION MODELS

H.-P. BUNGE (Dept of Geosciences, Princeton University, Princeton NJ 08544,
email: bunge@geo.princeton.edu)

General circulation models are a flexible tool to probe mantle flow. In one of their most important applications they relate geologically derived past plate motion models explicitly to high resolution seismic mantle maps. Here we explore the approach using the 3D spherical TERRA mantle convection code. Allowing for more than 100 million grid points throughout the mantle, sufficient to fully resolve the lithosphere, we probe the circulation of the mantle to test both geodynamic and plate motion hypotheses with tomographic data. Our circulation experiments are highly successful in explaining a number of prominent seismic velocity anomalies in the deep mantle, especially those related to past subduction. They also confirm a simple whole mantle convection style with a substantial viscosity increase between the upper and lower mantle and little resistance from the endothermic phase transition. A significant amount of core heating is needed to explain anomalously slow mantle imaged under Africa and the Pacific. Importantly, we find that the most persistent discrepancy between geodynamic and seismic mantle models is entirely due to systematic errors in the current mesozoic and cenozoic plate motion input models suggesting to improve these models by using information from seismic tomography. We highlight the potential utility of the tomographic data by taking the late mesozoic subduction history of the western United States as an example. Allowing for a geologically inferred episode of low-angle subduction during the laramide, which uplifted much of the eastern front of the rocky mountains, we find a spectacular correlation between geodynamic and seismic images of the Farallon slab can be obtained. We also note that geodynamic mantle models must be evaluated by applying the same tomographic filtering that biases current seismic mantle models. By tracing seismic rays through our models, we critically reevaluate the common assumption of zero mean and Gaussian distributions in travel-time residuals.

EARTH ROTATION MONITORING: STATUS AND PROSPECTS

Christoph REIGBER (GeoForschungsZentrum Potsdam, Div. Kinematics andDynamics of the Earth, Telegrafenberg A 17, D-14473 Potsdam, Germany, e-mail: reigber@gfz-potsdam.de)

Rotation is the major feature of our planet's motion and its precise knowledge is required for various navigational, global geodetic and astronomical tasks. Irregularities in both the rotation rate and the position of the rotation axis in space are manifestations of changing mass redistributions within, on and outside of the planet and of torques acting on it. Their precise knowledge provide a unique and global measure of changes taking place in the various spheres of the Earth system.
International cooperative efforts for observing the Earth rotation date back almost exactly a century and have culminated in the space geodetic observation programs of the International Earth Rotation Service (IERS) which include satellite (SLR, LLR, GPS, DORIS) and radioastronomy (VLBI) based techniques. Analyses of the observations provide nowadays a monitoring of the Earth orientation and realizations of the terrestrial reference frame at the "0.3 mas accuracy level, corresponding to 1 cm on the Earth surface. This level of accuracy is continuously improving thanks to advances in technology, more robust tracking networks and improved data reduction and analysis techniques. The precise terrestrial reference frame sets the framework for regional networks being established for e.g. deformation monitoring, water vapor mapping and surveying tasks. The improved accuracy and temporal resolution of the Earth's rotation parameters is triggering investigations of their subdiurnal to multi-year variability caused by geophysical processes taking place in the Earth system components. In order to support such practical applications and frontier research activities best, the IERS is presently adjusting its structure and functions to the user needs. One of the major challenges for the future will be to realize within an integrated global geodetic monitoring system highly accurate, consistent, long-term Earth rotation series with very high temporal resolution. The presentation will desribe the present status in monitoring the Earth rotation and is trying an outlook into near future developments and needs.

JSG14/E/12-A3 0900

ASSESSING THE PLANETARY ANGULAR MOMENTUM BUDGET WITH ATMOSPHERIC UPPER AIR AND OCEAN MODEL DATA

DAVID A. SALSTEIN, Rui M. Ponte, Richard D. Rosen (Atmospheric and Environmental Research, Inc., 840 Memorial Dr., Cambridge, MA 02139, USA, email: salstein@aer.com) Detlef Stammer (Massachusetts Institute of Technology, Department ofEarth, Atmospheric and Planetary Sciences, Cambridge, MA 02139, USA)

Atmospheric and oceanic information are used in combination with Earth rotation parameters to assess the angular momentum budget of the planet about the axis of rotation, on a variety of timescales. For the atmospheric data the 50-year long NCEP/NCAR reanalysis products capture variability at levels as high as 10 hPa. In addition, separate data sets of the stratosphere include comprehensive calculations on levels as high as 0.3 - 1 hPa. Because stratospheric winds vary strongly at semiannual, annual, and quasi-biennial timescales, incorporating these data is particularly important. We assess the regions within the atmosphere that have the strongest variations on intraseasonal, seasonal, and interannual timescales. In the last case, El Niño events are clearly related to the strength of the zonal circulation in the atmosphere. Available estimates of oceanic axial angular momentum, calculated from model-derived zonal current and mass fields, are also used to assess the role of the ocean in explaining some of the discrepancies still present in the solid Earth and atmosphere's combined angular momentum budget. In considering excitations for polar motion in the equatorial plane, atmospheric and oceanic effects can approach similar magnitudes on a number of timescales. Within the atmosphere, the mass field, related to surface pressure, is the agent that most

excites polar motion on subseasonal scales. We discuss the extent to which a closed budget is achieved within the estimated uncertainties in all momentum quantities, as a function of timescale.

JSG14/L/08-A3 0930

INFLUENCE OF CORE DYNAMICS ON THE ROTATION OF THE EARTH

Gauthier HULOT (Institut de Physique du Globe de Paris, 4 Place Jussieu, 75252 Paris Cedex 05, France, email: gh@ipgp.jussieu.fr)

The visco-elastic body rotation of the Earth's mantle, usually referred to as the "Earth's rotation", is well known to display variations. These variations occur as a result of some mechanical forcing acting on the mantle and produced by both external interactions (Luni-Solar tidal forces) and internal interactions (with the fluid enveloppes and the core). This forcing produces changes within the angular momentum of the mantle, which results in the observed changes within both the rate of rotation (Length of Day, LOD) and the position of the rotation axis. The present review will focus on the specific influence of core dynamics, thought to play a dominant role in modifying the Earth's rotation on decade time scales. We will briefly recall the two approaches currently used for studying this influence. One consists in inferring the core angular momentum (AM) from magnetic observations, assuming conservation of core+mantle AM and checking that variations within the Earth's rotation are correctly predicted. The other consists in searching for core-mantle coupling mechanisms that can produce such variations. We will then first focus on the LOD variations and present a set of results obtained by various teams. It will be shown that the AM approach clearly leads to the conclusion that core dynamics is responsible for the decade variations within the LOD. Results obtained through the second approach are not as clear cut, and arguments in favor or against each type of coupling (electromagnetic, topographic, or gravitational) will be discussed, together with the possible role of the inner core. We will next turn to the possible influence of core dynamics on the position of the rotation axis. This subject has received much less attention up to now. This is likely due to the combined facts that the dynamics of the core (under strong influence of the Coriolis forces) does not permit an easy approch of the problem in terms of AM conservation, and that the variation of the position of the rotation axis (usually determined in terms of the position of the pole of rotation within the mantle frame of reference) is not very well constrained on decade time scales. It will however be argued that core dynamics can also produce variations that are nearly compatible with the available observational constraints. Finally, the possible influence of core dynamics occuring on time scales less than one year (as testified by the occurrence of so-called geomagnetic jerks) will be briefly discussed.

JSG14/L/09-A3 1000

NUTATIONS: OBSERVATIONS, THEORETICAL MODELING, AND IMPLICATIONS

P. M. Mathews, (Department of Theoretical Physics, University of Madras, Chennai 600025, India) email: mathews@imsc.ernet.in T. A. Herring, (Department of Earth, Planetary and Atmospheric Sciences, M.I.T., Cambridge, MA, U.S.A), B. A. Buffett (Department of Geophysics and Astronomy, University of British Columbia, Vancouver, B.C., Canada)

The VLBI data available now permit estimation of the amplitudes of a large set of nutation terms with a formal precision much better than 10 except for a few terms. Recent advances in theory enable these estimates to be closely matched by model predictions. Apart from an excess (nonhydrostatic) flattening of the core mantle boundary (CMB), inferred earlier from nutation data, and the effects of mantle anelasticity and ocean tides on nutations, the couplings of the fluid outer core to the mantle and to the solid inner core through magnetic fields at the CMB and the inner core boundary (ICB) are found to have a significant role in accounting for the observations. The inner-core-induced normal mode (PFCN or FICN) plays an important part in this context. We shall present the estimates obtained for various parameters by a least squares fit of analytical theory to data, and their interpretation in geophysical terms. A precise estimate for the Earth's ellipticity, magnetic coupling parameters at the CMB and ICB and their implications, revision of the estimate for the CMB flattening, questions regarding the inner core flattening, and possibilities for constraining an elasticity and ocean tide models, will be discussed

JSG14/W/05-A3 Poster 1100-01

CORE: 19+ YEARS OF VLBI UT1/LOD, AAM, EL NIÑO AND LA NIÑA

THOMAS A CLARK (Email: clark@tomcat.gsfc.nasa.gov), Chopo Ma (Email: cma@leo.gsfc.nasa.gov) and Ben Chao (Email: chao@denali.gsfc.nasa.gov), all at NASA/GSFC, Laboratory for Terrestrial Physics, Greenbelt MD 20771 USA.

Since 1980, the global VLBI network has produced more than 2000 one-day determinations of UT1 with a frequency of at least one measurement per week. The accuracy of the early measurements was hundreds of msec, while more recently ~5 msec is common. We have used this 19+ year record of UT1 to derive Length of Day (LOD), which mirrors changes in angular momentum in the fluids in earth's interior, atmosphere and hydrosphere. Observed decadal-scale variations arise largely from changes in the earth's core, and from global-scale climatic and ocean circulation variability which affect LOD with a peak-to-peak range ~1 msec over the 19+ year data set.
On shorter time scales, LOD is highly correlated with total atmospheric angular momentum (AAM). The annual average LOD signature due to AAM has a peak-to-peak amplitude ~900 msec. LOD is highly correlated with AAM derived from various global climate models (GCMs) and we present detailed comparisons with the NCEP GCM. We note that VLBI data has proven to be a useful, independent proxy for validation of various GCMs.
After removing the decadal and average annual components, LOD shows the interannual to intra-seasonal variability of the atmosphere. Of particular interest is the LOD signature of the 1997/8 El Niño/La Niña events when LOD increased ~ +400 msec in ~1997.2 , followed by a ~-600 msec transition into La Niña in 1998.4, and with an integrated "sundial error" of ~0.2 seconds. The observed LOD variations are highly correlated with conventional ENSO indices; it is rather remarkable that radio astronomical observations of quasars can be so closely correlated with barometric pressure differences between Darwin and Tahiti!
The VLBI community has begun a program that will improve the temporal coverage and accuracy of earth orientation measurements. The new Mark-4 VLBI data system will give a twofold increase in the sensitivity and a significant improvement in correlation capability. This program has been named CORE: Continuous Observation of the Rotation of the Earth.

JSG14/E/03-A3 Poster 1103-02

BENEFITS FROM A COMBINED GPS/GLONASS ANALYSIS FOR EARTH ROTATION STUDIES

Markus ROTHACHER (Astronomical Institute, University of Berne, Sidlerstr. 5, M CH-3012 Berne, Switzerland, email: rothacher@aiub.unibe.ch) Robert Weber (Department of Advanced Geodesy, Technical University of Vienna, Gusshausstr. 27-29, A-1040 Vienna, Austria)

Since the start of the International GLONASS experiment (IGEX) in October 1998, the Center for Orbit Determination in Europe (CODE) is processing a global network of GPS/GLONASS receivers on a routine basis. This development opens up the possibility to study the benefits that may result from a combination of the IGEX solutions with the global GPS-only solutions (IGS network) for the estimation of earth rotation parameters (ERPs). An improvement in the ERP estimates is to be expected mainly because of the following circumstances: (1) by adding GLONASS data, the number of satellites involved increases from 27 (present GPS constellation) to about 41;(2) the different orbit inclinations of the two systems (55 and 65 degrees in the case GPS and GLONASS, respectively) should help to separate LOD and nutation rate estimates from variations in the orbital elements common to all satellites; (3) because the revolution periods of the GLONASS satellites, in contrast to those of GPS, are not in a 2:1 commensurability with the Earth's rotation, the impact of orbital biases on the determination of subdaily ERPs are less critical; (4) the improved satellite geometry should result in a better decorrelation of station heights and troposphere zenith delay parameters and thus, indirectly, to more accurate ERP estimates.RPs from combined GPS/GLONASS solutions will be presented and they will be compared to values from GPS-only solutions to assess the impact of the factors listed above.

JSG14/E/22-A3 Poster 1106-03

COMBINATION OF VLBI, GPS AND SLR DATA AT THE OBSERVATION LEVEL - NEW RESULTS

Per Helge Andersen (Forsvarets forskningsinstitutt, P. O. Box 25, N-2007 Kjeller, Norway, and Institute of Theoretical Astrophysics, P. O. Box 1029, Blindern 0315, University of Oslo, Norway, email: per-helge.andersen@ffi.no)

A significant number of VLBI and SLR stations are equipped with GPS receivers. A few true fundamental stations with all three techniques even exist. Each technique has its strength and weakness with respect to the determination of geodetic parameters and together they complement each other in a way that should be fully taken advantage of in the data analysis. The simultaneous analysis of different data types at the observation level, due consideration of the physical interrelations, and presentation of results in a common reference system, are the main ideas behind the development of the GEOSAT software. A new and improved version of the software has been implemented with an automatic generation of 1) observation residuals and observation partial derivatives for VLBI, GPS and SLR, consistent at the 0.1 ppb level, and 2) a simultaneous arc-by-arc UD-filtering at the observations level. A very advanced multi-level (presently four parameter levels including stochastic parameter representations at each level) SRIF arc combination software for long-term solutions has been developed and validated. The main elements of the processing scheme will be presented. The first results with a simultaneous analysis of different space geodetic data types (VLBI, GPS, and SLR) at the observation level were presented at the IERS-98 symposium in Potsdam. That analysis was based on data from Jan 12 - Jan 23 in 1994. The analysis has recently been extended with significantly more observations. Results from the new analysis will be presented.

MONITORING GLOBAL GEOPHYSICAL FLUIDS BY SPACE GEODESY

B. F. CHAO (Space Geodesy Branch, NASA's Goddard Space Flight Center, Greenbelt, Maryland 20771, USA; email: chao@denali.gsfc.nasa.gov), V. Dehant, R. S. Gross, R. D. Ray, D. A. Salstein, M. Watkins

Since its establishment on 1/1/1998 by the International Earth Rotation Service, the Coordinating Center for Monitoring Global Geophysical Fluids (MGGF) and its seven Special Bureaus have engaged in an effort to support and facilitate the understanding of the geophysical fluids in global geodynamics research. Mass transports in the atmosphere-hydrosphere-solid Earth-core system (the "global geophysical fluids") will cause the following geodynamic effects on a broad time scale: (1) variations in the solid Earth's rotation (in length-of-day and polar motion/nutation) via the conservation of angular momentum and effected by torques at the fluid-solid Earth interface; (2) changes in the global gravitational field according to Newton's gravitational law; and (3) motion in the center of mass of the solid Earth relative to that of the whole Earth ("geocenter") via the conservation of linear momentum. These minute signals have become observable by space geodetic techniques, primarily VLBI, SLR, GPS, and DORIS, with ever increasing precision/accuracy and temporal/spatial resolution. Each of the seven Special Bureaus within MGGF is responsible for calculations related to a specific Earth component or aspect -- Atmosphere, Ocean, Hydrology, Ocean Tides, Mantle, Core, and Gravity/Geocenter. Angular momenta and torques, gravitational coefficients, and geocenter shift will be computed for geophysical fluids based on global observational data, and from state-of-the-art models, some of which assimilate such data. The computed quantities, algorithm and data formats are standardized. The results are archived and made available to the scientific research community. This paper reports the status of the MGGF activities and current results.

THE ROTATIONAL AND GRAVITATIONAL EFFECT OF EARTHQUAKES

Richard GROSS (Jet Propulsion Laboratory, California Institute of Technology, 4800 Oak Grove Drive, Pasadena, CA 91109, USA, email: Richard.Gross@jpl.nasa.gov)

The static displacement field generated by an earthquake has the effect of rearranging the Earth's mass distribution and will consequently cause the Earth's rotation and gravitational field to change. Although the coseismic effect of earthquakes on the Earth's rotation and gravitational field have been modeled in the past, no unambiguous observations of this effect have yet been made. However, the Gravity Recovery And Climate Experiment (GRACE) satellite, which is scheduled to be launched in 2001, will measure time variations of the Earth's gravitational field to high degree and order with unprecedented accuracy. In this presentation, the modeled coseismic effect of earthquakes upon the Earth's gravitational field to degree and order 100 will be computed and compared to the expected accuracy of the GRACE measurements. In addition, the modeled second degree changes, corresponding to changes in the Earth's rotation, will be compared to length-of-day and polar motion excitation observations.

LONG-PERIOD TIDAL VARIATIONS OF THE EARTH'S ROTATION RATE

SHAILEN D. DESAI and Richard S. Gross (both at Jet Propulsion Laboratory, California Institute of Technology, Pasadena, CA 91109, U.S.A, email: Shailen.D.Desai@jpl.nasa.gov, Richard.Gross@jpl.nasa.gov), John M. Wahr (Department of Physics, University of Colorado, Boulder, CO 80309-0390, U.S.A., email: wahr@lemond.colorado.edu)

Long-period tidal variations of the Earth's rotation rate are caused by the redistribution of mass associated with the respective elastic solid Earth tides, the ocean tide heights, and the anelasticity of the Earth's mantle, and by the relative angular momentum associated with the long-period ocean tide currents. The dominant contribution, from the elastic solid Earth tides, is known to high accuracy from theoretical and numerical analyses. However, the lack of global observations of the long-period ocean tides has limited the accuracy of predicted contributions

from these ocean tides. The anelastic response of the mantle at frequencies smaller than the seismic frequencies are somewhat uncertain but could be inferred from observations of the long-period tidal variations of the Earth's rotation rate with improved predictions of the contribution from the ocean tides.
Almost global empirical models of the monthly and fortnightly ocean tides estimated from TOPEX/POSEIDON altimetry are used to predict their respective contributions to variations of the Earth's rotation rate. Observed long-period tidal variations of the Earth's rotation rate are estimated from the SPACE98 time series and the residual between these observations and the sum total of the predicted contributions from the elastic solid Earth tides and the ocean tides is used to infer anelastic properties of the Earth's mantle at the monthly and fortnightly periods.

TEMPORAL VARIATIONS OF OCEAN TIDAL TERMS IN UT1–UTC

Oleg TITOV (Astronomical Institute of Saint-Petersburg University, Bibliotechnaya sq., 2, Petrodvorets, Saint-Petersburg, 198904, Russia, email: oleg_titov@usa.net)

Global redistribution of mass water causes a variations in Universal Time. VLBI technique allows to detect and estimate the corresponding oceanic tides with periods near 12 and 24 hours. Usually, scientists obtain the estimates using global set of VLBI data. Possibility of the tides variations from year to year is considered this paper. About 500 VLBI experiments (NEOS-A, CONT'96, etc.) from 1991 till 1998 year were analyzed. All reductional calculations have been made using OCCAM software. Least squares collocation method (LSCM) provides us the time series of UT1–UTC variations with high temporal resolution (one point for 3-5 minutes). The full number of points exceeds 100.000. Therefore the standard deviation of yearly estimates is reasonable. Variations of UT1–UTC obtained using the LSCM are in a good agreement with ones recommended by IERS Conventions. Estimates of main tidal terms in UT1–UTC independently for every year as well as for full set of data are presented. It is shown that the yearly estimates are slightly differ from each other. The various reasons of the effect are discussed.

ATMOSPHERIC ANGULAR MOMENTUM FUNCTIONS SIMULATED WITH THE JMA GLOBAL MODEL FOR THE PERIOD OF 1955-1994

I. Naito (National Astronomical Observatory, Mizusawa, Iwate, Japan), Y-H Zhou (Shang Hai Observatory, Shang Hai, China), M. Sugi (Meteorological Research Institute, Tsukuba, Japan), R. Kawamura (Toyama University, Toyama, Japan), and N. Sato (Japan Meteorological Agency, Tokyo)

Axial and equatorial atmospheric angular momentum (AAM) functions calculated from an ensemble mean data of the three independent 40-year integrated values for the period of 1955-1994 under the observed near-global sea surface temperature (SST) condition by Japan Meteorological Agency (JMA) global model are discussed in comparison with those calculated from the reanalysis data during 1968-1994 of National Center for Environmental Prediction (NCEP) and from JMA's operational objective analysis data during 1984-1994 and the inferred functions during 1968-1994 from the observed length of day (LOD) and polar motion data, respectively. For comparisons in seasonal variation during 1984-1994, in general, the wind term for the axial AAM function agrees well with those from JMA's operational and NCEP's reanalysis data and roughly with the inferred function from the observed LOD. However, its semi-annual term is over-estimated, suggesting that the model unreliably simulates the subtropical zonal winds. On the other hand, the pressure term for the equatorial AAM function is considerably over-estimated with respect to those from JMA's operational and NCEP's reanalysis data, indicating that the SST driven global atmospheric motion induces too large seasonal variations in redistribution of atmospheric mass occurring mainly between the Eurasian Continent and the North Pacific Ocean.

SEASONAL-SCALE THREE DIMENSIONAL ANGULAR MOMENTUM BUDGETS FOR ATMOSPHERE-MANTLE SYSTEM

Yuichi Aoyama (School of Mathematical and Physical Science, The Graduate University for Advanced Studies, Mizusawa, 023-0861, Japan, email: aoyama@miz.nao.ac.jp) Isao Naito (National Astronomical Observatory, Mizusawa, 023-0861, Japan, email: naito@miz.nao.ac.jp)

Atmospheric contributions to seasonal variations of length of day (LOD) and wobble are evaluated during 1988 - 1997. The data sets used here are SPACE97 for LOD, EOP97C04 for wobble, and two atmospheric angular momentum (AAM) functions calculated from objective analysis data of Japan Meteorological Agency (JMA) and reanalysis data of National Centers for Environmental Prediction (NCEP). The axial AAM functions agree well in annual variation and roughly in semi-annual variation with inferred function from the observed LOD. However, there is a discrepancy between the equatorial AAM functions and the inferred function from the wobble in annual variation, where the wind terms show a considerable disagreement between JMA and NCEP, which arises mainly from tropospheric wind. Spatial distributions of regional wind contributions in annual variation to the LOD and the wobble are further discussed. In semi-annual variation for equatorial component, on the other hand, the AAM functions explain only a small part of the observed wobble, indicating that there remain a major other source.

ON THE CHANDLER WOBBLE AND ITS EXCITATION

Dr Aleksander Brzezinski

For the estimation of the Chandler wobble parameters it is important that the input time series expressing polar motion and its excitation are possibly long and homogeneous in time. The two series which seem to meet such requirements, hence are potential sources of new information about the Chandler wobble, are: 1) polar motion (PM) series spanning 1899.7-1992.0, derived from a new global adjustment of the optical astrometry observations by Vondrak et al. (1998), and 2) 40-years time series of the atmospheric angular momentum (AAM) estimates, computed on the basis of results of the NCEP/NCAR reanalysis project by Salstein and Rosen (1997). In this presentation we report an attempt to obtain from the new PM and AAM series improved estimates of the Chandler wobble parameters, the frequency of resonance F and the quality factor Q. Different stochastic models are used to express the wobble excitation. Finally, based on the AAM reanalysis data we address the problem, to which extent the observed Chandler motion can be explained by the atmospheric excitation.

VARIATIONS IN EARTH'S GRAVITATIONAL FIELD CAUSED BY THE POLE TIDE

S.R. DICKMAN (Department of Geological Sciences, State University of New York, Binghamton, NY 13902-6000, USA, email: dickman@bingvmb.cc. binghamton.edu)

The pole tide is the oceanic response to the Chandler wobble. The re-distribution of mass accompanying the pole tide causes periodic changes in Earth's gravity field. If the Chandlerian polar motion m is decomposed into prograde and retrograde components according to m = MP exp(ist) + MR exp(-ist), where s is the Chandler frequency, then the pole tide's effects on gravity can be theoretically predicted in terms of MP, MR, and oceanic response factors.
I have employed a previously developed spherical harmonic dynamic ocean tide model to calculate the open-ocean response factors for the pole tide. Using these factors and the Chandler wobble amplitude observed over the past decade, I have computed the 14-month periodic contributions to the spherical harmonic coefficients of the gravitational potential. For example, including tidal loading of the underlying solid earth, the pole tide's contribution to J2 is typically ~1.3x10^-12, whereas its contributions to C21 and S21 are typically ~3.6x10^-11 and ~2.2x10^-11, respectively.
In addition to these results, I will also discuss how observationally based oceanic response factors -- determined, e.g., from satellite analyses or tide gauge data -- could be used to produce alternate estimates of the pole tide contributions to gravity. An illustration including the North and Baltic Seas, where the pole tide has long exhibited dramatic enhancements, will be presented.

BOUNDS ON CORE-MANTLE COUPLING AT SEASONAL PERIODS FROM COMBINED ROTATIONAL AND GRAVITATIONAL DATA

S.R. DICKMAN (Department of Geological Sciences, State University of New York, Binghamton, NY 13902-6000, USA, email: dickman@bingvmb.cc. binghamton.edu)

Excitation of variations in the Earth's rotation is often separated into 'matter' and 'motion' terms, which act to change Earth's inertia tensor and provide relative angular momentum, respectively. The outcome of any such excitation also depends on how well the core and mantle are rotationally coupled. Geophysicists have generally assumed zero axial coupling on time scales shorter than decadal. Recent work [Dickman & Nam 1995], in which observed and predicted tidal changes in the length of day were compared, found that such coupling is indeed weak on a nine-day time scale. However, the situation is unclear at longer periods. Knowing the frequency dependence of rotational coupling would yield more accurate estimates of excitation, and could provide clues to the state of Earth's deep interior.
A wide variety of processes -- some of which are not very well quantified -- contribute to seasonal changes in the length of day. Comparisons between observations and predictions, with the latter based on differing amounts of core-mantle coupling, may be too uncertain to allow the true extent of coupling to be resolved. Alternatively, recognizing that second-degree gravity coefficients reflect the total mass re-distribution contributing to rotational excitation [e.g. Eanes et al. 1997], we can incorporate the seasonal components of time- variable gravity data into our predictions, leaving only the 'motion' terms to be modeled (e.g. ocean currents) or measured (e.g. winds). Preliminary bounds on the extent of axial coupling at seasonal periods will be discussed.

ATMOSPHERIC FORCING OF POLAR MOTION AND CLIMATE PATTERNS

Jolanta NASTULA (Space Research Centre of the PAS, 00-716 Warsaw, Bartycka 18a, Poland, Email: nastula@cbk.waw.pl) and David A. Salstein (Atmospheric and Environmental Research, Inc. 840 Memorial Drive Cambridge, MA 02139, USA, Email: salstein@aer.com)

Atmospheric excitation of polar motion occurs by means of angular momentum exchange with the solid Earth in the equatorial plane. We assess such atmospheric forcing by comparing geodetic polar motion and atmospheric excitation functions. Atmospheric excitation of polar motion has different strengths on various time scales; we contrast the "subseasonal" and the "seasonal-interannual" regimes, with 150 days, the boundary between the two. Atmospheric excitation functions were computed from the new 50 year - long reanalysis system of the U.S. National Centers for Environmental Prediction and National Center for Atmospheric Research, which include effects of winds up to 10 hPa and surface pressure. In exploring how different regions were responsible for high frequency polar motion, we had already isolated the Eurasia, North American, and other regions as important for exciting high frequency polar motion, with the northern and central Eurasian region (EUR) especially prominent in this regard. Here we search for connections between EUR and certain well-known atmospheric behavior: the El Nino, the North Atlantic Oscillation, and the North Atlantic/Eurasian patterns. Additionally, empirical orthogonal function were computed for both temporal bands. The first such modes contain patterns with strong variations over southern oceans.
However, use of the inverted barometer correction (IB) reconfirm the overriding importance of Eurasia. Using the results of an ocean model run, we assess the regional variability of the excitation function within the oceans also.

INTERANNUAL VARIATIONS IN LENGTH-OF-DAY AND ATMOSPHERIC ANGULAR MOMENTUM WITH RESPECT TO ENSO CYCLES

Joachim Hoepfner (GeoForschungsZentrum Potsdam, Division 1: Kinematics and Dynamics of the Earth, Telegrafenberg, D-14473 Potsdam, Germany, email: ho@gfz-potsdam.de)

At interannual time scales, the excitation of variations in Length-Of-Day (LOD) is caused by two prominent signals in the atmosphere: The El Nino-Southern Oscillation (ENSO) and the Quasi-Biennial Oscillation (QBO). In this study, the axial Atmospheric-Angular-Momentum (AAM) component CHI3 is related to changes in LOD. Focussing on the interannual variations in the solid Earth-atmosphere axial angular momentum budget, we consider the Low- Frequency Component and the Quasi-Biennial Oscillation in LOD and AAM in their temporal variability. In particular, we use the time series of LOD data of the series EOP (IERS) 97C04 from 1962 to 1998 and of CHI3 data of the series AAM (NCEP) Reanalysis from 1958 to 1998, AAM (JMA) from 1983 to 1998, AAM (ECMWF) from 1988 to 1996, and AAM (UKMO) from 1986 to 1998. To separate the interannual signals, we have applied low-pass and band- pass filters. For comparison, the monthly data of the Southern Oscillation Index (SOI), as given by the NOAA by the difference in the surface pressure between Tahiti and Darwin, Australia, have been processed and are exhibited in the same manner. Concentrating on interannual time scales, the main results are quantitative estimates of the variability of two components, in particular of the Low-Frequency Component and the Quasi-Biennial Oscillation, in the LOD and AAM variations and also in the SOI variations and quantitative estimates of the total interannual AAM and SOI signals. Besides, the decadal LOD component is available as a function of time. The results show the character and the time evolution of the various portions. They should contribute to the problem of the interpretation concerning the interannal LOD changes associated with the global-scale ENSO cycles.

ATMOSPHERIC ANGULAR MOMENTUM VARIABILITY SIMULATED WITH THE ECHAM3-T21 GLOBAL CIRCULATION MODEL AND ITS INFLUENCE ON THE EARTH'S ROTATION PARAMETERS

JOCHEN ELBERSKIRCH, Andreas Hense (both at Meteorologisches Institut, Universit at Bonn, Auf dem Hugel 20, 53121 Bonn, Germany, e-mail: jelbers@uni-bonn.de

The simulated Atmospheric Angular Momentum (AAM) budget of the ECHAM3-T21 global circulation model (GCM) is analysed. Five simulations with different initial conditions are forced by observed monthly means of sea surface temperature and global ice coverage (GISST-dataset from Hadley center, Bracknell) for the corresponding period from 1949 to 1994. The three components of AAM are compared to the Earth's rotation parameters (change of length of day and polar motion), respectively. A frequency analysis is performed with Fourier- and Wavelettransformation. The third component of simulated relative AAM for the mean of the five simulations shows significant variability on different timescales, particular on the interannual timescale and it correlates very well with the timeseries of the change of LOD. The correlation of the other components are somewhat lower, which is not surprising. For the understanding of the physical process of the AAM transfer between atmosphere, ocean and solid earth, a canonical correlation analysis is carried out. This technique yields typical spatial anomaly patterns of maximum correlation between AAM and torques for all components. The application of lagged correlation analysis shows the spatial development of anomalous mountain torques if anomalies of relative AAM are existent. The mountain torque offers a very surprising pattern before and when the maximum anomaly of relative AAM occurs. To compare the results of the ECHAM3 model the NCEP Reanalysis data from 1958 - 1997 are also used.

INTERANNUAL VARIABILITY IN EARTH ROTATION AND ATMOSPHERIC ANGULAR MOMENTUM: EL NIÑO CONNECTIONS

J. O. DICKEY (Jet Propulsion Laboratory, California Institute of Technology, 4800 Oak Grove Drive, Pasadena, CA 91109-8099; tel 818–354–3235; e-mail: jean.o.dickey@jpl.nasa.gov); P. Gegout (Ecole et Observatoire des Sciences de la Terre Laboratoire de Dynamique Globale, rue Rene Descartes 67084 Strasbourg Cedex, France; Tel: [33] 3 88 41 66; email: Pascal.Gegout@eost.u-strasbg.fr); S. L. Marcus (Jet Propulsion Laboratory, California Institute of Technology, 4800 Oak Grove Drive, Pasadena, CA 91109-8099; tel: 818–354–3477; e-mail: steven.l.marcus@jpl.nasa.gov)

Comparisons between length of day (LOD) and the strength of the ENSO cycle, represented by the Southern Oscillation Index (SOI, the difference in sea level pressure between Darwin and Tahiti) series, have indicated striking agreement, with high interannual values of LOD generally coinciding with ENSO events. During an ENSO event, the SOI reaches a minimum, leading to an increase in atmospheric angular momentum (AAM) associated with the collapse of the tropical easterlies. Further increases in AAM may result from a strengthening of westerly flow in the subtropical jet streams. Conservation of total angular momentum then requires the Earth's rate of rotation to slow down, thus increasing LOD.
The impact of the 1997-98 ENSO event will be presented in context of angular momentum exchange utilizing LOD, SOI and AAM (both global and latitudinally belted) data. We have utilized the NCEP reanalysis from 1959 to 1998 from the surface to 100mb to examine the effect of the tropospheric zonal winds. Special emphasis will be placed on the globally coherent polarward propagation observed on interannual time scales; decadal variability will also be addressed. The techniques utilized include traditional recursive filter and multi-channel singular spectrum analysis (M-SSA); comparisons will be made with previous events, especially the 1982–83 event.

OCEAN INDUCED VARIATIONS OF EARTH ROTATION ON TIME SCALES FROM HOURS TO YEARS - RESULTS FROM A NUMERICAL WORLD OCEAN MODEL

Juergen SUENDERMANN, Maik Thomas (both at Institut fuer Meereskunde der Universitaet Hamburg, Troplowitzstr. 7, D-22529 Hamburg, Germany, email: suendermann@ifm.uni-hamburg.de)

The world oceans motion and mass fields cause significant variations of Earth orientation parameters on various time scales. Generally, these ocean induced changes are attributed either to tidal forces or variations of the general circulation. Analogously, numerical world ocean models can still be divided into Ocean General Circulation and tidal models. But it is questionable if the neglect of non linear interactions by a linear superimposition of both components of motion is accurate, especially with respect to frequencies that are typical for both circulation and tides. To include non linear interactions an OGCM is additionally forced with the complete astronomical tidal potential without decomposition into fourier components. Long-time integration and a time step of one hour offer a wide spectrum of analysis of ocean induced oscillations of Earth rotation. Time series of relative and rotational angular momentum resulting from three model runs from 1949 to 1994 with different forcing conditions are used to examine the role of the oceans with respect to excitation of polar motion and changes in length-of-day on time scales from hours to years. Since the model allows to treat the particular contributions of the three oceans separately, characteristic frequencies of global ocean basins can be identified.

THE ROLE OF ATMOSPHERE AND OCEAN IN EXCITING VARIABILITY IN THE EARTH'S ROTATION AND GRAVITY FIELD

Thomas J. JOHNSON (U.S. Naval Observatory, 3450 Massachusetts Ave. NW, Washington, DC 20392-5420, USA, email: tj@casa.usno.navy.mil) Clark R. Wilson (NASA Headquarters, Code YS, 300 E St. SW, Wash. D.C. 20546; and The University of Texas at Austin, Austin, TX. 78712, email: cwilson@hq.nasa.gov) Benjamin F. Chao (NASA Goddard Space Flight Center, Code 926, Space Geodesy Branch, Greenbelt, MD 20771 email: chao@denali.gsfc.nasa.gov)

This research examines the role of the atmosphere and ocean in exciting the temporal variability in the Earth's rotation and gravity field. The main focus of this paper will be on the role of the ocean as predicted by 10 years of data products from the Parallel Ocean Climate Model. Unlike earlier rigid-lid models, this free-surface ocean model allows the estimation of the variability in the oceanic angular momentum and Stokes coefficients resulting from mass redistribution and relative motion that is more representative of the real ocean. First, we compare the atmosphere and ocean model's angular momentum time series to the polar motion and length of day variations. Then, we use the Stokes coefficients computed from the atmosphere and ocean model's mass redistribution to examine the Earth's temporally varying gravity field. These temporal variations are observable as variations in the Earth's geocenter location and as perturbations of an orbiting satellite's orbital elements. We also investigate the seasonal and interannual variability predicted by the atmosphere and ocean models. These comparisons can be useful in estimating the possible role of other geophysical processes, such as continental water storage in exciting the variations in the Earth's rotationand gravity field.

HYDROLOGICAL AND OCEANIC EXCITATIONS OF EARTH ROTATION

C. R. Wilson [1,2,3] and J. L. Chen [1] Center for Space Research, University of Texas at Austin [1] Department of Geological Sciences, University of Texas at Austin [2] NASA Headquarters, Washington D.C. [3]

Motion and redistribution of water on the continents and in the oceans are likely to be the major contributors to the residual polar motion excitation not accounted for by the atmosphere. We investigate continental water storage change and its excitation of polar motion and length-of-day (LOD) variation using both a data assimilating hydrological model and climatological average datasets. We estimate oceanic mass contributions to earth rotation changes from TOPEX/Poseidon sea level observations adjusted by a simplified steric sea level change model. The results are compared with the residual excitations after atmospheric contributions are removed using the NASA GSFC GEOS-1 atmospheric model. Our findings include the following: Continental water storage change plays an important role in exciting polar motion and LOD at seasonal time scales; hydrological models exhibit significant differences with regard to the predicted contribution to earth rotation changes, indicating the immaturity of understanding of the global hydrological cycle; The assimilated-data hydrological model provides generally better agreement with earth rotation observations; and non-steric sea level changes indicate a significant polar motion and LOD excitation source from ocean mass redistribution over a wide range of time scales.

EARTH ROTATION AND OCEAN CIRCULATION INTERACTION

Nils-Axel Mörner Paleogeophysics & Geodynamics, S-10691 Stockholm, Sweden,
email: morner@pog.su.se

The ocean circulation is not only driven by thermo-haline forces. The interchange of angular momentum between the hydrosphere and the solid Earth is another fundamental factor. This can be demonstrated for the ENSO-events, for the last centuries' instrumental data, for decadal-to-century changes during the Holocene, for the high-amplitude climatic-eustatic changes some 13-10 ka ago, and for the main glacial/interglacial cycles. The oceans have a remarkable heat-storing capacity. Any change in the ditribution of the water masses will have strong effects on the global climatic temperature distribution. The oceans contain huges masses of water of a reasonably high density that are constantly circulating both horizontally and vertically over the globe. Any irregilarity in this circulation leads to a redistribution in total mass which affects the sea level and has to be compensated by an interchange of angular momentum between the hydrosphere and the solid Earth. This means that we in the recorded past changes in climate and in sea level can obtain information about possible past changes in ocean circulation, too. And this is exactly what our paleo-records seem to indicate. During sunspot minima, the solar wind intensity decreased (read by increased in-fall of cosmic ray incrersing the 14C production and 10Be content) which led to a speeding-up of the Earth's rate of rotation affecting the ocean circulation so that the a major current like the Gulf Stream sent less warm equatorial water along its northern branch towards NW Europe at the same time as Arctic water penetrated further south giving rise to severe cold periods in NW Europe and warm periond in S. Europe and N. Africa. The sudden changes in rotation at around 13,000 BP and 1000 AD, were both linked to trans-polar geomagnetic VGP-shifts and deformations of the gravitational potential surface besides their strong signals in the ocean circulation system.

TEN-YEARLY POLAR MOTION CONNECTED WITH PRECIPITATION CHANGES OVER NORTH AMERICAN AND EURASIAN CONTINENTS

Tetsuya Iwabuchi (The Graduate University for Advanced Studies, Mizusawa, 023-0861, Japan, email: iwabuchi@miz.nao.ac.jp) Isao Naito (National Astronomical Observatory, Mizusawa, 023-0861, Japan, email: naito@miz.nao.ac.jp)

A hydrologic excitation model of ten-yearly polar motion appearing in the combined polar motion data of five-daily IPMS and SPACE94 during 1962-1995 is proposed. The model is based on the exponential decay of the land water storage supplied by precipitation. The NOAA monthly gridded precipitation anomaly data in 5 degrees-square are used for the model estimation. By assuming that the land water decreases exponentially with time, about 37% of the ten-yearly polar motion can be explained when decay parameter of 3.7 month. The seesaw-like changes of precipitation that efficiently excite the ten-yearly polar motion are also confirmed between the North American Continent and western region of the Eurasian Continent. From these results, a new look at the ten-yearly hydrological cycle system is advocated, which consists of atmospheric variations connected with the North Atlantic Oscillation, see-saw like sea level changes along both coastal regions in the North Atlantic Ocean, and precipitation changes in the North American Continent and the Eurasian Continent. The essential factor to determine the ten-year scale in the system is considered to be hydrological cycle in the two continent.

INFLUENCES OF HYDROLOGICAL MASS REDISTRIBUTIONS ON EARTH ROTATION

R. DILL, H. Drewes, B. Richter, H. Schuh DGFI, Marstallplatz 8, D-80539 München, Germany email: dill@dgfi.badw.de

Hydrological processes cause local, regional and global redistributions of water masses which have an impact on the rotation of the Earth. We distinguish between direct and indirect influences of these mass motions on the rotation vector. Direct effects result from the displacements of water (matter term) which change the tensor of inertia of the whole Earth and from the velocity of water masses relative to a terrestrial reference frame (motion term). Redistributions of water masses influence also indirectly the Earth rotation by changing the tensor of inertia of the solid Earth due to load deformations. The indirect effects of atmospheric and oceanic loading and also the influence of small surface deformations caused by snow and ice loads or groundwater level variations are studied. Different realistic models of global snow cover are used to estimate and compare the magnitude of the resulting perturbations in Earth rotation. By a combined approach of atmospheric water balance, river runoff and sea level variation,the monthly continental ground water storage is determined. The influence of global and regional ground water variations will be discussed. Small regional effects are also looked at, especially the drying up of the Aral Sea and the filling of big new dams, like the proposed Three Gorges Dam in China.

JSG14/P/01-A3 Poster **1206-23**

CLIMATE CYCLES IN VARIATIONS OF THE GRAVITY FIELD AND POLAR MOTION

Horst JOCHMANN (GeoForschungsZentrum Potsdam, Division of Kinematics and Dynamics of the Earth, Telegrafenberg, D-14473 Potsdam, Germany, email: vroni@gfz-potsdam.de)

Global change is accompanied by mass redistributions (e.g. mass exchanges between the hydrosphere and the cryosphere, and variations of the global atmospheric and oceanic circulations). These changes of the mass distribution at the earth produce temporal variations of

the earth's rotation and the gravity field. The discussions with respect to earth rotation are confined to polar motion, because the variation of this parameter is mainly caused by redistributions of masses, while length of day variations depend nearly completely on motion effects. So, polar motion is more closely related to gravity field variations than changes of the length of day.The amplitude spectrum of the temporal variation of polar motion contains well known climate cycles (e.g. 11, 13, 22, 35 and 80 years). Similar cycles are found in the atmospheric excitation function of polar motion. But, this excitation function can not be identified as the only source of these cycles. It was found that inner core motion contributes to a certain extend to the climate cycles in polar motion.
Modem satellite missions (CHAMP and GRACE) will determine the gravity field with increased accuracy in near future. This allows a more accurate calculation of its temporal variation. Estimating the influence of long term atmospheric mass redistributions on the gravity field it could be shown that besides the dominating annual period a number of low frequent periods are expected to be contained in the gravity field. The amplitudes of these terms are in the same order of magnitude as the annual one and can be partly identified as climate cycles. The expected temporal behaviour of the Stokes coefficients infers the global property of the climate cycles.

EARTH ROTATION, ICE AGES AND SEA-LEVEL CHANGES: INFLUENCE OF MANTLE VISCOSITY AND SOLID-EARTH STRATIFICATION ON THEIR INTERDEPENDENCE

L.L.A. Vermeersen, R. SABADINI (Dipartimento di Scienze della Terra, Sezione Geofisica, Universita di Milano, Via L. Cicognara 7, I-20129 Milano, Italy)

It has been realized long before the plate tectonics revolution of the sixties that there might exist close connections between changes in the position of the earth's rotation axis with respect to the earth's surface (polar wander), variations in sea level and the rise and decline of Ice Ages on geological time scales. Quantitatively, the modeling of these interrelationships has received renewed attention in the last few years, after initial attempts to relate these phenomena in the eighties by means of viscoelastic solid earth relaxation models had shown its feasibility. We show that the radial mantle viscosity profile and the layering of the solid earth have important influences on these interactions.

CORE MANTLE ANGULAR MOMENTUM EXCHANGE IN GEODYNAMIC MODELLING

Weijia Kuang and Benjamin F. Chao (Space Geodesy Branch, Code 926, NASA, Goddard Space Flight Center, Greenbelt, MD 20731, USA, email: Kuang@santafe.gsfc.nasa.gov)

Kinematic studies of geomagnetic data and Earth rotation observations have demonstrated that the decadal fluctuation of the length of day (LOD) results from the exchange of the angular momentum between Earth's core and the solid mantle. However, our knowledge about the dynamics responsible for the angular momentum exchange, i.e. the coupling torques across the core-mantle boundary (CMB), is limited in the past based on very simple theoretical models.
To understand better the dynamics of the angular momentum exchange across the CMB, we introduce a heterogeneous mantle into our geodynamo model that simulates 3-D convective flow in the Earth's outer core. In the model, the mantle rotates subject to the coupling torques exerted on the CMB. In particular, we assume that the CMB is spherical but superimposed with a small amplitude (< 3 km), large scale (~ 1000km) and non-axisymmetric topography. We also assume that the electrical conductivity of the lower mantle (D"-layer) is finite and spatially variant. The heterogeneity introduced in the model follows the lower-mantle seismic tomography. With this model, we are able to study the topographic coupling and the magnetic coupling along with the convective flow in Earth's outer core. Furthermore, this model can be used to examine the effect of the couplings on the polar motion and nutations of the Earth.

THE EARTH'S POLAR ZONALITY MOTION DURING THE LATE WEICHSELIAN BASED ON PALAEOCRYOSPHERE STUDIES

Robert MOKRIK (Institute of Geology, Sevcenkos 13, 2600 Vilnius, Lithuania,
email: mokrik@geologin.lt)

Periglacial periods during the Pleistocene in the Estonian Homocline have formed a permafrost up to 500m thick. Final phase of permafrost according to radiocarbon data had an extensive period of periglacial activity occured 30-26 ka BP during the Huneborg-Denekamp Stadial time before Late Weichselian ice maximum. It is 6 ka BP earlier than in the West Siberian Craton (24-15 ka BP). That was related with polar zonality movement of the Earth. Permafrost processes caused metamorphism in the Cambrian-Vendian aquifer. As a result, the mineralization of groundwater decreased in comparison with the initial pre-Pleistocene period from 4-10 to 0,5-1 g/l. Hydrocarbonate-sodium chlorides prevail in the groundwater owing to degrees of calcium and magnesium carbonates and sulphates. The last cryogenese (30-26 ka BP) had lightened oxygen -18 isotope composition of groundwater at 2 per mil. The last Scandinavinian Ice Sheet 11 ka BP had retreated northwards from the Estonian Homocline. It formed ice-dammed Baltic Ice Lake (BIL), having to 80m higher level in comparison with the Ocean. BIL took part in recharge of the Cambrian-Vendian aquifer for a short time. That is why an additional oxygen-18 lightening (1,5-2 per mil) of groundwater has been happened. Total isotope oxygen-18 lightening of groundwater during the Pleistocene is 13-14 per mil. Existence of the permafrost in Estonia is confirmed also by data of ratio uranium isotopes 234 U/238U activity in the Cambrian-Vendian aquifer. This ratio varies up to 40. These waters are unique in the European hydrogeological practice and reflect the cyclic cryosphere change during Quaternary. The permafrost in the Estonian domain caused great thermokarst activity which originated the valley shapes of lakes Peipus, Vortsjarv, Gulf of Parnu and Gotland Proper.

ON COSMOLOGICAL ORIGIN OF CERTAIN GEODETIC FEATURES OF THE EARTH

A.O. Adekugbe-Joseph (Center for Fundamental Study, P.O.Box 22415 University of Ibadan P.O., Ibadan, Oyo State, Nigeria. Email: nigeria@netbox.com)

The angle 66.5 degrees of inclination to the ecliptic of earth's rotational axis (rotational slanting of the earth), has been predicted accurately, and the ratio of polar diameter to equatorial diameter,(polar flattening of the earth), of 0.997 has been recalculated exactly, within a new cosmological model.
An instantaneous rate of increase of earth's radius of 0.108cm/yr, as well as instantaneous relative drift rate of 0.108y cm/yr of two points with longitudinal separation of y degrees along the equator, have been calculated as consequences of the expansion of the earth with the universe in the new model. A remarkable agreement of the predicted rate of increase of earth's radius of 0.108cm/yr, earth's rotational slanting of 66.5 degrees and earth's polar flattening of 0.997 is shown.
The slight westward deflection in the north and eastweard deflection in the south of continental plates have also been explained as local consequence of the new cosmological model.
These numbers as well as the westward deflection in the north and eastward deflection in the south of continental plates are increasing, but discernible changes occur in time scales of between 10 million and billion years only.

THE EARTH GRAVITY MODEL: STATUS AND PROSPECTS

Byron D. Tapley The University of Texas at Austin Center for Space Research R1000 Austin, TX 78712

The requirements for an Earth Gravity Model with both high spatial resolution and high accuracy have been articulated for over three decades. During the past decade, there has been considerable improvement in the global properties of the current models. A number of new, high accuracy tracking systems has provided data sets with enhanced accuracy and better global coverage. The use of satellite altimeter measurements has substantially improved the coverage over the oceans, and the release of several important gravity sets collected over the continents has allowed These improvements. Along with the improved models, the demands for gravity to support a number of important scientific investigations has increased. The utilization of the data from the highly successful TOPEX/Poseidon and ERS altimeter missions is still limited by geoid error. Further, the interest in mass variations within, and themass exchange between, the atmosphere, oceans and solid surface have lead to increased interest in the temporally varying characteristics of the gravity field. To satisfy the increased demands, there have been a number of new gravity mappingprograms that span the spectrum from improved surface measurements tonew an exciting satellite missions. In this presentation, we summarize the status ofcurrent knowledge in the modeling of the earths gravity field, note some of the limitations in the current data, discuss the currents requirements and describe future opportunities to improve the gravity model. In particular, the promising suite of space missions, CHAMP, GRACE and GOCE, which are scheduled to be implemented during the first decade of the next century will be described and their contributions to the gravity model development will be discussed.
Finally, the conceptual and computational challenges associated with these new data sets will be described.

OCEANOGRAPHY FROM GRAVITY MEASUREMENTS.

Chris W Hughes and Trevor F Baker (CCMS Proudman Oceanographic Laboratory, Bidston Observatory, Birkenhead, Merseyside L43 7RA, UK, Email:cwh@ccms.ac.uk, tfb@ccms.ac.uk)

In principle, measurements of the global gravity field should provide information about tides and ocean circulation. In practice, to date, this has been greatly complicated by the fact that terrestrial observations of time variations in these quantities have been at a limited number of sites, for which the movement of the observation point due to deformation of the earth must be taken into account. Satellite observations have the advantage of being global and decoupled from the solid earth, and have provided useful information about changes in gravity at tidal periods and in relation to post-glacial rebound, but are generally limited to very coarse spatial resolution. The launch in 2001 of a pair of satellites dedicated to monitoring the earth's gravity field and its variations on length scales down to 300 km will dramatically change the way such information can be used. Over the oceans it will be possible to invert this gravity information to give a measure of changes in ocean plus atmospheric mass distribution, and therefore in ocean bottom pressure. This is a fundamental quantity which relates not only to the moment of inertia of the ocean, but also to its coupling with the solid earth. New theoretical results suggest, and model diagnostics confirm, the important role of ocean bottom pressure in western boundary currents and at high latitudes, via a coupling of the oceanic angular momentum and vorticity balances. Results will be presented showing that it should be possible to use variations in global gravity to infer changes in abyssal ocean currents and important aspects of the thermohaline circulation - a unique ability for a remote sensing technology.

HYDROLOGICAL AND GLACIOLOGICAL APPLICATIONS OF GRACE; ESPECIALLY GRACE/GLAS SYNERGY AND ANTARCTIC MASS BALANCE

John Wahr (Dept of Physics and CIRES, U of Colorado, Boulder, CO 80309, US,
email: wahr@lemond.colorado.edu) CHARLES BENTLEY (Dept of Geology and Geophysics, U of Wisconsin, 1215 West Dayton Street, Madison, Wisconsin 53706, US,
email: bentley@geology.wisc.gov) Duncan Wingham (Dept of Space and Climate Physics, University College London, 17-19 Gordon Street, London, England WC1H OAH, email: djw@mssl.ucl.ac.uk)

GRACE is a dedicated satellite gravity mission, approved and scheduled for a 2001 launch as part of NASA's Pathfinder Program and with assistance from DLR. GRACE will map the earth's gravity field to unprecedented accuracy and spatial resolution every few weeks. Time-variable gravity inferred from these measurements has applications for virtually all of the earth sciences, including hydrology, oceanography, glaciology, climatology, and solid earth physics. We will discuss the sort of hydrological and glaciological information that can be derived from the GRACE data. We will then concentrate specifically on using the data to learn about the mass balance of the Antarctic ice sheet. We will show that by combining GRACE data with laser altimeter measurements from NASA's GLAS mission, it should be possible to determine Antarctica's contribution to the present-day rise in global sea level to an accuracy approaching 0.2 mm/yr over a five year period.

GLOBAL AND REGIONAL GEOPHYSICAL PROCESSES AFFECTING THE GRAVITY FIELD AND ITS TIME VARIATIONS

R. SABADINI, L.L.A. Vermeersen, G. Di Donato (Dipartimento di Scienze della Terra, Sezione Geofisica, Universita di Milano, Via L. Cicognara 7, I-20129 Milano, Italy,
Email: bob@sabadini.geofisica.unimi.it); R. Devoti, V. Luceri, P. Rutigliano, C. Sciarretta (Telespazio, Matera, Italy); G. Bianco (ASI, Matera, Italy).

Integrated studies based on physical models of global and regional processes are of paramount importance to understand the complexities of the evolving Earth and, at the same time, to face the need of society to mitigate the consequences of environmental changes. Gravity data acquisition and modelling of global and regional geophysical processes at short and long time scales are keys to these issues. Joint inversions of secular changes in low degree harmonics of the geopotential based on new SLR analyses constrain the viscosity profile of the mantle and ongoing mass redistribution over the surface of the Earth, which is likely to be due to present-

day ice mass instabilities in alpine glaciers and/or to changes in the mass balance in Greenland and Antarctica. The rheological parameters inferred from the long wavelength, time dependent gravity field, and the density anomalies at crustal and lithospheric level, obtained from high resolution gravity space missions (GOCE), can be used as input lithospheric and mantle parameters in regional tectonic models. These allow to make predictions on important issues affecting our environment, such as sea level rise and stress accumulation in active seismic areas. Results are shown for the Mediterranean, severely affected by these natural risks.

ABSOLUTE SEA LEVEL AND GLOBAL GLACIAL ISOSTATIC ADJUSTMENT

W.R. Peltier(Department of Physics, University of Toronto, Toronto, Ontario, Canada M5S-1A7, email: peltier@atmosp.physics.utoronto.ca)

The global viscoelastic and self-gravitating theory of glacial isostatic adjustment(GIA), as recently reviewed in Peltier(1998, Rev. Geophys., 36, 603-689), has been extensively tested against a wide range of geological and geophysical observations. Since the future GRACE mission of NASA will deliver a rather high resolution model of geoid hight time dependence and since a major, and perhaps dominant, contribution to this time dependence is expected to be due to the GIA process, we clearly require the best possible theoretical model of this field. Geoid height is of course synonymous with absolute sea level. I will describe a complete analysis of the expected signal that includes the full influence of rotational feedback due to the changes of earth rotation that accompany this dynamical process.

CHANGES IN THE GEOPOTENTIAL OBSERVED WITH SLR

C. COX, S. Klosko (Raytheon ITSS Corp., Greenbelt, MD 20770; 301-441-4010;
email: ccox@magus.stx.com) B. Chao (Laboratory for Terrestrial Physics, NSAS/GSFC, Greenbelt, MD 20771)

Existing analyses of Satellite Laser Ranging (SLR) tracking data has yielded solution rates for low-degree zonals, in some cases up through J5. The secular zonal rate solution is improved using additional data and a new analysis technique applied in the processing of the SLR data. The new method effectively results in a continuous ephemeris in selected Keplerian orbit components, providing better estimates of the orbit plane accelerations, while retaining some of the accuracy of the shorter orbit solution arcs. The preliminary results of this technique, as applied to multiple satellite (LAGEOS, LAGEOS-2, Starllete, Stella, TOPEX/POSEIDON, and Ajisai) solutions for the secular rates will be presented. Additionally, the results of other new approaches for improving the resolution of the time varying gravity model by extending the temporal solutions to the low degree tesseral terms will be discussed. The secular zonal results, and those obtained earlier by Nerem and Klosko (1996) and Cheng et al. (1997) are combined with observed global sea level rise, and the secular polar motion rates in an inverse solution to provide constraints on geophysical models describing post-glacial rebound and ice sheet mass balances. Although the number of well resolved geopotential terms is limited, the inverse solutions are promising and provide results consistent with IPCC estimates of ice sheet mass balance and realistic contrasts between upper and lower mantle viscosity.

OBSERVING THE TIME-VARYING EARTH'S GRAVITY FIELD USING SATELLITE TRACKING DATA

M. K. Cheng and B. D. Tapley, Center for Space Research The University of Texas at Austin Austin, Texas 78759-5321, U.S.A., e-mail: cheng@csr.utexas.edu

Mass redistribution within the Earth causes the temporal variations in the Earth's gravity field. Analysis of the long-term satellite laser ranging (SLR) tracking data has provided the capability for measuring the time-varying Earth's gravitational field. In this paper, we present recent results for the secular rates of low degree and order geopotential coefficients and the seasonal variations of the zonal harmonics from analysis of over 23 years SLR data collected from 8 geodetic satellites, including Starlette, Ajisai, Stella, LAGEOS I and II, Etalon I and II, BE-C. In addition, DORIS data provide an important complement to the SLR data to monitor the temporal variations in the non-zonal terms. Comparisons of the results from analysis of the satellite tracking data and predicted from the geophysical models demonstrate that analysis of long-term SLR data can provide a global constraint on modeling of the long-term changes of the Earth system, such as the post glacial rebound and the mass balance of polar ice, and be able to observe the meteorological mass transport between the atmosphere, solid earth and ocean. The continuous long-term SLR data are invaluable for enhancing our understanding of the Earth system dynamics and its role of the meteorological excitation on the Earth's gravity field.

GEODETIC CONSTRAINTS ON MASS REDISTRIBUTION IN THE EARTH SYSTEM

Erricos C PAVLIS (JCET/UMBC, NASA Goddard, Code 926, Greenbelt, MD 20771, U.S.A., E-mail: epavlis@Helmert.gsfc.nasa.gov)

The continuous redistribution of mass within the Earth system causes concomitant changes in the Stokes' coefficients describing the terrestrial gravity field. Secular changes in J2 due to post-glacial relaxation have been observed since many years. Similar changes in J3 have been attributed to changes in the ice sheets of Greenland and Antarctica. Seasonal changes in these coefficients have also been closely correlated with mass transfer in the atmosphere and oceans. The system is also affected by the hydrological cycle, which however is the most difficult to measure accurately so far. It is thus important to find means to measure the total effect so that we can infer the least well-known component after subtraction of the other ones. Satellite laser ranging data to LAGEOS 1 and 2 have already contributed in this effort the most accurate results yet. The sparseness of the SLR data (due to the lack of several Lageos-like targets), places limits on the maximum resolution of these series of results. This new analysis doubles the resolution of our previous results and extends our series up to the recent past. This data set of the past six years has been analyzed in a consistent manner using NASA Goddard's GEODYN/SOLVE II software and following the IERS Conventions 1996. We present and discuss our low-degree Stokes' coefficients time-series with emphasis on the geocenter variations and compare them to those inferred geophysically. The spectral contents of the series are also compared and discussed.

JSG14/W/24-A3 Poster 1709-04

SEASONAL VARIATIONS OF THE EARTHÍS GRAVITY FIELD DETERMINED FROM SATELLITE LASER RANGING

R. S. NEREM, R. J. Eanes, P. F. Thompson, and J. L. Chen (all at the Center for Space Research, The University of Texas at Austin, Austin, TX, 78712, email: nerem@csr.utexas.edu)

Mass redistributes itself in the Earth system on a variety of temporal and spatial scales reflecting complex interrelated processes in the oceans, atmosphere, groundwater, glacial/polar ice, among others. The measurement of these variations is thus important for a variety of studies attempting to understand the interrelations of the different components of the Earth system, and how they may change with time due to anthropogenic influences. We have used Lageos-1 and Lageos-2 satellite laser ranging (SLR) data to determine long wavelength seasonal variations of the Earthís gravity field from 1993 to the present. Due to the altitude of these satellites, and the non-continuous nature of the measurements, these data can detect seasonal gravitational variations only for wavelengths of roughly 10,000 km and longer (a degree 4 spherical harmonic expansion). We have compared the observed annual variations for a complete 4 x 4 spherical harmonic expansion as observed by Lageos 1/2 SLR data to those predicted from a variety of atmospheric, oceanic, and hydrologic models. We have used the observed variations to optimally select the best set of model predictions. The correlation of the maps of the observed and modeled annual geoid variation is as high as 0.8, with an rms difference of close to 1 mm. Given the sparse temporal and spatial distribution of the SLR data, and the limitations of the geophysical models, we consider this agreement to be as good as can be expected before the launch of a dedicated satellite gravity mission. Similar results will also be presented for variations in the Earthís geocenter location. The implications of these results for planned future dedicated satellite gravity missions will be discussed.

JSG14/E/02-A3 Poster 1712-05

GEOCENTER MOTION DETERMINED WITH GEODETIC DATA. COMPARISON WITH SURFACE LOADING DATA

J-F CRETAUX, A. Cazenave, L. Soudarin (LEGOS-GRGS/CNES, 18, Avenue Edouard Belin, 31401 Toulouse Cedex 4, France, e-mail: Jean-Francois.Cretaux@cnes.fr)

DORIS and SLR data were processed and combined in order to determine the Earth center of mass over the 6-year period from January 1993 to december 1998. The seasonal variations of the DORIS-SLR reference frame origin were computed by determining 3 translation parameters between monthly coordinates of the DORIS and SLR networks. These translation parameters are interpreted as the geocenter motions. These variations that are due to the mass redistribution inside the surface fluid envelops of the Earth were compared to the variations of the 1 degree geopotential coefficients also computed with the same data. During the 1993-1998 period the geocenter coordinates obtained by space geodetic measurements were then compared to geocenter variation obtained from various geophysical sources, i.e. atmospheric pressure, ocean mass, and surface ground water load.

THE GRAVITY CHANGE INDUSED BY THE ANNUAL POLAR MOTION AND THE EFFECT OF SEA SURFACE HEIGHT VARIATIONS ON ITS CHANGE

Tadahiro SATO (National Astronomical Observatory, 2-12 Hoshigaoka-cho, Mizusawa-shi, 023-0861 Japan, e-mail: tsato@miz.nao.ac.jp) Yuichi AOYAMA (The Graduate University for Advanced Studies, 2-12 Hoshigaoka-cho, Mizusawa-shi, 023-0861 Japan, e-mail: aoyama@miz.nao.ac.jp) Masatusgu OOE (National Astronomical Observatory, 2-12 Hoshigaoka-cho, Mizusawa-shi, 023-0861 Japan, e-mail: ooe@miz.nao.ac.jp) Yoich FUKUDA (Graduate School of Science, Kyoto University, Kitashirakawa, Oiwake-cho, Sakyo-ku, Kyoto, 606-01 Japan, e-mail: fukuda@kugi.kyoto-u.ac.jp)Kazuo SHIBUYA (National Institute of Polar Research, 1-9-10 Kaga, Itabashi-ku, Tokyo, 173-8515 Japan, e-mail: shibuya@nipr.ac.jp)

Recent relative and absolute gravimeters have enough potential to detect such weak and long-period gravity change due to the effect of earth's polar motion for instance. In addition to the observations of polar motion itself at high precision, the observation of the polar motion effect on gravity gives us an important data to understand the characteristics of earth's behavior at a low-frequency band. The polar motion effect on gravity is mainly consisted of the three components of semi-annual, annual and Chandler (of 14 months). In this study, the annual component is mainly discussed based on the comparison of the 5-year observation from a superconducting gravimeter at Syowa Station, Antarctica. One great advantageous thing in the gravity observation at Syowa is that its observation is almost free from such irregular and long-term effects due to the variations in under ground water, which are one of the major noise sources in the measurement of polar motion effect. The observed gravity changes were compared with the theoretical estimated ones, i.e. the sum of the effects of solid tide, ocean tide, polar motion and SSH (Sea Surface Height) variations. The effect of SSH variations were estimated using the data obtained from POCM (Parallel Ocean Climate Model). Based on the SST (Sea Surface Temperature) data which were used to derive the POCM, the effect of SST variations on SSH was corrected. The comparison results suggest; (1) both the observed annual amplitude (1.2 micro Gals) and phase (25.5 degrees) measured by referring on an epoch of 2000, are well explained by the above four effects, and (2) the gravity effect of SSH variations (about 0.2 micro Gals in amplitude) plays an important role to explain the observed annual gravity change especially to its phase.

INTERANNUAL VARIABILITY OF THE EARTH'S GRAVITATIONAL FIELD: EL NINO CONNECTIONS

P. GEGOUT (Ecole et Observatoire des Sciences de la Terre, Laboratoire de Dynamique Globale, 5 rue Rene Descartes, 67084 Strasbourg Cedex, France; tel: [33] 3 88 41 66 94;
email: Pascal.Gegout@eost.u-strasbg.fr); J. O. Dickey (Jet Propulsion Laboratory, California Institute of Technology, 4800 Oak Grove Drive, Pasadena, CA 91109-8099; tel: 818-354-3235;
email: Jean.O.Dickey@jpl.nasa.gov); D. Dong (Jet Propulsion Laboratory, California Institute of Technology, 4800 Oak Grove Drive, Pasadena, CA91109-8099; tel: 818-393-1827;
email: dong@cobra.jpl.nasa.gov)

Temporal variations of the even zonal combination of the geopotential are investigated using the geodetic satellite Lageos I from 1980 to 1998. Our purpose is to investigate the interannual variability of the Earth's gravitational field and its connections with El Nino and La Nina, events. Gravity variations relative to redistributions of groundwater, atmospheric and oceanic masses are estimated and compared to Lageos I determination. After the removal of a composite seasonal cycle, the use of recursive filtering and multi-channel singular spectral analysis reveals strongsimilarities between observed interannual variability and El Nino Southern Oscillation proxies.

GRAVITY VARIATIONS COMPUTED FROM A COUPLED ATMOSPHERE-OCEAN MODEL

Eric W. LEULIETTE and R. Steve Nerem (both at Center for Space Research, University of Texas at Austin, 3925 W Braker Lane Suite 200, Austin TX 78759, USA, email: leuliette@csr.utexas.edu) Gary L. Russell (NASA/Goddard Institute for Space Sciences, New York, NY 10025, USA, email: russell@giss.nasa.gov)

The Gravity Recovery and Climate Experiment (GRACE) will return high resolution measurements of the Earthís gravity field for five years beginning in 2001. The projected accuracy of this mission will allow for the observation of mass flow in various components of the coupled solid Earth/ocean/atmosphere system. General circulation models offer a way to assess the impact of these mass changes on the gravity field and the prospects for detecting climate signals in the gravity field. Using monthly-averaged fluid mass diagnostics from a coupled atmosphere-ocean model developed at GISS, we estimate the seasonal and secular geoid signals from sea level, snow, sea ice, soil moisture, and surface pressure can be compared to estimated errors for GRACE. We have used different climate scenarios to access the ability of gravity missions to identify climate change. All annual mass flows are well above the preliminary GRACE measurement errors at half wavelengths of 1000 to 10000 km. In addition, differences between the annual ocean column mass and snow mass annual as predicted by each model scenario (control versus %1 annual CO2 increase), differ at amplitudes that are significant when compared to the GRACE errors. Mass flows with significant secular trends have been used to estimate the magnitude of climate change over five years. These redistributions should be detectable by GRACE in principle, although they can not be separated using GRACE data alone.

VARIATIONS OF GEOCENTER AND EARTH ORIENTATION DEDUCED FROM ESTIMATES OF OCEAN MASS REDISTRIBUTION

Wolfgang BOSCH (Deutsches Geod‰tisches Forschungsinstitut, Marstallplatz 8, D-80539 München, Germany, email: bosch@dgfi.badw.de)

A consistent and homogeneous time series over more than six years is now available for global sea level variations monitored by Topex/Poseidon altimetry. The variations, dominated by a well known annual oscillation, are known to be caused by heating and cooling of the thermocline. The sea level variations therefore represent basically a volume change rather than a mass redistribution. We estimate the residual mass redistribution by using available climatologies to remove the steric effect and compute simultaneously the impact on both, variations of the Earth's center of origin and the Earth's orientation. The results are illustrated and analyzed on spatial and temporal scales.

JSG14/W/01-A3 Poster **1727-10**

FUTURE CONSTRAINTS FOR POST-GLACIAL REBOUND FROM GRACE

Mark TAMISIEA and John Wahr (Department of Physics and CIRES, C.B. 390, University of Colorado, Boulder, CO 80309, USA, Email: tamisiea@colorado.edu)

GRACE, a dedicate gravity mission to be launched in 2001, will provide much more information on the secular change of the geoid coefficients than is currently available. Secular variations of the geoid could provide useful constraints for determining the radial viscosity profile of the earth from post-glacial rebound. However, other mechanisms such as hydrology, current ice mass changes, and sea level rise also cause such variations. With the new GRACE data, the spatial pattern of the variations may allow for separation of these mechanisms.
In this talk, we create a synthetic geoid that includes various secular effects and determine the contamination of the post-glacial rebound signal from the other mechanisms' signals. We also begin to determine the extent to which the original input viscosity profile can be recovered.

JSG14/W/20-A3 Poster **1730-11**

ESTIMATION OF THE GRAVITY CHANGES INDUCED BY THE MASS VARIATIONS IN THE FLUID EARTH

Yoichi Fukuda (Department of Geophysics, Graduate School of Science, Kyoto University, Japan, KitashirakawaOiwakecho, Sakyo-ku, Kyoto 606-8502, Japan, email: fukuda@kugi.kyoto-u.ac.jp) Tadahiro Sato (National Astronomical Observatory, Mizusawa, 2-12 Hoshigaoka-chyo, Mizusawa-shi, 023- 0861 Japan, email: tsato@miz.nao.ac.jp) Yuichi Aoyama (The Graduate University for Advanced Studies, 2-12 Hoshigaoka-chyo, Mizusawa- shi, 023-0861 Japan, email: tsato@miz.nao.ac.jp) Lorant Foldvary and Kazuo Tsutsui (both at Department of Geophysics, Graduate School of Science, Kyoto University, Japan, Kitashirakawa Oiwakecho, Sakyo-ku, Kyoto 606-8502, Japan, email: fl@kugi.kyoto-u.ac.jp)

The recent progresses of the precise gravity measurements using superconducting gravimeters and absolute gravimeters enable us to observe very weak gravity signals induced by the various kinds of dynamic processes in and on the Earth. Because gravity changes reflect actual mass movements, the data of gravity measurements give us useful information to understand the dynamic processes. As an experimental study, we estimated the gravity changes induced by the sea level variations. We first employed SSH (Sea Surface Height) variation data from POCM (Parallel Ocean Climate Model) to evaluate their gravity effects, and then applied the EOF analysis to investigate the characteristic of the gravity changes. The results show that one of the EOF components is strongly correlated with ENSO like SSH variations. The amplitude of expected gravity changes in the pacific equatorial regions possibly reaches 2 to 3 micro Gals. This amount of amplitude could be enough detectable by a careful gravity observation. On the other hand, several satellite gravity missions are now under planning and some of them will soon be realized. Thus we also estimated the gravity effects of the sea level variations at the satellite orbit height level. Although the spatial coverage of the satellite gravity measurements are much superior than the ground measurements, the ground measurements are still important because of their high precision and temporal sampling rate. Using the simulated data set, we investigate the effective distribution of gravity observation points on ground. The same investigation has been carried out for gravity effects of the atmospheric pressure and soil moisture variations.

VARIATION OF THE GEOCENTER AT SECULAR AND GEOLOGICAL TIME-SCALE

GREFF-LEFFTZ Marianne, Institut de Physique du Globe de Paris, 4 place Jussieu, 75252 Paris Cedex 05, France.

The degree one deformations of the Earth, in a reference frame related to the centre of mass of the planet, are computed using a theoretical approach (Love numbers formalism) at secular time-scale, where the Earth has a viscoelastic behavior and at geological time-scale, where the mantle is a vis cous fluid. For a Maxwell model of rheology, the degree one relaxation modes associated with the viscoelastic Love numbers have been investigated : the Mo mode does not exist and there is only one transition mode (instead of two) generated by a viscosity discontinuity.The translations at each interface of the incompressible layers of the Earth's model (especially at the surface, at the Core-Mantle boundary (CMB) and at the Inner Core boundary (ICB)) are computed. They are viscoelastic when the Earth is submitted to Pleistocenic deglaciation and of about the meter. In a quasi-fluid approximation (Newtonian fluid) because of the mantle density heterogeneity, their order of magnitude are of about 100 m at the surface, 1 km at the CMB and 10 m at the ICB (which is in a quasi-hydrostatic equilibrium at this time-scale).

NON-TIDAL PLUMB LINE VARIATION: A NEW GEODYNAMICAL QUANTITY IN STUDYING THE VARIATIONS IN THE EARTH'S GRAVITATIONAL FIELD AND ITS ROTATION

Zheng-xin LI (Shanghai Observatory, Chinese Academy of Sciences, 80 Nandan Road, Shanghai, 200030, China, email: lzx@center.shao.ac.cn)

Non-tidal plumb line variation (PLV) on ground is related to the variations of the Earth gravitational field but it remains unsolved whether or not one can actually measure them in practice. The paper describes the efforts in using the traditional techniques to detect the non-tidal PLV. Based on the results obtained recently at two different locations, Jozefoslaw of Poland and Yunnan of China, where parallel gravimetry and astrometry observations have been carried out more than 20 and 10 years, interannual PLV, in the order of 0.01"-0.02", have been discovered. It is clear now the existence of the non-tidal PLV at these two locations and the possibility in measuring them in practice by either of the two techniques at interannual time scales. Although only results of the two locations have been obtained, and only interannaul part ot the non-tidal PLV has been studied at the moment, it is already very interesting to see the correlationship between the interannual PLV derived from some astrometric observations and a certain number of geodynamical quantities. It is quite possible that the non-tidal PLV discovered here will be used as a new geodynamical quantity one day with which the studying related to the variations in the gravitational field and its rotation might be carried out in a better way.

GLOBAL GRAVITY CAMPAIGNS - FROM THE GROUND (GGP) TO THE SKY (GRACE)

DAVID CROSSLEY (Saint Louis University, Department of Earth and Atmospheric Sciences, 3507 Laclede Ave., St. Louis, MO 63103, USA, email: crossley@eas.slu.edu) Jacques Hinderer (Ecole et Observatoire des Science de la Terre, 5 rue Ren Descartes, 67084 Strasbourg, FRANCE, tel +33.88.60.50.63 fax +33.88.61.67.47 email: jhinderer@eost.u-strsbg.fr)

The GGP global geodynamics campaign is now returning high precision data from 17 superconducting gravimeter stations. These sites are clustered in Europe and Japan and more widespresd in other parts of the globe. When the 6 years of the campaign are over we will for the first time be able to separate various types of global gravity signals, associated for example with rotation of the Earth, to local gravity changes caused by environmental factors.
At the same time, the planned mission GRACE will look at the global gravity field in a very different way. Connecting the two campaigns is the need for ground truth for the GRACE mission. This talk will discuss ways in which the GGP sites, supplemented with absolute gravimeter measurements, may be useful to the GRACE mission.

A 750 DAY RECORD OF GRAVITY VARIATIONS AS SEEN BY A SUPERCONDUCTING GRAVIMETER (GWR C026) AND AN ABSOLUTE GRAVIMETER (FG5-206) IN STRASBOURG (FRANCE)

Jacques Hinderer, Martine Amalvict, Jean-Paul Boy and Pascal Gegout (all at Ecole et Observatoire des Sciences de la Terre, 5 rue Descartes 67084 Strasbourg Cedex, France, e-mail: jhinderer@eost.u-strasbg.fr)

This paper is devoted to a comparative analysis of a 750 day long record of gravity changes as observed both by an absolute gravimeter (FG5 model 206) and a superconducting gravimeter (GWR model C026) which are operating in parallel in Strasbourg. This study extends previous related studies by adding one more year of relative and absolute gravity data at the same station. The relative gravity (as well as the atmospheric pressure) is sampled every 2 sec and numerically decimated to 1 min in agreement with the GGP (Global Geodynamics Project) recording standard. The absolute gravity values (with a drop repetition of 15 sec) consist in several days (about a week) of continuous measurements performed generally once every month. Two main objectives will be sought: on one hand, the alibration capability of AG/SG parallel registrations will be further tested, especially with respect to stability in time, duration requirement and precision; in particular, we will show the mean value of the scale factor resulting from a least squares adjustment using all the AG/SG values available during the 750 day time span. On the other hand, the absolute gravity values will be superimposed onto the continuous superconducting gravimeter observations in order to estimate long term gravity changes at our station. We will attempt to separate true (geo)physical effects from instrumental causes (e.g. drift of the cryogenic meter). A special attention will be paid to the gravity signature of the polar motion and to the respective capability of both types of instruments to exhibit it.

RELATIVE AND ABSOLUTE GRAVIMETERS IN LARGE AREAS

A.Sas-Uhrynowski, Y.ZANIMONSKIY (Institute of Geodesy and Cartography, Warsaw, Poland, e-mail: zgf@igik.edu.pl)

The advantages of the satellite missions to map the Earth's gravity field are increased with presence of the additional terrestrial data. Fast accumulation of the gravimetrical data with high accuracy in special and least known areas especially is necessary. In this connection the traditional methods of gravimetric serveys should be improved. The modernization of the Polish Network shows that usage of relative gravimeters on a long (up to 350 km) distances between stations is quite effective. It is a great desire to use the Portable Ballistic Gravimeter as an additional device This device was under R&D at the Institute of Geodesy and Cartography for a few years . It consists of an original parts and operates under special algorithm. The base of this algorithm is randomization of the systematic errors. PBG have been extensive field tested as autonomous as alongside other absolute gravimeters . The repeatability was estimated 0,01mGal for weekly and monthly intervals. Now we have the autonomous small-size and resistant to field conditions unit. The payment for this advantages is change of the instrument's metrological status. PBG is a working measuring instrument and it have to be calibrated at the standard such as Polish Gravity Reference Network. The relative connection is obtained by looping between two stations three days in a row. During this time PBG works automatically at the second consecutive station. The purpose of new algorithms for data processing is to bring together results obtained by means of so different instruments. Results of the recent measurements are going to discuss too.

EVALUATION OF SIX YEAR SUPERCONDUCTING GRAVIMETER OBSERVATION AT GFZ POTSDAM SITE

JUERGEN NEUMEYER, Franz Barthelmes, Hans-Juergen Dittfeld (GeoForschungsZentrum Telegrafenberg A17, 14473 Potsdam, Germany, e-mail: neum@gfz-potsdam.de, bar@gfz-potsdam.de, ditti@gfz-potsdam.de)

The high accurate Superconducting Gravimeter TT 18 has been continuously recorded gravitational variations at GFZ Potsdam site for six years. This data set and environmental parameters recorded at the same time have been used for analysing the data and separation of different geophysical effects.
In a first step the short and long period Earth tides are analysed and the tidal parameters are compared with the Wahr Dehant model. Selected tidal parameters are used for determination of the complex eigenfrequency of the Earth¥s Nearly Diurnal Free Wobble and the result is compared with theory.
Gravity variations caused by atmospheric pressure, groundwater table and rainfall are estimated by using different approaches. The admittance coefficients are determined and the quality of the reduction is discussed.
After reduction of the environmental effects the polar motion is extracted from the residual data set and compared with smoothed records from space techniques. The free oscillation of the Earth caused by big Earthquakes is used for separation and splitting of the different modes.
The decay of the modes is illustrated by means of the Wavelet Transform.
Finally an attempt is made for determination of the three translational modes of Earth solid inner core (Slichter Triplet) using the Cepstrum method.

STUDY TO PROPOSE A GRAVITY NETWORK AS GROUND TRUTH FOR SATELLITE MISSIONS

Bernd RICHTER, W. Schwahn, D. Simon, R. Falk, H. Wilmes (all Bundesamt fuer Kartographie und Geodaesie, Richard Strauss Allee 11, D-60598 Frankfurt a.M. / Germany (email: richter@ifag.de)

Special satellite missions (CHAMP, GRACE) are initiated to study the fine structure of the Earth gravity field and its temporal variations. For the first time space borne derived gravity variations can be compared with series observed at the Earth surface. Various gravity variations and their contributions to the Earth borne and space borne sensors will be discussed. Due to the temporal resolution of the satellite data only gravity variations can be analysed which have a long-term periodical or non-periodical variation nature or a secular trend. As a test case periodical signals are preferable because of the higher sensitivity of models to periodical pattern. In addition the spatial disturbance for long-period variations is at least regional, usually of global character. The annual gravity variation is a potential candidate which should be detectable by satellite and ground borne.

DETERMINATION OF GEOPENTIAL VARIATIONS USING SATELLITE LASER RANGING

Wu Bin , Pen Bibo , ZHU Yaozhong and Hsu Houze

The mass redistribution within the Earth produces variations of geopential on a wide range of timescales. In this study, Lageos-1 and lageos-2 satellite laser ranging (SLR) data from November 1992 to December1997 are used to determine the variations of low degree armonic coefficients of geopential, J2, J3 and J4. In the span of data, both lageos-1 and lageos-2 SLR data are available in every monthly arc analysis, which makes the disadvantage of single satellite geodynamic analysis overcome. Our results show that : 1) The harmonic coefficients J2 and J4 are determined in every monthly arc with low correlation by simultaneously using Lageos-1 and Lageos2 SLR data. 2) The time series of J2 mainly comprises an annual and a semi-annual variation. 3) The J2 variation from two satellites SLR data instead of the effective J2 from single satellite is used to calculate the change of length of day (LOD) caused by the mass redistribution within the Earth. Combining the LOD determined from space geodetic data and the result in this study, one can obtain the relative angular momentum contribution to the LOD and provide an observational constraint on the wind and ocean currents effects on LOD.

CONSTRAINTS ON MANTLE ANELASTICITY FROM EARTH ROTATION AND TIDAL PARAMETERS

Yaozhong ZHU, Bin Wu and Bibo Peng

The response of the solid Earth to tidal forces is influenced, in part, by properties of the Earth's interior, which can be modeled with Love number. In this work, we compare the theoretical degree 2 Love numbers predicted by two frequency-dependent models of mantle anelasticity with the recently observed results derived from tides and the Earth rotation variations at M2, Mf, Mm, Chandler wobble and 18.6-year frequencies. The response of mantle anelasticity at different frequencies is analyzed, and the observed results of space geodesy are used to constrain the theoretical models of anelasticity. We find that Zschau's model can interpret the observed amplitude of anelastic Love number in the regime from the seismic frequency to the 18.6-year frequency. However, the theoretical Love number k2 predicted by a single absorption-band model do not agree well with the observed values at M2, Mf, Mm, Chandler wobble and 18.6-year frequencies. Based on anelastic model and ocean tide model determined by Topex/Poseidon satellite altimetry data, we also present the theoretical values of the tidal response at Mf and Mm frequencies in consideration of mantle
anelasticity and non-equilibrium ocean tide effects.

A NUMERICAL APPROACH TO THREE DIMENSIONAL TECTONOMAGNETIC MODELING BY SURFACE INTEGRALS

Shin'ya SAKANAKA (Aso Volcanological Laboratory, Institute for Geothermal Sciences, Kyoto University, Choyo-son, Aso-gun, Kumamoto 869-1404, Japan, email: sakanaka@aso.vgs.kyoto-u.ac.jp).

Local geomagnetic changes are sometimes accompanied by tectonic activities such as earthquake occurrences, volcanic activities, and crustal movements. Mechanical stress change in the crust is expected as one of mostly probable causes of the local magnetic changes. In order to investigate such local magnetic changes, a new method of numerical calculation for tectonomagnetic modeling is developed and entailed problems in application of the method are discussed in this study. The new method in this study is based on surface integrals numerically estimated over the surface of a magneto-elastic medium, instead of volume integrals traditionally employed in this research field. At first, as an example of calculations for three dimensional tectonomagnetic models, magnetic changes due to an inclined columnar pressure source are evaluated in respect of several parameters. Next, making use of one of advantages of the surface integral method, which can treat arbitrarily shaped demagnetized areas, an effect of a combination of inflated and deflated sources with a demagnetized area is evaluated.

SEISOMAGNETIC EFFECT CONSIDERING THE INHOMOGENEOUSLY MAGNETIZED CRUST

Mitsuru UTSUGI and Yasunori Nishida (both at Division of Earth and Planetary Sciences, Hokkaido University, Sapporo 060-0810, Japan, e-mail: mithuru@ares.sci.hokudai.ac.jp and nishida@ares.sci.hokudai.ac.jp)

We present a new method to evaluate the geomagnetic change due to the inhomogeneously magnetized crust. From this method, quantitative analysis of the seismomagnetic effect can be made in the general geologic and tectonic situations in the Earth' crust. To represent the inhomogeneity of the crustal magnetization, we divide the crust into a number of compartments. Each compartment is assumed to have its own magnetic properties such as the magnetization and the stress sensitivity. Seismomagnetic field may be expressed by the summation of that from each compartment. In the present study, we used a cubic-shaped body as the compartment. The seismomagnetic field is expressed by the surface integral of a function including displacement and strain over the cubic body. In general, this finite integral cannot be solved analytically. However, the 2-D integral can be represented by analytical form using elliptic integrals to reduce the dimension of the integral to 1-D. Some model calculations reveal that the seismomagnetic fields are significantly enhanced near the place where the magnetic properties change sharply, as well as the place near the fault region.

MAGNETIC FIELD GENERATION BY ELECTROKINETIC COOUPLING IN 3-D RESISTIVITY STRUCTURES

Tsuneo ISHIDO (Geological Survey of Japan, 1-1-3 Higashi, Tsukuba, 305-8567, Japan, email: ishido@gsjscal.gsj.go.jp)

The flow of a fluid through pores and cracks in a rock may transport electric charge along the flow path by the interaction of the moving pore fluid with the electrical double layer at the pore surface. This process is known as electrokinetic coupling. The total current density is composed of a drag current density caused by charges moved by fluid flow and a conduction current density caused by electric conduction. In order to evaluate the effects of complex 3-D resistivity structures on the generation of magnetic field at the ground surface, numerical simulations were performed. The present numerical approach simulates magnetic fields caused by subsurface fluid flow by a three-step process. First, it calculates the distributions of drag current, etc. from the underground conditions (pressure, temperature, salinity, flow rate, etc.) computed by thermohydraulic simulations. Second, it calculates the distributions of electric potential and conduction current within a 3-D finite-difference grid. Finally, it calculates the magnetic field distribution by applying the Biot-Savart law to the distributions of drag and conduction currents. The effects of inhomogeneous and anisotropic resistivity structures on the enhancement of magnetic signals on the ground surface, and its implications for earthquake-related magnetic anomalies will be discussed.

ELECTROKINETIC PHENOMENA ON THE SURFACE OF PARTIALLY SATURATED ROCKS

Olivier GENSANE, Boris Konyukhov, Jean-Louis Le Mouel, Pierre Morat (Departement de Geomagnetisme et Paleomagnetisme,Institut de Physique du Globe de Paris, 4 place Jussieu , 75005 Paris, FRANCE, Email:gensane@ipgp.jussieu.fr)

A theoretical model and results of an experimental investigation of electrical self potential (SP) and conductivity (EC) variations on the surface of a partially saturated pillar under varying mechanical stress and atmospheric pressure in an underground limestone quarry are presented. The developed model is based on the theory of the electrical double layer and poroelasticity of partially saturated rocks. The obtained theoretical results show that SP and EC variations depend on the saturation coefficient and on the ratio of the conductive to total porosity. These results allow the local electrokinetic coupling coefficient to be obtained for partially saturated rocks as a function of the saturation, porosity and elasticity modulus. Experimental studies include SP and EC measurements on the surface of two limestone pillars. One of them is homogeneous and the other one contains a system of unstable cracks initiating mechanical stress variations. Obtained experimental results are in good agreement with the theoretical model. SP variations under varying atmospheric pressure are used for the estimation of the local electrokinetic coupling coefficient. Variations of the mechanical stress in the vicinity of active cracks are estimated using the local electrokinetic coupling coefficient and measured SP variations. These results are explained by existing fracture interaction models.

ELECTROMAGNETIC SIGNALS RELATED TO MICROMOVEMENTS OF LIMESTONE BLOCKS: A TEST IN KARST CAVES (CENTRAL ITALY)

A. ERMINI (Department of Physics and Energy Science and Technology, University of Roma Tor

Vergata,Via di Tor Vergata, 00133 Rome, Italy); P. F. Biagi (Physics Department, University of Bari, Via Amendola 173, 70126 Bari, Italy); S.P.Kingsley (Sheffield Centre for Earth Observation Science, University of Sheffield, Hicks Building, Hounsfield Road, Sheffield S3 7RH, United Kingdom)

Since 1992 equipments for detecting electric and magnetic signals has been running inside two karst caves located in Central Apennines (Italy). The signals are recorded every ten minutes in the frequency range from some hundred Hz to some hundred kHz. On the occasion of rainfall, atmospheric pressure variations and heating we revealed electric and magnetic signals simoultaneous with seismoacusic (f=0.5, 25,150kHz) signals. We propose a possible model to justify the observed phenomenology based on the micromovements of the limestone blocks that constitute the roof of the caves. The electrification on the new contacts created by micromovements of the limestone blocks can provide an adequate mechanism for generating charges. Such charges will redistribute in the caves so that charged capacitors can occur with respect to the floors of the caves. The moisture film on the walls of the caves can behave as a resistor and/or an inductance. In such a way equivalent RC or RCL circuits can be adopted and the electric and magnetic signals we recorded can be connected with the electric and magnetic energy stored in these circuits. Obviously, we have to suppose that several geometrically different capacitors become active in the caves during the phenomenology. The possibility that a similar phenomenology can happen wherever discontinuities as faults, geodetic blocks and fractured zones exist seems to be realistic. In these cases, the electromagnetic energy recorded is mostly of radiating than stored type.

JSA15/W/06-A3 1030

SELF-POTENTIAL ANOMALIES ON VOLCANOES

M. J. S. JOHNSTON (U.S. Geol. Surv, Menlo Park, Ca 94025, USA, Email: mal@usgs.gov)
J. D. Byerlee, and D. Lockner (both at U.S. Geol. Surv, Menlo Park, CA 94025)

Self-potential (SP) anomalies observed above suspected magma reservoirs, dykes, etc on various volcanoes (Kilauea, Mt Unzen - Japan, Piton de la Fournaise - Reunion Is., Miyake Jima - Japan) generate transient surface electric fields of tens of millivolts/km and generally have a positive polarity. Without a more plausible explanation, these SP anomalies are usually attributed to electrokinetic effects with poorly constrained properties. Contributions to electric fields might also be expected to result from fluid vaporization and gas transport away from hot dike intrusions, particularly since this vaporization process can dramatically change the local electrical resistivity structure. Laboratory observations of electric fields generated by pulses of fluid (water) through a hot rock at atmospheric pressure indicate the relative amplitudes of electrokinetic (EK) and fluid-vaporization (FV) potentials to be dramatically different and the signals are opposite in sign. Above vaporization temperatures, FV effects of positive sign in the direction of gas flow dominate, whereas, below these temperatures, EK effects of negative sign dominate. This suggests that the primary contribution to self-potential arises from gas-related charge-transport processes at temperatures high enough to produce vigorous boiling and vapor transport. At lower temperatures, the primary contribution is from electrokinetic effects modulated perhaps by elevation effects and low-temperature CO2 and SO2 gas flow. If charge generation is continuous, as could well occur above a newly emplaced dike, positive static potentials will be set up that could be sustained for many years, and the simplest method for identifying these hot, active regions would be to identify the SP anomaly they generate.

JSA15/E/33-A3 1050

SELECTED RESULTS OF LABORATORY INVESTIGATIONS OF PULSE ELECTROMAGNETIC RADIATION FROM ROCKS SUBJECTED TO STRESS AND DESTRUCTION

Michal STEFANIUK (Faculty of Geology, Geophysics and Environment Protection, University of Mining and Metallurgy, Al.Mickiewicza 30, 30-059 Krakow, Poland, Email: stefan@geolog.geol.agh.edu.pl); Tomasz Czerwinski (Geophysical Exploration Company, ul. Jagiellonska 76, 03-301 Warsaw, Email: pbg1@ikp.atm.com.pl)

The goal of the presented study was to examine a possibility of applying the electromagnetic emission from rocks into predicting rockbursts and other local geodynamic processes connected with deformation and destruction of rocks. A hand-operated press loaded rock specimens. Electromagnetic emission time-series were recorded with a two-channel equipment consisting of an EM field detector, a set of amplifiers and filters, and two digital recorders. The measurement stand was electromagnetically screened. Maximum amplitudes and spectra of recorded signals were then analysed. Rock samples of granite, syenite, sandstone, quartzite, marble, limestone, graphite, and black coal were examined. The comparative analysis of specific parameters of electromagnetic emission from different rocks was made. The coefficient of emissivity, characterising a tendency of rocks to generate electromagnetic radiation signals and the results of time-domain and frequency-domain signal analysis were subjected to the comparative analysis. The parameters were statistically processed and data files corresponding to each type of rock were compared. An attempt to evaluate a relation between the maximum signal amplitude and the strain applied to a rock sample was also made. As a result of the study, different tendencies of individual rocks to emit electromagnetic radiation were observed, the correlative dependence of the amplitude of signal emission on sample's strain was obtained, and the change of spectral composition of a signal, depending on a rock type, was evaluated. The obtained results characterise qualitatively and quantitatively the electromagnetic signal emission from selected rocks, and can make the basis for studying the genesis of this phenomenon.

JSA15/W/11-A3 1110

ELECTRO-SEISMIC PHENOMENA IN SATURATED AND UNSATURATED SOIL

Boris KONYUKHOV (Laboratoire de Geomagnetisme, Institut de Physique du Globe de Paris, 4, Place Jussieu, 75252 Paris cedex 05, FRANCE, E-mail: borisk@ipgp.jussieu.fr)

Electrokinetic phenomena coupled with seismic waves propagation in saturated and unsaturated soil are considered in a view of distant earthquakes registration. In fine-grained low permeability clayey soil the effect of the alternating electric potential generation is governed by the excitation of the colloid-vibration potential. In high permeability soil such as a sand with a rigid matrix, this effect is related to the porosity streaming potential excitation. In the last case the generation of an alternative electric potential has been related to the expulsion of fluid from the permeable upper soil layer under the action of excess pore pressure caused by a propagating seismic wave. In sand-clay mixture the electro-seismic phenomena are more complicated and highly depend on a clay content. It is shown that in a sand-clay mixture, with the clay content lower than some critical value, electro-seismic phenomena are controlled by the colloid-vibration potential generation and the streaming potential generation in the case of the clay content higher its critical value. The suggested models have obtained estimates of this electric field generated by seismic waves produced by different sources in the different type of soils, and physical properties of the soil measured in laboratory. The alternative electrical field is shown to be able to reach the value 10-4 V/m for natural microseism sources and 1.5 V/m for distant earthquakes.

JSA15/E/04-A3 1130

STUDY OF BEHAVIOR OF PIEZO-COMPENSATING CHARGES IN SYNTHETIC ROCKS

Tomonori MATSUDA, Hideki Sasaoka, Chihiro Yamanaka and Motoji Ikeya (Graduate School of Science, Osaka University, Machikaneyama, Toyonaka, Osaka 560-0043, Japan,
E-mail: tomonori@ess.sci.osaka-u.ac.jp)

Free transient electric charges induced by stress reduction were measured for synthetic rocks made of cement and pieces of man-made piezoelectric ceramics or quartz crystals in different arrangements. We suggested an electromagnetic model of a fault, in which bound charges cancel the stress-induced piezoelectric polarization field around the fault zone [1]. When stress is changed by faulting or by micro fracturing of rocks, the piezoelectric polarization field changes giving free charges. Electromagnetic waves are generated by the change of the polarization. The peak height and the width of the electric pulse depend on the arrangement of ceramics [2]. Possible charge movements of (1) paraelectric orientation and (2) ferroelectric orientation are studied. The movement of bound charges was also simulated using a computer for these synthetic rocks containing one and two piezoelectric ceramics in different orientations.
The effective piezoelectric coefficient of granite was obtained as 1.4x10-15 C/N, which agrees well with theoretical estimation considering paraelectric, paired charges [3]. Some incredible legends on earthquake precursors have been explained as electromagnetic phenomena using numerical values of induced charges in these experiments [4]. Preseismic and coseismic electromagnetic nature might be clarified from the laboratory experiments.

JSA15/E/05-A3 1150

A POSSIBLE ROLE OF THE TWO-PHASE FLUID IN SEISMO-ELECTROMAGNETIC PHENOMENA

Nadezhda YAGOVA (Institute of the Physics of the Earth, B.Gruzinskaya 10, Moscow, 123810, Russia, e-mail: vpilipenko@uipe-ras.scgis.ru) Viktor Yagov (Dept. of Thermophysics, Moscow Power Engineering Institute, Krasnokazarmennaya, 14, Moscow, 111250, Russia)

A new mechanism for the generation of electromagnetic fields in the Earth crust in the ULF/VLF frequency range is suggested. Among the possible mechanisms of the low frequency seismo-electromagnetic variations the electrokinetic effect seems to be one of the most promising. Some physical features which may strongly influence the fluid pressure gradients and thus field amplitudes are discussed. The rock pore water at seismogenic depths is highly mineralized. The realistic model of its phase state requires the account for at least 2 admixtures: carbon dioxide and NaCl. This leads to the existance of two-phase vapor-liquid mixture down to first ten kilometers. The following processes become important for the electrokinetic effect in the two-phase vapor-liquid mixture in the zone of super-critical to sub-critical phase transition: 1) The initial pressure/temperature impulse leads to the appearence of a segment with the sub-critical two-phase mixture. 2) Pressure impulses appear under bubble collapse, which leads to the impulsive fluid flow and changes the amplitude of the induced electric field. 3) The rock conductivity essentially changes if the diameters of a low-conductive bubble and of a pore are comparable. If the earthquake preparation is supported by microfracturing, the boundary between one-phase super-critical fluid and two phase vapor-liquid mixture displaces. The effect may be revealed in rock conductivity and in the ULF/VLF variations of the geomagnetic field.

JSA15/E/46-A3 1210

CONVECTION CURRENT PRIOR TO RUPTURE IN SATURATED ROCKS

Shingo YOSHIDA (Earthquake Research Institute, University of Tokyo, Tokyo 113-0032, Japan, also at Institute of Physical and Chemical Research (RIKEN), Email: shingo@eri.u-tokyo.ac.jp)

Laboratory experiments have been performed to clarify generation mechanism of seimo-electric signals. We pay attention to the interaction between rupture nucleation process and pore water movement. We have developed a triaxial apparatus specially designed for this purpose, in the framework of the International Frontier Program on Earthquake Research of the Institute of Physical and Chemical Research (RIKEN). This apparatus can deform rock specimen electrically isolated from the surroundings at a very slow strain rate (1^-10/s). We use co-axial type feedthroughs which Nishizawa (1997) developed on the basis of a Bridgman's self-sealing mechanism. Using cylindrical specimen of intact rock saturated with water, we carried out deformation tests at a constant strain rate keeping constant confining pressure and pore pressure. During a deformation test, we continuously measured electric current through the specimen, or electric potential difference between top and bottom surfaces of the specimen. In addition, the differential stress, displacement, local strains, and pore fluid movement from the intensifier were recorded at a sampling frequency up to 1 kHz. The volumetric strain rate was obtained from the average of the strain measurements at four positions. We found that the convection current flew before the main fracture, showing good correlation with the volumetric strain rate and the water flow rate. The current density of the signal was about 1 mA/m^2. This result suggests that the current is caused by an electrokinetic effect due to the water flow associated with accelerating evolution of dilatancy before the fracture.

INVESTIGATIONS OF TECTONOMAGNETIC VARIATIONS IN UZBEKISTAN AND EARTHQUAKE PREDICTION

Vsevolod SHAPIRO (Institute of Geophysics, 100 Amundsen str., Ekaterinburg, 620016, Russia. Fax:+7 3432 678872, Email: seva@maglab.mplik.ru); Kakhar Abdullabekov, Mirzoid Muminov, Sabit Maksudov (Institute of Seismology, 3 Khurshid str. Tashkent, 700012, Uzbekistan.
E-mail: root@seismo.tashkent.su)

Investigations of tectonomagnetic variations proved to be informative in the study of the modern geodynamic processes such as investigations of the seismotectonic processes, study of the earthquake (EQ) prediction and volcano eruption, and more sphere of application in geodynamics. Observations in situ during past several years have documented magnetic signals, which are attributed to precursory stress changes. The specific signatures of the geomagnetic variations in Uzbekistan were set up. The methods for forecasting of EQ's main parameters (magnitude M, time T and location L) were developed. Based on this approach we have predicted M, T and L for numerous EQs in Uzbekistan with M equal or above 4.0. A number of magnetic precursors of events in different regions of the globe were observed in

areas with weekly magnetised crust, that is practically excluded piezomagnetism as a source of observed variations. The ongoing efforts to indentify "non-piezomagnetic" source is lead to conclusion about electric currents as an origin of observed variations. Lab and theoretical modelling is giving rise to deduction that one of the most probable sources of such variations is electrokinetic currents.

JSA15/E/54-A3 1420

REGIONAL GEOMAGNETIC VARIATIONS AND TEMPORAL CHANGES OF SEISMIC ACTIVITY: OBSERVATION OF A SO FAR UNKNOWN PHENOMENON, ATTEMPTS OF INTERPRETATION

Gerald DUMA (Central Institute for Meteorology and Geodynamics, Hohe Warte 38, A-1190 Vienna, Austria, email: duma@zamg.ac.at)

It will be demonstrated, that regional geomagnetic variations of high amplitudes can be correlated with the temporal changes of seismic activity in several main earthquake zones of Japan, China, California, Greece, Italy and Austria and in the volcano region of the Mt. Vesuvius. This applies to long term magnetic variations as well as to the diurnal magnetic changes (Sq-variations), the latter indicating a considerable impact of the external ionospheric electromagnetic field on the dynamics of the Earth's crust. Another observation makes this hypothesis more credible: the seismic activity in the vulcano region of the Mt.Vesuvius exhibits a periodicity of about 11 years, in phase with the solar activity cycles (Duma, Vilardo, 1997). The observations can be best interpreted, both qualitatively and quantitatively, by the effect of a changing magnetization of crustal material and associated variations of tectonic stress. This phenomenon has been described by several authors in the period from 1960 to 1980 (e.g. F.D.Stacey, M.J.Johnston, T.Nagata, W.F.Kean and others), mainly based on laboratory results and not on magnetic measurements in earthquake zones. Results obtained e.g. by D.Beamish (1982, temporal variation of the lithospheric electromagnetic response function) and by F.Florindo and L.Alfonsi (1995, geomagnetic jerks and the occurrence of strong earthquakes) will be discussed in this context.
Although the present observations relate to the diurnal and long term range, they might possibly lead to a better understanding of related short term effects as well.

JSA15/E/17-A3 1440

PRESEISMIC AND COSEISMIC GEOELECTRIC POTENTIAL CHANGES

S. UYEDA, T. Nagao, Y. Orihara, I. Takahashi, T. Yamaguchi (RIKEN International Frontier Program on Earthquake Research, Tokai University, Shimizu 424-8610, Japan, email: suyeda@st.rim.or.jp); T. Mogi (Kyushu University); Y. Tanaka (Kyoto University); D. S. Widarto and E. M. Arsadi (RD Ctr for Geotechnology-LIPI, Indonesia)

Clear coseismic geoelectric potential changes have been observed for some earthquakes (EQ) by the VAN-type observation systems: 1) 1988 Jan. 24 M6.0 EQ in northern Okinawa Island by long- dipole network at about 50 km of epicentral distance (r). This EQ was preceded by a possible precursory change on Jan. 18. 2) 1996 March 6 M5.8 Yamanashi-ken Tobu EQ at r=10 km. This EQ was preceded by changes on Jan. 29 and Feb. 28. 3) Five EQ's off southern Sumatra Island in 1997 by short-dipole networks distributed in an area several kilometers wide at Liwa, southern Sumatra; Sept. 13 M5.0 EQ at r=147 km, Oct. 29 M5.7 EQ at r=152 km, Nov. 16 M5.5 EQ at r=5.5 km, Nov. 23 M5.1 EQ at r=174 km and Dec. 20 M5.0 EQ at r=146 km. None of these Indonesian EQs showed clear pre-seismic changes. 4) Less convincing coseismic change was observed for shallow 1997 May 22 M5.1 EQ by short and long dipoles in Kozu Island at r= 6 km. This EQ, however, was preceded by a more convincing change on May 20. The changes were recorded by multiple dipoles simultaneously. Except the Indonesian cases, epicentral distance was small. Both preseismic and coseismic changes mentioned above were the only changes detected during the observation period of respective station. No changes were detected at more than one station and no station has experienced more than one sizable EQ so far. Simultaneous detection of changes at multiple stations and repeatability of correlatable changes and EQ are still to be awaited. Critics on the VAN - method often argue that if VAN's SES is generated by stress changes at EQ source, coseismic changes much stronger than SES should be observed, contrary to VAN's experience. Reception of the coseismic changes reported here do not seem to support the criticism, however, because within the timing precision of the recording system, the changes took place at the time of arrival of seismic waves. They may be so-called "seismo-electric effect". True co-rupture changes have not been observed at our frequency range (<Hz)

JSA15/E/19-A3 1500

POSSIBLE ELECTROMAGNETIC PRECURSORS FOR 1995 HYOGO-KEN NANBU (KOBE) EARTHQUAKE

Y. ENOMOTO (Mechanical Engineering Laboratory, Tsukuba, Japan); Y. Fujinawa (National Research Institute for Earth Science and Disaster Prevention, Tsukuba, Japan); M. Hata (Aichi Prefectural University, Aichi,Japan), M. Hayakawa (University of Electro-Communications, Chofu, Japan), Y. Kushida (Yatsugatake South Base Observatory, Kita-Koma, Japan); K. Maeda (Hyogo College of Medicine, Nishinomiya, Japan); T. Nagao (Tokai University, Shimizu, Japan), K. Oike (Kyoto University, Uji, Japan); T. Okamoto (Fukui College of Technology, Sabae, Japan); and S. UYEDA (RIKEN International Frontier Program on Earthquake Research, c/o Tokai University, Shimizu 424-8610, Japan, email: suyeda@st.rim.or.jp)

A synthesis of reported possible electromagnetic precursors related to the devastating 1995 M7.2 Hyogo-ken Nanbu (or Kobe) earthquake is presented. The data include: DC geoelectric potential change (Okamoto et al., 1996); ELF (223Hz) magnetic field peak (Hata et al., 1997); VLF (1-9kHz) Radio (Jav e pulse-like signal peaks (Fujinawa and Takahashi, 1995); Abnormal behavior of VLF (ca. 10 kHz) Omega wave transmission (Hayakawa et al., 1996); Peaks in the number of spike-like VLF (1-20kHz,) and LF noise (163kHz) (Yamada and Oike, 1996); MF to HF (higher than 1 MHz) fluctuation of earth current (Y. Enomoto, pers. com.); 22.2MHz emissions (Maeda and Tokimasa, 1996): Back-scattered VHF FM-wave (77.1 MHz) (Kushida,1996). These signals were interpreted either as emitted from the earthquake source area like in the VAN case, or as caused by pre-seismic ionospheric disturbances above the focal region. Many of the reported precursors in ELF to MF range occurred 7 days before the main shock and there seems to be a general tendency that higher frequency precursors occurred closer to the earthquake occurrence. Precaution against lightning discharges seems critically important as they generate similar signals. It was probably the first case where multiple electromagnetic methods detected possible precursors for one earthquake, some stations being hundreds of kms distant from the epicenter. Totality of the reported anomalous phenomena appears to warrant further investigation.

JSA15/W/29-A3 1540

ELECTRIC AND MAGNETIC FIELDS ACCOMPANYING SEISMIC AND VOLCANIC ACTIVITY

M. J. S. JOHNSTON and R. J. Mueller (U.S Geol. Surv, Menlo Park, CA, 94025, USA, Email: mal@usgs.gov)

Continuous ground-surface observations of local magnetic and electric fields have been obtained in the near field of numerous felt earthquakes, near active faults and on volcanoes during the past 25 years. These data provide a reference set of data documenting the form and amplitudes of these fields during seismic and volcanic activity. The primary features of data taken along the San Andreas fault show that 1) near-fault magnetic field disturbances rarely exceed a few nanoteslas, 2) coseismic signals, with amplitudes from 0.7 nT to 1.3 nT, are routinely measured for earthquakes with magnitudes greater than 5.5, 3) preseismic signals of about 1.5 nT have been observed on just two occasions, 4) anomalies of a few nanoteslas are generated during aseismic strain events, and 5) near-fault electric field disturbances rarely exceed a few mv/km. These observations are generally consistent with seismomagnetic models based on geodetically and seismically determined fault parameters for these events. Electrokinetic processes resulting from rupture of fluid filled compartments at hydrostatic to lithostatic pore pressures can generate transient signals in the frequency band 100 Hz to 0.01 Hz. Large-scale fluid driven processes are not evident in either near-fault magnetic field measurements or local strain measurements in the epicentral region minutes to weeks before large earthquakes. For volcanic events, contributions from different physical processes can be identified during the various eruption stages. Slow processes (weeks to months) include near-surface thermal demagnetization effects, piezomagnetic effects, and effects from rotation/displacement of magnetized material. Rapid processes (seconds to days) include piezomagnetic effects from instantaneous stress redistribution with explosive eruptions and electrokinetic effects from rupture of high fluid pressure compartments commonly encountered in volcanic regions. The most interesting signal in the Long Valley Caldera is a systematic decrease of 0.8-1 nT/year in magnetic field that has occurred in the caldera since 1989 in concert with inflation of the resurgent dome. The net change of 8 nT can be explained with a simple volcanomagnetic model involving pressure increase of 50 MPa/year at a depth of 7 km under the resurgent dome. This model is derived from the intrusion model that best fits the surface deformation data. Ionospheric disturbances generated by trapped atmospheric pressure waves are excited by earthquakes and volcanic eruptions and propagate to great distances.

JSA15/E/08-A3 1600

VOLCANOMAGNETIC SIGNALS ASSOCIATED WITH THE QUASI-CONTINUOUS ACTIVITY OF MERAPI VOLCANO (INDONESIA): 1990-1998

Jacques ZLOTNICKI (Laboratoire de Geoophysique(a), UMR 6530, 3d av de la recherche scientifique 45071 Orleans cedex 02, France. Email :jacques.zlotnicki@cnrs-orleans.fr) Marcel Bof (L.E.T.I., Dsys, Cea Grenoble, 17 rue des Martyrs, 38054 Grenoble, France); Paul Yvetot(a), Laurent Perdereau(a) & Yochi Sasai (Earthquake Research Institute(b), Tokyo University, Japan)

Merapi volcano in Java Island (Indonesia) is an andesitic stratovolcano, which presents long periods of effusive activity during which an endogenous dome is continuously growing. The viscous lava dome gives rise to unstable blocks which collapse or to pyroclastic flows. When the volcano does not exhibit any surface activity, the overpressure within the volcano slowly increases. Depending on the quietness duration the unrest of the volcano can start with an explosive phase during which the former dome is partly destroyed. Different time constants magnetic variations are observed during the 1990-1998 period which includes one gas plume emission on August 26, 1990 and four eruptions on Jan., 1992, Nov., 1994, Jan. 1977, and July 1998. Compared with other types of active volcanoes the observed volcanomagnetic variations are very small, almost a few nanoteslas. To identify the variations associated with the global activity of the volcano from the signals correlated with each unrest phase, one has to dissociate the different time constant variations over the nine years time span. When long-term trends are removed from the magnetic field in each station of the network, an outstanding correlation between all the magnetic differences is emphasised. The variations point out cycles of activity that fit the stress field evolution within the edifice. Some of the volcanomagnetic variations are precursory signals as the three months decrease, up to 1.8 nT, preceding the 1992 eruption, or the long period decrease, of 2 nT in a remote station, before Jan., 1997 eruption.

JSA15/E/30-A3 1620

COSEISMIC ELECTROMAGNETIC VARIATIONS MEASURED DURING AN ERUPTIVE PHASE OF MERAPI VOLCANO/CENTRAL JAVA

Andreas MUELLER (GeoForschungsZentrum Potsdam, 14471 Potsdam, Germany, Email: grassus@gfz-potsdam.de)

During an eruptive phase of the Merapi volcano/Central Java in July 1998 magnetotelluric measurements were carried out in order to get structural information about the volcanoes interior During the volcanoes activity in the campaign we decided to extend the measuring time at one side in order to observe electromagnetic changes connected to the eruption. A clear correlation was found between the electromagnetic variations and a nearby seismological station. While the correlation in the magnetic component can be explained by the movement of the induction coils in the earth's magnetic field the correlation in the electric channels remains unclear. Several mechanisms proposed by other researchers will be discussed here.

JSA15/E/10-A3 1640

ELECTROMAGNETIC SIGNALS RELATED TO MARCH 9, 1998 ERUPTION OF LA FOURNAISE (REUNION ISLAND).

Jacques ZLOTNICKI (Laboratoire de Geophysique(a), UMR 6530, 3d av de la recherche scientifique 45071 Orleans cedex 02, France. Email: jacques.zlotnicki@cnrs-orleans.fr) & Departement des Observatoires Volcanologiques(b),, I.P.G.P., France) Jean Louis Le Mou & Jean Louis Cheminee(b), (I.P.G.P., Paris, France) Paul Yvetot(a) & Marie Hanne Ardisson(a), Michel Parrot (LPCE, Orleans,France)Thomas Staudacher (Observatoire du Piton de la Fournaise, Reunion)

La Fournaise volcano is a very active basaltic volcano, which has erupted in March 1998, after 6 years of quietness. First fissures opened on the north flank of the 2640m- high cone. After some hours, the effusive activity was located at the cone basis and gave rise to two cones. Two days later a small cone appeared on the Southwest cone flank, the activity of which subsided a few days later. On August 10, a new effusive activity appeared on the northern flank, outside Enclos Fouque caldera wall. The effusive activity lasted till October. Since several years a lot of magnetic (total field and components), telluric and Self-Potential recordings have been performed on this volcano. We will focus on the spatial and temporal variations: Magnetic signals, a few nT in amplitude, have appeared some weeks before the eruption; Magnetic signals were emphasised the day of the outburst, when the magma has migrated towards the ground surface. Amplitudes, up to 7 nT, were recorded; Telluric signals have been recorded in several autonomous stations. Some signals have appeared with a phase delay, depending on

the location of the station compared to the emplacement of the activity; Finally, SP signals, up to 2.5 V/km were recorded at the station located on northern cone foot.

JSA15/E/40-A3 1700

MOTIONALLY-INDUCED EM FIELDS: NATURAL NOISES FOR MONITORING MIYAKE-JIMA VOLCANO, IZU-BONIN ARC, JAPAN

Yoichi SASAI (Earthquake Research Institute (a), Univ. of Tokyo, Bunkyo-ku, Tokyo, 113-0032, Japan, email: sasai@eri.u-tokyo.ac.jp); Jacques Zlotnicki (Laboratoire de Geophysique (b), UMR 6530, 3d av de la recherche scientifique, 45071, Orleans, cedex 02, France); Makoto Uyeshima (a), Wataru Sekiguchi (a), Paul Yvetot (b), Yasunori Nishida (Graduate School of Science, Hokkaido Univ., Sapporo, 060-0810, Japan), Kunio Rikiishi (Fac. Sci. and Tech., Hirosaki Univ., Hirosaki, 036-8561, Japan); Yoshiharu Nagaya (Hydrographic Office, Japan Maritime Safety Agency, Chuoh-ku, 104-0045, Japan)

Miyake-jima is one of the most active basalt volcanoes in Japan. Since it has erupted at a rather regular interval in 1940, 1962 and 1983, the volcano is suggested now at a very preparatory stage to the next eruption. The typical activity is the flank fissure eruption: Basaltic magma rises up silently toward a depth of a few km below the summit and then extrudes rapidly by making tensile cracks. In order to monitor the gradual uprise of magma head, the EM observations started in 1995. Now we have 8 proton precession magneto- meters, 2 short-span SP arrays, a continuous MT station and a long base-line SP array using telephone cables. Miyake-jima volcano is surrounded by the Pacific Ocean where the dominant ocean current Kuroshio, 100 km wide and 2 - 4 knots speed, flows changing its direction with time. The meander of Kuroshio results in magnetic field changes of more than 10 nT with a few months' duration along with the associated SP variations. They may completely obscure possible volcano-electromagnetic effects.
Electric potential differences by submarine cables and magnetic field data on nearby islands are available to investigate the nature of the motionally- induced fields. Analysis of tidally-induced magnetic fields on Miyake-jima island revealed a typical feature of the island effect, i.e. spatial discrepancy of the Z component amplitude due to distortion of induced electric currents by a resistive island. Electric field data from near-shore electrodes connected with telephone cables over the island seem to be effective for cleaning the irregular magnetic variations arising from meandering Kuroshio.

JSA15/P/06-A3 1720

VOLCANIC LIGHTNING

Stephen R. MCNUTT (Alaska Volcano Observatory, Geophysical Institute, Univ. of Alaska Fairbanks, P.O. Box 757320, Fairbanks, AK 99775, USA, email: steve@giseis.alaska.edu)

Volcanic lightning is a common yet poorly studied phenomenon. A literature search shows that lightning has occurred at more than 55 volcanoes in association with eruptions of various types and sizes; it is especially common during larger eruptions. Reports at night are slightly more numerous than those during the day, presumably because lightning is easier to see at night. Volcanic lightning was responsible for the only deaths reported at Paricutin from 1943-1952 and also killed one person during the eruptions at Rabaul in 1994. A particularly well documented case of lightning occurred at Mt. Spurr, Alaska in 1992. Lightning was detected on seismic stations as simultaneous spikes and simultaneous gain-ranging (a feature that normally lowers the gain at a station when the signal level begins to saturate). Spikes had typical durations of 0.04-0.05 sec. Using uniform criteria we found 28 lightning flashes in the June 27 eruption, 29 in the August 18 eruption, and 3 in the September 17 eruption. The August lightning was strongest, June the weakest, and September intermediate, using peak voltages on station RSO, 94 km away. In all three eruptions the first lightning was recorded 20-26 minutes after the onset of the eruption, suggesting that charge separation occurred in the convecting cloud rather than at the vent. Data recorded by a Bureau of Land Management lightning detection system for the August eruption showed negative polarities for the first 12 recorded flashes and a positive polarity for the last. This suggests a charge separation based on particle size. All three eruptions were quite similar with durations of 3.5-4 hours, and tephra volumes of 44-56 million m3. The August eruption, however, produced stronger volcanic tremor, 30 cm2 reduced displacement as compared with 16 cm2 for June, and thus tremor amplitude correlates crudely with lightning strength. The September eruption occurred during the coldest and driest atmospheric conditions, which may explain the small amount of lightning. In general, lightning is important because it can confirm that eruptions are in progress, although the information may be limited by the long delay from eruption onset to first lightning and the variability of eruptive and atmospheric conditions.

JSA15/W/07-A3 1740

IMAGING DEEP RESISTIVITY STRUCTURE OF ACTIVE FAULTS IN NE JAPAN: PRELIMINARY RESULTS

T. GOTO (Aichi Univ. Educ., Kariya, Japan, email: tgoto@auecc.aichi-edu.ac.jp); Y. Ogawa (Geol. Surv. Japan, Tsukuba, Japan);M. Mishina (Tohoku Univ., Sendai, Japan);M. Uyeshima (ERI, Univ. Tokyo, Tokyo, Japan);T. Kasaya, M. Ichiki, N. Oshiman (DPRI, Kyoto Univ., Uji, Japan)S. Sakanaka (AVL, Kyoto Univ., Kumamoto, Japan);Y. Takahashi, T. Nishitani (Akita Univ., Akita, Japan);Y. Takahashi, Y. Honkura (Tokyo Institute of Technology, Tokyo, Japan); H. Satoh (Hokkaido Univ., Sapporo, Japan)H. Murakami(Kochi Univ., Kochi, Japan)

Deep resistivity structure of active faults in NE Japan was investigated by wide-band magnetotellurics(MT). The study area is under compression tectonics. The thrust fault systems on both sides of the mountain range are believed to help uplift the mountain block. The recent deep reflection data support this idea. We had 15 MT sites aligned on a 45km profile running across the mountain range. We used simultaneously 5 sets of 5 component MT systems and 5 sets of telluric- only systems. Preliminary two-dimensional inversion results using TM mode revealed the deep sub-vertical conductors, which probably coincide with the deep active faults imaged by the reflection seismic experiments. Lower crustal conductor at around 20km depth also underlies the whole profile.

VARIATION OF FREQUENCY CONTENT OF ELECTROMAGNETIC RECORD AT THE APPROACH AND AFTER THE 21 JULY 1995, M=5.7, YONGDEN EARTHQUAKE

Jacques Zlotnicki (CNRS, Laboratoire de Geophysique d'Orleans, 3D Avenue de la Recherche Scientifieque, 45071 Orleans, Cedex 02, France, E- mail: jacques.zlotnicki@cnrs-orleans,fr); Vladimir KOSSOBOKOV (International Institute for Earthquake Prediction Theory and Mathematical Geophysics, Russian Academy of Sciences, 79-2 Warshavskoye Shosse, Moscow 113556, Russia, E- mail: volodya@mitp.ru); Jean-Lois Le Mouel (IPGP, Laboratoire de Geomagnetisme, 4 Place Jussieu, 75252 Paris, Cedex 05, France, E-mail: lemouel@ipgp.jussieu.fr)

The frequency temporal analysis of electromagnetic field recorded during 05/30/95- 08/18/95 at the site about a hundred kilometers to the north from the epicenter of the 21 July 1995 Yongden earthquake (China) has shown a clear systematic variation. In an ultra low range from 0.1 to 0.005 Hz a dramatic threefold decrease of the frequency of the maximal energy concentration is observed, i.e. from 0.05 on 05/30/95 to 0.015 Hz few hours before the earthquake. The decrease is a step-like, nearly monotonous and continues after the Yongden earthquake for about two weeks reaching the minimum of 0.01 Hz just before an abrupt disappearance. At the after the main seismic event stage the record shows three multiple frequencies of maximum energy concentration, thus suggesting a transition of the lithosphere crust system to a chaotic behavior. The results are subject to further understanding and interpretation. More data, both electromagnetic and seismic, are needed to outline the source of the observed phenomenon, its relation to tectonic environment and stress field, as well as to the universal scenarios of transition to a catastrophe.

JSA15/P/03-A4 0920

ANOMALOUS IONOSPHERIC SPORADIC E LAYERS OBSERVED BEFORE THE HYOGOKEN-NANBU EARTHQUAKE OF M 7.2

Tadanori ONDOH (Space Earth Environment Laboratory, Kitano, Tokorozawa, 359-1152, Japan, email: 77771903@people.or.jp)

Strong sporadic E layers of foes above 6.5 MHz (~ 100 km in altitude) were observed for 1300-1430 JST on January 15, 1995 at Shigaraki, 100 km northeast of the epicenter of Hyogoken-nanbu earthquake which occurred at 0546 JST on January 17, 1995 near Kobe, Japan, and also at 1300 JST on January 15 at Kokubunji, 500 km east of the epicenter. The day of January 15, 1995 was a geomagnetically quiet one ($\sum K=3$), and the local geomagnetic index for 12-15 JST on January 15 was K= 0 at Kakioka near Kokubunji. There was no solar flare during the daytime of January 15. The sporadic E layer normally appears during the daytime from April to August at mid and low latitudes in the northern hemisphere. Consequently, the anomalous sporadic E layers observed on January 15 seem to be a precursory ionospheric phenomenon of the Hyogoken-nanbu earthquake of January 17,1996. Radon emanations of about 10 times the normal ion density were observed within 200 km from the epicenter before the Hyogoken-nanbu earthquake (Wadatsumi 1998). However, the Radon increase is too small to produce the anomalous sporadic E ionization, even if the Radon emanations would go up to the ionosphere. Since the sporadic E layer is often observed simultaneously with strong lightning discharges in the tropical region, the anomalous sporadic E layers of January 15 could be caused by unknown seismo discharges.

JSA15/W/30-A4 0940

INVESTIGATION OF ELECTROMAGNETIC WAVE RADIATION IN THE VLF RANGE ASSOCIATED WITH EARTHQUAKES

Hisatoshi BABA, M. Sugiura, T. Asada (Research Institute of Science and Tecnology, Tokai University, 1117, Kitakaname, Hiratsuka, Kanagawa, 259-1292, Japan; ph:+81-463-58-1211; fax:+81-463- 50-2034; E-mail: hbaba@keyaki.cc.u-tokai.ac.jp); M. Kawazoe (School of Engineering II, Tokai University, 2-28-4, Tomigaya, Shibuya, Tokyo, 151, Japan; 81-3-3467-2211); and S. Iizuka (Faculty of Marine Science and Technology, Tokai University, 3-20-1, Orido, Shimizu, Shizukoka, 424-8610, Japan; ph:+81-543- 34-0411)

Investigations of electromagnetic radiation possibly associated with earthquakes have been made in the last two decades. In some studies the relation between the change in the electromagnetic noise level and the occurrence of earthquakes has been discussed. However, the discussions on the relationship between the changes in the noise level or the changes in the frequency of signals per hour and the occurrence of earthquakes were not sufficient, because wave forms of these signals were in most cases not recorded. In the present study, signals in the frequency range from 1 kHz to 10 kHz are recorded. Most of these signals have been determined to be atmospherics. Therefore one of the fundamental problems is to establish a method of delineating signals that are related to earthquakes from those that are not related to them. The location of the source of atmospherics generally changes every time, while signals associated with an earthquake appear to be generated in a definite area close to its epicenter. This feature, if established, would be useful in distinguishing signals related to an earthquake from atmospherics. In our instrument, signals are recorded digitally, and the direction of approach is calculated for each signal. During the one and one half years period of our observation we have obtained a result that among the four earthquakes that occurred during this period, three generated signals in the areas close to their epicenters several days prior to their occurrences. The magnitudes of these earthquakes were about 5, their depths 20 to 40 km, and the epicentral distances from our recording networks less than 100 km. We have concluded that these signals can be regarded as being precursors of the three earthquakes. Earthquakes, which occurred in the ocean floor, did not generate signals in the areas close to their epicenters. These earthquakes were of magnitude smaller than 4, more than 50 km in depth, or more than about 100km in distance.

JSA15/E/49-A4 1000

A COMPARATIVE STUDY OF THE LITTHOSPHERE - IONOSPHERE COUPLING MECHANISMS

Michail GOKHBERG, Oleg Pokhotelov and Sergei Shalimov (all at Institute of Physics of the Earth, 123810 Moscow, Russia, Email: gokhberg@dir.iephys.msk.su; pokh@uipe-ras.scgis.ru)

A review of coupling mechanisms that could transform geophysical field anomalies generated at the source of seismical activity into large-scale ionospheric disturbances is presented. The problem is critically analyzed from different points of view, which involve magnitude and intensity of the possible sources in the lithosphere and on the Earth's surface, energy transfer upward into the ionospheric level (both dissipation and transformation into the ionospheric disturbances), the possibility of the ionospheric anomalies discription in terms of unique model. Nonstationary boundary conditions that might modulate evaporation and outgassing rate are discussed. The latter processes can produce large scale atmospheric thermal and electromagnetic anomalies possibly related to the earthquake preparation and comprise green-house and radon gas anomalies. Two hypothetical coupling mechanisms are outlined: by electromagnetic low-frequency waves and by acoustic-gravity waves, which can be generated by the nonstationary atmospheric gas anomalies. The propagation of these waves through the atmosphere up to the ionospheric heights, and corresponding dissipation factors are considered. An efficiency of action by these waves from below upon the ionospheric plasma, and their possibility to cause observable ionospheric pattern is quantitatively estimated.

JSA15/W/08-A4 1040

SOME FEATURES OF THE ULF BAND ELECTROMAGNETIC FIELD CHANGES RELATED WITH EARTHQUAKE SWARM

Yukio FUJINAWA, Takumi Matsumoto (NIED: National Research Institute for Earth Science and Disaster Prevention, E-Mail: fujinawa@bosai.go.jp), Kozo Takahashi (CRL: Communications Research Laboratory), Hiroshi Iitaka, Shigeru Yamane (ETL: electrotechnical Laboratory), Takeshi Nakayama, Hideo Sakai (Toyama University), Toyoaki Sawada (Kyoto University),and Yuji Enomoto (MEL: Mechanical Engineering Laboratory)

Electric field variations of dc, ULF (0.01_`0.7 Hz), VLF (1_`9 kHz) bands have been observed by using the borehole antenna at ten sites in Central Japan including the Hodaka site, Gifu Prefecture. Conspicuous anomalous changes were found at the Hodaka site to accompany with the nearby seismic activity at the border of Nagano, Gifu and Toyama. Prefectures occurred during the period from August to November 1998. The anomalous change correlated with the crustal activitiesis is the second one during the observation period at Hodaka site since 1993. The first one was observed at the time of a small scale steam explosion in July 1996. The change is so clear that it is easy to discriminate from the normal calm state except very short duration of changes which were very probably induced by the large-scale lighting activities. The present electric field changes appeared in the whole three frequency bands of dc, ULF and VLF bands, but the former two bands dominated, and the VLF band appeared only at the occasion of conspicuous earthquake activities. The VLF band components were small in amplitude, so as not to be observed at nearby stations of distance about several tens kilometers with the result that the source were not located by the location system available now (Fujinawa et al., 1997). But it is suggested that the source of the VLF band was in the region of seismic activity. The vertical components provided larger signals in comparison with the horizontal components suggesting that the ULF and dc components are induced by the sources deep underground. The electric anomalous changes are suggested due to the electro-kinetic effects related to the water flow activated by the magma injection around the zones. Strong similarities among the electric field anomalous changes hitherto reported by the VAN group (Varotsos et al., 1996), Uyeda group at the time of the off-Noto peninsula earthquake in 1993 (Nagao et al., 1996) and those at the Izu-Oshima observation sites at the time of small volcanic activity of 1990 in the Izu-Oshima island by us (Fujinawa et al., 1992) indicated that the anomalous electric signals associated with earthquake can be attributed to electric field changes induced by water flow causing earthquake in agreement with the seismogenetic process hypotheses on the basis of dominant role of fluids in the stress-concentrated region (e.g., Sibson, 1981; Bernard, 1992).

JSA15/W/17-A4 1100

MODELLING OF THE "TERMINATOR-TIME" EFFECT: CONSIDERATION OF A SUGGESTED EARTHQUAKE PRECURSOR

Craig J. RODGER, and Mark A. Clilverd (both at UASD, British Antarctic Survey, Cambridge CB3 0ET, UK, email: cjro@mail.nerc-bas.ac.uk); Neil R. Thomson (Physics Department, University of Otago, Dunedin, New Zealand)

It has been reported that propagation of very-low frequency (VLF) waves in the Earth-ionosphere waveguide might provide an indication of imminent earthquakes. Such narrow band data from Inubo, Japan suggested that transmissions from Omega, Japan, 1000 km away, might be influenced by pre-earthquake processes. In this report the authors defined the Terminator Time (TT) as the time where a minimum occurs in the received phase (or amplitude) during sunrise and sunset. A few days before an earthquake the TT was observed to significantly deviate from the monthly averages, producing a longer "VLF day". The TT effect has been explained through some rather simple modelling by a 1-2 km drop in the VLF reflection height at the lower ionospheric boundary.
Here we consider the application of more realistic propagation models to this situation. Comparisons are made between the more realistic models, those presented previously, and the effects of known influences upon the altitude of the lower ionospheric boundary.

JSA15/W/31-A4 1120

METHOD OF MEASURING "ABSOLUTE" VLF/LF PHASE (FREE OF NON-PROPAGATION EFFECTS) TO TEST FOR SEISMIC- INDUCED IONOSPHERIC PERTURBATIONS

Richard DOWDEN and James Brundell, (LFoEM Research, 161 Pine Hill Rd, Dunedin, New Zealand,) Neil Thomson, (Physics Department, University of Otago, New Zealand.)

A seismic-induced ionospheric perturbation appears a few days before an earthquake and continues for days or weeks after the earthquake [1]. The perturbation induced by the Kobe earthquake was measured by the advance/retard of the terminator times (TT) of the 1000-km propagation of the 10.2 kHz transmission from Omega Japan (Tsushima) to Inubo. This perturbation was that expected if the VLF reflection height had decreased some 1-2 km [1]. If so, the corresponding midday phase change due to propagation of the VLF signal would have been 10° to 20°. Over several days, any slow phase drift due to propagation can be masked by phase drift in the receiver. Thus a receiver using a reference which is off frequency by only 1.5 parts in 10^11 (about that of a rubidium oscillator) logging the received phase of a perfect transmitter at exactly 10.2 kHz would see a spurious phase drift of 5°/ day. This is about that of the Kobe effect due to propagation. This is why the TT method was used instead. However, a drift-free receiver can be made using an oscillator of only mediocre stability of only 1 part in 10^6 (about that of a cheap quartz wristwatch) provided the oscillator is reset to zero phase every second by GPS. The "selective availability" of GPS means that the individual GPS pulses can be early or late by up to 1 microsecond. This will introduce a phase jitter in even a perfect oscillator at 10.2 kHz of up to 3° but there would be no long term drift at all relative to GPS which can be the reference for all such receivers in a network. The phase jitter is reduced to below detectability if the phase received from a stable transmitter is averaged over several hours about midday. Phase records from such a drift-free receiver over some months show a slow phase drift of a few tenths of a degree per day due to the seasonal variation of the midday sun altitude. Large phase perturbations due to solar flares occur but these are easily allowed for. Departures from this seasonal drift, accumulating, say, 1° over a few days would be noticeable. This is less than a tenth of the effect of Kobe earthquake. A network of many receivers, each logging many transmissions, enables hemisphere-wide perturbations (e.g., solar flares) to be allowed for and also allows location of the perturbing source.

JSA15/E/39-A4 1140

STUDY OF IONOSPHERE DISTURBANCES, CALLED BY QUARRY EXPLOSIONS, IN RANGE OF EXTREMELY LOW FREQUENCIES

Mikhail GOKHBERG (United Institute of Physics of the Earth, B. Gruzinskaya, 10, Moscow, 123810, Russia, e-mail: gokhberg@dir.iephys.msk.su); Alexander SARAEV and Mikhail Pertel (St. Petersburg State University, Universitetskaya nab. 7/9, St. Petersburg, 199034, Russia, e-mail: aks@aks.usr.pu.ru)

Parameters of ionosphere processes are used for the study of wide class of seismic signals, including the ionosphere precursors of earthquakes. One of the most effective ways of modeling of seismoionosphere connections is the influence on ionosphere by powerful explosion. Earlier for study of ionosphere disturbances was applied the method of soundings in megahertz frequency band. Very low frequencies 10-15 kHz (system "Omega") was used also. We studied the explosion acoustic influence on the propagation of extremely low frequencies (ELF) radio waves with use of the ELF radio station "Zevs", situated on Kola peninsula. Its operational frequencies changes from 30 up to 200 Hz, a long-range action makes about 10 000 km. The observation point was near St. Petersburg on distance 950 km from transmitter. Quarry explosions near transmitter, observation point and profile between them were taken into account. The amplitudes of electric and magnetic fields before explosions as background situation, and also in time and after explosions, as response on acoustic influence were registered. The disturbances of electric and magnetic field amplitude, observable after explosions, as oscillations with period about one hour, were registered. The depth of modulation reaches 15-35 %. The oscillations of such period in the ionosphere correspond to the phenomena, observable in the ionosphere before earthquakes. The obtained results indicate about perspective of use of the ELF-station "Zevs" for monitoring of ionosphere disturbances, connected with earthquakes preparation. The work was performed with the support of "Universities of Russia" program, N 2140.

JSA15/E/09-A4 1200

STATISTICAL PARAMETERS OF ULF ELECTROMAGNETIC NOISES AND SEISMICITY

Nadezhda YAGOVA, Viacheslav Pilipenko (Institute of the Physics of the Earth, Moscow 123810, Russia, e-mail: vpilipenko@uipe-ras.scgis.ru);Kiyohumi Yumoto (Kyushu University, Fukuoka 81-812, Japan; e-mail: yumoto@geo.kyushu-u.ac.jp)

The analysis of ULF (ultra-low-frequency 0.001 - 0.1 Hz) geomagnetic noises at 3 low-latitude stations of the network "210 Magnetic Meridian" showed that their intensity is controlled mainly by the geomagnetic activity. For geomagnetically quiet conditions the ULF background amplitudes and spectral content remain stable for several months. The analysis of amplitudes and spectral slope of nighttime magnetically quiet ULF noises showed some middle-term (several weeks) enhancenments at the low frequencies correlated with moderatelly strong (M>5.5) close-by earthquakes. No anomalous variations at the magnetically conjugated Australian stations were observed. These variations of ULF noise paramaters have a local character and they cannot be explained by known magnetospheric or seasonal meteorological phenomena. The hypothesis about their possible seismic origin is discussed. The spectral features of these noises are in accordance with this suggestion. It is proposed that the existing global networks of magnetic stations could be effectively incorporated into seismic warning systems.

JSA15/E/44-A4 1220

NEW PECULIARITY OF THE NATURAL BACKGROUND ARJUND 1 HZ FREQUENCY RANGE

Michail GOKHBERG, (Institute of Physics of the Earth, 123810 Moscow, Russia,
Email: gokhberg@dir.iephys.msk.su)

In my report the diurnal and seasonal distribution of the wide band natural noise level in the frequency range 0.5-5 Hz are resented. These results are based upon the analysis of data during 1996-1997 obtained at two observatories: one is located in the center of European part of Russia (obs. Borok) and another one in the middle of Siberia (obs. Mondy). The correlation of intensity variation from the different parameters as index of geomagnetic activity, local temperature, clouds, rain precipitation, local storms, etc. are discussed. Strong variations of intensity are sown. The typical time scale corresponds to several gradations: hours, days and month. Such variation of intensity is related to the natural phenomena in the absence of seismic activity start to be a critical issue for the use of this frequency range for earthquake prediction. Some points of view and recommendation for discrimination possible anomaly related with earthquakes and the background intensity variation are presented. The special attention in the discrimination problem solving is paying to the simultaneous registration of electric and magnetic field components. The discrimination ability in this case is effectively enhanced.

POSSIBLE TECHNIQUE FOR EM MONITORING OF UNDERWATER EARTHQUAKES AND TSUNAMI

BOYARCHUK K.A. (General Physics Institute, 38 Vavilov Str., Moscow, 117942, Russia, Email:boy@kapella.gpi.ru); Pulinets S.A. (IZMIRAN, Troitsk, Moscow Region, 1420942, Russia, E-mail: pulse@izmiran.rssi.ru); Svirko Yu.P. (Applied Physics Department, University of Tokyo)

Electromagnetic field variations over the ocean can occur during earthquakes and tsunami because of the following effect. It is known that the acoustic wave propagation in an electrolyte solution, for example in ocean water, is accompanied by stimulation of a variable electric field inside a solution. The reason of given effect is the charge separation because of various weights and mobility of cations and anions. Owing to that the ions of different kinds are dragged in different way by driven solvent. Underwater earthquakes can cause strong perturbation of a water layer at the epicenter area, and the gear of transfer of energy from the oscillating bottom to a layer of a liquid can be a resonant type. Thus a layer of water by a depth about several kilometers is a natural resonator with a determined set of frequencies, lying in range of frequencies of seismic processes. Therefore effective transfer of energy from the driven bottom to the bulk of water is possible. The similar effect can be responsible for generation EM waves of a range 0.1 - 10 Hz in seismic regions. Thus the application of given effect for monitoring of geophysical hazards is possible.

ELECTRICAL POTENTIAL SIGNALS FROM FRACTURED CRUSTAL ROCKS

O. C. CLINT (1), P. R. Sammonds (1), Yoshida, S (2), (1) Rock and Ice Physics Laboratory, University College London, London, UK. (2) Earthquake Research Institute, University of Tokyo, Tokyo, Japan

Fluid flow through porous rocks yields measurable electrical convection currents. The electrical potential anomalies due to this fluid flow depend on the applied pressure gradient. If the existing pore network of a rock medium changes during compaction and dilatancy, a corresponding electrical potential should be observed. We report results from triaxial deformation experiments on sandstone to investigate these expectations. The temporal electrical potential change and streaming potential were measured during constant strain rate experiments. Confining pressures were varied between 20MPa to 100MPa with pore fluid pressures ranging between 10MPa to 50MPa at room temperatures. Microseismicity was

recorded concurrently and analysed to provide information on the strain- induced micro-cracking. We show pre-cursory electrical potential signals can be observed from crustal rocks undergoing deformation and the effect of a varied range of pore fluid salinity is presented. Temporal variations of electrical potential difference change markedly during compaction and dilatancy. Microseismicity show an exponentially increasing event rate and decreasing b-value during this period. Our measurements can be interpreted using an electrokinetic model and suggest micro-cracking during dilatancy is a dominant source of the electrical phenomenon.

MODELING EXPECTED AND OBSERVED PIEZOMAGNETIC FIELD CHANGES IN THE LONG VALLEY CALDERA, CALIFORNIA

Yoichi SASAI (Earthquake Research Institute, Univ. of Tokyo, Bunkyo-ku, Tokyo, 113-0032, Japan, email: sasai@eri.u-tokyo.ac.jp); Malcolm J. S. Johnston and Robert Mueller (both at US Geological Survey, 345 Middlefield Road, Menlo Park, CA 94025, USA); Yoshikazu Tanaka (Geothermal Research Center, Fac. Sci., Kyoto Univ., Choyo-son, Aso, Kumamoto, 869-1404, Japan); Jacques Zlotnicki (Laboratoire de Geophysique, UMR 6530, 3d av de la recherche scientifique, 45071, Orleans, cedex 02, France); Tadanori Goto (Dept. Environmental Earth Sci., Aichi Univ. Educ., Kariya, Aichi, 448-8542, Japan)

In Long Valley Caldera, remarkable changes in the total intensity have been observed, associated with a dramatic inflation near the central resurgent domes since 1989 (Mueller and Johnston, 1998). Total intensity changes during the first seven years can be interpreted in terms of piezomagnetism due to inflation of a spherical pressure source at a depth of 8 km. This same source explains the main features of the deformation data. However, neither the deformation data nor the magnetic data can be interpreted by such a single source model during heightened deformational and seismic activity in late 1997. In particular, the deformation data requires additional sources and can be satisfied by the addition of either an intrusive dyke at a depth of 4 km to 8 km, dipping by 45 degree located on the SE side of the main spherical pressure source, or a more complex model involving a combination of a deep-seated pressure source (depth 13 km) and slip on a vertical strike-slip fault with its top 4km deep beneath the south moat. We calculate the piezomagnetically generated magnetic fields expected from these models and compare these with the observed fields. Furthermore, we installed 5 proton magnetometers in the summer of 1998 to attempt to provide better differentiation between these two possible sources in the future.

HYDROTHERMAL SYSTEM AND FAULTING IN LONG VALLEY CALDERA INFERRED -BY SELF-POTENTIAL MAPPING

Jacques ZLOTNICKI (Laboratoire de Geophysique(a), UMR 6530, 3d av de la recherche scientifique 45071 Orleans cedex 02, France. Email: jacques.zlotnicki@cnrs-orleans.fr); Tadanori Gotoh (Dept. Environmental Earth Sci., Aichi Univ. Educ., Kariya City, 448-8542, Japan); Malcolm Johnston (U.S. Geological Survey, Menlo Park, CA 94025, USA); Alban Mille(a) & Jean-Francois Delarue(a), Yoshikazu Tanaka (Beppu Geothermal Research Lab. of Kyoto Univ., Beppu, Japan); Yochi Sasai (Earthquake Research Institute(b), Tokyo Univ., Japan)

Long Valley caldera, located at the east of the Sierra Nevada, is a huge active volcanic complex. The caldera corresponds to an elliptical depression, about 32 km from the east to west by 17 km from north to south. Mainly on the northern, western and southern sides, 1000 m- high walls are encountered. After 250 years of relative inactivity, episodes of accelerated deformation with associated seismic swarms started in 1980 and have continued to the present. The net uplift of the resurgent dome in the centre of the caldera as a result of magma intrusion now exceeds 70 cm and affects more than 100 km2. During summer 1998, a large SP mapping of the central part of the caldera was completed through the region previously mapped by Anderson et al. (1976) to identify changes since that time. Profiles were also extended in the NW and SE directions past the caldera boundaries. The surveys were done along several kilometres long loops in order to check the closure errors. The measurement interval was 200 m and more than 80 km of profiles was measured. Large SP anomalies, up to 500 mV, were observed. Some of them present a negative linear relationship with the topography; we can associate these anomalies with the so-called "topographic effect". Other anomalies point out sharp flanks that could be associated with superficial faulting and hydrothermal activity. For instance, smooth SP anomalies are related to the Casa Diablo geothermal field.

THEORY OF SEMS AND REPRODUCTION EXPERIMENTS OF EARTHQUAKE-PRECURSOR LEGENDS (VIDEO)

Motoji IKEYA, Chihiro Yananaka, Hiroshi Matsumoto and Synji Takakai (Department of Earth and Space Sciences, Graduate School of Sciences, Osaka University, 1-1 Machikaneyama, Toyonaka, Osaka 560, Japan)

Mysterious phenomena told as legends, proverbs and folk stories related to earthquakes and some of those reported retrospectively by citizens as precursors to the Kobe earthquake in 1995 have been examined and reproduced in electromagnetic (EM) experiments using a Van de Graaff generator and in rock-compression using 500 ton compression machine. (1) Unusual animal behaviour such as alignment and jumping of fish, both reported as precursors of the Kobe earthquake, were caused by pulsed electric fields. Rock fracture experiments produced EM waves and some unusual animal behaviour. (2) Malfunctioning of home electric appliances before the earthquake was reproduced, and so were noises on TV and radio, rapidly moving or stopping of the hands of a quartz clock, buzzing air-conditioner and refrigerator and so on. Laboratory experiments indicate that legends, proverbs and old sayings are not superstitions and can be reproduced and elucidated by intense seismic EM waves and appearance of pulsed charges at the epicenter. Physics, which produces SEMS, is due to the piezo-compensating charges released by stress changes. An ensemble of released charge pairs radiate EM waves resulting in pulsed EM waves whose propagation and attenuation were calculated. The scaling laws derived theoretically agree well with empirical ones. Physics of SEMS has quantitatively been established based on an electromagnetic model of a fault having piezoelectric quartz grains in the bedrock. NEW METHODOLOGY FOR ANA LYSIS OF ELECTROMAGNETIC FIELD DISTIFRBANCES AND EARTHQUAKES

H.N. SRIVASTAVA (India Meteorological Department New Delhi-110003, India, e-mail: snb@imd.ernet.in)

There is growing observational evidence between electromagnetic field anomalies as precursory to earthquakes. However, the results are often considered as chance particularly after the controversy about VAN predictions in Greece. Instead of applying a simple statistical methodology using Null hypothesis, a new method is proposed for interpretation of data which is based on the Principal components analysis. We need to choose physically linked parameters like specific area (including selectivity, if any), epicentral distance, focal depth, magnitude, source mechanism and other paramters to work out the loading factors in relation to the impending earthquakes. Case examples are given using observations to validate the new methodology.

PHYSICAL MECHANISMS FOR THE GENERATION OF ELECTROMAGNETIC FIELDS DURING EARTHQUAKES

A. GUGLIELMI (Institute of Physics of the Earth, B. Gruzinskaya, 10, Moscow, 123810 Russia, Email: gugl@scgis.fisgeos.iitp.ru)

The theory describing the excitation of electromagnetic field by the earthquakes is outlined. The inertial, inductive, piezomagnetic and electrokinetic mechanisms are considered in details. The generation of electromagnetic waves in the ULF frequency band under the action of elastic waves and also due to the inelastic motion in an earthquake centre is studied. The solution of the problem on electromagnetic field of a propagating fault in the frame of two-dimensional model is presented. Particular attention has been given to the expressions describing the magnetic signal amplitude versus the magnitude of earthquake. The magnetic signal observed by Iyemory et al. at the 1995 Hyogoken-Nanbu earthquake (M = 7.2) is interpreted in the framework of the presented theory.

PHYSICAL MECHANISMS OF GENERATION OF ELECTROMAGNETIC ULF SIGNALS PRECEDING EARTHQUAKES

Viacheslav PILIPENKO, Evgenij Fedorov (Institute of the Physics of the Earth, Moscow 123810, Russia, e-mail: vpilipenko@uipe-ras.scgis.ru); Vadim Surkov (Moscow Engineering Physics Institute, Moscow 115409, Russia; e-mail: vpilipenko@uipe-ras.scgis.ru)

The existing theories of the emergence of anomalous electromagnetic emissions and impulses in the ULF frequency range (up to 10 Hz) preceding earthquakes are critically revised. For a better physical insight simplified easy-to-use analytical estimates of the expected effects have been derived. The principal results of the existing numerical models are reproduced in a much simpler way without mathematical complexities. The considered phenomena comprise electrokinetic effects, seismo-inductive effects, filtration of underground fluid, charge relaxation related to micro-crack formation, large-scale current systems produced by dislocations or water evaporation, inductive effects caused by seismo-acoustic impulses from micro-cracks, plasma oscillations, etc. It is demonstrated that none of the theories can be fully adopted because of essential intrinsic difficulties. The comparative elementary analysis of the structure of hypothetical electromagnetic disturbances, produced by a lithospheric source, and of common electromagnetic noises suggests some simple technique for the discrimination of multi component signals from those two sources, based on the difference in their polarization structures.

ACTIVE ELECTROMAGNETIC MONITORING OF EARTHQUAKES

Fedir DUDKIN and Valery Korepanov (Lviv Centre of Institute of Space Research, 5-A Naukova str., 290601, Lviv, Ukraine, e-mail: vakor@isr.lviv.ua)

Changes of electromagnetic (EM) fields during and before the earthquakes (EQ) have been clearly observed in many cases. The most difficult problem is to detect them because of very low level of these fields. Also any conclusion can be made today about the connection with seismic hazards of their other parameters such as frequency band, polarization etc. Because of this the extraction of noise-like seismogenic EM emission on the noisy EM background is an extremely complicated task.
A possibility of active EM sounding is investigated. It is widely used in geophysics for the study of crust deep conductivity structure. And it is also known that both the speed of seismic waves and the crust mean longitudinal conductivity can change before the EQ (Scholtz model), what is provoked by crust structural changes and hence can be very good observed in the regular field of artificial source. The development of local changes and irregularities (such as cracs and boundaries shifts) preceding the EQ also can be monitored using active EM sounding. This method has especially great advantages when the monitoring is executed near big cities or industrial centers where EQ effects are the most harmful. This is because having constant and known frequency of the monitored signal the well-developed methodology of synchronous detection can be applied, which is known to be able to extract useful signals with signal-to-noise ratio lower than 10-5.
Some examples of cracks and inner boundary uplifts were calculated which show significant contribution in the sounding EM field changes for the deformations about some few hundreds of meters at the depth till 40 km.

MATHEMATICAL MODEL OF GENERATION AND PROPAGATION OF SEISMO-ELECTROMAGNETIC (EM) AND SEISMO-TEMPERATURE (T) SIGNALS

Oleg NOVIK (Moscow State Geol.Prospect.Acad.,117246,POB51,Moscow,Russia
email: Onovikl@glasnet.ru); Sergey Ershov (Keldysh Inst. for Appl. Math. of Russian Acad. Sci., Moscow); Irina Mikhaylovskaya (Moscow State University. email: irina@nw.math.msu.ru).

Our model medium includes: a) the lithosphere zone with the conductive layer (c.l., 0.1 S/m) in the upper mantle and the conductive block (c.b., 0.1 S/m) in the crust; b) the atmosphere zone up to the low boundary of the ionosphere domain D. As the matter of fact, the structures with the cross-section size 10 to 50 km and the conductivity of order above were discovered in most of seismic lithosphere zones at the depth >10 km. Proceeding from these data we construct the mathematical model and describe numerically and graphically the em- and t-signals caused, in presence of geomagnetic field, by the elastic (e) displacements of the bottom of the c.l. (during 5 sec, amplitude up to 3 cm, freq. up to 1.5 Hz). The signal forming includes: 1) the appearance of the em-signal (~150 pT during 1 sec after the beginning of the displacements); 2) the e-, em- and t-field diffraction on the c.b.; 3) the correspondence between the spatial structures of the e-, em- and t-waves and the correspondence between their spectra; 4) the saturation of the c.b. with the energy of the disturbed e-field; 5) the outrunning of the seismic wave by the em-wave (~0.1 sec per 1 km of the trace) and the em-emission into atmosphere (up to 60 pT at the earth surface and up to 10 pT at the height of 30 km); 6) the t-disturbance of the sedimentary layer (up to 0.02K); 7) the delay of the surface em-signal as regard to the beginning of displacements; 8) the change of the amplitudes and spectra of the surface em-t-signal after the change of the elastic displacements at the depth. These properties of the em-t-signal are similar by different input data of the computations.

ANOMALOUS PHENOMENA PRECEDING EARTHQUAKES

Igor I. ROKITYANSKY (Institute of geophysics, POB-338/7, Kiev-146, Ukraine, email: earth@igph.kiev.ua)

The concept of earthquake (EQ) unpredictability has grown over the last decade. According to A.Gusev (EOS,1998,10 Feb, p.71, 4 Aug, p.373), it can be expressed as follows: EQs are unpredictable within the framework of the present paradigm. A paradigm is a system of accepted ideas and laws considered by the scientific community as the truth for a certain period of time. A phenomenon that is unexplainable within the framework of the present paradigm can be labeled as an anomaly. When the quantity of anomalies reaches a critical value, the paradigm changes, opening a way for an explanation of the anomalies. EQ precursors offer a collection of anomalies: luminosity of the atmosphere, changes in ionosphere parameters, EM-emission, cloud lineaments, SES (Seismic Electric Signals). Three stages of paradigm changes are considered, and the conclusion is made that the second stage is necessary. This implies an expansion of physics via the introduction of new entities and laws. To support the conclusion, searches for other anomalies had been conducted. The results will be presented from metrology, bio-, geo-, astro- and nuclear physics, and chemistry. Speculative ideas concerning possible extension of physics are also reviewed.

MAGMA-INTRUSION SWARM GENERATION AS A PLAUSIBLE EXPLANATION OF SEISMIC ELECTRIC SIGNALS (SES) AND CRUSTAL EARTHQUAKES (EQ) IN GREECE

Igor I. ROKITYANSKY (Institute of geophysics, POB-338/7, Kiev-146,Ukraine, email: earth@igph.kiev.ua)

Crustal intrusions occur widely in the Earth's crust. In some places they form giant, radiating dike swarms (Earnst et al., 1995, Earth Sci.Rev.,v.39,1-58) extending up to 2,000 km from the center. Guterman & Khazan (1994, Geophys.J., v.16,N1,22-29) proposed the magma intrusion mechanism as an explanation for the recent strong shallow EQs. Proceeding from the two results, a model of the magma intrusion swarm is developed. It includes the mantle reservoir - plume head (MR), the deep channel (DC) from the MR to the central crustal chamber (CCC), and several chains of secondary crustal chambers (SCC) spreading quasi-radially from the CCC for up to hundreds of kilometers. A SES station placed in the vicinity of a DC or a CCC will be sensitive to magma flow toward any distant SCC. If conditions for an EQ in a peripheral chamber are favourable, the SES will also be recorded near the DC-CCC, even hundreds of kilometers away from an impending EQ. With four most effective SES stations (IOA, ASS, KER, PIR) in place in Greece, one can anticipate observing four principal intrusion swarms with DC-CCC in the vicinity of each of these stations. Mutual crossing and overlapping of the swarms can explain the puzzling characteristics of the SES: selectivity, lack of reversibility, and alternation. To progress from the outlined scheme to a meaningful pattern, all seismological, geo-electrical, geothermal, geodetic, and geological data obtained in Greece should be reviewed and utilized. The question to be answered is: what does the SES represent? Is it the magma flow, or the beginning of the flow, the process of the opening of the magma channels. To clear up the question, SES observations in volcanic areas would be helpful.

SPONTANEOUS POTENTIALS, GEOMAGNETIC ANOMALIES, ENDOGENOUS ENERGY, IONOSPHERIC COUPLING, AND SEISMIC AND VOLCANIC PRECURSORS

C. BELLECCI (II Universita di Roma, Tor Vergata, Roma, Italy); G. M. Crisci (UNICAL, Arcavacata di Rende, Cosenza, Italy); G. P. Gregori (IFA-CNR, via Fosso del Cavaliere 100, 00133 Roma, Italy; e-mail: gregori@atmos.ifa.rm.cnr.it); V. Lapenna (ITAAA-CNR , Potenza, Italy); I. Marson (Universita di Trieste, Italy); and G. Paparo (IDAC-CNR, Roma, Italy)

According to Gregori (PEPI, 77, 39, 1993), a great heterogeneity exists of the underground electrical circuits that relate the deep dynamo currents with shallow structures, such as even the magma chamber of volcanoes. Such an inference, provided it is correct, must imply: (1) that volcanism and geothermal heat flow are supplied (at least partially) by Joule's heating; (2) that the e.m. coupling between ground and ionosphere is quite different in different regions; (3) that the prime supply to volcanoes can be Joule's, and that its time variations ought to be closely correlated with the local spontaneous potentials, and with the geomagnetic secular variation (one should, however, also allow for different case histories to be supplied e.g. by frictional heat transformed from geodynamic energy); (4) that the geomagnetic anomalies within every volcanic area ought to reflect the geometry of the prime DC circuit that supplies its Joule's heating; (5) that the geo-e.m. precursors of either earthquakes or volcanic activity, either within ground or within the ionosphere and/or airglow, are not the same everywhere, due to the different morphologies of the underground circuits, and to their consequent ionospheric coupling (therefore, the well known controversi e s are nonsense). One seismic case history concerned with the Appennino Lucano is presented. An interdisciplinary experiment on the island of Stromboli is going to be started for checking whether such an entire interpretation is supported by observations, or not: the timing of Stromboli's explosions ought to be directly related to the variations of its spontaneous potentials.

ELECTRICAL SELF-POTENTIAL ON THE CENTRAL CONE OF ASO VOLCANO

Yoshikazu TANAKA (Aso Volcanological Laboratory, Kyoto Univ., Aso Kumamoto, 869-1404, Japan, email: tanaka@aso.vgs.kyoto-u.ac.jp); Hideaki Hase (AVL, email: hase@aso.vgs.kyoto-u.ac.jp), Takeshi Hashimoto (AVL, email: hasimoto@aso.vgs.kyoto-u.ac.jp) and Shinya Sakanaka (AVL, email: sakanak a@aso.vgs.kyoto-u.ac.jp)

Aso is one of the most active volcanoes in Japan. After huge eruptions occurred in 80,000 years ago, resurgent volcanism at many part of the cones finished in ages ago. Many hot springs were developed around west part, and the historical volcanic activities remain only at west flank of Mt.Nakadake. We conducted SP measurement in the summer of 1998 to reveal a geothermal activity of the volcano. Using CU-CUSO4 and Pb-PbCl2 electrodes, potential differences in each 100m were measured by a digital voltmeter with accuracy 1mV. Along a north-south route close to the active crater, the SP showed "W" character like change, namely, the SP decreased in proportion to height at the foot, but it changed to increase at 4km far point of the crater. The decrease rate is 150 mV/Km and increase rate is about 50-75 mV/Km. The decrease change is well known as a topographic effect caused by down flow of the ground water. While, the positive anomaly near the crater will be associated with upward fluid flow heated by magma. Thus, a monitoring of the SP will be useful to watch the volcanic activity.

TECTONOMAGNETIC INTERPRETATION OF LONG AND SHORT TERM CHANGES IN THE GEOMAGNETIC FIELD OBSERVED IN THE IZU PENINSULA

Naoto OSHIMAN (DPRI, Kyoto Univ., Gokasho Uji, Kyoto, 611, Japan, E-mail: g53032@sakura.kudpc.kyoto-u.ac.jp), Y. Sasai, Y. Ishikawa (ERI, Univ. of Tokyo) and Y. Honkura (Tokyo Institute of Technology)

Remarkable crustal activities, the anomalous crustal uplift and earthquake swarms, have continued for about 20 years in the Izu peninsula. The swarm activities, occurred off the coast of Ito intermittently since 1978, are interpreted as intrusions of magma or pressurized fluid. We have observed the total intensity of the geomagnetic field in the north-eastern part of the peninsula with a dense network of proton magnetometers since 1989. No remarkable swarm activities were observed there during the period from 1990 to 1992. However, after occurrence of a small swarm in Jan., 1993, five large activities were observed off the coast of Ito. At the closest observation site (KWN) to the swarm area, the total intensity changes showing a good correlation with occurrences of the swarm were observed. Namely, decrease in the total intensity at KWN, was observed before the occurrence of the swarm, and a recovery phase was observed after the activity. Another remarkable geomagnetic change is a long term change observed at one site located at northernmost area of our dense observation network. Decrease in the total intensity with almost constant rate has been observed since 1991. We try to interpret those long and short term geomagnetic changes in the Izu peninsula, on the basis of the thermal magnetic effect.

ELECTRICAL STRUCTURE OF ASO VOLCANO INFERRED BY BIPOLE-DIPOLE METHOD

HASHIMOTO.T, Hase.H., Sakanaka.S., Tanaka.Y., Masuda.H., Amita.K. (Institute fro Geothermal Sciences, Graduate School of Science, Kyoto Univeristy, Choyo-son, Aso-gun, Kumamoto, 869-1404, JAPAN, Email: hashimoto@aso.vgs.kyoto-u.ac.jp); Kanda.W. (Sakurajima Volcano Observatory, Kyoto University); Djedi.S.W., Mogi.T., Ikoma.Y. (Faculty of Engineering, Kyushu University); Handa.S. (Department of Agriculture, Saga University); Shimoizumi.M. (Politech College, Kitakyushu) Koyama.T., Ogawa.T., Kagiyama.T., and Masutani.F. (Earthquake Reserch Institute, Tokyo University)

We conducted a bipole-dipole electrical resistivity survey at Aso Volcano in December 1998. Aso is an active volcano with a large caldera, which locates at the central part of Kyushu island, southwestern Japan. Recently, Kaneshima et al. (1996) inferred a oblique crack vibrating at the depth of 1-1.5km beneath the active crater of Aso by means of broadband seismic observations. They speculated that ground water-heat interaction causes the intermittent vibration with a dominant period of 15 seconds. We are going to inspect this model from the viewpoint of electric or electromagnetic exploration. We deployed two transmission bipoles and 13 magnetic and telluric receivers around the central cones of Aso volcano. The amount of injection current was around 15(A). In the poster we will present the mapping of resistivity tensors. We will also propose a plausible model, which can satisfy both the seismic and electrical results in the asthenosphere.

SPATIAL AND TEMPORAL MAGNETIC ANOMALIES ON VOLCAN DE COLIMA, WESTERN MEXICO

H. LOPEZ-LOERA & J. Urrutia-Fucugauchi,(Laboratorio de Paleomagnetismo, Instituto de Geofisica, UNAM, D. Coyoacan 04510 D.F., Mexico)

Volcan de Colima in western Mexico has been characterized by frequent eruptive events in historic time; present activity includes the episodic growth of a summit lava dome, intense fumarolic activity, and small lava, pyroclastic and debris flows. Volcan de Colima, which is one of the Decade volcanoes, forms the southern end of an elongated N-S volcanic complex that includes another tall stratovolcano Nevado de Colima. Total field magnetic measurements have been taken along a 45 km transect at various times since 1995. Three distinct sectors can be observed: Sector A between stations 10 and 23 km characterized by low amplitude, low frequency anomalies and no temporal changes, Sector N between stations 23 and 35 km characterized by low frequency anomalies and low amplitude temporal changes, and Sector C between stations 35 and 45 km over the volcano summit, characterized by low frequency, high amplitude highs and lows and large amplitude temporal variations. Sector A is on the volcano flank over volcanic conglomerates of the Atenquique Formation and the Nevado de Colima debris avalanche deposits. Sector N is over andesitic lavas and breccias. Sector C is over andesitic lavas and breccias on the summit caldera and active dome. Modeling suggests several source bodies extending several hundred meters deep. Temporal changes over sector C are possibly associated with thermal changes; particularly a magnetization/demagnetization process related to eruptive activity (magma movement, intense hydrothermal activity and groundwater circulation). A 1500-2500 nT composite magnetic low characterizes the present cone summit and avalanche caldera; the anomaly experiences consistent temporal changes superimposed over the high amplitude low frequency magnetic anomaly.

AUTOMATED SYSTEM FOR MAGNETIC SURVEILLANCE OF ACTIVE VOLCANOES

Ciro Del Negro (Istituto Internazionale di Vulcanologia - CNR, Piazza Roma 2, 95123 Catania, Italy, Email: delnegroc@iiv.ct.cnr.it); Fabrizio Ferrucci (Dipartimento di Scienze della Terra, Università della Calabria, Arcavacata di Rende, Cosenza, Italy, Email: f.ferrucci@unical.it); Rosalba Napoli (Istituto Internazionale di Vulcanologia - CNR, Piazza Roma 2, 95123 Catania, Italy, Email: napolir@iiv.ct.cnr.it)

Geomagnetic observations to monitor volcanic activities have been intensively carried out during the past decade. Significant correlation between volcanic activity and changes in the geomagnetic field were observed on several volcanoes. However, it is possible to assess that, in spite of the significant efforts devoted to establishing and expanding magnetic networks on volcanoes around the world, the limited availability in space and time of data substantially denied access to the quantitative evaluation of the dynamics of volcanoes, at temporal and spatial scales suitable for purposes of the mitigation of volcanic hazards. Our laboratory has been developing methods, hardware and know-how for the automated acquisition and management of data simultaneously acquired at a variety of remote magnetic stations. In order to provide a basis for short-term decision-making in the forecasting and control of volcanic activity linear and non-linear inversion techniques for the real-time processing of data have also been implemented. The developed system is entirely automated between the stages of data acquisition and processing. Memorised data are accessible by authorised external users via Internet. The on-line availability of crude or pre-processed data at authorised users connected to a wide-area network, fosters the possibility of monitoring active volcanoes without concentrating all human resources in a single observatory, at a given site. The system has been designed for uploading data at a distant user immediately after acquisition and re-

formatting. Then, data processed at the "distant desk" can be downloaded a few hours later and used by the personnel in charge of the volcano forecast on the spot.

GM COUNTING ANOMALLY PRECEDING VOLCANIC SWARM WAS EXISTED AND TELLS PREPARING MECHANISMS OF QUANTAM AND GEOCHEMISTRY

Masayasu HATA (Aichi Prefectural University, Aichi, Japan, email: hata@ist.aichi-pu.ac.jp); Ichi Takumi (Nagoya Institute of Technology, Aichi, Japan email: takumi@ics.nitech.ac.jp); and Yoshikazu Yamada (Tousei Electro-Beam Inc., Tokyo, Japan)

We have set up a Geiger-Muller counter vertically inside a closet of steel in thickness of 0.5mm, at the occasional volcanic swarm area of Cape Shiofuki in Itoh-city, Izu-peninsula, Japan. The counter often showed an anomalous peaky increase by about three times of the usual background level of 48cpm in the afternoon of 15 to 16 JST fairly accurately, for the period of one and half months preceding the swarm on April '98. The increase disappeared soon after the start of the swarm. Simultaneously observed ELF band magnetic flux showed the same tendency day after day, but with a different pattern and with a longer residual succession of the radiation after the swarm. The peaky pattern was considered owing to a high-energy radiation of probably light (electron) particle emitted from the deep crust, which was modulated by a surface induced current of the upper atmosphere current by the solar radiation. So, one another GM counter set up horizontally showed an inverse correlation with the original one. Further, the counting increase well correlated with the discharging current in the air and further negatively with the electric field of ELF band. This is estimated due to ionization of the air by the high-energy radiation from the earth crust.

ON SECULAR CHANGES IN THE MAGNETIC FIELD EXPECTED FROM SUBDUCTION PROCESS OF THE PHILIPPINE SEA PLATE IN THE SURUGA BAY AREA, JAPAN

Yoshimori HONKURA and Naoto Imasaka (both at Department of Earth and Planetary Sciences, Tokyo Institute of Technology, Tokyo 152-8551, Japan, email: yhonkura@geo.titech.ac.jp)

Some local magnetic anomalies found in the the Suruga Bay where the Philippine Sea plate subducts beneath Japan have been interpreted as due to seamounts existing on the subducting Philippine Sea plate. In order to examine how these seamounts affect the generation of a great interplate earthquake at the Suruga trough, often referred to as the Tokai earthquake, we made a numerical simulation of earthquake generation, applying the rate- and state-variable friction law to the plate interface and incorporating the seamounts in the simulation as an additional normal stress exerted locally to the interface. Through this simulation we can estimate stress changes in the crust during a cycle of earthquake generation and hence changes in magnetization of the crust. The overriding plate mainly consists of accretionary sediments and their magnetization is weak, resulting in very small changes in the magnetic field which are hard to detect on the Earth's surface in general. However, anomalous changes in the magnetic field can be expected in the vicinity of the seamounts, because of their strong magnetization. Moreover, a notable stress change can also be expected in association with a pre-slip occurring in the vicinity of the seamounts some hours before the generation of an interplate earthquake. Numerical estimation shows that changes in the magnetic field on the Earth's surface associated with such a pre-slip are still small, but changes are abrupt and hence would be easiert detect.

ON THE CAUSE OF AN ANNUAL VARIATION IN THE GEOMAGNETIC TOTAL INTENSITY DATA

Maroka NEKI, Tsuneomi Kagiyama, and Hisashi Utada (Earthquake Research Insti tute, Univ. Tokyo, Tokyo 113-0032 JAPAN, email: neki@eri.u-tokyo.ac.jp, kagiyama@eri.u-tokyo.ac.jp, utada@utada-sun.eri.u-tokyo.ac.jp)

Continuous measurement of the geomagnetic total intensity is now a powerful tool to monitor crustal activities. However, local geomagnetic data taken for that purpose often contain periodic variations of non-tectonic origin, such as an annual variation. In order to examine gradual geomagnetic changes relating to geothermal activity, for example, this may be a significant noise. This paper aims to clarify the cause of such a geomagnetic annual variation. We applied a hypothesis that a thermally induced magnetization change of near surface rocks causes this variation. We tested this hypothesis by using two datasets from different volcanoes, one from the Kirishima where magnetization is relatively weak (typically 1 A/m) and the other from Izu-Oshima with intense magnetization (typically 10 A/m). We measured magnetization and its temperature dependence of rock samples from the two volcanoes in the range 0 –30 °C. We also obtained a total intensity anomaly map around magnetometer sites in each volcano were clear annual variations are seen. The short wavelength anomaly was then inverted to the equivalent source on the surface. We found that the observed annual variation in the total intensity can be quantitatively explained by an annual variation in the equivalent source due to temperature change. This result indicates that correction of this effect is necessary in order to extract a real tectonomagnetic signal.

SHORT-TERM PREDICTION OF ROMANIA'S VRANCEA EARTHQUAKES BASED ON ELECTROMAGNETIC PRECURSORS

B.D.ENESCU, D.Enescu and A.P.Constantin (National Institute for Earth Physics, P.O. Box MG-2, Bucharest-Magurele, 76900 Romania, email: denescu@infp.ifa.ro)

The electromagnetic data used in this paper were recorded at Muntele Rosu Observatory during the periods from December 1996 to January 1997, and December 1997 to Septemeber 1998. This observatory consists of : 1) a three-axis magnetic field sensor, which is a Bartington-type MAG-03 MS; 2) nonpolarizable electric sensors ; 3) a data – acquisition module, which is an MAG-03 DAM ; 4) a computer for data storage and preliminary processing.
Data recording and preliminary processing yielded time variation diagrams of the magnetic and electric components; namely, three diagrams refer to the components of magnetic flux density, Bx, By and Bz, and two others to the horizontal components Ex and Ey of the electric field. The times when Vrancea earthquakes of magnitudes M > 3.9 occurred within these periods investigated are marked on the diagrams. The 3.9 magnitude was imposed as a threshold by the very records, which only showed significant variations in the run-up to Vrancea earthquakes of M > 3.9.
The diagrams show that significant magnetic and electric anomalies (perturbations) arose prior to all Vrancea earthquakes of magnitudes M > 3.9 (in total 19 earthquakes) during the period of the study. All but one of the anomalies (perturbations) occurred at similar precursor times (of order of days). Consequently, the results obtained in this paper prove that Vrancea earthquakes are preceded by electromagnetic anomalies that may be regarded as their short-term precursors.

GEOELECTRIC POTENTIAL VARIATION MONITORING IN SOUTHERN SUMATRA, INDONESIA - CO-SEISMIC VARIATION

Toru MOGI (Department of Earth Resources Eng., Kyushu University, Fukuoka 812-8581, Japan, email: tmogi@mine.kyushu-u.ac.jp); Yoshikazu Tanaka and Hideaki Hase (both at Aso Volcanological Laboratory, Kyoto University, Choyo-son, Aso-gun, Kumamoto Pref., 869-1400, Japan, tanaka@aso.vgs.Kyoto-u.ac.jp); Edy M. Arsadi and Djedi S. Widarto (both at RD Ctr for Geotechnology-LIPI, Jalan Sangkuriang, Bandung 40135, Indonesia, widarto@bdg.centrin.net.id); Toshiyasu Nagao and Seiya Uyeda (both at RIKEN International Frontier Program at Tokai University, Shimizu 424-8610, Japan, suyeda@mail.st.rim.or.jp)

Five geoelectric potential monitoring stations have been in operation since September, 1997 in an area near Liwa town, southern Sumatra, Indonesia, to examine the relationship between geoelectric potential changes and earthquakes. Co-seismic geoelectric changes ranging between 1 and 8 mV/100m were observed for five mb>5 earthquakes at multiple stations during September and December, 1997. Co-seismic variations were observed for the following earthquakes (EQ); Sept.13 mb5.0 EQ at r=147km, Oct.29 mb5.7 EQ at r=152km, Nov.16 mb5.5 EQ at r=95km, Nov.23 mb5.1 EQ at r=174km and Dec.20 mb5.0 EQ at r=146km. In October 1998, in order to obtain more detailed information, the sampling interval was made from ten seconds to one second and simultaneous seismic monitoring was started at all sites. Co-seismic geoelectric potential changes were observed for nine more earthquakes during October to December 1998; (Sep.28 Mw6.5 EQ at r=993km, Oct.8 mb5.2 EQ at r=100km, Oct.21 mb5.1 EQ at r=148km, Oct.31 mb=5.3 EQ at r=590km, Nov.5 mb4.9 EQ at r=20km, Dec.7 mb5.2 EQ at r=99km, Dec.11 mb=5.4 EQ at r=97km, Dec.13 mb5.3 EQ at r=123km and Dec.20 mb5.6 EQ r=210km) Comparing the potential change records and seismograms, we found that the onset time of potential change coincided with the arrival time of seismic wave and theamplitude of potential change, which was different from site to site, was correlated to the intensity of the ground motion.

DEVELOPMENT OF THE EARTH-RESISTIVITY MONITORING SYSTEM FOR DETECTING THE STRESS CHANGE OF EARTH'S CRUST

Futoshi YAMASHITA and Takashi Yanagidani (both at Disaster Prevention Research Institute, Kyoto University, Gokasho, Uji, Kyoto, 611-0011, Japan, email: futoshi@rcep.dpri.kyoto-u.ac.jp)

We have developed the system which measured the earth-resistivity continuously and precisely with high stability, which means it becomes possible to monitor the stress state of Earth's crust via resistivity change. The principle of resistivity measurement is the same as the 4-pole method in electric prospecting. However, we use AC as current source in stead of DC in conventional methods. This system adopts an AC voltmeter with phase-sensitive-detection so-called lock-in amplifier, so it can precisely measure potential and current that flows through the Earth under very severe noise environments. It is verified by the laboratory tests that this system can make continuous resistivity measurements with 4 digits-precision with long-term stability. We are convinced of that this system can be applied to in-situ measurement, and have started the observations at several sites. The system have been measuring with high stability agreeable to our design, and at a site near the seaside, we have detected the daily resistivity change, which may be caused by tidal loading.

REMOTE OBSERVATIONS OF LIGHTNING DISCHARGES IN SEISMOACTIVE REGIONS

SOBOLEV G.A., N.I.Migunov, and N.I.Rosanov (United Institute of Physics of the Earth, Russian Academy of Sciences, Moscow, 123810, B.Gruzinskaya 10, email: sobolev@uipe-ras.scgis.ru)

The hyperbolic system of passive radar location of lightning discharges was applied for the study of the relationship between earthquakes and powerful sources of natural radio emission. Within the territory, covered by an effective radius of monitoring of a recording system, were located all seismoactive regions of Eastern Europe. The detailed analysis on Northern Caucasus territory was chosen where a number of earthquakes took place with magnitude >4. Mainly the atmospherics were recorded varying from powerful cloud-to-ground discharges in the frequency range 0.5-50 kHz. In the recorded signals the amplitude of the first half-period was >2 V/m at the distance of 100 km from the source of radiation. The mean square error of determination of co-ordinates of the radiation sources was 5-10 km. The territory of the Northern Caucasus reveals zones where, by seismic data, are located the earthquake epicenters. According to the results of remote observations, the value was determined of the ratio of the number of lightning discharges in seismically active zones to the total number of lightning discharges in a seismically active region. A correlation is established between the changes in the value of this ratio and the periods of seismic activity in separate parts of the territory under control. In order to establish a similar dependence between the number of thunderstorms and the periods of seismic activity, the meteorological data on thunderstorms in seismoactive region are insufficiently informative. It is suggested that the recorded changes in the value of the relative intensity of the flow of natural radioemission can be accounted for by the effect of earthquakes on the electric state of the atmosphere near the ground. Ionisation and electrification of the boundary air layer in the periods of seismic activity is, apparently, followed by a considerable increase of the number of centers of condensation of water vapour with further formation of fog and other atmospheric phenomena. In this case, the development of cloudiness is limited and the electric conductivity of air is reduced, which facts can result in decrease of the number of lightning discharges in seismically active zones. Therefore, the results of electromagnetic monitoring of a seismically active region confirm the reality of connection between earthquakes and lightning discharges.

GEOMAGNETIC INVESTIGATIONS FOR MONITORING EARTHQUAKES IN BEIJING AREA, CHINA

Zhan ZHIJIA, Gao Jintian, Zhang Hongli, Zhao Congli and Shen Wenzhi (All at: Institute of Geophysics, China Seismological Bureau, Beijing 100081, China)

In order to monitor the seismic activity, there is a dense seismomagnetic network in the Beijing area. The seismomagnetic precursor information was obtained before several earthquakes, which occurred in the Beijing and its neighbouring areas. According to the anomalous information of geomagnetic precursors, the M=4.5 Baodi earthquake on November 18, 1993, the M=4.3 Baodi earthquake on July 20, 1995 and the M=3.8 Baodi earthquake on July 28, 1998 were better predicted. There were the precursory anomaly with the amplitude f =5.2 nT, the precursory time T =7 months and the epicenter distance d = 10 km for the M =4.5 Baodi earthquake (1993); the anomaly with f =4.5 nT, T= 3 months and d = 15 km for the M =4.3 Huailai earthquake (1995); and the anomaly with f=3 nT, T=43 days and d=10 km for the M=3.8 Baodi earthquake (1998). After the M = 6.2 Zhangbei earthquake of January 10, 1998 (about 180 km apart from Beijing), we set up the temporary seismomagentic network in the western part of the Beijing area for monitoring the seismic activity. The research results of geomagnetic data showed that there was not any anomaly and we predicted no earthquake with M > 5.0 in the Beijing area during January-February, 1998. The practical situation was consistent with the prediction. The investigation results show that the geomagnetic method has active effect and good prospect in earthquake prediction study. Therefore, the seismomagnetic precursor research should be strengthened in the future.

THE CRUST ELECTRICAL STRUCTURE SURROUNDING SOME EARTHQUAKE FOCI AND MTOBSERVATION BEFORE AND AFTER ZHANGBEI EARTHQUAKE

Guoze ZHAO, Yan Zhan, Ji Tang, Qianhui Deng, Jijun Wang, Zhao Jiang and Guodong Liu (Institute of Geology, Seismological Bureau China, Beijing 100029,China, email:zhaogz@public.bta.net.cn)

MT measurements were carried out in some larger shock areas during the last a few years. They are Shacheng earthquake (M=7.0, 1720), Xingtai earthquake (M=7.2, 22/3/1966), Yanggao earthquake (M=6.1, 19/10/1989) and Zhangbei-Shangyi earthquake (M=6.2, 10/1/1998) that are in a seismic active region in northern part of North China. It is shown by MT data that first two earthquakes occurred in areas near the conjunction places of a detachment fault in the upper crust and steep vertical fault in the middle and lower crust. Great difference of the resistivity between both sides of the vertical faults appeared. The later two foci occurred near a boundary of two bodies with different conductivity features.
After the main-shock of Zhangbei-Shangyi earthquake magnetotelluric measurements were carried out at the epicenter (site MMC) and at site 511 which is 26km south-east of the epicenter. MT data were previously obtained at site 511 in June 1, 1994. This site was again occupied in January 13 and 20, 1998 and the various data sets show significant changes in apparent resistivity and impedance phase following the earthquake. MT data were measured continuously at site MMC from 16 to 19 of January. No measurement had been carried out at site MMC before main shock, but a change of apparent resistivity was also observed. The apparent resistivity for the TE polarization (Rhoyx) at site 511 corresponding to NNW direction generally decreased on Jauary 13 and 20, 1998 in comparison with the data observed in June 1, 1994. The greatest decrease appeared for MT periods of 0.2 sec to 2 sec and from 10 sec to 200sec. The maximum amount of decrease is about 30% at 0.5sec. The values of Rhoyx observed on January 20, 1998 are larger than those for January 13. On the contrary, for TM polarization (Rhoxy) corresponding to NEE direction, the resisitivity generally increased before main-shock and then decreased after shock.

SEISMO-IONOSPHERIC EFFECTS DURING VIBROSEISMIC SOUNDING

V.V. KUZNETSOV, S.Y. KHOMUTOV, V.V. Plotkin, O.M.Grekhov, A.F. Pavlov, A.N. Fedorov (Institute of Geophysics SB RAS, Koptyug av., 3, Novosibirsk, 630090 Russia;
e-mail: hom@uiggm.nsc.ru)

The synchronous disturbances on the ionosphere were registered by the doppler sounding at the "Klyuchi" station (Institute of geophysics, Novosibirsk) when the seismic vibrator with 100 tons force amplitude mounted at the "Bistrovka" testing area of Siberian Branch of SB RAS (Novosibirsk) is operated. The vibrator generated the seismic oscillations in the sweep-mode with the frequency change from 6 to 9 Hz during about 45 min. The observed disturbances appeared as a outside frequencies in the Doppler spectrum. They drifted synchronously with seismic sweep-signal frequency with some time delay. The effect was noted during the daytime using the reflections from stable E-layer on the height about 100 km. It was absent during the night when the radioreflections are obtained for the sporadic Es- and F-layers. The distance between the ionosonde and vibrator is amount to about 50 km. The time delay between the initial sweep-signal and the its corresponding appearance in the ionosphere is estimated to 7-8 minutes. This is agreed with the time interval of the acoustic signal propagation to the radioreflection heights. It is noted that the similar infrasonic and seismic sweep-signals were detected by the ground measurements at the "Klyuchi" station.

MAGNETOTELLURIC MONITORING OF SEISMICITY IN THE NORTHERN GREECE IN ORDER TO IDENTIFY DISTURBANCES RELATED TO EARTHQUAKES.

Cezary ROZLUSKI (Institute of Geophysics, Polish Academy of Sciences, ul. Ks. Janusza 64, 01-452 Warszawa, Poland; e-mail: cpr@igf.edu.pl)

A strong earthquake, followed by a sequence of aftershocks, occurred on May 13, 1995 in the northern Greece (Ms = 6.6, lat: 40.2 N, lon: 21.7 E).
The magnetic (coils) and telluric (VAN dipoles) data from Ioanina (northern Greece) station have been analyzed in the frequency domain before and after the main shock. The single scalar parameter as a function of magnetic and electric field has been introduced in order to identify possible disturbances related to earthquake events in the area. It has been attempted to correlate that parameter with seismic activity.
The seismic events have been chosen with selection criteria to distinguish those events, which are more likely, the source of magnetotelluric disturbances.

TOWARDS INCREASING RELIABILITY AND INFORMATIVENESS OF THE ELECTROTELLURIC MEASUREMENTS IN GEODYNAMIC MONITORING.

Yeugeny CHIRKOV (United Institute of the Earth Physics of RAS, 10 Bolshaja Gruzinskaja, Moscow, 123810 Russia; email: chirkov@uipe-ras.scgis.ru).

The results of electrotelluric monitoring the aftershock's activity Djava-Racha earthquake (Caucasus, 1991) obtained by use two measurement arrays situated close together are presented. Experimental evidence of local nature of the majority signals (SES-type) has been given. Possible models of the relation between precursor signals and prepared earthquake are discussed. The model of electrotelluric measurements from the technical point of view is introduced. Multistage ways and means to increase reliability of electrotelluric measurements on a wide spatial scale are proposed. It is shown that the estimation of spatial characteristics of the source (type, position, moment) is very useful for eliminating the noise, isolating the signal and making theoretical estimation of signal's generation mechanism.
New way of measurements, informative parameters and technical means for estimation spatial characteristics of source are proposed. There are presented the results of mathematical imitation modeling and field experiments showed the efficient work of proposed system.
The possibility of various application proposed approach to electrotelluric measurements (cost-saving monitoring of large area, efficient ways for interpretation results of complex measurements, isolating the precursor signals, and experimental study of source location) are discussed.

SOME RESULTS OF MAGNETOTELLURIC MONITORING OF GEODYNAMICAL PROCESSES ON BISHKEK TEST GROUND

Svetlana E. BALANDINA, Boris S. Svetov (both at Geoelectromagnetic Research Institute RAS, Troitsk, Moscow region, Russia, e-mail: svetov@geo.igemi.troitsk.ru).

In 1993-1998 continuous recording of 5 component of magnetotelluric (MT) variations (Hx, Hy, Hz, Ex, Ey) was perfomed in Bishkek (Kirgizstan), with a sampling rate equal to 0.1 Hz. This data set has been used for determination of time domain responses of transfer functions and of electromagnetic field of interior (geodynamical) origin. As it known the components of MT fields are connected by convolution relation of the type: Hz(Ex,y)(t)=K1(t)*Hx(t)+K2(t)*Hy(t)+D(t), where K1 and K2 - pulse responses of MT transfer functions and D(t) - is residual field of interior origin mainly. This equation is solved by iterative (adaptive) procedure. At a second stage, time variations of transfer functions and of residual field have been analyzed. MT data were averaged with sampling equal to 6 minutes, 1 hour and 1 day. Considerable variations of these values, with duration ranging from several hours to several months have been discovered. They are connected either to changes of the ionosphere current system or to changes of the geoelectrical section and to generation of electromagnetic fields in the Earth interior. We found no stable correlation between variations of MT data and individual seismic events (earthquakes). On the other hand a correlation between low pass filtered (three-month filter) MT data and energy of geodynamic process in the vicinity of measuring site has been established. The energy was determined using seismic events within 200-km radius around the MT site. More over MT data permit to forecast variations of the energy two months forward. These conclusions are preliminary because they were made on the basis of limited data series and on MT observation in one station only. They are illustrated by measured data and results of their processing .

EVOLUTION OF MAGNETOTELLURIC, MAGNETOVARIATIONAL AND TOTAL MAGNETIC FIELD PARAMETERS IN CENTRAL ITALY. RELATION TO LOCAL SEISMIC ACTIVITY

Domenico DI MAURO, Giuliana Mele, Antonio Meloni, Paolo Palangio (Istituto Nazionale di Geofisica - via di Vigna Murata, 605 - Rome, Italy, e-mail:dimauro@ingrm.it) Tomasz Ernst, Roman Teisseyre (Institute of Geophysics, Varsaw, Poland, e-mail: ternst@igf.edu.pl)

Seven consecutive years (from the summer 1991 to the spring 1998) of magnetotelluric and magnetovariation measurements at Collemeluccio (41º 43N, 14º 22E, in central Italy) have been collected. These data analysed by means of tensor decomposition on the geoelectric potential and robust estimation on the geomagnetic field allowed the investigation of the electric properties at different times and spatial lengthscales. The MV analysis on the simultaneous data from the geomagnetic observatory at L'Aquila (42º 23N, 13º 19E about 100 km away from Collemeluccio) reveals lateral and in depth electrical conductivity heterogeneities. The variation of some indicators, which lead to the phenomenon of electromagnetic induction, are presented here in their time evolution while the non-inductive contribution has been compared to some tectonomagnetic field observations and to local and regional seismic activity. Tectonomagnetic field observations in central Italy were also made using data simultaneously recorded at four magnetometer stations, and using L'Aquila observatory as a reference for differentiation.

LIMITED PREDICTION OF THE EARTHQUAKES IN THE REGION OF LAKE BAIKAL

Yili DASHEVSKII, Nina Nevedrova, Institute of Geophysics SB RAS, RUSSIA,
Email: dashevsk@uiggm.nsc.ru

In recent years we see a revival of interest in earthquakes prediction on the basis of some new trends, Instead of predicting the time, place and magnitude of a future earthquake, attempts are made to estimate an earthquake probability in a given window of time, place, and magnitude. It's evident that for a successful life-saving prediction we must consider a prediction methods, which are testable by others. This money-consuming approach is based on a sufficient data getting from different sources.
In parallel with this full-scale target a more conservative goal also exists. Sometimes the amount of monitoring data is insufficient to describe complex space-time-magnitude behavior of earthquake occurrence. In such a case all that is required is to obtain the prediction information which is in a correspondence with the quantity and quality of geophysical data. This type of prediction is given the name "limited prediction".
Long-term electrical and electromagnetic time-lapsed measurements are carrying out in the region of Lake Baikal. The objective is to find out the electrical and electromagnetic precursors for the earthquakes. We solve the inverse problem for electromagnetic data and correlate seismic events with the variations of electrical conductivity at different depths, inside the geological space. We considered about 600 earthquakes occurred within the area 300´300 sq. km in 1991-1996. Shlumberger monitoring array sensed 43 of them as conductance variations of tolerant shape at the depth 750m. Only earthquakes of energy class (K) and epicenter distance (R) which meet the condition 0.6K - 3lgR+8 > 0 have been detected. We confirmed this practical relationship using theoretical evaluations of deformations within Baikal Rift Zone and consider it as a basis of a limited prediction in this area.

TECTONOMAGNETIC MANIFESTATIONS OF COMPRESSION EPISODE IN THE BAIKAL RIFT DURING 1992-1993

Pyotr DJADKOV and Oleg Mikheev (both at Institute of Geophysics, av. Acad. Koptyug, 3, Novosibirsk, 630090, Russia, E-mail: djad@uiggm.nsc.ru)

On the basis of the tectonomagnetic monitoring information the episode of the horizontal

compression stress predominance was detected in the Baikal rift in 1992-1993. A number of unusual tectonomagnetic anomalies took place before, during and after this extraordinary occurrence. The beginning of this episode was related to the appearance of regional positive tectonomagnetic anomaly (with amplitude up to 2 nT under accuracy 0.1 nT) in 1992 in the Selenga depression where 60 stations of repeated and 4 stations of continuous observations are located. The confirmation of this episode of compression was found later in other information obtained by determinations of temporal variations of the earthquake focal mechanisms and extensometer observations. The number of the earthquakes with the thrust component of displacement in the earthquake sources reached 60 - 80 % in the Baikal rift zone, while such earthquakes occurred very rare in other periods. In the same time we observed the disappearance of the season changes in the difference of magnetic field between two stations Stvolovaya and Enhaluk at the Baikal coast. Before 1992 these season changes (1-1.5 nT) had the good correlation with the season variations of the Lake Baikal water level. After the compression episode the high-rate extension process which was confirmed by GPS- measurements was developed in this region in 1994-1995. In this period the 0.5-1 nT tectonomagnetic anomalies with duration of 2 to 4 weeks were accompanied the space-time clusters of the M = 3 - 4 earthquakes at a distance up to 80 km.

BAIKAL: THE RESULTS OF MULTIDIMENSIONAL ANALYSIS OF THE TIME SERIES OF ELECTROMAGNETIC MONITORING SYSTEMS

MOROZ YU.F, (Institute of Volcanic Geology and Geochemistry, FED RAS.); Petropavlovsk-Kamchatsky, (683006. Russia. (4150058293) ; e-mail: ivgg@svyaz.Kamchatka.su.); Mandelbaum M.M., (GFUGP "Irkutskgeofizika", Ministry of Natural Resources, I.P., Ministry of Natural Resources)

Monitoring the electromagnetic field with artificial source is being conducted at the eastern coast of Lake Baikal at the area of 60x60 km. A 200 kWt power generator is used as the source. There are 12 observational sites with the distance from one to 40 km between them. One site is located at the opposite shore of the lake. Measurements are made once a day. Depth of the controlled part of the earth crust does not exceed 2-3 km. The time period of monitoring is 18 years. Continuous time series of apparent resistivities, meteo parameters, water level in Lake Baikal are studied using modern computer programmes for multidimensional analysis. As a result it was established that electric conductivity of rocks does not depend on the water level in Baikal, air temperature and atmospheric pressure. As a rule, regular variations in the range period from few days to a year are not observed in the behaviour of electric resistivity in the upper layers of the earth crust. However, in some cases variations are observed in power spectrum in the range period from 80 to 200 days and more. These variations have local character and are probably connected with the close-to-electrode processes. Increase of canonical coherence in the multidimensional series of apparent resistivities is observed before high seismicity in the Baikal rift zone. The increased coherence anticipates earthquakes of energy class 15 and more in the radius of 650 km. The anomalous effects are also revealed in the aggregate signal of multidimensional series of the apparent resistivities, which are connected, with the earthquakes of energy class 12 and 13. When the number of channels is increased the resolution of the aggregate signal increases as well, so that the effects may be observed of the earthquakes of energy class 10 and 11 with epicenters located near the test area. The canonical coherence and aggregated signal anomalies may serve as possible forerunners of large earthquakes in the Baikal rift zone.

SOME MECHANISMS OF GEOMAGNETIC FIELD FLUCTUATUONS AND THEIRS STATISTICAL ANALYSIS

J.GORODISKY (Carpathian Branch of Subbotin Institute of Geophysics NASU, 3b, Naukova Str., 290601, Lviv, Ukraine, E-mail: valentyn@carp.lviv.ua)

As we already had shown the magnetic effect caused by electrokinetical processes on the surface of quasihomogenous halfspace isn't absent and statistical features of the anomalous Geomagnetic fields fluctuations contais information about the geodynamical processes evolution. We have analysed by the help of Monte-Carlo method the stochastic model of electrokinetic-magnetic effect in the quasihomogenous medium. The mechanism of electric currents spatial dividings is based on the effect of surface conductivity influence on the rock conductivity for microcapillar racks (d<50 mm). The main results are as follows. 1) The distribution of magnetic field changes as a result of random changes of microcapillars structure in case of constant value of the microcapillars space distribution dispersion is similar to the distribution of magnetic field in static case. The main feature of these distributions is symmetry of positive and negative values of effect. 2) In the case of nonconstant value of microcapillars space distribution dispersion the main feature of the distribution of magnetic field changes is asymmetry of positive and negative values of effect. The first result may be useful for the evaluation of natural magnetic noise when monitoring active faults by geomagnetic methods. The 2nd result we consider as a useful link for the magnetic image of tectonically active environments evolution constraining. Similar results we also obtained for the model that is based on the concentration mechanism of electric currents spatial dividing. It is significant, that in regions of active chemical transformations of magnetic minerals, the statistical analysis of anomalous geomagnetic field fluctuations also contains additional information about these processes activity. As we have shown such analysis is useful especially in the positive magnetic anomalies cases.

LOCAL GEOMAGNETIC FIELD CHANGES AND SEISMICITY OF ARMENIA

GRIGORIAN A.G., Nazaretian S.N. (National Service of a Seismic Guard Rá, Leningradian,5, Gyumri, Armenia. email: serge@shirak.am) Skovorodkin Yu.P. (UIPE of RAS, B. Gruzinskaya, 10, Moscow, Russia. email: yupsk@uipe-ras.scgis.ru)

On the territory of Armenia the network of geomagnetic observatories is created which allows measuring the variations of components D, î and Z of Earth's magnetic field. The data of stations Jradzor,Garni and TÁvuch (30 km, 150 km and 200 km from epicenter of Spitak earthquake of 07.12.1988 y.) for time period 1986-1993 years are used in analysis From these data the ratio of amplitudes A of variation of each component of the magnetic field synchronously measured by each pair of stations (parameter N(A)) is obtained for periods of variations 5-25 min, 30-60 min and 5-10 hours. From the beginning of observations up to moment of Spitak earthquake the trend in the behavior of N(A) is observed for all 3 components D, H, Z and for all periods of variations. On the background of trend the sharp changes of N(A) are observed during two intervals: from March to July of 1986 y and from February to December of 1988. The first sharp change of N(A) corresponds to Parvany earthquake (13.05.1986), the second one to Spitak earthquake (07.12.1988). The tendency of returning movement of parameter N(A) to the initial value is observed after Spitak earthquake. It is supposed that the reason of parameter N(A) changes is the variation of electric conductivity of the rocks of terrestrial crust, which is created by the vertical filtration of high conducting fluids.

GEOMAGNETIC MONITORING FOR STUDYING MODERN GEODYNAMIC AND EARTHQUIKE PRECURSORS IN THE CARPATHIANS

Valentina KUZNETSOVA, Valentin Maksymchuk, Yuriy Gorodyski, Igor Dotsenko, Igor Chobotok (Carpathian Branch of Subbotin Institute of Geophysics NASU, 3b, Naukova str, 290601, Lviv, Ukraine, email: valentyn@carp.lviv.ua)

During the last 20 years geomagnetic monitoring have been held sustematically in the territory of sesmoactive Transcarpathian Trough where every year 2-10 earthquakes of magnitude M=2,5-3 occur. Maximal possible force doesn't exceed M=6. Geomagnetic monitoring consists of: 1) Repeat high-accurate plane and profile geomagnetic observations to study peculiarities of modern geodynamics and the block structure of lithosphere, as well as to determine zones of active tectonic faults. The zones of anomalous temporal geomagnetic changes with values of 2-7 nT/year have been mapped. 2) Regime continuous geomagnetic observations at a network of 4 stations both to study temporal changes in a broad frequency range and to search for earthquake precursors. During 1982-1997 24 anomalous effects were found, 15 of which were accompanied by earthquakes. Anomalous effects are characterised as follows: duration of 1.5-3 months, effect intensity - 2.5-5 nT, the earthquake moment mainly concerning the final stage or the post resumed field initial level. 3)Investigations of temporal changes of Wiese vector. Temporal changes corresponding to high seismicity activity period in the Carpathians region in 1990 are determined. The dynamic linearization zone is revealed. Physical mechanism of geomagnetic field anomalous temporal changes generation has been studied. Electrocinetic mechanism of anomalous magnetic effect generation for the quasihomogeneous medium is proposed and statistically studied.

USE OF APPARENT RESISTIVITY TIDES VARIATIONS FOR SEISMIC ACTIVITY MONITORING

Alexander SARAEV, Mikhail Pertel (St. Petersburg State University, Universitetskaya nab. 7/9, St. Petersburg, 199034, Russia, e-mail: aks@aks.usr.pu.ru); and Zinovy Malkin (Institute of Applied Astronomy RAS, nab. Kutuzova, 10, St. Petersburg, 191187, Russia, e-mail: malkin@ipa.rssi.ru)

A good correlation of apparent resistivity variations of electromagnetic soundings methods with artificial and natural fields in extremely low frequency range (units - thousands of a hertz) and earth tides deformations were observed. The apparent resistivity variations of 7-15 % were connected with deformations of 0.2 - 0.3 m. Both direct (rise of the earth surface and increase, lowering of the earth surface and decrease of apparent resistivity), and inverse relation were obtained. The various character of relations can be explained by a various degree of rocks water saturation. At small water content the fluid distribution in the rock has islands, not connected character. In case of compression the degree of fluid connections increases, the network of interconnected channels grows and rock resistivity decreases. On the contrary, at the biggest water content the fluid completely fills the rock pore space. At a pressure increase in this case happens compression of channels, and resistivity of the rock is grows. Tides effects should be taken into account for increase of electromagnetic soundings accuracy. The results can be used for the study of regularities of rocks geoelectric properties changes before earthquakes, for selection of tension sensitive zones and placing of the receiving devices, for choice of optimum frequencies for monitoring of a geoelectrical section intervals with the best tension sensitivity, and also for the taking into account of tides effects, as of the hindering factor at monitoring of seismic activity. This method of study of the earthquake precursors is oriented on large volumes of rocks in situ and has the possibility of realization of regular reproduced observations. The work was performed with the support of "Integration" grant, N 326.66.

EARTHQUAKE-ASSOCIATED PERTURBATION IN THE LOW-LATITUDE IONOSPHERE

Anna DEPUEVA and Nina Rotanova (both at IZMIRAN, Troitsk, Moscow Region, 142092, Russia, email: depueva@izmiran.rssi.ru)

Topside vertical sounding data were analysed in order to study earthquake-associated perturbations in the ionosphere. A few separate great earthquakes were considered, whose epicenters were situated inside a narrow zone close to the magnetic equator. It was shown that low-latitude ionosphere reacts on a forthcoming earthquake in a special way. Equatorial seismoionospheric effect manifest itself as electron density fall at the F-layer peak level and higher altitudes. Electron density spatial (longitude - latitude) distribution looks like a «funnel» over the earthquake preparation zone area. Some evidences in favour of the seismic origin of the above-said phenomenon will be presented including that arizing from the method of natural orthogonal components application. A particular emphasis will be made on lithosphere-ionosphere coupling taking into account already known mechanism of E- and F-layers interaction due to vertical upward ExB plasma drift and diffusion over the dip equator.

ELECTROMAGNETIC AND PLASMA DISTURBANCES IN THE IONOSPHERE OVER EARTHQUAKE REGIONS

N.V. ISAEV and O.N. Serebryakova, (Institute of Terrestrial Magnetism, Ionosphere and Radiowave Propagation,142092 Troitsk, Moscow Reg., Russia.)

The recent results of investigation of seismic-ionospheric effects are presented below. Data from the low-orbiting satellite COSMOS-1809 were used to search for a correlation between seismic activity and increases in ELF/VLF emissions for different regions. The data of 100 revolution of satellite were choosen for the analysis of ionospheric effects of this seismic activity. Analisys enables to drow the following conclusions. The electromagnetic emissions in the frequency range of 140-450 Hz are regularly observed within the L-shells with the root in the seismoactive zone. Near a zone of seismic activity (??=?6) at the altitude ~ 950 km bursts of ELF radiation are observed at the frequencies f=140 and 450 Hz in the magnetic and electric components. The radiation excess above the background level can reach more than an order of magnitude. The radiation bursts are observed minutes to hours beforehand an earthquake and during several hours after it. The sizes of the disturbed region are usually 400-600 km, and greater in the period of aftershock activity than during the earthquake development. The small-scale plasma irregularities dNe/Ne? 3-8% with characteristic scales 4-10 km along the orbit has been revealed in geomagnetic field tubes connected with epicentral region in which seismogenic ELF emissions were observed simultaneously. The empirical models of distribution of ELF-emissions for different regions were constructed on the basis of statistical study of these measurements. For these regions amplitude-spatial distributions of siesmoelectromagnetic radiation were constructed both for electric and magnetic components and distributions of the signal (-to-) noise ratio were constructed as well.

Analysis of seismogenic ELE/VLF radiation had shown that main signal characteristics (frequency, amplitude etc.) were sufficiently different for different seismo-active regions of the Earth. This fact is evidence of seismoelectromagnetic parameters dependence on physical-chemical propertiesof Earth's crust and lithospheric processes. Characteristic features of ELF/VLF radiation related to submarine earthquakes were exposed (radiation of higher frequencies, amplification of natural ELF/VLF radiation, take place, because electromagnetic connection between lithosphere and ionosphere is absent. The generation mechanism of earthquake-related small-scale plasma inhomogeneities was developed.

MODELING OF POSSIBLE IONOSPHERIC PRECURSORS OF STRONG EARTHQUAKES

Vitali KIM and Valeri Hegai (both at IZMIRAN, Troitsk, Moscow Region, 142092 Russia, email: kimvp@izmiran.rssi.ru)

Possible changes of electron density in the nighttime mid-latitude ionosphere caused by seismogenic electric fields before strong earthquakes are calculated. The results indicate that the background electron density in the E region changes by 20-30% relative to its undisturbed value above the epicentral zone of forthcoming earthquake. In the middle part of E region, a dense layer of metal ions can be formed. Horizontal distribution of electron density in the F2 region is perturbed in non uniform manner within the area of horizontal size of about 400 km. he changes are stronger in the lower F2 region where irregularities of various scales (from 10 to 150 km) are developed in course of time. In the upper ionosphere, a geomagnetic field aligned inhomogeneity of plasma density is produced around the geomagnetic force line passing through the imminent earthquake epicentrum. It will result in enhancement of probability of whistler appearance in the forthcoming earthquake epicentral zone.

RELATION BETWEEN ELF AND VLF EMISSIONS ON THE INTERCOSMOS 24 SATELLITE AND CONCENTRATION OF RADON IN EARTHQUAKE REGIONS

Yu.M.MIKHAILOV, G.A.Mikhailova and O.V.Kapustina (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation of Russia's Academy of Science, Troitsk, Moscow region, 142092, Russia, e-mail: yumikh@charley.izmiran.rssi.ru)

For study of ionosphere-lithosphere processes for the first time the comparative analysis has been carried out between radon concentration in seismoactive region and spectral characteristics of the ULF-ELF electromagnetic emissions, registered by satellite over the same seismoactive region. The regular observations data of radon level in the Kangra Valley, India, situated on the north boundary of the Indo-Australian plate were used. The choice of this place was done due to the storage time of \alpha -track detectors, which registered radon concentration, being 1 day, lowest of all known stations. On the Intercosmos 24 satellite the electric component of ULF/ELF waves was registered with help of ten narrow band filters in the frequency range from 8 to 970 Hz. In days, when anomaly radon concentration bursts have been observed, simultaneous increasing of electric field on the factor more than ten at frequency 8 Hz and on the factor 2-3 in the intensity maximum from 150 to 623 Hz was observed. That effect was observed only at night and was localized exactly in space above the fault. In spectral distribution of emission maximum in the frequency range from 150 to 623 Hz was allocated, which coincided with the amplitude spectra maximum of fractional hop whistlers, observed on other satellites at night, and so with frequency distribution of atmospherics intensity in the waveguide Earth-ionosphere. This fact ensures statement, that the noises are generated by the lightning discharges, and their amplification simultaneously with radon anomaly bursts was due to decreasing of ELF-waves attenuation under influence of seismic nature electric field. That is a mechanism of the lithosphere-ionosphere interaction at the earthquake preparing phase proposed by the authors.

THE EXPERIENCE OF SHORT-TERM EARTHQUAKE PREDICTION USING THE ELECTROMAGNETIC RADIATION METHOD AT NORTH CAUCASUS

Vitali A. MORGOUNOV (Institute of Physics of the Earth, Moscow 123810, B.Grusinskaya 10, Russia, email: vam@uipe-ras.scgis.ru); Alexander G. Zdorov (Central Geological Expedition, Essentuki 357600, Kislovodskaya st. 203, Russia)

The experience of utilization of the electromagnetic radiation method (EMR) for scientific prediction of the earthquakes (EQ) is discussed. Prolonged observations from the network of stations carried out at North Caucasus at the test band (65x85 km), allowed to study peculiar local features in the generation of seismo-anomalous EMR and to begin the procedure of scientific prediction of local EQs of the background level. For the period of continuos registration of EMR (1990-1998), 16 seismic events occurred during which the observation stations were located within the EQ's preparation zone. 8 EQs were accompanied with clear EMR precursors. The useful signal exceeded the background values by up to 20 dB. The anomaly lasts up to two days, and the lead time of the signal before the event varies from two to four days. The intensity of EMR does not exhibit any explicit dependence on the EQ's magnitude, in agreement with the model of EM-radiators within the skin layer. Miss the target were registered in 8 cases, one as false alarm. Thus, the probability of correct "scientific alarms" of the time of the event could be estimated as W~0.5 for the region of a low seismicity, where M~3-4 is the long-awaited event. The probabilit of false alarm is very low Wf ~0.06 for especially isolated events. All the EQs with M>4 were accompanied by clear-cut anomalous EMR spikes. The study of EM precursors of destructive seismic events during the last decades, testifies to the improvement of the method efficiency with the energy of EQ. 9 years of uninterrupted monitoring draw to the conclusion that on the average every next weak seismic event could be predicted.

KAMCHATKA: THE RESULTS OF MONITORING LOW FREQUENCY ELECTROMAGNETIC FIELDOF THE EARTH

MOROZ YU.F., Institute of Volcanic Geology and Geochemistry, FED RAS. Petropavlovsk-Kamchatsky , 683006. Russia (4150058293); e-mail: ivgg@svyaz.Kamchatka.su

The results of studying structure of the earth's electromagnetic currents and variations of the electromagnetic field are considered. The observational network is located within the subduction zone. It includes 4 sites at the distance of 50 to 120 km between them. Registration and transmission of the information is performed using radio telemetered system. Sampling frequency of the channels is one minute. The electromagnetic field structure has been studied in the range period from few hours to a year and more. Spectral-temporal characteristics, coherences, phase relationships and amplitude frequency functions between the components of the electromagnetic field have been studied using multidimensional analysis. The following anomalous effects, connected with large earthquakes and seismicity around Kamchatka (of almost 300km radius) have been detected. 1.Change to 180O of the phase relationship between yearly variations of the magnetic inclination and horizontal, vertical components of the magnetic field during the highest seismicity in 1996-1997 (over the period of 1990-1998). 2. Change to 90O of the phase relationship between yearly variations of the orthogonal component (NS and EW) of the earth's electric currents within the time intervals when large earthquakes of M=7.1 and 7.3 occur. 3. Change of canonical coherence of yearly variations (T=12 and 24 hours) of the Earth's electric currents and of variations of the geomagnetic field from the most common values of 0.8-1 to 0.3-0.5 values 10-30 days prior to the large earthquakes of M>7. 4. Occurrence of the bay-like disturbances in the earth's electric currents from 3-4 days up to one month and a half duration before the large earthquakes of M>7. 5. Occurrence of the oscillating-type quasi-periodical variations with the time period from 1 to 6 days prior to the large earthquakes of M>7.

PULSED ULF EM SIGNALS – PRECURSORS FOR OPERATIVE MONITORING EARTHQUAKES

An. P. NAUMOV (D.I.Mendeleyev Institute for Metrology, St. Petersburg, 198005, Russia, email: slovo@mail.line.ru)

We regularly observed Electromagnetic (EM) pulses of ULF range signals when working in the seismic dangerous regions of the Crimea and Tien Shan. Investigations of geomagnetic variations of these regions have confirmed tectonic nature of discovered signals. Their morphology was studied: the range of frequencies 0,001-5 Hz, the amplitude of almost square-wave pulses from 0,2 to 1-2 nT. Short pulses with an amplitude up to 20 nT and 6-20 seconds duration of the other origins (tectonic too) were observed in the form of pulse packets. Parallel synchronous work of several vector-magnetometers (3 or 4) in the area of coherent ULF signals allows to define coordinates of the source. The described signals appear before the seismic events: a time of signals gap always occurs prior to the moment of earthquake. Comparison of ULF signals and magnetic bay-like precursors also indicates correlation of observing results before earthquake. The measurements of ULF tectonic signals during of three-year interval show stability in time of the sources and their mode of the generation of ULF EM fields. The similar results with EM signals in the range of radio frequencies are discussed. Hence, there is a possibility to realise reliable operative monitoring of earthquakes by careful measuring of ULF EM signals-precursors.

ANOMALOUS PARTICLE DIFFUSION ASSOCIATED WITH ATMOSPHERIC DISTURBANCES

Oleg POKHOTELOV, Vyacheslav Pilipenko (Institute of Physics of the Earth, 123810 Moscow, Russia, Email: pokh@uipe-ras.scgis.ru); Michel Parrot (LPCE/CNRS, 3A, Avenue de la Rechercher Scientifique 45071 Orleans Cedex 2, France, email: mparrot@cnrs-orleans.fr)

A new mechanism of the atmosphere-magnetosphere interaction, which might be called "acoustic-magnetospheric cyclotron accelerator" is proposed. The idea of this mechanism stems from the fact, that strong acoustical perturbations in the ionosphere (e.g., due to earthquakes, thunderstorms, etc.) may generate magnetic disturbances in the magnetosphere. We suggest the following scenario: strong acoustic oscillations, reaching the ionospheric E-layer, may result in the generation of the field-aligned currents. On one hand the magnetic effect of these currents in the magnetosphere has considerable magnitude. On the other hand the ground signature of these magnetic disturbances is essentially weaker. Alfven waves, generated by acoustic disturbances in the upper atmosphere, may induce resonant energizing and subsequent diffusion of particles, trapped in the magnetosphere, across L-shells. This idea may be fruitful in the interpretation of some occasional increases in inner zone particle fluxes, which do not correlate with the solar or magnetospheric activities. Using this conception we provided a reasonable explanation for a number of satellite observations of occasional increases in inner zone particle fluxes which do not explicitly related to solar or magnetospheric processes.

ELECTROMAGNETIC MONITORING BY THE METHOD OF RADIOTRANSLUCENT IN THE BAIKAL RIFT ZONE

Anatoly M. Popov and Alfred B. Baduev (Institute of the Earth's Crust, Irkutsk, Russia, email: popov@earth.crust.irk.ru); Nikolay A. Telpukhovsky, Vadim M. Akulov and Anatoly V. Moshanov (East-Siberian Institute of physics-technical and radiotechnical measurements, email:eopsr@niiftri.irkutsk.ru); Yury B. Bashkuev and Mikhail G. Dembelov (Institute of Natural Sciences, Ulan-Ude)

In 1997 a highly exact amplitude and phase monitoring of electromagnetic signals from the standard radiostation RTZ-50 on the 50 kHz frequency was organized by the authors on the Irkutsk-Ulan-Ude direction crossing the southern part of the lake Baikal. The basis of the equipment complex consists of the quantum clock HP5061-A relatively to which the control (Irkutsk) and measurements (Ulan-Ude) of the phase of standard frequency have been carried out, PC IBM and other serial equipment. Digitization of the signals is conducted with the frequency 200 kHz. The control of the quantum clock's work relatively to the State standard is exercised by means of the satellite systems GLONASS or GPS.
The monitoring results have showed that the reflected signal from ionosphere is practically absent for the period of 4-5 hours of the world time. Therefore while being in search of the earthquake's precursors it's expedient to analyze the characteristics of the signals during the period of time closed to the indicated one. Basing on the values accepted within the 4-5 hours period the annual amplitude course (value 30 db) and signal phase (1,5 mks) were obtained. The calculations demonstrate that changes of the phase connected with the seasonal variations of the conductivity of the upper layer (winter-summer) aren't sufficient to create the anomaly's value which is being observed. Also the local anomalies timed to the earthquakes have been fixed that perhaps indicates their connection with the seismic processes.

IONOSPHERIC IMAGES OF STRONG EARTHQUAKES (EXPERIMENT AND THEORY)

PULINETS S.A., Hegai V.V., Depuev V.Kh., Gaivornoskaya T.V., Legen'ka A.D. (IZMIRAN,Troitsk, Moscow Region, 1420942, Russia, E-mail: pulse@izmiran.rssi.ru) Liu J.Y. (National Central University, Jungli, Taiwan, E-mail: jyliu@jupiter.ss.ncu.edu.tw)

Many years of studies of the ionospheric precursors of strong earthquakes resulted in revealing of the ionospheric variations parameters set intrinsic exclusively to the seismic activity coupling processes. Spatial (latitude-longitude) and vertical distribution of the electron density, its behavior in local time and relatively to the anticipated earthquake instant, magnetically conjugated effects, ion composition variations - all together create the ionospheric image of the anticipated earthquake which couldn't be mixed with any other kind of the ionospheric variability. The self-consistent physical model of seismo-ionospheric coupling was created which is based on the effect of the strong quasistatic electric field generated in the future epicenter area. The model could be tested directly by experimental measurements, and many other effects observed over the area of the anticipated earthquake (for example, the ELF and VLF noises) could be explained by the model.
The conception of the groundbased and satellite monitoring of the earthquake precursors is proposed. The special accent is made on the GPS/GLONASS ionospheric measurements.

TECTONIC FAULTS ACTIVITY AS A POSSIBLE SOURCE OF THE IONOSPHERE MODIFICATION

PULINETS S.A., Kim V.P., Hegai V.V., Depuev V.Kh. (IZMIRAN, Troitsk, Moscow Region, 1420942, Russia, E-mail: pulse@izmiran.rssi.ru) Radicella S.M. (Abdus Salam International Center for Theoretical Physics, Trieste, Italy, E-mail: rsandro@ictp.trieste.it)

Ionosphere topside sounding data from the INTERCOSMOS-19 satellite have been utilized to study longitude distribution of the night-time midlatitude F2 region peak electron density NmF2 in the Southern hemisphere over the array of tectonic faults in the Andes area for low geomagnetic activity periods in July 1979 and in July 1980 when solar activity was high and nearly the same, however, in July 1980 there was intensified tectonic activity in the Andes area, and in July 1979 the tectonic activity was lower. The results show that in July 1980 the observed value of NmF2 as a function of longitude decreased by a factor of ~ 3 with the change of longitude from 280 to 295 E over the latitude range 30-45 S, whereas the appropriate longitude profiles of NmF2 observed in July 1979 and reproduced by the ionospheric model IRI-90 do not reveal any appreciable longitude variations above the Andes area. Using model simulation we interpret the observed longitude anomaly of NmF2 in July 1980 as a result of the F2 region modification caused by a hypothetical large-scale long-living perturbation of the vertical electrostatic field on the Earth's surface associated with intensified tectonic activity.

IONOSPHERIC ULF/ELF WAVE AND PLASMA EARTHQUAKE PRECURSORS: SATELLITE MEASUREMENTS AND ELECTRODYNAMIC MODEL

Valery SOROKIN, Vitaly Chmyrev and Nikoly Borisov (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation, Russian Academy of Sciences, IZMIRAN, Troitsk, Moscow Region, Russia, 142092, email: sova@izmiran.rssi.ru)

The satellite data are used as experimental basis for the electrodynamic model of earthquake precursors in the atmosphere and the ionosphere. According to this model the chain of processes forming the lithosphere – ionosphere coupling starts from the injection of radioactive substances and charged aerosols into the atmosphere prior to earthquake. This leads to increase of atmospheric conductivity and forms the vertical electromotive force in the near ground layer. Such modification of Earth – ionosphere electrical circuit results in change of vertical electric current in the atmosphere and the ionospheric electric field. Development of the acoustic-gravity wave instability stimulated by the increased DC electric field is followed by formation of horizontal periodic irregularities of the ionospheric conductivity. An excitation of such irregularities leads to formation of field - aligned currents and plasma density disturbances stretched along the geomagnetic field. When satellite crosses these structures it observes the small-scale plasma density fluctuations and ULF geomagnetic oscillations. The nature of seismic related ELF emissions in a frame of this model is connected with transformation of electromagnetic noises propagating in the Earth – ionosphere wave guide on the small – scale irregularities of ionospheric conductivity excited by AGW instability. The other effect of the electric field increase is an additional Joule heating of the lower ionosphere that results in an elevation of the F-layer maximum, a decrease of electron density in the maximum of this layer and a redistribution of ion composition in the upper ionosphere.

SCIENCE OVERVIEW OF INTERNATIONAL SOLAR CYCLE STUDIES (ISCS): 1998-2002

S. T. WU (Center for Space Plasma and Aeronomic Research and Department of Mechanical and Aerospace Engineering The University of Alabama in Huntsville Huntsville, AL 35899 USA); V. N. Obridko (IZMIRAN, Troitsk Moscow Region, 142092, Russia); and M.A. Shea (Air Force Research Laboratory, 29 Randolph Road, Hanscom AFB, Bedford, MA 01731-3010, USA)

In August 1997, the Scientific Committee on Solar-Terrestrial Physics (SCOSTEP) initiated a program for the study of the rising phase of the 23rd solar cycle. This program, entitled "International Solar Cycle Study (ISCS)", consists of three working groups and one panel. These are: Solar energy flux study from the interior to the outer layer (WG1); Solar magnetic field variability study from the lower atmosphere through the inner corona (WG2); and Solar emissions, its origin and transport through the heliosphere (WG3). The Panel is Environmental Applications. In this paper we discuss the preliminary scientific results in the above mentioned topics during the early phase of the rising 23rd solar cycle. The programmatic aspects of ISCS will also be discussed.

TOTAL SOLAR IRRADIANCE: MEASUREMENTS AND RESULTS

Claus FRÖHLICH (Physikalisch-Meteorologisches Observatorium Davos, World Radiation Center, CH-7260 Davos Dorf, Switzerland, email: cfrohlich@pmodwrc.ch)

Since November 1978 with the start of the NIMBUS7 total solar irradiance monitoring started a complete set of TSI measurements from space are available, yielding a time series of more than 20 years. From measurements made by five of these radiometers a composite record of solar total irradiance can be compiled. The radiometric, instrumental and operational influences and constraints are discussed in order to assess the precision and accuracy of this composite. Moreover, it is the basis for an evaluation of the influence of solar activity on total solar irradiance. An empirical model that parameterises the combined influences of dark sunspots and bright faculae features on solar irradiance is able to explain more than 95\% of the variance. After removing the magnetic influence with the model, the remaining `quiet sun' shows no trend over the whole period, indicating that the sun's output has not changed over the past two solar cycles.

VARIATIONS OF SOLAR SPECTRAL IRRADIANCE FROM THE NEAR UV TO THE INFRARED: MEASUREMENTS AND RESULTS.

M. FLIGGE (ETH, Zurich, Switzerland), C. Frohlich (Physikalishes- Meteorologishe Observatorium Davos, Switzerland); J. Pap (University of California, Los Angeles, USA), and Sami Solanki (ETH, Zurich, Switzerland); and Ch. Wehrli (Physikalishes- Meteorologishe Observatorium Davos, Switzerland)

Solar spectral irradiance variations are known to exhibit strong wavelength dependence with the amount of variability increasing towards shorter wavelengths. The bulk of solar radiation occurs at visible wavelengths. The spectral radiation longward of 300 nm accounts for 99% of the total solar radiative output. Deposited in the Earth's troposphere and biosphere, this part of the solar irradiance spectrum determines direct solar radiative forcing and is therefore of particular interest for climate studies. In the following measurements of solar irradiance and irradiance variability from ear UV to the IR are reviewed with particular emphasis on the results obtained from the VIRGO (Variability of Irradiance and Gravity Oscillations) and SOLSPEC (Solar Spectrum Measurement) instruments.

SOLAR UV AND EUV IRRADIANCE: MEASUREMENTS AND RESULTS

Gary ROTTMAN and Thomas Woods (both at the University of Colorado, 1234 Innovation Dr., Boulder, CO 80303, USA; e-mail: gary.rottman@lasp.colorado.edu)

The ultraviolet (l < 300 nm) irradiance from the Sun is completely absorbed by the Earth's atmosphere; and although it comprises less than 1% of the total radiative output of the Sun, it enhances the effects of direct solar forcing. The irradiance at these short wavelengths has a dominant influence on the heating and composition of the atmosphere, and it thereby has indirect influence on greenhouse gas composition, wave activity and mean circulation, and perhaps on hydrological cycles. The bulk of the total solar irradiance (TSI) originates in the solar photosphere and varies by much less than 1%. In comparison, the ultraviolet irradiance, with its origin in the tenuous and magnetically active layers of the solar atmosphere, is far more variable - ~10% at 200 nm, a factor of 2 at 121 nm, and factors exceeding 10 in the EUV. Instruments and techniques steadily improve, and today a fairly consistent understanding of solar variability has emerged. This paper will review the following topics: 1) the state-of-the-art in measuring the Sun, 2) today's observational programs, and 3) the current understanding of both the magnitude and variability of the ultraviolet irradiance.

MODELLING OF SOLAR IRRADIANCE VARIATIONS

Peter A. FOX, Oran R. White (both at High Altitude Observatory, National Center for Atmospheric Research, P.O. Box 3000, Boulder, CO 80307, Email: pfox@ucar.edu, orw@ucar.edu); Juan Fontenla (771 W. Dahlia, Louisville, CO 80027, Email: jfontenla@mho.net); Eugene H. Avrett and Robert L. Kurucz (both at Harvard Smithsonian Center for Astrophysics, 60 Garden St, Cambrdige, MA 02138, Email: avrett@cfa.harvard.edu, kurucz@cfa.harvard.edu).

The study of solar radiative variability is of immediate importance and application to problems in terrestrial upper atmospheric chemistry and circulation. Over the past decade, regular measurement programs for parts of the solar spectrum have been established. However, the physical understanding of these measurements has not yet been achieved. To improve our understanding and to make quantitative estimates of this variability requires a study of the entire solar spectrum. Our approach to this requirement is to combine empirical image analysis with the theory for emission, absorption, and transfer of radiation in the solar atmosphere.
Our ultimate goal is the successful combination of observed solar images with semi-empirical models and theory for calculation of a mixed line+continuum spectrum emitted from realistic representations of the observed solar disk. These pixel by pixel calculations properly weight the computed specific intensities for calculation of the Sun's irradiance at any particular wavelength and time. In this talk we present results and discussion of quantitative models of the total irradiance, specific spectral bands in the UV, IR and visible, and particular spectrum lines.
The synthetically generated irradiances are presented for a range of realistic solar activity conditions, representing the quiet, moderate, and active Sun and are represented as images, spectra or irradiances and compared to extant observations.

PHYSICAL ORIGIN OF LONG TERM IRRADIANCE CHANGES

Sabatino SOFIA (Department of Astronomy, Yale University, P.O. Box 208101, New Haven, CT 06520-8101, USA, Email: sofia@astro.yale.edu)

Various analyses of climate data carried out in recent years have provided convincing support for the existence of a solar component on timescales of decades to centuries. The amplitude of the activity-related modulation of total irradiance measured over the last 20 years appears to be insufficient to yield significant climate effects, at least according to most current climate models. Thus, either the model are significantly wrong (e.g. the spectral irradiance may produce climate change in excess of its energy content), or there must be a solar variability mechanism not connected to active regions and network. Theoretical considerations indicate that a variable, deep-seated magnetic field such as would be produced by the dynamo mechanism would modify (slightly) the structure of the whole Sun. As a consequence, all the global solar parameters (radius, temperature and luminosity) would be affected. Because the total irradiance depends on the solar luminosity, this could be the mechanism responsible for long term irradiance changes.
A variety of supporting evidence exists in confirmation of such mechanism, such as variations of the solar oscillation spectrum and possible variations of the solar radius. We will discuss the details of the mechanism, the supporting data, and the additional work required to understand its properties to the degree required to determine the climate implications.

VARIABILITY OF SUNLIKE STARS

Richard R. RADICK (Air Force Research Laboratory, Space Hazards Branch, National Solar Observatory, Sunspot, New Mexico, USA, email: radick@sunspot.noao.edu)

Stars with approximately the same temperature, luminosity, chemical composition, and average activity level as the Sun may now readily be identified. The variability of several such sunlike stars has been monitored regularly in chromospheric Ca II HK emission for over three decades and photometrically for fifteen years; larger stellar samples have been observed less comprehensively. Similar solar time series exist. A comparison of solar variability with its stellar analogs indicates that the Sun's current behavior is not unusual among sunlike stars, although some observations do suggest that the amplitude of the Sun's cyclic variation, measured photometrically, may be smaller than its stellar analogs.
If the behaviour of a sample of sunlike stars is representative of the range for the Sun's possible behaviour, then it is instructive to examine not only how closely sunlike stars resemble the present-day Sun, but also how they differ. Thus, the behaviour of sunlike stars may provide insight about states of solar activity, such as Maunder minima, which have not been observed on the Sun during the modern era.

CLIMATE RESPONSE TO VARIATIONS OF THE SOLAR IRRADIANCE SINCE 1700 IN COUPLED AOGCM SIMULATIONS

Reinhard VOSS (Max-Planck Institut fuer Meteorologie, Bundesstr 55, D-20146 Hamburg, Germany, email: reinhard.voss@dkrz.de); Ulrich Cubasch (DKRZ, Bundesstr 55, D-20146 Hamburg, Germany, email: cubasch@dkrz.de)

In our study an atmosphere-ocean general circulation model (AOGCM) has been used to investigate the potential impact of variations of the solar irradiance on climate. Two different reconstructions of the solar irradiance for the period 1700 to 1992 (Hoyt and Schatten (1993), Lean et al. (1995)) have been used. For both reconstructed time series two AOGCM simulations have been performed. The results are compared to a control simulation with fixed solar irradiance and experiments with increasing CO2 concentration. The AOGCM, which has been employed, is the ECHAM3/LSG in a T21 horizontal resolution (ca. 5.6 deg. in the grid space). In the solar runs long periodic fluctuations, which are mainly associated with the Gleissberg cycle, show the largest signal. The signal associated with the 11-year solar cycle is only weak. The temperature increase during the last century in the solar experiments is weaker than the observed warming. Assuming that the model forcing and response is realistic, other factors than the solar irradiance must contribute to the observed warming. In the troposphere the solar variability induces a temperature pattern similar to the one caused by the increase of atmospheric CO2 concentration. The land-sea contrast is enhanced and the maximum warming in the free atmosphere is located in the upper tropical troposphere for increasing solar irradiance. In the stratosphere the impact of the solar variability on the temperature is small, whereas for the geopotential height in 30 hPa the correlations with the solar forcing exceed locally 0.9.

JSA16/W/03-A3 Invited **1430**

THE EFFECT OF UV IRRADIANCE VARIATIONS ON THE EARTH'S ATMOSPHERE AND CLIMATE

Joanna D. HAIGH and Alice Larkin (both at Space and Atmospheric Physics, Blackett Laboratory, Imperial College of Science, Technology and Medicine, London SW7 2BZ, UK, email: j.haigh@ic.ac.uk)

Variations in solar ultraviolet irradiance have greatest impact in the middle and upper atmosphere. In the stratosphere UV increases result in heating, due to absorption by ozone and oxygen, and also in enhanced production of ozone which further modifies the solar and infrared radiation balance. Previous studies have suggested that such changes in stratospheric thermal structure may impact the climate of the lower atmosphere through modification of the latitudinal structure of the radiative input and of planetary wave activity.
This talk will describe high spectral resolution calculations of the direct impact on radiative heating rate profiles of changes in the solar UV spectrum. The effects of such variations in heating rate on the climate of the middle and lower atmospheres of two different GCMs (the UGAMP UGCM and the UKMO Unified Model) will be described. The sensitivity of the simulations to the specification of ozone changes will also be discussed.

JSA16/E/34-A3 Invited **1500**

EFFECT OF PARTICLE FLUX VARIATIONS ON CLIMATE

Eigil FRIIS-CHRISTENSEN (Danish Space Research Institute, Juliane Maries Vej 30, DK-2100 Copenhagen, e-mail: efc@dsri.dk)

A number of studies have reported on a high correlation between solar activity variations and climate. Solar activity variations manifest themselves in different forms like variations in total solar irradiance, in variations in the UV range and in variations of the solar wind parameters. The correlations have indicated that a considerable part of the global warming during this century may have been caused by solar activity variations. Never the less, until now no single physical process has been proven capable of having the needed effect on climate. This presentation will review some of the available evidence that the cosmic ray flux through its modulation by the solar wind may contribute significantly to the formation of clouds. This will change the radiative properties of the atmosphere and hence the climate.

LONG-TERM SOLAR-TERRESTRIAL RECORDS FROM COSMOGENIC RADIONUCLIDES

Juerg BEER, (Environmental Physics, EAWAG, Duebendorf, Switzerland)

Direct solar terrestrial records are limited to the telescopic era starting at about 1600 AD. To extend these records further back in time one has to rely on proxies of solar and terrestrial parameters. Cosmogenic radionuclides proved to be useful tools for such a reconstruction of the solar variability over millennia. Cosmogenic radionuclides such as 10Be, 36Cl, and 14C, are continuously produced by the interaction of cosmic ray particles with the atmosphere. Fluctuations the solar wind lead to magnetic modulation of the cosmic ray flux that induces corresponding changes in the production rates of these nuclides. As a consequence the production rate is high during periods of low solar activity and vice versa. After the production the fate of the radionuclides depends on their geochemical properties. 10Be and 36Cl are transported attached to aerosols or as a gas (36Cl) and after a mean residence time of 1 year they are removed from the atmosphere mainly by wet precipitation. 14C, on the other hand, is oxidised to 14C02 and exchanged with the biosphere and the ocean. In order to reconstruct the long-term solar variability archives are needed that store the radionuclides in a stratigraphically undisturbed way. The best archives are ice cores (10Be and 36Cl) and tree rings (14C) respectively. During the last 10'000 years the 14C tree ring record exhibits several peaks which can be attributed to quiet sun periods (e.g. Maunder minimum 1645 - 1715). Beside the well-known 11 year Schwabe cycle several periodicities in the range of decades to millennia can be found in all the radionuclide records which, most likely, represent solar variability. A comparison of the 10Be and 36Cl records with 14C based on a carbon cycle model allows to separate production and system effects. Comparisons with climate records indicate that periods of high production rates (low solar activity) generally coincide with periods of cold climate. Potential and limitations of radionuclides to establish long-term solar terrestrial records are discussed.

LONG TERM SOLAR-TERRESTRIAL RECORDS FROM SEDIMENTS

G.CINI CASTAGNOLI, G. Bonino and C.Taricco (Dipartimento di Fisica Generale dell'Universit, Via P.Giuria 1, 10125 Torino, Italy and Istituto di Cosmogeofisica del CNR, Corso Fiume 4, 10133 Torino, Italy)

We discuss here the d18O and d13C profiles of Globigerinoides ruber measured in the GT90/3 shallow water Ionian sea core, dated with high precision. The core, extracted from the Gallipoli platform, is dated with high precision and sampled at 2.5 mm, corresponding to 3.87 years. The dating of the core has been performed by 210Pb radiometric method and by a detailed tephroanalysis. The high precision of the core dating allows to transform the depth scale into a time scale with an accuracy of ~1%. The d18O and d13C profiles cover the period 1200-1975 AD. The long time series allows a) to obtain highly reliable results from spectral analysis and b) to evaluate the importance of the variations of solar origin with respect to the variation in the trend. d13C and d18O show an inverse relationship with a correlation coefficient of about -0.7. The spectral analysis of the d18O time series performed with different methods shows a dominant decadal periodicity, in antiphase with the sunspot solar cycle, while the d13C time series shows it in phase with the sunspot cycle. These components are identified at high significance level by Monte Carlo singular spectrum analysis (MC-SSA). The two records show the presence of the well-known climatic features of the Little Ice Age, the Maunder and the Sporer minima and the early 20th century global temperature rise. Yearly cloud coverage of the same region, deduced by annual percentage of rainy days recorded in Lecce (Puglia), and the annual average temperature measured in Reggio Calabria from 1875 to 1972 AD are compared to the d13C and d18O profiles. The cloud coverage decreases during this period, while d13C increases. This is in agreement with the fact that the light is the principal factor regulating d13C fractionation, mediated by symbiotic algae, as known from laboratory experiments performed at different light levels. We estimate an increase in insulation of about 10 W/m2 during the century. The corresponding increase in d13C is of the order expected by controlled experiments. At the same time, air temperature rises, opposite to cloud coverage, and d18O decreases.

ANALYSIS OF THE ARCHIVES OF CA K OAR OBSERVATIONS

M. FOFI, I. Ermolli and M. Centrone (all at OAR - Osservatorio Astronomico di Roma, Roma, I-00136 Italia)

We present the first results of the analysis performed on historical Ca K filtergrams and PSPT

data obtained at the OAR. In particular we analyse Ca K (0.6 A) full-disk filtergrams obtained from daily observations made during solar cycles 19 and 20 (1964-1979), in order to describe temporal variations of geometrical properties of the magnetic regions. We use PSPT 1k X 1k images, to calculate different describers that are correlated to various solar variability indices (radio flux, MgII, total irradiance and sunspot number).

JSA16/E/42-A3 Poster **0830-02**

SOLAR VARIABILITY ON SECULAR AND MILLENNIAL TIME SCALES FROM COSMOGENIC ISOTOPES AND THE SEARCH FOR CORRESPONDING CLIMATE SIGNALS

Werner MENDE, (NOAA SEC, 325 Broadway, 80303 Boulder CO USA, mende@bbaw.de)

The variability potential of the total solar irradiance (TSI) on time scales from days to millennial is considered and compared with the spectral variability of cosmogenic isotopes (10Be) and with 18O- ice-core records (SUMMIT, data to 60 kyr BP) in corresponding frequency bands. Low-frequency periodic components could be identified in cosmogenic isotopes and in 18O records the occasional modulation of these signals by the geomagnetic field is a strong argument in favour of the solar provenance of these components. These low-frequency periodicities can be used for the prediction of the solar activity in the range of the 11-year Schwabe cycle and beyond. An estimation of the TSI-variability on longer time scales could be obtained by extrapolation of the spectral shapes of the TSI measurements observed by satellites. After removal of broad spectral excess around the rotational frequency the 20-years TSI-spectrum can be considered as a 5/3-Kolmogoroff like spectrum and formally extrapolated to longer time scales. The slope of this extrapolation is in a good agreement with the slope of spectral variability observed in cosmogenic isotopes from greenland ice-cores on millennial time scales. If the cosmogenic isotope variability is in a nearly linear relation to the TSI change, then this would be of relevance for climate change on secular time scales. Historical temperature records are compared with a reconstruction of TSI on the base of cosmogenic isotope records. The low-frequency solar components could be identified in various climate records by appropriate band filterings.

ON OSCILLATORY FEATURES IN CLIMATE DYNAMICS

Alina PRIGANCOVA (Geophysical Institute, Slovak Academy of Sciences, 842 28 Bratislava, Slovak Republic, E-mail: geofpria@savba.sk); Basil Petropoulos (Research Center for Astronomy and Applied Mathematics, Academy of Athens, 10573 Athens, Greece)

The global change approach to study the Sun-Earth system gives a growing amount of evidence that climate dynamics is affected by a great many of factors. The solar variability is very likely to be ranged among them. As a possible tracer of such an influence are characteristic features in climate dynamics presented by persistent peculiarities in its time structure. To illustrate time structure pattern on long-term scales the data on monthly averages of main meteorological parameters, air temperature T and precipitation totals P, for a number of observatories are used. The requirement for the length of individual time series to be as long as possible was utilised as a criterion for their option among available data from the would-wide network of observatories. That is most dense for the limited parts of the global territory. Mainly, observatories located in the latitudinal and longitudinal strips crossing Central Europe are considered to make it possible to do some generalisation on the modulation patterns in climate dynamics. The calculated annual and interannual anomaly field profiles are compared. Finally, there is presented a discussion on utilisation of features revealed for prognostic aims.

LONG - TERM VARIABILITY OF THE SOLAR WIND AND ITS CLIMATIC CONSEQUENCES

Alexander SHIROCHKOV and Ludmila Makarova (both at Arctic and Antarctic Research Institute, Saint - Petersburg, 199397, Russia, e-mail: shirmak@aari.nw.ru)

The Sun-Earth relationship as a factor capable to affect the Earth weather and climate has been studied for many years. A level of the Sun UV radiation (expressed as the sunspot number W) was used as the sole indicator of the amount of the Sun energy transferred to the Earth. The achievements and failures of such an approach are well known. On the other hand, the solar wind can provide substantial amount of energy into the Earth's atmosphere, which can influence the Earth's weather and climate under definite conditions. We explore the long - term temporal variations of the most geoeffective solar wind parameter - its dynamic pressure Psw for the whole satellite epoch (1960 - 1996). This parameter's changes in time do not coincide with the corresponding variations of the sunspot numbers. The Psw value determines a distance between the magnetosphere magnetopause and the Earth and this distance value is proportional to the energy amount transferred from the solar wind to the near- Earth space. We show that the Psw value (and subsolar distance between the magnetopause and the Earth) directly influences such hydrometeorological parameters as the stratospheric temperature, ozone content at stratopsheric altitudes, structure of the tropopause, time of the spring change of the atmospheric circulation, and temperature anomalies on the Earth surface. Besides Psw value is closely connected with times of the spring openings of the arctic rivers as well as with the polar seas areas covered by the ice and the polar seas surface temperature anomalies. As the most probable physical mechanism responsible for these relationships a modified version of the global electric circuit where the magnetosphere magnetopause is an external element will be proposed.

THE EFFECT OF COSMIC RAY PRODUCED-CLOUDS ON CLIMATE

Blanca MENDOZA and Juan Ramirez, (Instituto de Geofisica UNAM, Ciudad Universitaria, 04510, Mexico D.F., Mexico, email: blanca@tonatiuh.igeofcu. and unam.mx Arturo Quintanar, Centro de Ciencias de la Atmosfera UNAM, CiudadUniversitaria, 045210, Mexico D.F., Mexico.)

Results, which assess the effect of the solar activity on climate, through the modulation of cosmic rays, are presented. In particular, a climatic model is developed where the clouds are included as forcings. It is assumed that the amount of cloudiness is modulated by the cosmic ray flux along the solar cycle.

WAVELET ANALYSIS OF THE SUNSPOT, GEOMAGNETIC AND CLIMATIC VARIATIONS IN ST.PETERSBURG

Dmitri I. PONYAVIN (Institute of Physics, University of St.Petersburg, 198904, Russia, e-mail: ponyavin@snoopy.phys.spbu.ru)

Wavelet transform analysis was applied to the sunspot, geomagnetic and air surface temperature variations recorded in St.Petersburg from 1775 to 1999. Patterns of wavelet transforms were compared, and coherence at different time and time-scales was found. A quasi 35- and 11-year oscillation of the sunspot and geomagnetic activity was approximately in phase with the air temperature data at least the later half of the 20th century.

THE SEPARATION OF ANTHROPOGENIC AND SOLAR VARIABILITY IN THE NORTHERN HEMISHERIC TEMPERATURE RECORD ON A FILTER TIME SCALE OF 14 YEARS BASED ON THE FREQUENCY MODULATION FUNCTION OF THE SOLAR CYCLE AND COSMOGENIC ISOTOPES

Werner Mende, Rita STELLMACHER, (Freie Universitaet Berlin, Carl-Heinich-Becker-Weg 6 - 10, D-12165 Berlin, email: mende@bbaw.de); Juerg Beer, (EAWAG Duebendorf, Swizerland)

The global and hemispheric temperature records are investigated on a decadal time scale. The most important forcing functions for temperature variability are characterised by proxy data. For the historic reconstruction of the solar forcing function cosmogenic isotopes and the frequency modulation function of the solar cycle (Sun melody) are used. The anthropogenic forcing function is parametisized by a hyperbolic model. Spectral filterings are used for a removal of all variability components with period lengths shorter than 6 years. For the separation of the different variability sources a nonlinear minimal-parametric model on a hemispheric aggregation level is used. The regression model is solved by a Levenberg-Marquardt procedure and the solution provides a relatively consistent picture of the contributions of the different variability sources to the observed climate variability on a filter time scale of 14 years. The results are in a good agreement with the global sensitivity of temperature against solar forcing given by general circulation models. Low-frequency variability components of the solar irradiance forcing function (88 years and longer) could also be identified in the hemispheric temperature records. Band filtering could separate the induced temperature variation. There is good phase coherence between the reconstructed solar forcing function and the corresponding frequency band in the temperature record.

LONG-TERM VARIABILITY OF SOLAR ACTIVITY AND ITS LINK TO SHARP CLIMATIC OSCILLATION DURING THE HOLOCENE

Oleg RASPOPOV, Oleg Shumilov (SPbF IZMIRAN, P.O.Box 188, St.Petersburg; 191023, Russia, e-mail:oleg@omr.izmi.ras.spb.ru); Valentin Dergachev (Physico-Technical Institute RAS, St.Petersburg, 194021, Russia); Bas Van Geel (University of Amsterdam, 1098 SM Amsterdam, the Netherlands); Johannes Van der Plicht (Center for Isotope Research, University of Groningen, the Netherlands); Hans Renssen (Free University, De Boelelaan 1085, 1081 HV Amsterdam, The Netherlands)

Recently obtained terrestrial, marine, and ice core data demonstrate the sharp climatic changes during the warm interglacial period of the last 12,000 years. These newly developed Holocene palaeoclimate records indicate that 2300-2400 years periodicity in the development of the most sharp cooling events took place. During the last 1000 years cooling events also showed 210 and 88-90 years periodicity. Analysis of geophysical, radiocarbon (14C), and 10Be data demonstrated that mentioned cooling events are very well correlated with sharp increase of 14C and 10Be concentration. It means that the cooling events are correlated with the sharp increase of galactic cosmic ray fluxes and decrease of solar activity. Some recently obtained experimental data demonstrate that the galactic cosmic ray fluxes influence on optical properties and radiation balance of the atmosphere. The data indicates that cosmic ray enhancement leads to the temperature decrease in the middle and high latitudes. Thus periodically caused cooling events during Holocene can be connected with the decrease of solar activity. The decrease of solar activity leads to the increase of galactic cosmic ray fluxes and decrease of the solar radiation. Both these factors lead to solar radiation decrease near the Earth surface and thus create conditions for sharp climatic cooling. The work was supported by Russian Foundation for Basic Research and INTAS.

CLIMATIC FORCING OF THE ~ 2400-YEAR VARIATIONS IN THE RADIOCARBON CONCENTRATION OF THE EARTH'S ATMOSPHERE

Valentin A. Dergachev, Sergey S.Vasiliev (Both at: Ioffe Physico-Technical Institute RAS, Politekhnicheskaya 26, St.Petersburg, 194021, Russia, email: v.dergachev@pop.ioffe.rssi.ru); Oleg M. RASPOPOV (SPbF IZMIRAN, P.O.Box 188, St.Petersburg, 191023, Russia,
email: oleg@omr.izmi.ras.spb.ru)

Spectral analysis of the available long-term series of the radiocarbon concentration based on the tree-ring count, using the classical harmonic methods of time series analysis, led to exhibition of spectral lines at a number of periods. However, the some harmonic features are not independent. Applying the methods of analysis on the non-stationary time series, as the frequency-time method and bi-spectral analysis to the radiocarbon concentration during the last 8000 years, we resolve a number of periods: 2400, 940, 720, 570, 500, 420, 360, 230, 210, 190 years. The strongest feature in this time series is a long period of ~ 2400 years. Analysis shows that the periods of 210, 420 and 720 years are primary. Besides, the primary periods are modulated by the long 2400-year period. Taking into account the structure of bi-spectrum, it was shown that the ~ 2400-year modulation have the climatic forcing.

ON THE INFLUENCE OF SOLAR RADIATION SCATTERING ON THE INTERPRETATION OF OZONE MEASUREMENT RESULTS

Olga ZYRYANOVA(Institute of ionosphere of Ministry of Sciences - Academies of Sciences of Republic Kazakhstan, Almaty, 480068, Kamenskoe Plateau e-mail: angel@ionos.alma-ata.su);, Ibragim Suleimenov (Institute of ionosphere of Ministry of Sciences - Academies of Sciences of Republic Kazakhstan, Almaty, 480068, Kamenskoe Plateau e-mail: sul@ionos.alma-ata.su)

In present paper it is shown that well-known multi - wave ozone measurement technique based on the spectral data has a theoretical limit which is connected with light scattering processes. The role of such processes is of most significant in sunrise. It is shown that for the theoretical interpretation of experimental data obtained for large solar zenith angles one have to take into account superposition of light beams. These beams may be described as a result of solar radiation reflection from effective partly penetrable mirrors each of them is connected with the separate atmosphere layer. Reflection coefficient of such mirrors is determined by the value of scattering albedo.

THE MANIFESTATION OF SOLAR VARIABILITY IN CLIMATIC CHARACTERISTICS OF PREBAIKALIA

Gely Zherebtsov and Vladimir KOVALENKO (both at Institute of Solar-Terrestrial Physics SD RAS, P.O.B. 4026, Irkutsk, 664033 Russia, e-mail: uzel@iszf.irk.ru)

Evidence for the actual manifestation of solar variability in climatic characteristics of Prebaikalia (Irkutsk, Bratsk, and Zima) is presented. The relevant influence on ground air temperature is quantified. The study revealed a high degree of correlation (correlation coefficient is 0.97) between the mean power of solar activity cycle and the ground air temperature in Prebaikalia averaged over a solar cycle. It is shown that the main significant variations in air temperature in the region during 1881-1960 were caused by solar variability. The amplitude of temperature variations during this period was 1 degree. Since the 1960s till the present, with the influence of solar variability continuing, there has been a pronounced effect of another factor whose role is progressively increasing, and in the last decade it was even higher than the contribution of solar variability. During 1960-1997, the rise in temperature unassociated with solar activity was 1.7 degree. This new factor is most likely to be a global warming of the atmosphere. This assumption is consistent with model calculations indicating that the most drastic manifestation of a global warming should be expected in inland regions of Eurasia.
An analysis of seasonal variations in ground air temperature showed that the recorded variations are most pronounced during the winter-spring period and are most likely associated with a reduction in the stationary time of the Siberian anticyclone. This suggests that the global atmospheric circulation rather than a local change in the energy balance of the atmosphere constitutes the mechanism for the realisation of regional climate variability factors. An analysis is made of the relationship between solar activity characteristics and hydrometeorological parameters of Lake Baikal and the Angara river. The analysis revealed a high degree of correlation between the solar activity cycle length and long-term fluctuations of Lake Baikal's level, and the rate of water inflow to the lake and the duration of the unfrozen state of Baikal and the Angara. The origin and possible mechanisms of these correlations are discussed.

CHANGES OF SOLAR RADIATION INPUT IN THE LOWER ATMOSPHERE AS AN IMPORTANT LINK IN SOLAR-CLIMATE CONNECTIONS

Svetlana VERETENENKO and Mikhail Pudovkin (Institute of Physics, St.Petersburg State University, Ulianovskaya st., 1, St.Petersburg, Petrodvorets, 198904, Russia, e-mail: vereten@SV2135.spb.edu)

Variations of solar radiation input in the lower atmosphere caused by cloud cover changes associated with solar activity phenomena have been investigated at the network of actinometric stations of Russia. It was revealed that the half-yearly totals of global radiation, characterizing the entire amount of solar energy coming to the Earth's surface during cold or warm half a year, may be affected appreciably by galactic cosmic ray (GCR) variations, solar flare activity and auroral phenomena at high latitudes, their effects depending on the latitudinal belt and season. The negative correlation between the global radiation totals and the cosmophysical factors under study is observed in the high-latitudinal region, whereas at middle latitudes the solar radiation input was found to correlate with GCR intensity and solar flares. In turn the changes of the solar energy incoming the high-latitudinal atmosphere during a year are shown to influence the zonal circulation intensity in the following cold period. The results obtained allow us to conclude that the solar radiation input modulated by different solar activity phenomena through cloud cover changes seems to be an important factor affecting the troposphere dynamics and may be involved in the physical mechanism of solar activity influence on the lower atmosphere state.

SOLAR ACTIVITY AND THE LOWER ATMOSPHERE STATE

Mikhail PUDOVKIN and Svetlana Veretenenko (Institute of Physics, St.Petersburg State University, Ulianovskaya st., 1, St.Petersburg, Petrodvorets, 198904, Russia,
e-mail: pudovkin@snoopy.phys.spbu.ru)

The relationships between the solar activity associated variations of the cosmic ray fluxes and the state of the lower atmosphere are discussed. It is shown that the bursts of Solar Cosmic Rays, with the energy being enough to penetrate the stratosphere heights, cause the decrease of the solar radiation intensity at the Earth's surface, whereas the Forbush-decreases of the Galactic Cosmic Rays result in the increase of solar radiation intensity at latitudes higher than 60 degrees. Long-term variations of the solar radiation input in the lower atmosphere depending on the solar cycle phase, season and latitudinal belt are considered too.
The found changes of the solar irradiance are supposed to be caused by the variations of its scatter by some layer (homogeneous or in the form of clouds) at the heights of about 10 km. Results of the numerical modelling seem to confirm the suggested mechanism of the solar activity effects on the lower atmosphere circulation including the changes of the radiation budget due to the cloud cover variations.

SOLAR EXTREME ULTRAVIOLET MEASUREMENTS FROM THE NASA TIMED SATELLITE

Thomas N. WOODS, Frank Eparvier, Gary J. Rottman, Stanley C. Solomon (all at Laboratory for Atmospheric and Space Physics, University of Colorado, 1234 Innovation Dr., Boulder, CO 80303, USA; e-mail: tom.woods@lasp.colorado.edu); Scott M. Bailey (Center for Atmospheric Sciences, Hampton University); Raymond Roble, O. R. White (both at High Altitude Observatory, National Center for Atmospheric Research); Judith Lean (Naval Research Laboratory); W. Kent Tobiska (Federal Data Center, Jet Propulsion Laboratory).

The Solar EUV Experiment (SEE) on the NASA Thermosphere, Ionosphere, and Mesosphere Energetics and Dynamics (TIMED) mission will measure the solar vacuum ultraviolet (VUV) spectral irradiance from 0.1 to 200 nm. This solar radiation is the dominant global energy source for the heating of the thermosphere, creating the ionosphere, and driving the diurnal cycles of wind and chemistry in the upper atmosphere. The variability of the solar VUV irradiance over the 11-year solar cycle ranges from 10% to over a factor of 10, with more variability at the shorter wavelengths.
To cover the wide spectral range of 0.1 to 200 nm, two different types of instruments are used: a grating spectrograph for spectra above 25 nm and a set of silicon soft x-ray photodiodes with thin film filters for below 30 nm. Redundant channels of the spectrograph and soft x-ray photodiodes provide in-flight calibration checks on the time scale of a week, and annual rocket underflight measurements provide absolute calibration checks traceable to NIST photometric standards. Both types of instruments have been developed and flight proven as part of a NASA solar VUV irradiance rocket experiment. These solar rocket measurements in 1997 and 1998 will be presented.
The Applied Physics Laboratory (APL) is developing the TIMED spacecraft for a shared launch on a Delta vehicle at the Johns Hopkins University (JHU). The TIMED mission is being planned as a two-year mission with a circular orbit altitude of 600 km and an orbit inclination of 74°. There are three other TIMED instruments, which measure the composition, temperature, infrared cooling, and winds in the upper atmosphere.

CALCULATION AND PROCESSING OF MT.WILSON SPOT, PLAGE AND WEAK FIELD INDICES

Roger ULRICH, John Boyden, Daryl Parker, Judit Pap (all at the Department of Physics and Astronomy, University of California, Los Angeles, 405 Hilgard Ave., Los Angeles, CA 90095-1562, USA); Linton Floyd Code 7660, Naval Research Laboratory, Washington DC, 20375, USA)

The synoptic magetograph observations at Mount Wilson Solar Observatory taken in the 525.0 nm line are used to derive spot (MWSI), plage (MPSI) and weak field indices (MWFI). The MPSI has been shown to be closely correlated with and a good surrogate for solar UV irradiance as measured by satellite instruments. The MPSI and MWSI together have been used to model total solar irradiance measurements from satellite observations.
The MWFI is a new index intended to represent the slow variability of the weak magnetic fields, which are likely connected with variations in both UV and total irradiance. The MPSI and MWSI are defined as the sum of the fields in all magnetograph pixels with fields in a certain range (e.g. between 10 and 100 gauss for the MPSI), divided by the total number of pixels while the MWFI is the ratio of the area covered by fields having absolute values between 4.8 and 5.2 gauss to the area covered by fields with absolute values less than 0.4 gauss. In this paper we describe the calculation and processing of these indices, including refinements of previous versions of the MPSI and MWSI which take into account changes in spectrograph instrumentation and observation protocols and which are intended to make the data base more internally consistent.

SOLAR ULTRAVIOLET IRRADIANCE: UARS SOLSTICE OBSERVATIONS

Gary ROTTMAN, Thomas Woods, Giuliana De Toma, Julius London, Marty Snow, Cindy Russell, Barry Knapp (at the University of Colorado, 1234 Innovation Dr., Boulder, CO 80303, USA; e-mail: gary.rottman@lasp.colorado.edu); Oran R. White (National Center for Atmospheric Research, PO Box 3000, Boulder, CO 80307-3000, USA)

The Solar Stellar Irradiance Comparison Experiment (SOLSTICE) on the Upper Atmosphere Research Satellite has made daily observations of solar ultraviolet irradiance since October 1991. The SOLSTICE spectrometer observes the Sun at wavelengths between 120 and 420 nm, and provides daily spectra with a spectral resolution of 1 nm. The UARS data record spans a time from near the maximum of solar cycle 22 in 1991, through solar minimum in about 1996-1997, and now into the new solar cycle 23.
Time series of SOLSTICE data have a long-term relative accuracy of 1 to 2%, although the short-term relative accuracy may often exceed 0.05%. These time series have been analyzed as a function of wavelength. They provide an estimate of the solar cycle change during the declining phase of cycle 22 and during the rising phase of cycle 23 (to the summer of 1999). Short and intermediate-term variations are examined, and are compared to the long-term records.

DETECTION OF CLIMATE OSCILATIONS BY ENHANCED MONTE CARLO SSA

Milan Palus (Institute of Computer Science, Czech Academy of Sciences, Pod vodarenskou vezi 2, 182 07 Prague 8, Czech Republic, email: mp@uivt.cas.cz); Dagmar NOVOTNA (Institute of Atmospheric Physics, Czech Academy of Sciences, Bocni II/1401, 141 31 Prague 4, Czech Republic,
email: nov@ufa.cas.cz)

Monte Carlo singular spectrum analysis (MC SSA), based on a so-called surrogate data technique, is a tool for detection of signals embedded in coloured noises, which are usually present in geophysical data. We propose to enhance the MC SSA by evaluating and testing the regularity of dynamics of the SSA modes against the coloured noises null hypothesis, in addition to the test based on variance. The method is illustrated in the detection of oscillations with a period of approximately eight years in historical surface air temperature records obtained from several European locations, as well as in the detection of approximately five-year cycles in the global surface air temperature series. The lengths of detected cycles related to the lengths of the periods in solar inertial motion and the possible solar-terrestrial relations are discussed.

WHAT CAN BE A MECHANISM UNDERLYING THE SUNSPOT CYCLE?

Milan Palus (Institute of Computer Science, Czech Academy of Sciences, Pod vodarenskou vezi 2, 182 07 Prague 8, Czech Republic, email: mp@uivt.cas.cz) Dagmar NOVOTNA (Institute of Atmospheric Physics, Czech Academy of Sciences, Bocni II/1401, 141 31 Prague 4, Czech Republic,
email: nov@ufa.cas.cz)

A property of nonlinear oscillators - mutual dependence between their instantaneous amplitude and frequency is tested in the yearly and monthly records of the sunspot numbers using the histogram-adjusted isospectral surrogate data and the Barnes model as the ARMA surrogates. The instantaneous amplitudes and frequencies are obtained by means of the analytic signal approach using the discrete Hilbert transform. In several tests the amplitude-frequency correlations has been found significant on levels ranging from $p<0.03$ to $p<0.07$, which supports the hypothesis of a driven nonlinear oscillator as a mechanism underlying the sunspot cycle.

SOLAR-FORCED COUPLED GCM EXPERIMENTS AND COMPARISON WITH OBSERVATIONS

William INGRAM, Simon Tett, Peter Stott (all at Hadley Centre for Climate Prediction and Research, Meteorological Office, London Road, Bracknell, Berks, RG12 2SY, UK); Myles Allen (Space Science Dept, Rutherford Appleton Laboratory, Chilton, OX11 0QX, UK & Dept of Physics, University of Oxford); Gareth Jones and John Mitchell (both at Hadley Centre)

We have run the coupled model HadCM2 forced with reconstructed solar irradiance variations, both following Hoyt and Schatten (1993) and Lean et al (1995). For the twentieth century we have an ensemble of simulations with each, as well as volcanic and anthropogenic forcings. We have then used "optimal fingerprinting" to look in the twentieth century observations for the modelled response patterns in space and time, concentrating on the decadal time scale as having most general interest. There are serious issues of degeneracy (patterns resembling

linear combinations of each other), implying that investigations which do not include the full set of forcings could reach spurious conclusions. However, a solar contribution to the early-century warming is robustly detectable under the assumptions of the method (linearity, the accuracy of the modelled internal climate variability, and the accuracy of the modelled patterns of response, though not their amplitudes).

JSA16/E/10-A3 Poster **0830-20**

LONG-TERM VARIABILITY OF SOLAR PROTON FLUX AND ITS CONNECTIONS TO GLOBAL OZONE DISTRIBUTION

Alexei KRIVOLUTSKY (Central Aerological Observatory, Pervomayskaya 3, Dolgoprudny 141700, Moscow Region, Russia, alkriv@mycomp.netclub.ru); Nina Perejaslova and Margarita Nazarova (both Institute of Applied Geophysics, Moscow, Russia)

Solar proton fluxes measured during 1969-1999 by Russian polar system of "Meteor" satellites and global total ozone distribution (ground based observations and TOMS data) were used to investigate long-term total ozone response to cosmic factors using linear regression simple and multiply statistical analysis. Yearly averaged data of total solar proton fluxes at different bands of energy and yearly averaged total ozone data for different latitudinal belts were used for analysis. Clear response of total ozone has been revealed for the years, which contain strong solar proton events (1972, 1989, 1991 and 1997). This response of total ozone depends on latitude strongly. The analysis has shown negative response at high latitudes and positive response for the lower latitudes both for Northern and Southern Hemispheres with zero effect at 40 N approximately. Local minimum of ozone response was found near by equatorial region. So that the response of total ozone to SPEs has global nature and was not concentrated near polar region. It is not easy to understand the evidence of solar particle influence at low latitudes. The positive sign of such response in this region also needs special attention based on photochemical modelling because of this result is in contrast to traditional conception of the ozone destruction by NOX. Some possible mechanisms are discussed.

ROLE OF SOLAR EUV AND SOFT X-RAY RADIATION PATROL FOR GLOBAL CLIMATE VARIABILITY INVESTIGATIONS

S.V. AVAKYAN (Aerospace Physical Optics Laboratory of S.I. Vavilov State Optical Institute. Tuchkov Lane 1, St. Petersburg, 199034, Russia, email: avak@soi.spb.su)

In the present paper process of excitation of the Rydberg atomic and molecular states should be taken into account in the solar-terrestrial connections as a source of the information at the ground on the solar shortwave activity (associated with the solar flares, solar cycles and solar rotation). This mechanism is associated with the sporadic ionospheric radio- and IR-emission in characteristic spectrum of Rydberg transitions. The principal geoeffective part of the solar spectrum can be exactly EUV and soft X-ray fluxes, because the variations of all types: cyclic, with solar rotation, and the most intensive - during large solar flares, in these spectral ranges of radiation have the highest amplitudes. Therefore the permanent monitoring of solar soft X-ray and EUV spectral radiation (of wavelengths less than 120 nm) for sufficiently long periods to fully assess the long-term climate variations is very important. At present in the world such a solar patrol does not exist but there is a plan of its realisation by development of the Project "Creation of the permanent space patrol of solar extreme ultraviolet and X-ray radiations". This Project was supported by the grant of International Science and Technology Center in 1996 and 1998/99. European Union financed these stages of our Project with the scientific collaborators from France and Germany. At present the EUV spectrometer (57(16) - 153 nm) and soft X-ray and EUV radiometer (0.14 - 135 nm) have been built and are now being tested and calibrated. In this paper the possible transfer mechanism of the upper atmosphere response on the solar activity to the ground is discussed and the connection of the future Solar Patrol Mission data with this problem is considered.

TOTAL SOLAR IRRADIANCE (TSI) VARIABILITY MEASUREMENTS FROM SPACECRAFT PLATFORMS

Robert B. LEE III (NASA Langley Research Center, Atmospheric Sciences Division, MS 420, Hampton, Virginia 23681-2199, USA, Email: r.b.lee@larc.nasa.gov); Robert S. Wilson, Aiman Al-hajjah, Jack Paden, Dhirendra K. Pandey, and Susan Thomas (All at Science Application International Corporation (SAIC), Suite 300, One Enterprise Parkway, Hampton, Virginia 23666-5845, Email: r.s.wilson@larc.nasa.gov)

Long-term total solar irradiance (TSI) variability and the mean TSI magnitude were analyzed using TSI data sets from 1978-1998, spacecraft pyrheliometric missions Earth Radiation Budget Satellite (ERBS), Nimbus-7, Upper Atmospheric Research Satellite (UARS), and Solar and Heliospheric Observatory (SOHO) Spacecraft radiometers]. The analyses suggest that the mean TSI value derived from each long-term spacecraft mission decreased chronologically from a high of 1371 Watts per square meter [1986 Nimbus-7 value] to a low of approximately 1365 Watts per square meter [1986 and 1996 ERBS values]. The ERBS pyrheliometer has produced the longest TSI spacecraft data set (October 1984 through January 1999). The recent UARS, Space Shuttle Atmospheric Laboratory for Applications and Science (ATLAS) Solar Constant (SOLCON), and SOHO measurements suggest that the most likely TSI magnitude is in the 1365-1366 Watts per square meter range at minimum solar magnetic activity as indicated by minimum sunspot numbers. The TSI long-term variability component was found to vary with a period of approximately 10 years. Between long-term minima (1986, 1996) and maximum (1989-1991) sunspot magnetic activity, the component varied as much as 2 Watts per square meter above its minimum magnitude.
The TSI data sets were analysed to identify the possible existence of an additional TSI variability component with a period longer than 10 years as well as the effects of sunspot cycle length on TSI variability.

SOLAR FORCING OF GLOBAL CLIMATE AND ITS CONTRIBUTION TO ANDRONIAN WARMING

Paul E. DAMON and Alexei N. Peristykh (both at Department of Geosciences, University of Arizona, Tucson, Arizona, 85721 USA; e-mail: damon@geo.arizona.edu)

Before the beginning of the industrial age (ca. 1850), global climate during the past 8 millennia was surprisingly stable. d18O variation in Greenland ice cores during the past 8 millennia has not been very great despite the fact that the difference between d18O during summer and winter is as great as between Holocene and the Warm ice age and the effect on Greenland precipitation of about five air masses with more or less distinct d18O signatures [Cole, personal communication, 1988]. If we assume that the variations are due to changes in the temperature gradient alone, until the beginning of the industrial age, the temperature range for the North Atlantic region was only ca. +/-0.5 ˚C and part of this is the result of changes in the Earth's orbit [Berger, 1988].
In contrast, the temperature rise since the beginning of the industrial period has been ca. 0.7 ˚C. Accompanying this period there has been an extinction of many faunal species, and large changes in river discharge with accompanying industrial metals and chemicals and other consequences. To our descendants looking back in time, the boundary between Holocene and the industrial stage of human history will represent a relatively sharp boundary that we will refer to as the beginning of the Andronian geologic stage.
At the end of the 19th century (ca. 1880), the Earth entered a Contemporaneous Solar Maximum (CSM) that seems to be equivalent to the Medieval Solar Maximum (MSM) [Jirikowic and Damon, 1994]. The MSM occurs between AD 1090 to AD 1270 [Stuiver et al., 1998]. The MSM is approximately equivalent to the "Early Medieval Warm Epoch that lasted a few centuries around AD 1000-1200" [Lamb, 1965]. Because of the relative stability of global climate during the last 8000 years prior to the industrial era, it has not been possible to demonstrate that the "Early Medieval Warm Epoch" was global in extent [Hughes and Diaz, 1994].
We conclude that the Sun has contributed about 15% or 0.1˚C to Northern Hemisphere warming to 1997.

RHYTHMS OF A SOLAR SYSTEM, EARTH ATMOSPHERE AND OCEAN CLIMATE

Boris SHERSTYUKOV (All-Russia Research Institute of Hydrometeorological Information-World Data Center, 6 Korolev St. Obninsk, Kaluga Reg. Russia, email: SBG@wdc.meteo.ru)

The external factors of Earth climate changes in the altitude zones 00-30, 30-60, 60-90 N and El Nino are considered. The analysis of the solar and geomagnetic activity indexes astronomical data and climate for 1900-1998 years is executed. In barycentric solar co-ordinate system the Earth disturbances under an operation varying asymmetry of a solar system, anomalies of orbital motion and oscillations of the Earth concerning a barycentre the Earth – Moon Is shown, that the listed factors influenced for climate changes of 20-century in Northern hemisphere: in low altitudes - about 25 % of a general temperature variability, in mean altitudes 14 % and in high altitudes 8 %. The solar activity determines accordingly 16, 7, and 4 % of a temperature dispersion and its influence is increased in 1.5 times when asymmetry of planets configuration is increased too. Moon determines 17, 8, 4 % of dispersion and its influence more noticeably when asymmetry of planets configuration is absent.
The new method of detection and prognosis of rhythm is offered. The forecast of ocean temperature rhythm till 2008 composed and is shown that strong El Nino will be in 2000-2001 years.

SURROGATES FOR SOLAR UV/XUV IRRADIANCE

Linton FLOYD, Lynn Herring, Patrick Crane (all at Interferometrics Inc., Chantilly VA 20151, USA, Email: floyd@susim.nrl.navy.mil); Dianne Prinz (E.O. Hulburt Center for Space Research, Naval Research Laboratory, Washington, DC 20375, USA, Email: prinz@susim.nrl.navy.mil); D.L. Judge, H.S. Ogawa (both at Space Sciences Center, University of Southern California, Los Angeles, CA 90089-1341, USA, Email: djudge@lism.usc.edu)

We explore the level of correspondence between various solar indices (e.g. MgII core-to-wing ratio, F10.7 cm flux, and He 1083 nm equivalent width) and UV/XUV irradiances for 0.1-400 nm. The principal sources of data used in this analysis are from the Solar Ultraviolet Spectral Irradiance Monitor (SUSIM) and the CELIAS Solar EUV Monitor (SEM) aboard the Solar Heliospheric Observatory (SOHO). Responsivity degradation is accounted for in both instruments. Comparisons with results from other similar experiments are also presented. We find that variations in irradiances originating in the chromosphere and transition region are generally well described by the MgII index and that coronal irradiances are well described by F10.7. Both of these findings are consistent with those of other investigators. The continuum UV irradiance for wavelengths 160-263 nm is approximately linear with the MgII index. On the other hand, variations in the strong Ly-a emission line appear to be better fit by separate linear dependences on short- and long-term components of the MgII index. Other wavelength ranges possibly exhibiting this segmented MgII dependence are identified. The aggregate EUV/XUV irradiances as measured by the SEM zero-order channel from 1996 through mid-1998 are fit using a linear regression model involving MgII, F10.7, and GOES soft X-ray flux resulting in a correlation coefficient of 0.98.

POSSIBLE LINKS BETWEEN THE SUN'S RADIUS VARIATIONS AND THE EARTH'S CLIMATE EVOLUTION.

ROZELOT, Jean,(OCA/CERGA, Avenue Copernic, 06130 GRASSSE, FRANCE,
E-mail: rozelot@obs-azur.fr, Telephone: 33 4 93 40 53 53, Fax:33 4 93 40 53 33)

The purpose of this paper is to investigate whether the effects of the Sun's radius variations influence some Earth climatic changes. For this purpose, we first describe the available data sets concerning the temporal dependence of the diameter of the Sun. The time series may be divided into three categories; (i) the measurements made by means of the solar astrolabes, for instance at the Calern Observatory or in Brazil; available data cover the time period ranging from 1977 up to now; (ii) the reconstruction of longer series, starting from the XVII th century but only concerning the ``horizontal'' apparent diameter and (iii) the recent measurements of any solar diameters which permits to determine the true shape of the Sun (the helioid). All these data are here for one of the first time briefly discussed to test their significance on solar luminosity models. Because both the irradiance and diameter variations are small, their climatic impact is difficult to quantify. However, the observed evolution of the Earth's global surface temperature seems strongly correlated with these solar diameter variations over decadal even longer period of time. Finally, we indicate which difficulties remain to explain on physical grounds. An analysis of this nature is obviously subject to several uncertainties; but we propose coupled modes as a basic effect to understand the link between solar diameter irradiance variations and temperature effects on decadal time periods.

CAII K IMAGING TO UNDERSTAND UV IRRADIANCE VARIABILITY

R. KARIYAPPA (Indian Institute of Astrophysics, Bangalore 560034, India)

Because the radiative output of the Sun is one of the main driving forces of the terrestrial atmosphere and climate system, study of changes in the solar energy flux integrated over the entire spectrum and in many spectral bands has recently become of interest. To identify and understand the underlying physical mechanisms of total solar and UV irradiance variability and to estimate the contribution of various chromospheric features to UV irradiance, detailed analysis of spatially resolved data is required. The various chromospheric features (plages,

network elements, intra network regions, background chromospheric regions and quiet Sun regions) have been segregated from CaII K Spectroheliograms of NSO/Sac Peak and Kodaikanal Observatory. The different parameters of these chromospheric features have been derived, and compared with UV irradiance flux measured in MgII h & k lines by Nimbus 7 and NOAA 9 satellites to estimate the contribution of chromospheric features to UV irradiance variability. The important results of this detailed analysis of CaII K Images together with UV irradiance data will be discussed in this paper.

EVIDENCE FOR COSMIC TIMESCALES IN LAKE BAIKAL EVOLUTION

Vladimir F. Gelety and Gennady V. Kalmychkov (Institute of Geochemistry Irkutsk, Russia, email: gikil@igc.irk.ru); Alexander V. MORDVINOV (Institute of Solar-Terrestrial Physics, P.O. Box 4026, Irkutsk, 664033, Russia, email: avm@iszf.irk.ru); Anatoly M. Popov (Institute of the Earth's Crust, Irkutsk, Russia, email: popov@earth.crust.irk.ru)

It was shown earlier that the hydrologic regime and long-term evolution of Lake Baikal are sensitive to solar energy variations. The Lake is situated in the middle of the continent and water inflows into Lake Baikal from over the great region. Therefore Sun-climate relations appear clearly in temporal changes of parameters integrated over a bulk of water and accumulated from the great area. Continuous wavelet analysis was applied to study water level fluctuations in Lake Baikal. In the wavelet spectrum the 11-yr solar activity cycle is clearly delineated, besides usual meteorological timescales. Such influence of solar activity on water level is evidently caused through climatic changes. Wavelet analysis was also applied to study the records of biogenic silica concentration in the cores of bottom sediments obtained from the special drilling project at Lake Baikal. The previous studies of the cores revealed evolutionary changes of Lake Baikal during the past 5 million years. Diatom abundance in sediments shows dramatic changes on large timescales. Wavelet spectra demonstrate clearly unsteady and multiscale changes of biogenic silica. Wavelet spectra display also more-or-less regular changes induced by insolation changes according to the Milankovitch theory. Time scales at about 23, 41, 100, 400 and 800 thousand years were revealed earlier and appear in our spectra. Irradiance changes due to evolution of the Sun on geological timescale, if any, could be derived through comparison of these data and other records of geological or geophysical parameters sensitive to solar energy.

TIME-FREQUENCY ANALYSIS OF TOTAL SOLAR IRRADIANCE VARIATIONS

Alexander V. MORDVINOV (Institute of Solar-Terrestrial Physics, P.O. Box 4026, Irkutsk, 664033, Russia, email: avm@iszf.irk.ru); Richard C. Willson (Center for Climate Systems Research, Columbia University 12 Bahama Bend, CA 92118 USA, email: acrim@pop.net)

Wavelet analysis was applied to study the time-frequency behaviour of a composite time series of total solar irradiance represented by the Space Absolute Radiometric Reference. Wavelet spectra accurately describe unsteady and multiscale changes of solar irradiance within a wide time-frequency range. Wavelet analysis was also applied to time series of both Photometric Sunspot Index and full-disk Calcium II K-line index to identify the contribution of sunspots and faculae to the time-frequency behaviour of the irradiance. In this analysis data from the web site of the World Radiation Center and from San Fernando Observatory were used. In the wavelet spectrum of the Photometric Sunspot Index the energy concentrates at a 27-day periodicity. In parallel with the rotational period the energy increases at 13, 40, 54 and 81 days. These timescales correspond to multiple and combinatory frequencies of the solar rotation frequency. Long-term changes due to activity complexes appear in the spectra as well. As the cycle progresses, wavelet spectrum of the calcium index shows an energy cascade towards greater time scales. This seems imply that facular and/or magnetic network characteristic timescale depends on the phase of the 11-yr cycle. Analogous patterns on timescales of several months are seen in wavelet spectra of total solar irradiance.
Such energetic cascades characterise the relaxation of thermo-magnetic perturbations during the 11-yr solar cycle.

VARIATION OF SOLAR CYCLE LENGTH BASED ON WEIGHTED WAVELET Z-TRANSFORM

Mezak A. RATAG and Suaydhi (Indonesian National Institute of Aeronautics and Space, Lapan Jl. Junjunan 133, Bandung 40173, Indonesia, email: mezakr@indosat.net.id)

Time-variation of the solar cycle length has recently been suggested as having close association with climate. A number of methods to determine the cycle length have been proposed. They are mostly based on filtering techniques similar to the one employed by Friis-Christensen and Lassen (1991) or the median method developed by Mursula and Ulich (1998). These methods, however, have serious difficulties in defining the cycle length as well as in dealing with periodicities at both ends of the sunspot time series. In this paper we propose the use of weighted wavelet Z-transform (WWZ), applying the so-called Morlet wavelet, in determining the time-series of solar cycle length. This method is proven to be much better in overcoming the difficulties mentioned above. The resulting WWZ amplitude time-series is a very useful tool in comparing the behaviour of the 11-, 50-, 100-year and other cycles. It shows, for example, that the WWZ amplitudes of the 11- and the 100-year cycles - which presumably correspond to their relative significance - have approximately doubled during the last two centuries, while that of the 50-year cycle decreased to become about ten times lower than its values in 1700s.

ON THE GLOBAL MANIFESTATION OF THE QUASI-10-DAY PERIODICITY

Nikolai KLOCHEK and Marina Nikonova (Institute of Solar-Terrestrial Physics, P.O.Box 4026, 57, email: klochek@iszf.irk.ru)

Quasi-10-day periodicity manifests itself in various processes on the Sun and in interplanetary space, such as solar radio emission, X-rays, dynamics of solar flares, solar wind density, cosmic ray rigidity and, especially total solar irradiance variability. It also presents in wave disturbances of the Earth atmosphere, ionospheric variations, the Earth's seismicmnoise, the Earth's global hydrocycle and some biological processes. All these facts suggest this periodicity to be global. Along with the assumption of the solar origin of this periodicity the question of the mechanism of its excitation is still open. On the other hand it should be noted that the variable stars of the type of classical cepheids, related to G2 spectral class in their average brightness have the same main period of pulsations. This fact suggests the excitation of this periodicity on the Sun to be related with the periodic variations of the opacity of subphotospheric layers that, in its turn, results in the periodic variations of the solar irradiance. If this mechanism is true then the global manifestation of the quasi-10-day periodicity may be explained.

A NEW METHOD TO DETECT SOLAR VARIABILITY EFFECTS ON TREE-RINGS

Mezak A. RATAG (Indonesian National Institute of Aeronautics and Space, Lapan, Jl. Junjunan 133, Bandung 40173, Indonesia, email: mezakr@indosat.net.id)

A number of methods have been extensively used to detect possible impacts of solar variability on tree-rings. They are mostly developed on the basis of Fourier analysis. These methods are ideal tools if we are dealing with fluctuations characterised by truly or nearly constant period, amplitude, and phase. Periodic fluctuations, which behave as transient or nearly transient phenomena, will be very difficult to deal with. In many cases, the terrestrial data are in the form of unevenly sampled time series. These cause serious problems for the application of methods, which are based on Fourier analysis. Here we describe a new method to detect solar variability signals in tree-ring data, which is based on wavelet transform. Period analysis using the weighted wavelet Z-transform (WWZ), with Morlet wavelet, is applied to both the solar activity and the tree-ring time-series. The comparison of the results is made in WWZ time-frequency-amplitude space. This method is shown to be able to overcome the difficulties mentioned above. Various cycles can be analysed simultaneously.

TOTAL SOLAR IRRADIANCE CHANGE ASSOCIATED TO QUIET SOLAR NETWORK

I. Ermolli (OAR - Osservatorio Astronomico di Roma, Roma, I-00136 Italia); F. BERRILLI (Dipartimento di Fisica, Universita` di Tor Vergata, Roma, I-00133 Italia); A. Florio (OAR - Osservatorio Astronomico di Roma, Roma, I-00136 Italia)

An estimate for the change in total solar irradiance due to quiet solar network during a 28 months period (Jul 1996 - Oct 1998) at the beginning of solar cycle 23 is presented. The valuation is based on measurements of the colour temperature for network and internet work regions. These regions were identified with a numerical procedure applied on sub-arrays extracted from full-disk 1Kx1K CaK, Blue (409.6nm) and Red (607.2nm) continuum images obtained with the OAR-PSPT instrument. Our estimate for the change in total solar irradiance results of the order of 0.1%, and it is in good agreement with long-term irradiance variations measured from space.

PHENOMENONS GEOPHYSICAL IN TREE-RINGS

Nivaor Rodolfo RIGOZO and Daniel Jean Roger Nordemann (both at Space Geophysics Division, National Institute for Space Research-INPE, CP 515, 12201-970, São José dos Campos, Brazil, E-Mail: rodolfo@dge.inpe.br)

Solar activity variations may be studied directly, through observations, or indirectly, through natural records which permit to extend the length of the time series well beyond the present and historical observations. Climatic natural records may be investigated to study the global and regional influence on climate of the variations of the energy emission by the Sun associated to its activity. Tree ring studies are usually used to determine or verify climatic factors which prevail in a given place or region and may cause tree ring width variations. Few studies are dedicated to the geophysical phenomena, which may underlie these tree ring width variations. Among these records, tree ring width series are of particular interest because of their availability, their regional coverage in continental areas and the possibility of very low cost methodologies for their study. The digitised images of polished dead tree slices are transformed by appropriate software into annual growth ring radial width. Samples may also be obtained from live tree by using an increment borer, but up to now higher facility and precision are achieved with polished slices than with drilled samples. Means of the time series and elimination of bias/tendencies are obtained from individual trees and local group, within dendrochronology norms. The search for periodicities is made by spectral analysis including maximum entropy and iterative regression methods. The first results obtained from Auracaria angustifolias specie (recently dead trees of maximum ages 200 yr.) from Santa Catarina States in Southern Brazil show periods of 84.2 to 85 yr., 46 to 50 yr., 24.6 yr., 10.6 yr. and 5.8 yr. which may be attributed to Gleissberg cycle, the 4th harmonic of the Suess cycle, the Hale cycle, the Schwabe cycles and the 2nd harmonic of the Schwabe cycle, and 4 and 6.9 yr. from El Nino kind of events.

FORECAST OF THE MAJOR GEOMAGNETIC STORMS

Virginia SILBERGLEIT (Departamento de Fisica, Facultad de Ingenieria, UBA. Av. Paseo Colon 850. 1063-Buenos Aires. Argentina. Email: virginia@tormen.uba.ar)

Perturbed periods characterised by the maximum daily average AA index compiled from 1868 to 1992 are considered. The geomagnetic activity is studied by considering the even-odd effect with respect to sunspot cycles and applying Gumbel´first asymptotic distribution extreme values.
The present study shows that the largest geomagnetic perturbed periods have different intensities depending on the parity of the solar cycles in which they occur.

ON THE RELATIONS BETWEEN SUNSPOT NUMBER

Konstantin N. VISHERATIN (Institute of Experimental Meteorology, SPA "Typhoon", Obninsk, Kaluga region, 82 Lenin Avenue, Russia, 249020, email: typhoon@meteo.ru); Boris G. Sherstukov (All Russia Research Institute of Hydrometeorological Information - World Data Center, Obninsk, Kaluga region, 6 Koroleva Street, Russia, 249020, email: sbg@meteo.ru)

The daily sunspot numbers spectral analyses have been made. The data from 1818 - 1998 have been transformed to standard variables and padded with zeros to provide a better resolution. The analyses have been carried out for the various sample lengths. The results obtained show

that 11-yr line is revealed as triplet with periods of 10.04, 10.94 and 11.96 yr, and there is harmonic structure for the periods range between about 5 and 40 yr. A fitting of the obtained sunspot number periodicities resulted in conclusion that solar activity periods are decrease from about 40 year to 27 days approximately as the second power of integer numbers.

"SOLAR ROTATION PERIOD INFERRED FROM A FEW UV LINES OBSERVED BY SBUV/2 ONBOARD NOAA11 SATELLITE"

Rajmal JAIN, Lokesh Bharti, Kandarp Bhatt (Udaipur Solar Observatory, Udaipur - 313001, INDIA); Richard. P. Cebula (Hughes STX Corporation, Greenbely, MD, USA)

Analysis of two time series of UV irradinace variation, one of 745 days during 1989-1991 and other of 898 days during 1991-1993, measured by SBUV/2 instrument onboard NOAA11 satellite, has been carried out for 13 UV lines. The chosen UV lines may be divided in two wavelength domain i.e below and above 290 nm. The UV lines with wavelength below 290 nm are: Ni XIII; Si IX; Fe XII; Mg II; Mg I; and Si I while above 290 nm are: Ca XII; Fe XIII; Fe I(M and N); Ni XVI and Ca H and K. The time series of UV irradiance variation in the core and in the wings of each selected line were subjected to Fast Fourier Transform. The power spectrum of each line shows 27-day solar rotation periodicity unambiguously, however more pronounced in the wavelength domain below 290 nm. The shorter period of about 14 days, related to the solar activity on the invisible hemisphere, is also evident. The power of fundamental 27-day period reduces appreciably from core to wing in each line as well as with increase in wavelength. The 27-day period varies from 30 to 27 days almost in each line during ascending phase of the sunspot cycle 22 i.e during 1989-94. Further, the Fourier analysis of both time series enabled us to detect distinctly the 76 and 154 days periods of solar activity. These periods, however, are more pronounced in the lines with wavelength >290 nm. Our study unambiguously reveals that amplitude and frequency of fundamental solar rotation period as well as other periods of solar activity strongly depend on the wavelength of UV line under study and sunspot number during the solar cycle.

"CORRELATION STUDY BETWEEN SUNSPOT AND RAINFALL IN SOUTHERN RAJASTHAN SUBTROPICAL REGION OF INDIA"

Rajmal JAIN and S. C. Tripathy

The cross correlation among 102 years rainfall data in Udaipur (southern Rajasthan) sub-tropical region and sunspots show the influence of solar activity on the climatic conditions of Udaipur. The periodicity obtained using rainfall and other data sets, such as, water storage of Jaisamand lake and gauge measurements of two rivers, Jakham and karmoi, are similar to the periodicity of sunspots, which indicates a relationship between rainfall and sunspot activity. A period of about 27% is found to deviate from normal rains in the form of flood, excess and deficit of rains in Udaipur sub-tropical region. The possible physical mechanisms to explain sun-weather relationship in astro-physical context are discussed.

PROPOSED MECHANISM FOR EFFECTS OF GLOBAL ELECTRIC CIRCUIT ON CLOUD MICROPHYSICS

Brian A.TINSLEY, (University of Texas at Dallas, Richardson, TX 75083-0688 USA e-mail: Tinsley@UTDallas.edu); Kenneth V. Beard, (University of Illinois at Urbana-Champaign, Urbana, IL 61801)

The global atmospheric heat balance is sensitive to small changes in cloud albedo and opacity such as are produced by changes in the rate of production of ice from supercooled water at cloud tops. Also, the dynamics of winter storms respond to changes in precipitation efficiency resulting from changes in the production of ice. We have identified a hitherto neglected cloud microphysical process linking the rate of initial production of ice in many clouds to the vertical ionosphere-earth current density, Jz, that responds to changes in cosmic ray flux and to other solar wind and terrestrial inputs. (Tinsley will discuss the Jz response in the review JSA45). The cloud microphysical process entails an increase of the collision rate of 'evaporation aerosols' from the evaporation of smaller, electrically charged droplets with other, larger supercooled droplets at cloud tops. This increase is dependent on the electrostatic charge on the 'evaporation aerosols'. Sulphate and organic compounds scavenged by cloud droplets coat the 'evaporation aerosols' and condition them to be effective ice-forming nuclei. The 'evaporation aerosols' retain their initial charge for many minutes in the cloud environment. Image charge forces cause them to be strongly attracted to the droplets, whether the droplets are uncharged, or with like or unlike charges and ice nucleation is likely to occur on contact. We present numerical simulations showing that contact ice nucleation rates are dominated by image charge forces when the 'evaporation ice nuclei' carry only a few tens of elementary charges, and that this process

INCREASE OF THE TOTAL SOLAR IRRADIANCE SINCE THE LAST MINIMUM IN 1996

ANKLIN M (1), Fröhlich,C.(1), Willson R.C (2), Lee III, R (3), Wilson R.S (4) Crommelynck D(5), Dewitte S(5).1) Physikalisch-Meteorologisches Observatorium Davos, Dorfstr. 33, 7260 Davos Dorf, Switzerland, 2) Columbia University, 12 Bahama Bend, Coronado, CA, 92118, USA, 3) NASA Langley Research Center, Building 1250, Hampton, Virginia 23681-2199, USA, 4) One Enterprise Parkway, Suite 300, Hampton, Virginia 23666 ,USA, 5)Royal Meteorological Institute of Belgium, Av. Circulaire, 3 B-1180 Brussels

Total solar irradiance (TSI) has been monitored by the ACRIM II (Active Cavity Radiometer Irradiance Monitor), VIRGO (Variability of solar Irradiance and Gravity Oscillations) and ERBS (Earth Radiation Budget Satellite) experiments between 1996 - 1998. The anticipated increase if the TSI since the last minimum in the summer of 1996 has been observed. Small differences between these time series exist in the amplitude of the increase and in short term variability. Here we compare the VIRGO TSI with ACRIM II and ERBS. ACRIM II data is used to fill the gap in the VIRGO time series from June-October 1998, when SOHO was lost and no data could be received. Since VIRGO observes continuously it is possible to compare truly simultaneous observations, improving the quality of the comparison substantially. The main objective of the comparison is to get detailed information on the relative performance of the radiometers and to assess the confidential level of solar irradiance changes during the 1996-1998 period.

ON FINE STRUCTURE OF THE SOLAR CYCLISITY IN CONNECYION TO METEOROLOGICAL CYCLES

Edward KONONOVICH (Moscow University Sternberg Astronomical Institute, 119899, Moscow, Russia. E-mail: konon@sai.msu.su)

The beginning of the cycle 23 allows performing a comparison of the observed and predicted values of the Wolf numbers W given by various prognoses. The real value of such forecasting is the possibility too precise the character of the current maximum of the long-term solar cycle known as a 80-100 year one. This maximum covers the recent 90-ies and coincides with the last highest 11-year cycles. The same pattern occurred for the previous 80-year cycle maxima in 1770 and 1850, when they coincided with the triads of high 11-year cycle maxima with numbers 2, 3, 4 and 8, 9, 10; in the same way there is a coincidence of series of the 11-year lowest maxima with 80-year minima at 1793 and 1894. The smoothed month mean W-values (since 1750) are considered to reveal different kinds of such triads. Their connection with meteorological cycle recognised by E.Bruckner (1890) is proved. The fine structures of deferent 11-year cycles are analysed by means of MME-method. The frequencies of the quasi-biannual cycle are revealed and considered.

QUASI-BIANNIAL CYCLICITY IN THE SOLAR-ATMOSPHERIC RELATIONS AT VARIOUS LATITUDES

Ruslan Smirnov (Fedorov Institute of Applied Geophysics, Moscow 129226, Russia); Edward KONONOVICH (Moscow University, Sternberg Astronomical Institute, 119899, Russia, e-mail: konon@sai.msu.su)

The structure of the relations between the geomagnetic activity variations represented by the mean aa index and the root-mean-square temperature anomalies in the low troposphere for the time interval 1874 - 1979 is considered over the periods 2 - 30 years. The data on temperature anomalies were used for the Polar Cap, and also for latitudes 65, 40 and 20 degrees. Frequency characteristics of the relations were obtained separately for January and July. The results have shown, that the high levels of the relations are characteristic for the Polar Cap and especially for the periods of quasi-biannual oscillations (QBO). The relation degrees for QBO as a whole decrease with transition to moderate and low latitudes. A scenario of QBO excitation based on the increasing of the meridional circulation form recurrency is suggested. The important role is played by the areas of baroclynic instability of the troposphere as cites of the tropospheric reaction on cyclic changes of the solar activity.

JSA16/W/19-A3 Poster **0830-44**

THE MIDDLE ATMOSPHERE AS A CONTROLLER OF THE SOLAR ACTIVITY INFLUENCE ON THE LONG-TERM VARIATIONS OF THE CLIMATE

Edward KONONOVICH (Moscow State University Sternberg Astronomical Institute, Moscow 119899, Russia, E-mail: konon@sai.msu.su); Nikolaj Shefov (Obukhov Institute of Atmospheric Physics, Russian Academy of Sciences, Moscow 109017, Russia, e-mail: meso@omega.ifaran.ru)

It is emphasised that the energy losses caused by the upward propagation of different kinds of the atmospheric waves generated in the troposphere is an important factor of the energy balance of the lower atmosphere. The modulation of the energy sink rate occurs due to the variation of wave transparency of the middle atmosphere. This variation is produced by the wind regime change. The letter, in its turn, is caused by different amount of the solar ultraviolet radiation absorbed by the atmosphere during different phases of the solar cycle: at cycle maximum UV radiation is larger. As a result the additional amount of energy absorbed per day at solar maximum is larger then that in minimum. The difference is about 6 per cent if measured in terms of the thermal energy of the atmosphere at 50-90 km height (its variation during the solar cycle is taken into account). In the same time it is known that the kinetic energy of the turbopause is mainly accumulated in the dynamic waves. As a result the thermal energy escapes from the atmosphere through the infrared emission of CO2 molecules due to the transfer process caused by conductivity. The variation of the atomic oxygen concentration at heights about 85- 100 km, caused by the change of the solar activity, significantly regulates the infrared energy losses. The above-mentioned process possibly increases the troposphere energy input because of decrease of sink of energy during the enhancement of the solar activity. This process may stimulate the long-term climatic variations of the energy balance in the middle and lower atmosphere. An estimation of the rate of energy sink shows that the cooling of the lower atmosphere by 1 K due to the decrease of the of solar activity level may occur during the time interval about 100 years. This is in an agreement with the conditions, which possibly took place during the Maunder Minimum in 1645-1715.

SOME VARIATION REGULARITIES OF BACKGROUND RADIATION AND ATMOSPHERIC TEMPERATURE

Yury SIZOV, Kharlampy Kanonidi and Konstantin Kanonidi (All at the Institute of Terrestrial magnetism, ionosphere and radio wave propagation (IZMIRAN), 142092 IZMIRAN, Troitsk, Moscow region, Russia; e-mail: sizov@izmiran.rssi.ru)

Background radiation and atmospheric temperature measured and registered by the data acquisition system at IZMIRAN continuously during 1998 are considered. It is shown that temporary lines of background radiation (BR) as well as atmospheric temperature (AT) demonstrate existence of time intervals when one can observe daily and seasonal variations. Disturbed BR interval events happen sometimes. Amplitudes of BR quiet daily variations are not stable and its pp values vary from 2 to 6 microRoentgen/hour (mcR/h). During disturbed intervals an amplitude of BR variations growth up to tenths mcR/h. The spectral analysis of BR temporary lines for every month has shown a presence of very stable 24-hour period. Besides it is happen rather often 4, 6, 8, 12 hour as well as 1.5, 2 days periods. BR spectrum contains some other periods but it varies from month to month. There are common periods (for example - 24 h) in BR and AT rhythms.

Observatorium Davos, World Radiation Center, PMOD/WRC, Dorfstrasse 33, CH-7260 Davos-Dorf, Switzerland); Todd Hoeksema (Standford University, Palo Alto, California, USA)

We study one of the isolated active regions that crossed the solar disk during the 1996 minimum of activity. Its passage during several Carrington Rotations allows us to analyse the evolution ofthe angular distribution of the excess radiance of the facular region. We evaluate the total (i.e. in all directions) emission of faculae, its spectral and temporal evolution and relate it to the solar surface magnetic field. To fulfil this goal we use the SOHO/VIRGO and MDI data. The results are compared with facular models through a compound model for the active region that takes them into account. The effect of the active region on the solar luminosity is discussed.

SOLAR EUV VARIABILITY AS MEASURED BY SOHO/EIT

J.S. NEWMARK (SM&A Corp., NASA/GSFC, Code 682.3, Greenbelt, MD 20771,
Email: newmark@eitv2.nascom.nasa.gov); J.W. Cook, J.D. Moses, L.E. Floyd (at Naval Research Laboratory, Washington, D.C 20375)

The Extreme-ultraviolet Imaging Telescope (EIT) on board the SOHO (SOlar and Heliospheric Observatory) satellite provides wide-field images of the corona and transition region on the solar disc and up to 1.4 solar radii. Its normal incidence multilayer-coated optics select spectral emission lines from Fe IX,X (171 A), Fe XII (195 A), Fe XV (284 A), and He II (304 A) which allow us to describe Solar activity over a wide temperature range. We provide calibrated measurements of the Solar irradiance in all four lines for the first 2.5 years of the mission. Details concerning the calibration of the instrumental response are provided. Initial comparisons with SUSIM Lyman Alpha and Mg II indices are shown as well as comparisons with the SOHO SEM He II flux.

RADIANCE OF THE QUIET SUN AT FAR-ULTRAVIOLET WAVELENGTHS MEASURED DURING THREE YEARS OF THE SOHO MISSION

Udo SCHÜHLE and Klaus Wilhelm (Max-Planck-Institut für Aeronomie, D-37191 Katlenburg-Lindau, email: schuehle@linmpi.mpg.de); Anuschka Pauluhn and Isabelle Ruedi and Sami Solanki (Institute of Astronomy, ETH-Zentrum, CH-8092 Zürich); Philippe Lemaire (Institut d'Astrophysique Spatiale, CNRS-Universite Paris XI, F-91405 Orsay); Jörg Hollandt (Physikalisch-Technische Bundesanstalt, Abbestr. 2-12, D-10587 Berlin,

The SUMER spectrometer (Solar Ultraviolet Measurement of Emitted Radiation) on the Solar and Heliospheric Observatory (SOHO) measures the radiance of the solar spectrum in the far ultraviolet range between 66 nm and 161 nm with high spatial resolution since the start of the SOHO mission. The radiometric calibration of the instrument has been performed in the laboratory using a transfer source standard traceable to the primary source standard, the electron storage ring BESSY I. With the aim of a cross calibration among the ultraviolet instruments on SOHO an observational scheme had been designed which was reproducible with the quiet Sun as the source, and which was repeated regularly during the observational period of the SOHO mission. These observations were carried out about 20 times between 5. March 1996 and 6. November 1998 with the selected spectral lines of He I (58.4 nm), Mg X (60.9 nm and 62.5 nm), Ne VIII (77.0 nm), and N V (123.9 nm). Each measurement builds an average of about 20 minutes of the radiance of the quiet Sun network at the solar disk centre. After careful separation of the line emission from the superimposed contributions of different orders of the spectrometer and from the solar continuum, the spatially resolved measurements allow to draw a trend of the intensities of the quiet Sun network in these lines along the observational period between solar sunspot activity cycles 22 and 23.

GEOMAGNETIC ACTIVITY AND ATMOSPHERIC PRESSURE FLUCTUATIONS

Yury SIZOV and Kharlampy Kanonidi (both at the Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation (IZMIRAN), 142092 IZMIRAN, Troitsk, Moscow region, Russia; e-mail: sizov@izmiran.rssi.ru)

Temporary lines of local three-hour, three hour ak- and daily average Ak-indices of geomagnetic activity (calculated on K- indices of "Moscow" magnetic observatory, IZMIRAN) and hourly average values of atmospheric pressure P on the data of cosmic rays "Moscow" station of IZMIRAN for 1994 - 1995 are considered. It is shown, that between the local ak-indices of geomagnetic activity and variations of atmospheric pressure exist relations, which are expressed in the following. During increase of geomagnetic activity (GMA) in an interval 44 considered cases of increasing GMA a level of atmospheric pressure during 1994 - 1995: decreased approximately in 40 % of cases;· increased approximately also in 40 % of cases, i.e. up to 80 % of cases of long period changes of a level of atmospheric pressure _ (from 3 days up to 2-3 weeks) are definitely connected with GMA increasing. The oscillatory changes of the form of a P level with the periods 3 - 7 days were observed on a background changeable GMA or on a magnetic quiet background. The analysis of cross correlation functions specifies that between ak and P there is a dependence, what specify precise periodicity of these functions. By the spectral analysis of temporary lines and their correlation functions the common spectral maxima on the periods, common for both lines, are received. Under the diagrams of auto correlation functions two common periods are received: 14 and 27 day. The spectral analysis of cross correlation functions has allowed to reveal maxima on the periods: 5.4, 7.6, 9.2, 13.5, 28.1 day. The spectral analysis of temporary lines has shown presence of the following common periods: 3.7, 4.4, 5.5, 6.9, 7.9, 9.3, 13.2, 28 days.

MODEL STUDY OF ATMOSPHERIC COMPOSITION AND TEMPERATURE BEHAVIOR DURING THE CURRENT 11-YEAR SOLAR ACTIVITY CYCLE

Igor KAROL, V.A. Frolkis, A.A. Kiselev (all at Main Geophysical Observatory, 7 Karbyshev Str., St.Petersburg, 194021, Russia; e-mail: karol@main.mgo.rssi.ru)

A model study of influence of the current 11-year solar activity cycle on both the atmospheric composition and radiative regime is actual for assessment of this natural and of anthropogenic inputs in the total ozone coming changes. The investigation is based on the estimations of i) solar spectrum intensity changes during its current cycle and ii) natural and anthropogenic air pollution from IPCC-92/95 scenarios. The radiative forcing due to the both above factors is calculated. Special attention is paid to study of the diurnal course peculiarities of the short-lived atmospheric radicals in the phases of 11-year solar cycle. Sensitivity of air compounds content to solar radiation changes is analyzed. For this the 2-D time dependent radiative photochemical channel model of the 0-50-km atmospheric layer and temperate latitudinal belt 30-60o N with fixed zonal and convective transport is used. The basic atmospheric reactions among the oxygen, nitrogen, hydrogen, carbon, chlorine and bromine compounds are considered. The geographical inhomogenity of pollution sources along latitudinal circle is accounted. The tropospheric water vapor conservation occurs according to the NCAR/NCEP data.

INFLUENCE OF SOLAR VARIABILITY ON THE PRODUCTION OF ATOMIC OXYGEN O(1S) 558 NM EMISSION IN THE MIDDLE AND LOWER THERMOSPHERE

Gordon SHEPHERD and Rawatee Maharaj-Sharma (both at the Centre for Research in Earth and Space Science, York University, Toronto M3J 1P3, Canada, email: gordon@windeh.yorku.ca)

The Wind Imaging Interferometer (WINDII) on the Upper Atmosphere Research Satellite measures winds from the Doppler shifts of five different emissions from the thermosphere and upper mesosphere. As part of the measurement process the volume emission rate (photon s-1 cm-3) is accurately measured. This includes the atomic oxygen O(1S) emission at 558 nm, which during daytime is emitted over a large altitude range, from about 85 to over 250 km. Two distinct peaks in altitude are formed, one near 145 km (middle thermosphere) and the other near 100 km (lower thermosphere). Each involves very different production processes, so while both respond closely to solar variability effects, each is responding to different variability components of the solar spectrum. The correlation of these two emission regions with different solar indices is presented, for both daily averages, and for short term variations that include solar flares, which strongly (and only) affect the lower thermosphere peak. The relevant atmospheric processes are described.

IRRADIANCE VARIATIONS DURING A PERIOD OF LOW SOLAR ACTIVITY IN 1996

Michael STEINEGGER (Institut fuer Astronomie, Universitaetsplatz 5, A-8010 Graz, Austria); Wolfgang Otruba (Sonnenobservatorium Kanzelhoehe, A-9521 Treffen, Austria); Peter Brandt (Kiepenheuer-Institut fuer Sonnenphysik, Schoeneckstrasse 6, D-79104 Freiburg, Germany); Zeki Eker (Department of Astronomy, King Saud University, Riyadh 11451, Saudi Arabia); Arnold Hanslmeier (Institut fuer Astronomie, Universitaetsplatz 5, A-8010 Graz, Austria)

The last solar activity minimum around 1996 was characterised by several periods without any sunspots or faculae visible on the solar disk. Between these extremely quiet intervals, from time to time a single active region emerged and developed. The passage of these individual activeregions across the visible solar hemisphere was accompanied by a pronounced variation in the solar irradiance as observed by the VIRGO radiometers onboard SOHO.
Making use of photometric full-disk observations of the Sun (e.g. MDI, RISE/PSPT, TON Ca II K) we try to reconstruct the temporal behaviour of the three spectral and the total irradiance channels measured by VIRGO. The aim of this project is to identify the different contributions of the sunspots, the faculae, and the network to the irradiance variations, and to study in detail the sunspot and facular contrasts at the different wavelengths.

ANALYSIS OF THE SOHO/VIRGO TOTAL AND SPECTRAL IRRADIANCES BASED ON THE SOHO/MDI IMAGES

JUDIT PAP (University of California, Los Angeles, 405, Hilgard Ave., Los Angeles, CA 90095-1562); Michael Turmon (Jet Propulsion Laboratory, MS 126-347, 4800 Oak Grove Dr., Pasadena, CA 91109, USA); Richard Bogart (Center for Space Science and Astrophysics, Stanford University, Stanford, CA 94305, USA); Martin Anklin, Claus Frohlich, Christoph Wehrli (Physikalisch-Meteorologisches Observatorium Davos, CH-7260, Davos-Dorf, Switzerland); Linton Floyd (Naval Research Laboratory, Code 7660, Washington, DC 20375, USA); Ferenc Varadi (University of California, Los Angeles, 405 Hilgard Ave., Los Angeles, CA 90095, USA)

The Variability of IRradiance and Gravity Oscillations (VIRGO) experiment on SOHO has been measuring total solar and spectral irradiance since January 1996. The PMO6 and DIARAD instruments are monitoring total irradiance, whereas the SunPhotometer observes near-UV at 402 nm, visible at 500 nm, and near infrared at 862 nm. The VIRGO observations have shown that total solar and spectral irradiance vary in a similar fashion. The effect of sunspots, faculae and weak magnetic fields on the VIRGO irradiances will be estimated by means of the magnetograms and continuum images of the Michelson Doppler Imager (MDI) experiment on SOHO. The phase shift between the rise of VIRGO total irradiance and the SUSIM Mg core-to-wing ratio during the ascending phase of solar cycle 23 will also be examined.

SOLAR TOTAL AND UV IRRADIANCE VARIATIONS MODELLED BY THE MT. WILSON MAGNETIC INDICES

JUDIT PAP, Roger Ulrich, John Boyden, Daryl Parker, Ferenc Varadi (University of California, Los Angeles, 405 Hilgard Ave., Los Angeles, CA 90095, USA); Claus Frohlich (Physikalisch-Meteorologisches Observatorium Davos, Dorfstrasse 33, CH-7260, Davos-Dorf, Switzerland); Linton Floyd (Naval Research Laboratory, Code 7660, Washington, DC 20375, USA); Larry Puga and Rodney Viereck (NOAA Space Environment Center, 325 Broadway, Boulder, CO 80303, USA)

Total solar and UV irradiances have been monitored from space for two decades. Observations of solar activity have been performed at the Mt. Wilson Observatory in the 525.0 nm magnetically sensitive Fe I line. From the Mt. Wilson observations we have derived the so-called Mt. Wilson Sunspot Index (MWSI), the Magnetic Plage Strength Index (MPSI) and the Magnetic Weak Field Index (MWFI). MWFI is a new data product representing the slow variability of the weak magnetic fields. In this paper we examine the variations in total irradiance and the UV irradiance as represented by the Mg II h & k as a function of solar cycle and compare their variations during solar cycles 21, 22, and 23. The contribution of sunspots, plages and the weak magnetic fields to the variations of total solar and UV irradiances will be estimated with advanced statistical methods.

INFLUENCE OF CLIMATIC CHANGES, SOLAR AND GEOMAGNETIC ACTIVITY ON DYNAMICS OF MAGNETIC PARAMETERS OF CONTEMPORARY SEDIMENTS

Kurazhkovsky A.Yu., KURAZHKOVSKAYA N.A., Klain B.I. (everybody at Geophysical Observatory "Borok" of the United Institute of Physics of the Earth of Academy of Science of Russia, 152742 Borok, Yaroslavl, Nekouz, Russia, email: knady@borok.adm.yar.ru)

The results of investigation of correlative communications between magnetic parameters of contemporary sediments of Rybinsk reservoir and of the helio geophisical factors are given. The periodicity in dynamics of magnetic parameters of sediments, which coincide with 11-year's cycles of solar activity have been discovered. The back coupling between by planetary geomagnetic activity and quantity of a magnetization of ground sediments is detected. It was shown that periodicity and quantity of magnetic parameters of sediments depends from the temperatures of water, from a level of a reservoir and other geophysical conditions, in which occurred accumulation of sediments. Was found, that in the present region the dry and warm climate lead to decrease of a magnetisation and Koenigsberger's factor on quantity, and more wet and cold calls their increase.
The possibilities of application of obtained effects of dynamics of magnetic parameters of sediments for reconstruction and prognosis of regional climatic changes is considered.

VARIABILITY IN SOLAR ACTIVITY, GEOMAGNETIC FIELD AND GLOBAL TEMPERATURE DATA ON SHORT AND LONG TIME SCALES

Tamara KUZNETSOVA, Lev Tsirulnik (both at IZMIRAN, Troitsk, Moscow region, 142092, Russia, email: tvkuz@izmiran.rssi.ru)

Two approaches can be used to extract deterministic and noise part in data sets. The first approach which may be called "nonlinear time series analysis" gives information about system dynamics. We applied alternative approach and tried to find "how much determinism" there is in data sets and whether this determinism can explain main regularities in data sets. The problems are trends and quasi-periodicities in many solar and climate processes. A method of nonlinear spectral analysis (called the method of global minimum: MGM) has been used to find periodicities in annual Wolf sunspot numbers (W) during the period 1700-1997. The longest set of magnetic observations on the Earth (D-component at Hartland, 1810-1995) is used for calculation of geomagnetic spectrum. The powerest trend at period T~204 yr. in W testifies to the existence of the slowest non-stationary processes in sunspot formation. It is shown a positive correlation of the trend changes and global climate changes: Little Ice Ages, global warming from the beginning of our century. Analysis of the geomagnetic spectrum shows that significant spectral peaks of the spectrum have solar origin at the studied time interval. But harmonics of the solar model that have analog in the geomagnetic spectrum are not the powerest (for instance, the power spectral peak in the solar spectrum at T=11.1 yr. is lower confidence limit in the geomagnetic one). Comparison of the reported spectrum of global temperature (SSR method) and geomagnetic one (MGM) shows that all significant spectral peaks of both spectra in the studied ranges of periods coincide (with accuracy of errors). Deterministic processes responsible for the climate and geomagnetic changes on the Earth have the same periodicities. The Earth's atmosphere and magnetic field are sensitive to the same part of deterministic band of solar activity, not the powerest in the solar activity spectrum of W.

A PARTIAL CORRELATION ANALYSIS OF STRATOSPHERIC OZONE RESPONSE TO THE SHORT-TERM SOLAR UV VARIATIONS WITH TEMPERATURE EFFECT REMOVED

Shuntai ZHOU and A J Miller (NOAA/NWS/NCEP, USA)

Although stratospheric ozone response to the 27-day solar UV variation has been detected from satellite ozone and UV data, the total response is modulated by the variations in temperature. Photochemical and radiative theory, along with previous data analysis, indicate that the temperature effect on this time-scale is essentially linear and can be separated statistically from the ozone effect. In this study we utilise the statistical estimation technique of particial correlations to separate ozone response to the 27-day solar variation. Our data set includes 2000 days of satellite UV, ozone and temperature data from the SBUV(/2) and UARS measurements and the NCEP temperature analysis . We find that for the upper stratosphere, from 1 hPa to 5 hPa, the partial correlation coefficients of ozone and UV are considerably increased over the total correlation, there is no negative time lag (ozone leads UV), and the maximum ozone-UV correlation is obtained at a higher altitude compared with the previous total correlation analysis. In addition, we examine the ozone sensitivity to UV and temperature variations using linear regression with two independent variables. T he results indicate that the upper stratospheric ozone variation can be very well represented by a linear combination of UV and temperature variations. The ozone sensitivity to UV or temperature is generally independent of time periods used for analysis, though solar UV and temperature variations may be very different for different time periods.

SOLAR AND GEOPHYSICAL DIGITAL DATA – WINDOWS ON OUR ENVIRONMENT

Helen COFFEY (Solar-Terrestrial Physics Division, NOAA National Geophysical Data Center, World Data Center A for Solar-Terrestrial Physics, 325 Broadway, Boulder, CO 80303 USA,
email: hcoffey@ngdc.noaa.gov)

The Sun is the engine that drives the Earth's weather machine. The World Data Center (WDC) A for Solar-Terrestrial Physics maintains on-line digital archives for solar and geophysical databases via the Space Physics Interactive Data Resource (SPIDR) system and via ftp anonymous access. SPIDR is now available in Russia and Australia. A partial system resides at the WDC-C1 United Kingdom (UK). NOAA is using current technology to meet user requirements for data management, analysis, and distribution. The SPIDR system is being updated with new and improved technology. The available digital data will be reviewed, along with information about new developments occurring, such as including the Solar-Geophysical Data (SGD) databases in SPIDR. Users are asked for input on desirable future products and databases.

SOLAR CYCLE VARIATIONS OF SURFACE AIR TEMPERATURE

Katya GEORGIEVA, Boyan Kirov (both at the Solar-Terrestrial Influences Laboratory at the Bulgarian Academy of Sciences, Bl.3 Acad.G.Bonchev str., 1113 Sofia, Bulgaria, email: kgeorg@bas.acad.bg, bkirov@bgcict.acad.bg)

The influence of solar activity on weather and climate is one of the most controversial problems in Solar-Terrestrial physics. The main reason is that so far there is no convincing physical mechanism explaining such an influence, and, besides, the results themselves are rather ambiguous - some authors find a good positive correlation between solar activity and a given meteorological parameter, some find an equally good negative correlation, and some find no correlation at all. However, most of these studies use data for particular locations and/or for limited time periods. In the present paper long time series are examined of the global, hemispheric and zonal surface air temperatures, as well as from individual stations. It is found that the correlation between solar activity and temperature in the 11-year solar cycle changes in consecutive secular solar cycles - positive in the 18th Century, negative in the 19th and positive again in the 20th. This result pertains to both global and hemispheric (North and South) mean temperatures, and to individual midlatitude stations. As for the zonal temperatures, a good negative correlation at all latitudes is found in the 19th C, while in the 20th C the positive correlation is seen at low and midlatitudes, and lacks at high latitudes. This may mean that there are at least two mechanisms by which sun influences the climate, one of them working only at high latitudes and leading to negative correlation between solar activity and temperature in the 11-year solar cycle, the other one global and leading to correlation changing in sign in consecutive secular solar cycles, with the lack of correlation at high latitudes in the 20th C being the result of the competitive action of the two. Therefore, the physical mechanisms by which the solar activity influence atmosphere in the 11-year solar cycle could hardly be found without understanding the nature of the secular solar cycle.

IDENTIFICATION OF SOLAR IRRADIANCE FEATURES IN NSO MAGNETOGRAMS: HISTOGRAMS VS. MORPHOLOGICAL MASKS

Harrison P. JONES (NASA/Goddard Space Flight Center, Laboratory of Astronomyand Solar Physics, Southwest Solar Station c/o NSO, PO Box 26732, Tucson, AZ 85726, US, email: hjones@noao.edu) Karen L. Harvey (Solar Physics Research Corporation, 4720 Calle Desecada, Tucson, AZ 85718 US, email: kharvey@sprc.com)

Magnetograms obtained at the National Solar Observatory/Kitt PeakVacuum Telescope (NSO/KPVT) form a useful data set to help identify and understand sources of solar irradiance variations. In this paper we compare two techniques for identifying relevant magnetic features in a subset of NSO/KPVT magnetograms obtained with the NASA/NSOspectromagnetograph, which has been in daily operation since April 1992. One method, described by Harvey and White (1996), iteratively considers various morphological characteristics of the magnetogram toform spatial masks, which select such features as active regions, sunspots, and enhanced and quiet network. The other, described by Jones (1997), uses cuts in multidimensional histograms formed from the five cotemporal and cospatial spectromagnetograph images (line-of-sight magnetic flux and velocity, continuum intensity, equivalent width, and central line depth) to partition the data statistically. We spatially compare features determined by the two techniques for selected images and also compute histograms for data subsets marked by each of the Harvey and White masks to look for distinguishing thermodynamic characteristics and as a guide for refining the histogram classifications.

JSA16/W/42-A3 Poster 0830-62

ON THE 10.4 YEAR SOLAR SIGNAL IN GLOBAL AIR TEMPERATURES: THE RELATIONSHIP TO LONG-TERM SOLAR ACTIVITY

Peter THEJLL, (Solar-Terrestrial Physics Division, Danish Meteorological Institute, Lyngbyvej 100, DK-2100 Copenhagen O, Denmark (email: thejll@dmi.dk)

The presence of a 'solar' signal in global air temperature records has been studied in depth by R.G. Currie, and others, for a considerable time. The approximately 10.4 year signal is present on most continents, shows periods of phase coherence between neighbouring stations, and phase changes at certain geographic locations and at certain times. The distribution of the signal has been linked, at least on the North American continent to mountain chains - lines of phase change lie along e.g. the Rocky mountains. A trend towards growing signal amplitude and latitude, in the USA, has been reported. In a new analysis of the high-quality data part of the Climatic Research Units temperature dataset the above properties of the signal are verified, and a new link to the geographic distribution of the signal is shown. Stations with a strong signal in the band near 10.4 years are also likely to be stations near an ocean shore or a large lake. The relevance to recent discoveries of correlations between climate factors and solar activity will be discussed, and the relationship between the strength of the periodic signal and the correlation with the long-term evolution of Solar Activity, in terms of the Solar Cycle Length, will be considered.

NIMBUS-7 SBUV SOLAR SPECTRAL UV MEASUREMENTS: 1979-1987

Richard P. CEBULA and Matthew T. DeLand

Absorption of solar ultraviolet (UV) energy pays a dominant role in the thermal structure, dynamics, and photochemistry of the Earth's middle atmosphere. The first continuous studies of solar UV irradiance were begun using satellite instruments during the late 1960s and early 1970s. These early measurements suffered from significant absolute calibration uncertainties and extensive sensor sensitivity drifts. Early estimates of solar cycle variation at wavelengths important to middle atmospheric photochemistry (e.g. 200-300 nm) hence differed by factors of 2-5.
The launch of Nimbus-7 SBUV in November 1978 represented a major step forward in our understanding of short and long-term solar variability. SBUV solar irradiance measurements covering the wavelength range 160-400 nm were made for more than 8 years, spanning the maximum and declining phases of solar cycle 21. Although SBUV did not incorporate an onboard calibration system, the frequency of solar observations was varied periodically during the mission. The resulting data form the basis of an empirical model that we use to characterize instrument changes. Our goal is to achieve a long-term accuracy approaching that which we have recently obtained for NOAA-11 SBUV/2 (approximately 1-2%, 2 sigma). We present a progress report on our instrument characterization efforts. At the current level of the analysis the SBUV data already dramatically improve the accuracy of estimated solar irradiance changes during solar cycle 21. For example, at 200 nm, pre-SBUV estimates of solar cycle variations ranged from essentially none to nearly a factor of two. The SBUV-estimated solar cycle 21 variation at 200 nm, 5-8%, is in substantial agreement with measurements of long-term solar change during solar cycle 22.

THE TOTAL SOLAR IRRADIANCE MISSION: 2) MEASUREMENT OF SOLAR SPECTRAL IRRADIANCE FROM 0.2 MM TO 2 MM

Gary ROTTMAN, Jerald Harder, and George Lawrence

The Total Solar Irradiance Mission, TSIM, is a satellite to be launched in 2001 as part of the Earth Observing System (EOS). The scientific payload will consist of two instruments, one to measure the Total Solar Irradiance (TSI) and the second to measure solar spectral irradiance in the range 200 nm to 2 mm. This paper describes the Spectral Irradiance Monitor, SIM, which is a prism spectrometer capable of covering the full spectral range 200 nm to 2 micron with a resolving power greater than 30. The opticaldesign is a variant of a prism spectrometer first described by Fery in 1910 - the prism has a concave front surface and a convex, aluminized rear surface, and is therefore self-focusing. The absolute detector is a miniature, electrical substitution radiometer (ESR) with operation similar to the TIM detector described in the accompanying paper. The SIM is double redundant and self-calibrating. We plan to achieve an absolute accuracy of 0.3% (3s), and a precision and long-term relative accuracy of 0.01% per year. Details of our present understanding and characterization of the SIM will be provided.

CONSTRAINTS ON ELECTRICAL CONDUCTIVITY IN D"

Stephen GOOZOVAT and S.R. Dickman (Department of Geological Sciences and Environmental Studies, State University of New York at Binghamton, P.O. Box 6000, Binghamton NY 13902-6000 USA, email: dickman@bingvmb.cc.binghamton.edu)

Earth rotation studies in the past two decades have generally assumed zero axial coupling between the core and the mantle on time scales of less than a year. A recent study (Dickman & Nam 1995) comparing observed and predicted tidal changes in the length of day concluded that axial core-mantle torques are not likely to exceed 3x1018 Nm on a nine-day time scale.
We are attempting to use this upper bound to constrain the electrical conductivity of the lower mantle. At these time scales, we expect our constraints to apply to the lowermost few tens of kilometers of D".
In our approach we derive the field, H9, induced at the core-mantle boundary by the main field as the tidally deformed mantle periodically accelerates. On such time scales the diffusion of the induced field can be neglected. The axial torques produced by the interactions of H9 with the main field are then calculated for various epochs, for a variety of lowermost mantle conductivities. Our analysis will allow us to draw conclusions about the range of conductivities consistent with rotational observations.

JSA17/C/GA1.19/W/09-A3 **1420**

ABOUT THE ELECTRICAL CONDUCTIVITY OF THE LOWER MANTLE

Mioara Mandea ALEXANDRESCU (Institut de Physique du Globe de Paris, 4 Place Jussieu, 75252 Paris Cedex 05, France, email: mioara@ipgp.jussieu.fr); Dominique Gibert (Géosciences Rennes - CNRS/INSU, Université de Rennes 1, Bât. 15 Campus de Beaulieu, 35042 Rennes cedex, France, email: gibert@univ-rennes1.fr); Jean-Louis Le Mouël (Institut de Physique du Globe de Paris, 4 Place Jussieu, 75252 Paris Cedex 05, France, email: lemouel@ipgp.jussieu.fr); Gauthier Hulot (Institut de Physique du Globe de Paris, 4 Place Jussieu, 75252 Paris Cedex 05, France,
email: ghulot@ipgp.jussieu.fr); Ginette Saracco (Géosciences Rennes - CNRS/INSU, Université de Rennes 1, Bât. 15 Campus de Beaulieu, 35042 Rennes cedex, France, email: saracco@univ-rennes1.fr)

It has recently been proposed that geomagnetic jerks observed at the Earth's surface could be viewed as singularities in the time behaviour of the geomagnetic field with a regularity of about 1.5 when wavelet-analysed. In the present paper we note that such a signal should have suffered some distortion when diffusing from the core-mantle boundary (CMB) through the conducting mantle. Assuming that the upper mantle is an insulator, and given the electromagnetic time constant of the mantle, we compute the distortion that a pure singularity introduced at the CMB suffers as it traverses the mantle. We compute this distortion through its effects on the so-called ridge functions extracted from the wavelet transform of the signal. This distortion is very similar to the small but significant one that we observe in real data. We therefore speculate that jerks must have been pure singularities at the base of the mantle and infer an average estimate for the mantle electromagnetic time constant from the way the signal is distorted by fitting the synthetic ridge functions to the experimental ones. Assuming, for example, a thickness of 2000 km for a uniform lower conducting mantle, we find an electrical conductivity smaller than 10 S/m. This value is in reasonable agreement with values derived from high pressure experiments for a silicate mantle.

GEOMAGNETIC SECULAR VARIATION IN THE ANTARCTIC REGION AND THE 1969.5 PULSE

GIANIBELLI, Julio C. (Dep. of Geomagnetism and Aeronomny, Faculty of Astronomical and Geophysical Sciences, La Plata University, Paseo del Bosque s/n, 1900 La Plata, Argentina,
email: jcg@fcaglp.fcaglp.unlp.edu.ar)

The distribution of the South Hemisphere magnetic observatories in the antarctic and subantarctic region is heterogeneous. The trend in the vertical component of the magnetic field is positive, with the exception of two observatories, opposed longitudinally (Las Acacias-LAS and Canberra-CAN). The isoporic charts, previous and posterior to the field pulse about 1969.5, are showed. There are two isoporic foci in front to the Sanae Observatory, between 60º and 70º latitude and 0º and 330º longitude. The Walker and O Dea techniques to determine the magnetic field pulses are analysed.

THE RAPID DIFFUSION OF POLOIDAL MAGNETIC FIELD IN 3-D INHOMOGEOUS MANTLE WITH GRADUALLY LATERAL VARIATION

Ma Shi-ZHUANG (Institute of Geophysics, Chinese Academy of Sciences,Beijing 100101, China, email: szma@c-geos.ac.cn)

In order to understand the magnetic filed at core-mantle boundary, we have to continue down the observatory data of geomagnetic field through conducting region of lower mantle. Had considered the limitation on variable scale from study of the Earth's deep interior, the author built a pertubation theory of electromagnetic field in 3-D inhomogeous mantle with gradually lateral variation. It is unnecessary that the 1-D spherical symmetric distribution of the zero-degree approximation. As a direct application of the zero-degree approximation, it is presented how the gradually lateral variation of electric conductivity effect on anti-diffusion of poloidal magnetic field come from the outer core of the Earth.

PALEOMAGNETIC FIELD IN THE NEOGEA (ª1700 MA) AND THE RELATIONSHIP BETWEEN PROCESSES NEAR THE EARTH'S CORE AND SURFACE

D.M.PECHERSKY (United Institute of Physics of the Earth, Ac. Sci., Russia)

The data on changes in geomagnetic field reversals, intensity and direction, organisms, and velocities of continental plate movements during the last ª1700 m.y. are collected and analyzed. The following regularities were revealed: 1) long-term intervals of the steady field state with very rare reversals, spaced by 160-200 m.y. (a fractal dimension of about 0.9-1.0); 2) nearly chaotic field state, characterized by frequent reversals (a fractal dimension of 0.5-0.6); 3) in the first regime, the latitude dependence of variations in both intensity and direction are typical of dipole field, whereas in the second regime this dependence is different; 4) generally, the geomagnetic field exhibits no periodicity in its intensity, direction, and reversals throughout the Neogea: (a) in 95% cases, the "periods" consisted of only one or two oscillations, (b) oscillations of all geomagnetic elements with similar periods are commonly asynchronous, and (c) the "periods" often decrease or increase smoothly in time. The comparison of geomagnetic field pattern, on the one hand, and changes in the organic world and continental plate velocities, on the other hand, shows that either processes near the Earth's core and surface are synchronous (ª0±10 my) or processes of the second group lag behind those of the first group (by 40±20 my). The first case implies the presence of an "external" mechanism with a characteristic time comparable with geological periods, the changes of the second group are due to an "internal" mechanism" with a characteristic time comparable with geological eras. The value of this lag corresponds to a velocity of 4-10 cm/yr (this is the velocity of energy transfer from the mantle bottom to the Earth's surface). This value is in accordance with mean velocities of continental plate movements. However, there is no causal relation between the aforementioned processes. In Neogea, two time intervals are revealed that are characterized by specific behavior of all characteristics analyzed: (1) Phanerozoic-Riphean boundary interval and (2) Middle Riphean.

JSA17/W/06-A3 **1600**

DOES THE GEOMAGNETIC SECULAR VARIATION ANTICIPATE OR CORRELATE WITH DECADE LENGTH OF DAY VARIATIONS?

Alexandra PAIS, Gauthier Hulot and Mioara Mandea Alexandrescu (Institut de Physique du Globe de Paris, 4 place Jussieu, 75252 Paris Cedex 05, France, email: pais@ipgp.jussieu.fr)

In recent years, it has been pointed out that a secular variation indicator such as the secular variation of the declination in Europe, could be used to predict future changes in the length of day on decade time scales, because it essentially anticipates these changes by some 10 years (e.g. Le Mouel et al., 1992). In parallel, numerous studies have also shown that the secular variation could be used to compute core surface flows and to consequently predict, with no significant time delay, the instantaneous changes in the length of day (Jault et al., 1988, Jackson et al., 1993, Pais and Hulot, 1999). The present paper has two main purposes. One is to confirm the validity of both analyses, which is done by relying on a uniform set of annual means of geomagnetic field components for the period 1964--1996. The other one is to propose a simple explanation for the fact that the same magnetic data can be used to produce indicators that in one case anticipate and in the other correlate with no significant time offset the series of observed LOD decade variations. It will be argued that the reason for this is that the local value of the SV (hence of the SV of D) is mainly sensitive to the dominant non zonal core flows, which are responsible for the axial pressure torques acting on the mantle, while LOD instantaneous predictions (derived from core flows computations) are based on the weaker (but resolvable) zonal flows which reflect the dynamical, hence delayed, reaction of both the core and the mantle.

A NEW TOMOGRAPHIC MODEL OF D'' SHEAR VELOCITY AND ITS IMPLICATIONS

B. Y. KUO (Inst Earth Sciences, Academia Sinica, Taipei, Taiwan, ROC,
email: byk@earth.sinica.edu.tw); E. J. Garnero (Berkely Seismological Lab., University of California, Berkeley, CA 94720-4750, USA, email: eddie@seismo.berkeley.edu); T. Lay (Inst Tectonics, University of California, Santa Cruz, CA 95064, USA, email: thorne@es.UCSC.EDU)

More than 1500 S-SKS times, tailored to reduce uneven sampling, yield a global image of D'' shear velocity variations that is robust up to degree 12. SKS-S times at distances beyond 95 degrees primarily sample the D'' region, with suppressed contributions from uncertainties in source location, origin time and upper mantle structures. We parameterise D'' shear velocity perturbation with (1) spherical harmonic functions and (2) equal-area blocks, and show that they yield practically indistinguishable results. Synthetic simulations demonstrate that a high degree (L) inversion followed by a low degree (L1) synthesis effectively filters out components most biased by the expansion truncation, and that the global maximum resolution supported by the geometry and quality of the present data set is not much higher than degree 12. Degree 12 models are constructed by performing inversions with L>>12, regularised so that when synthesised to L1=12 the rms magnitude is 1%. In our preferred model (L=40, L1=12), most surface hotspots and almost all of the "roots" of the hotspots in the lower mantle as predicted by global flow modelling are located in low velocity regions. Three strongly negative patches (<-2%) punctuating the Atlantic-Indian low velocity zone seem to be affiliated geographically to three separate groups of hotspot roots, and the Pacific corridor hosts dozens of S. Pacific plumes. Although there is no intrinsic difference in resolvability, parameterisation (1) is a better representation for long wavelength signals but (2) is more flexible for imaging small scale structure. To exploit regional high resolution and recover fine structure where the data permit, we remove the degree 12 aspherical reference model from the data and invert the residuals using 10 degree blocks. The hybrid model preserves robust power at low degrees on a global scale and at high degrees for regions where constraints are better than the global average.

JSA17/E/05-A3 1640

AMPLITUDE OF CORE MANTLE BOUNDARY TOPOGRAPHY INFERRED FROM A STOCHASTIC ANALYSIS OF CORE PHASES

Raphael Garcia (Observatoire Midi-Pyrenees and ENS Lyon, email: garcia@pontos.cst.cnes.fr); Annie SOURIAU (CNRS, Observatoire Midi-Pyrenees Toulouse, email: Annie.Souriau@cnes.fr)

In order to constrain the topography of the core-mantle boundary (CMB), which is an important parameter for Earth dynamics, we performed a stochastic analysis of the different core phases (PcP, PKP and PKKP), which sample the CMB as transmitted and/or reflected waves. Of particular interest is the underside reflected phase PKKP, which help discriminate between CMB topography and D" structure, and which has in addition a great sensitivity to the CMB topography at the underside reflected point. The analysis is performed on the travel time residuals of relocated events provided by Engdahl et al. (1998), with an additional set of 260 PKKP data of various origins. The estimated CMB topography variance has a significant signal in the 2-10 degree wavelength range we investigated, with root mean square of 2.2 +/- 0.2 km for wavelengths larger than 2 degrees. Despite a poor Earth sampling, interesting correlation are observed with mantle structure. In particular, mantle velocity heterogeneities and CMB topography variations are correlated, as expected from most geodynamical mantle models. Moreover, CMB topographic lows of 1-2 km are observed in regions 250-500 km wide below hotspots. A tentative inversion of CMB topography has been performed in the best sampled areas, i.e. those which are sampled by both underside reflected rays and transmitted rays.

JSA17/W/03-A3 1700

ON THE SHORT SCALE TOPOGRAPHY OF THE CORE-MANTLE BOUNDARY

Clement NARTEAU, Jean-Louis Le Mouel, Jean-Paul Poirier, Mikael Shirman (Institut de Physique du Globe de Paris 4 Place Jussieu, 75252 Paris cedex 05 France, email: narteau, lemouel, poirier, email: shnirman@ipgp.jussieu.fr)

We used a two-dimensional cellular automata method to study the short-scale roughness of the CMB. We consider the dissolution of the silicate rock of the lower mantle into the liquid iron of the core infiltrated along grain boundaries. We assume that a cubic centimetre of solid rock is dissolved in average in a time Td, and we consider also the reverse process of crystallisation (with a time constant Tc). We thus obtain a quasi steady-state depth for the CMB.We model three states in the cellular automata, according to the concentration of mantle material: solid (mantle), liquid, and saturated liquid. The evolution of the roughness of the interface is controlled both by diffusion of the dissolved elements and by their concentration in the upper outer core. We study the characteristic values of Td and Tc in function of the intensity of the mixing process (buoyancy, force, diffusion) and the relationship between these time constants and the roughness of the CMB.

CORE MOTIONS AND GEOMAGNETIC IMPULSES

Mioara Mandea ALEXANDRESCU (1), Minh Le Huy (2), Alexandra Pais(1), Jean-Louis Le Mouël(1) and Gauthier Hulot(1) (1) (Institut de Physique du Globe de Paris, 4 Place Jussieu, 75252 Paris cedex 5, France, email: mioara, pais, lemouel, gh@ipgp.jussieu.fr); (2) (Hanoï Insitute of Geophysics - NCST, Nghia da - Tu Liem - Hanoï, Vietnam, email: lhminh@ipg.ncst.ac.vn)

The knowledge of geomagnetic field and its secular variation allow to compute the flow at the core surface. The poloidal and toroidal components of the fluid flow at the core-mantle boundary (CMB) at 50-year intervals have been calculated from different models over the last three centuries. The average motion on 300 years appears to be for the main fact symmetrical with respect to the equator. To time constant of degree 1 component of the motion is much larger than the time constant of the rest of the flow. We have also computed the acceleration field corresponding to the well-documented jerks of 1969, 1978, 1991. The geometry of these acceleration fields is the same, within a change of sign, for the three events. Moreover, this geometry has close connection with the geometry of the flow. In fact, the flow displays a kind of oscillation - non-sinusoidal - whose apexes are located at the jerk times. The corresponding mechanism and the effect of length of day oscillations are discussed.

JSA17/W/13-A4 0950

FLUCTUATIONS OF THE PALAEOMAGNETIC FIELD: MANIFESTATIONS OF TIDALLY FORCED ELLIPTICAL INSTABILITY OF THE EARTH'S FLUID OUTER CORE?

Behnam Seyed-Mahmoud, Keith ALDRIDGE and Gary Henderson (Dept. of Earth and Atmospheric Science, York University, Toronto, Canada; email: behnam@yorku.ca, keith@science.yorku.ca, gary@unicaat.yorku.ca)

The observed fluctuations in the intensity and inclination of the palaeomagnetic field over several thousand years (Laj and Kissel, 1999) may be due to a fluid instability excited in the Earth's outer core by the elliptical deformation produced in the mantle by the semi-diurnal tide. Our understanding of the elliptical instability derives not only from laboratory observations, but also from computations to predict the growth rate and velocity field at its onset. We have excited an elliptical instability in a rotating fluid shell through an elliptical distortion of its flexible inner boundary. Observations of the instability, and of the transition to turbulence that follows its onset, have been made using digital particle imaging velocimetry (DPIV). While the boundary distortion is applied continuously, two-dimensional Fourier transforms over a small region of the fluid show that the instability cycles through growth and decay. Laboratory observations show that, for a fluid shell with the same proportions as the Earth's outer core, the maximum growth rate of the fundamental instability occurs when the boundary distortion has a slight prograde rotation, close to that of the moon's orbit around the Earth.

JSA17/C/GA1.19/W/11-A4 1010

SECONDARY FLOW INDUCED IN A FLUID CAVITY BY THE PRECESSION OF THE SPHERICAL CONTAINER

Jérome NOIR, Dominique Jault , Philippe Cardin (LGIT Grenoble, France)

They are already a few experiments on the flow in a rapidly rotating and processing spheroidal cavity (Malkus 1968, Vanyo et al 1995). The primary response was a solid body rotation. Superimposed on this main flow is a set of cylinders with alternatively positive and negative vorticity, aligned with the mean bulk rotation vector. We have endeavoured to understand better this geostrophic response. We began our study by the spherical case.
Using the analytical determination of the solid body rotation by Busse in 1968, we investigate numerically the viscous flow. For small rate of precession, the secondary flow is dominated by inertial-waves spawned by the boundary layer. Increasing and decreasing the viscosity we find critical values for which a geostrophic flow, similar to the cylinders observed experimentally, dominates the viscous response. We still discuss how results translate to the finite ellipticity case.

JSA17/W/01-A4 1030

RESONANCES BETWEEN THE FREE-CORE-NUTATION AND THE SOLAR TIDAL WAVES IN THE GEOLOGICAL PAST

GREFF-LEFFTZ Marianne (I.P.G.P., 4 place Jussieu, 75252 Paris Cedex 05, France); Legros Hilaire (E.O.S.T., 5 rue R. Descartes, 67084 Strasbourg Cedexe, France)

We demonstrate how the knowledge of the temporal evolution of the terrestrial crust, the secular deceleration of the axial rotation of the Earth and the rotational eigen-mode of the core, may be inter-related, and how they can provide some information about the geodynamical history of the Earth. From the theory of the Earth's rotation for a simplified three elliptical layered Earth (mantle, fluid outer-core and solid inner-core), we compute the nearly-diurnal rotational eigenmode lambda of the core. This mode can be excited by the solar tidal forces and its period varies weakly with time depending on the axial component of the rotation vector, and on the evolution of the size of the inner core. For models of secular deceleration of the Earth and of temporal evolution of the inner-core radius, we compute the dates of exact resonance in the geological past, between the nearly-diurnal luni-solar tidal waves and lambda and we investigate, at these dates, the amplitude of the oscillations of the core and the dissipative frictional power at the fluid core's surface (Core-Mantle Boundary and Inner-Core Boundary). Finally, we discuss the influence of such a heat flux from the core at the CMB on the thermal D" layer, i.e., on the generation of deep mantle plumes, and on the dynamo processes within the fluid core, and we propose some correlation with surface observations.

JSA17/C/GA1.19/W/07-A4 1050

GLOBAL MAGNETIC ANOMALIES AND FOCUSES OF A GEOMAGNETIC SECULAR VARIATIONS IN THE TERMS OF ROSSBY HYDRODYNAMICAL VORTICES

Vladimir V. KUZNETSOV (Institute of Geophysics SB RAS, Koptyug av., 3, Novosibirsk 630090, Russia, e-mail: kuz@uiggm.nsc.ru)

A model is offered in which global magnetic anomalies (GMA) and focuses of geomagnetic secular variation (FSV) are considered as sources that are qiasi-independent from the source of main dipole magnetic field of the Earth. The GMA arise and exist as shallow-water Rossby hydrodynamical vortices in well-conducting medium of F-layer penetrated with outer magnetic field. It is possible if the thickness of F-layer is much less than the vortices sizes. The Canadian, Siberian and Antarctic GMA are anti-cyclonic vortices, and, on the contrary, the Brazilian GMA is cyclonic vortex. These vortices do not drift staying put not less than 12 Ma. But the FSV vortices drift along the equator westwards deflecting to the poles and then disrupt. Some hydrodynamic parameters of the F-layer substance are obtained from the drift velocities of FSV. The viscosity of F- layer substance is estimated as 107 Pa. The vortices of GMA are similar to Rossby vortices inside the atmospheres of large planets where the cyclone-anticyclone asymmetry is observed as well as in geomagnetic field.

JSA17/C/GA1.19/W/10-A4 1130

EFFECT OF THE STRATIFIED OCEAN OF THE CORE UPON THE CHANDLER WOBBLE

Stanislav I. BRAGINSKY (Institute of Geophysics and Planetary Physics, UCLA, Los Angeles, CA 90095, USA, email: sbragins@igpp.ucla.edu)

It is supposed that a stable stratified layer exists at the top of the fluid core; we call it the Stratified Ocean of the Core (SOC). The assumed model of the SOC has a sharp density drop on the boundary with the bulk of the core, and a homogeneous internal density gradient. The influence of the SOC upon the Chandler wobble is considered. It is shown that the action of Archimedean forces in the SOC creates inside this layer an additional fluid velocity of order of (C/2f)v. Here C is a relative density deficit in the SOC, v is velocity associated with the Chandler wobble without the SOC, and f 1/400 is a frequency of Chandler wobble measured in cycles per day. The effect of the SOC on the Chandler wobble is small: it increases the period of the Chandler wobble by 1 day, and its contribution to the dissipation of the wobble energy is about four orders of magnitude smaller than the observed dissipation.
A change of seismic velocity in the SOC due to a greater concentration of the light admixture is discussed. A comparison of conditions in the SOC with the conditions at the inner core boundary shows that an extra amount of the light fluid in the layer increases the seismic velocity; therefore, the SOC is a higher-velocity layer.

JSA17/C/GA1.19/W/02-A4 1150

DIFFERENTIAL COOLING OF A HIDDEN ATMOSPHERE OF THE CORE

John LISTER (Institute of Theoretical Geophysics, DAMTP, University of Cambridge, Silver St, Cambridge CB3 9EW, UK, email: lister@esc.cam.ac.uk)

Stratification of the fluid outer core below the CMB can be produced by a stabilising buoyancy flux across the CMB if either the heat extracted by mantle convection is less than that conducted up the core adiabat or if there is compositional transfer of a light component from the mantle to the core. The heat flux across the CMB is not spatially uniform, since the mantle cools parts of the core more strongly than others. Differential cooling of any stratified core layer would drive thermal winds analogous to the forcing of strong zonal winds in the Earth's atmosphere by the equator-to-pole variation in solar heating. Transport of heat can be achieved only by ageostrophic corrections to a leading-order geostrophic balance. While a geostrophic balance would predict flows which are orders of magnitude stronger than those observed by GSV, the magnetic braking inherent in a magnetostrophic balance reduces the predicted flows to the magnitudes observed and confines them to a shallow region at the top of the stratification. The existence of a stratified layer is thus consistent with the magnitude of GSV, but the frozen-flux assumption may have to be relaxed. If part of the CMB is cooled subadiabatically and part superadiabatically then any stratified region under the subadiabatic patch drains laterally into the adjacent deep superadiabatic convection. By this mechanism, any "Hidden Atmosphere" would drain to a depth of only a few kilometres and would not be significant.

JSA17/W/04-A4 1210

THERMAL CORE-MANTLE INTERACTIONS AND THE GEODYNAMO

Jeremy BLOXHAM (Department of Earth & Planetary Sciences, Harvard University, Cambridge, MA 02138, USA. Email: Jeremy_Bloxham@harvard.edu)

Models of the magnetic field at the core-mantle boundary derived from recent and historical

observations reveal certain features in the field that are persistent over the 300 year time interval spanned by the observations. Bloxham & Gubbins (Nature, 1987) proposed that these features may be due to thermal core-mantle interactions: large lateral variations in temperature in the lower mantle (that are inferred from seismic tomography and from models of mantle convection) result in lateral variations in heat flux at the core-mantle boundary which affect the pattern of flow in the core. Indeed, they found some correspondence between the pattern of these features in the magnetic field and seismic tomography.
Here we examine this proposal by imposing lateral variations in heat flux at the core surface in a numerical model of the geodynamo. In the simplest case, imposing variations given by just the Y(2,2) harmonic (with the phase as determined by seismic tomography), we find concentrations of flux at high latitude, symmetrically arranged in each hemisphere at longitudes corresponding to North America and to Siberia, similar to the pattern observed in the historical field models. Adding other harmonics yields other features identified in the field, including the central Pacific flux concentration.

JSA17/E/02-A4 1230

GRAVITATIONAL LOCKING OF THE INNER CORE AND THE GEODYNAMO

Bruce BUFFETT (Department of Earth and Ocean Sciences, University of British Columbia, Vancouver, BC, V6T 1Z4, Canada, email: buffett@eos.ubc.ca); Gary Glatzmaier (Department of Earth Sciences, UC Santa Cruz, Santa Cruz, CA 95064, email: glatz@emerald.ucsc.edu)

Mass anomalies in the Earth's mantle distort the equilibrium shape of the inner core, producing topography on the inner-core boundary of roughly 100m (peak-to-peak). Gravitational forces on the aspherical inner core are strong enough to lock the rotation of the inner core to that of the mantle. However, relative rotation of the inner core is still permitted if the boundary topography adjusts during rotation to remain nearly fixed with respect to the mantle. Predictions of inner-core rotation from numerical simulations of the geodynamo have previously assumed that the inner core rotates freely in response to electromagnetic torque. In this study we present numerical simulations in which the influences of gravitational forces on the inner core are included. Allowances are also made for viscous relaxation of the inner-core shape. We use these calculations to explore several intriguing possibilities. First, a steady rotation of the inner core relative to the mantle requires persistent electromagnetic stresses on the inner core to overcome the gravitational restoring force. Lines of magnetic force that cross the inner-core boundary is stretched around the inner core, amplifying the azimuthal component of the field. Further amplification arises through the release of compositional buoyancy at the inner-core boundary, which lifts and twists the azimuthal field. The combination of these two effects is liable to produce strong dynamo action at the base of the fluid core. Second, we examine the influence of gravitational locking of the inner core on the dynamics of the overlying fluid motions. Conventional assumptions about the force balance in the outer core suggest that the geodynamo operates in a regime known as the Taylor state, but such a state may not be applicable to the entire outer core when the inner core is gravitational locked to the mantle. We quantify these effects and make new predictions for the rotation rate of the inner core. We also look for evidence of gravitational oscillations about a steady rotation of the inner core, which would be manifest as changes in the length of day.

CHANGES IN THE NORTHERLY LIMIT OF ANTARCTIC SEA ICE SINCE THE 1930S

Peter WADHAMS (Scott Polar Research Institute, University of Cambridge, Lensfield Road, Cambridge CB2 1ER, UK. email: pw11@cam.ac.uk).

A paper by de la Mare (Nature, 389, 57-59, 1997) utilises positional information from whaling ships to hypothesise that the latitude of the Antarctic ice edge retreated southward significantly during the 1960s, by nearly 3 degrees. In the current investigation, other sources of information about the Antarctic ice edge location have been examined, including the work of ships of the Discovery Committee. It has been found that although a southward shift did occur, it was not as great, or as sharply defined, as postulated in the paper. A possible reason for the discrepancy is changing patterns of whaling strategy during the 1960s based on a change in species composition of the prey. The implications of a southward ice edge shift for water mass modification are also discussed.

JSM18/W/05-A4 1020

INFLUENCE OF THE VARIATION OF POLAR SEA-ICE EXTENT ON THE ATMOSPHERIC CIRCULATION, EL-NINO AND HYDROCLIMATIC REGIME OF THE YANGTZE RIVER BASIN

Gongbing Peng (Institute of Geography, Chinese Academy of Sciences, Beijing100101, P.R.China, email: zhangsh@lreis.ac.cn)

Monthly anomalous data of Antarctic sea-ice extent from Jan., 1973 to Sept., 1997 and of Arctic sea-ice extent from Aug., 1901 to Aug., 1995 are used. They are then compared with corresponding data of the atmospheric circulation, El-nino and runoff of Yichang, Hankou and Datong, which represent hydroclimetic condition of upper, middle and lower Yangtze River basin respectively. The influences of the sea-ice extent on them have been revealed by means of cross correlation calculation and synoptic-climatic analysis. Special attention has been paid to the connections of South and North Pacific subtropic highs, sea-surface temperature and trade wind of equatorial East Pacific, El-Nino, Walker and Hadley cells with Antarctic sea- ice and to that of north polar vorter, meridianal circulation of Asia, North Pacific subtropic high and El-nino with Arctic sea-ice.
The results show that the influences are significant. Several Synoptic climatic models have been established, dealing with the influence processes. It will be useful to hydroclimatic prediction.

JSM18/W/14-A4 1040

CORRELATIONS BETWEEN CHINA MONSOON PRECIPITATION AND OBSERVED ANTARCTIC SEA ICE

Lin ZHANG (Department of Polar Research and Ocean Forecasts, National Research Center for Marine Environment Forecasts, 8 D Hui Si, Hai Dian District, Beijing, China,
e-mail: linzh@polarmet1.mps.ohio-state.edu), David H. Bromwich and Keith M. Hines (both at Byrd Polar Research Center, The Ohio State University, Columbus, OH 43210, USA,
e-mail: bromwich@polarmet1.mps.ohio-state.edu)

A previous observational study found a statistically-significant correlation between East Asian monsoon parameters and 10 years of observed Antarctic sea ice. This fascinating link is re-examined with the much longer record of Antarctic sea ice now available. The SIGRID sea ice data from 1973-1986, SSMR sea ice data from 1979-1987 and SSM/I sea ice data from 1988-1997 are correlated to precipitation records available from 364 stations over China. The sea ice data are also correlated to parameters of the monsoon pressure distribution as suggested by the earlier observational study. While the earlier study used sea ice with distinctive trends in the 10-year record, the present study has a sufficient sea ice record to reasonably capture interannual variations on the order of a decade or less. This new study compliments earlier global climate modeling studies with the NCAR CCM2 as well as future modeling studies to be performed with the NCAR CCM3.

JSM18/W/17-A4 1120

THIS STUDY EVALUATES THE RELATIONSHIP BETWEEN ANTARCTIC SEA ICE AND GLOBAL CLIMATE VARIABILITY

Xiaojun YUAN, Lamont-Doherty Earth Observatory of Columbia University,
email: xyuan@Ideo.columbia.edu

This study evaluates the relationship between Antarctic Sea Ice and global climate variability. Temporal cross-correlations between Antarctic sea ice edge (SIE) anomaly and various climate indices are calculated. For the sea surface temperature (SST) in the eastern equatorial Pacific and tropical Indian Ocean, Southern Oscillation index, as well as the tropical Pacific precipitation, a coherent propagating pattern is clearly evident in all correlations with the detrended SIE anomalies (SIE*). Correlations with ENSO indices imply that up to 30% of the variance in SIE* is linearly related to ENSO. The SIE* has even higher correlations with the SST in the tropical Indian Ocean. In addition, correlation of SIE* with global surface temperature produces two characteristic correlation patterns: (1) an ENSO-like pattern in the tropics with stronger correlations in the Indian Ocean, and the Pacific and North American teleconnection (PNA) pattern in extra-tropics with stronger correlations in North America; and (2) a dipole like pattern in the tropical Atlantic with stronger correlations south of the equator. The SIE* anomalies in the western Indian Ocean, eastern Pacific and Weddell Sea of the Antarctic polar ocean sectors show the strongest polar links to extropolar climate. Linear correlations between SIE* in those regions and global climate parameters pass a local significance test at the 95% confidence level. The field significance is evaluated using colored noise that is more appropriate than white noise and shuffled noise. The fraction of the globe displaying locally significant correlations (at the 95% confidence level) between SIE* and global temperature is significantly larger, at the 99.99% confidence level, than the fraction expected given colored noise in place of the SIE*. Even so, one would still expect, by chance, to find a large number of significant correlations in any one individual correlation map.

ECMWF ANALYSES AND REANALYSES DEPICTION OF ENSO SIGNAL IN ANTARCTIC PRECIPITATION

David H. BROMWICH and Aric N. Rogers (both at Byrd Polar Research Center, The Ohio State University, Columbus, Ohio 43210, email: bromwich@polarmet1.mps.ohio-state.edu); Per Kållberg (European Centre for Medium-Range Weather Forecasts, Shinfield Park, Reading, U.K., email: per.kallberg@ecmwf.int); Richard I. Cullather (Department of Aerospace Engineering Sciences, University of Colorado, Boulder, Colorado 80309, email: Richard.Cullather@colorado.edu); James C. White (Institute of Arctic and Alpine Research, University of Colorado, Boulder, Colorado 80303, email: jwhite@spot.colorado.edu); Karl J. Kreutz (Climate Change Research Center, Institute for the Study of Earth, Oceans and Space, University of New Hampshire, Durham, New Hampshire. Now at Department of Marine Chemistry and Geochemistry, Woods Hole Oceanographic Institution, MS #25, Woods Hole, Massachusetts 02543, email: kkreutz@whoi.edu)

The El Niño-Southern Oscillation (ENSO) signal in Antarctic precipitation is evaluated using European Centre for Medium-Range Weather Forecasts (ECMWF) operational analyses and ECMWF 15-year (1979-1993) reanalyses. Operational and reanalysis data sets indicate that the ENSO teleconnection with Antarctic precipitation is manifested through a positive correlation between the Southern Oscillation Index and West Antarctic sector (120° W to 180°, 75° S to 90° S) precipitation from the early 1980s to 1990, and a negative correlation after 1990. However, a comparison between the operational analyses and reanalyses shows significant differences in net precipitation (P-E) due to contrasts in the mean component of moisture flux convergence into the West Antarctic sector. An analysis of mean fields related to moisture convergence shows that there are significant differences in the average wind fields between the operational analyses and the reanalyses for the most reliable period of overlap (1985-1993).
Further, it is found that variations in net precipitation in this region are determined more by the structure of the flow pattern than by moisture content. Some of the differences in flow pattern are attributed to an error in the reanalysis assimilation of Vostok Station data that suppresses the geopotential heights over East Antarctica. Reanalysis geopotential heights are also suppressed over the Southern Ocean, where there is a known cold bias below 300 hPa. Deficiencies in ECMWF reanalyses result in a weaker ENSO signal in Antarctic precipitation and cause them to miss the significant upward trend in precipitation found in recent operational analyses. Ice core analyses reflect both the upward trend and ENSO teleconnection correlation pattern seen in net precipitation obtained from operational analyses. This study confirms the results of a previous study using ECMWF operational analyses that was the first to find a strong correlation pattern between the moisture budget over the West Antarctic sector and the Southern Oscillation Index.

JSM18/P/01-A4 1200

A SEARCH FOR ENSO TELECONNECTION SIGNALS IN THE ANTARCTIC PENINSULA REGIONAL ATMOSPHERIC CIRCULATION AND CLIMATE IN THE AUSTRAL WINTER 1973-93

Steve Harangozo (British Antarctic Survey, Madingley Rd, Cambridge CB3 0ET, UK)

There is an increasing amount of evidence to implicate ENSO in modulating the surface climate in some parts of Antarctica on interannual time scales. The overall importance of ENSO in modulating interannual atmospheric circulation and climate variability is, however, far from clear at present. The way in which the ENSO signal becomes manifest in the Antarctic surface climate record remains an open question. This paper will present preliminary results of a study to detect ENSO signals in the atmospheric circulation and climate in the Antarctic Peninsula region of West Antarctica. The austral winter period (June-August) when interannual circulation variability is greatest is chosen for study. The study makes use of tropical SST data along with numerical analysed atmospheric circulation data.

Some of the key findings of this study to date are that: a) considerable variability exists in the winter extratropical atmospheric circulation between different ENSO warm events in the South Pacific/West Antarctica sector, b) the tropical climate/SST state in the central-western Pacific on seasonal time scales differs considerably between one ENSO warm event to the next and c) there is an apparent strongly linear association between seasonal climate/SST behaviour in the tropical Pacific and the South Pacific extratropical atmospheric circulation. These findings will be presented and their relevance for understanding interannual climate variability in the Antarctic Peninsula will be discussed.

JSM18/E/01-A4 1220

INTERANNUAL PERIODICITIES IN ANTARCTICA, WITH COMPARISON TO THE SOUTHERN OSCILLATION

Greig THOMPSON (350 Salen Heights Avenue South, Salem, Oregon, 97302 USA, email: gthomp@cyberis.net) and Charles STEARNS (Space Science and Engineering Center, University of Wisconsin, 1225 West Dayton Street, Madison, Wisconsin 53706, USA)

Climatic data sets from 11 manned Antarctic stations covering the period from 1957 to 1991 were analyzed for interannual variablility and possible relationship to the El Nino - Southern Oscillation (ENSO). Time series were constructed by removing the long term individual monthly means, centering and then normalizing by the standard deviation. This was done for surface temperature, pressure, potential temperature, coastal stations temperature average, coastal station pressure average, and the potential temperature difference between Scott Base and Amundsen-Scott station at the South Pole. Single Spectrum Analysis (SSA) uses data adaptive filters to discern quasi-periodic oscillations from noise in a time series. The data adaptive filters used were described by a set of mutually orthogonal vectors determined from the constructed time series under study. These base vectors were not necessarily sinusoidal and could therefore discern nonlinear aperiodic oscillations. The Maximum Entropy Method (MEM) of spectral analysis was used to resolve dominant quasi-periodic oscillations in the constructed time series. The MEM of estimating the spectral density fits an autoregression (AR) model to a series so as to maximize a lack of information (entropy) of the patterns in the time siries. SSA indicated that for any one of the station time series at least 4.6% and at most 18% of the total variance was described by anharmonic components with a period between 18 and 59 months. Spectral analysis using MEM resolved dominant quasi-periodic oscillations of 27 and 55 month periods in the SSA-filtered Southern Oscillation Index (SOI), confirming earlier investigations. Temporal changes in the amplitudes of these oscillations coincide with ENSO events. The differenced potentia-temperature time series between the South Pole and coastal stations showed interannual oscillations with periods on the order of the ENSO events.

SLOW OCEANIC TELECONNECTIONS LINKING THE ANTARCTIC CIRCUMPOLAR WAVE WITH TROPICAL ENSO

Ray G. PETERSON, Warren B.White (Scripps Institution of Oceanography University of California, San Diego La Jolla, California 92093-0230 USA email: rpeterson@ucsd.edu; E-mail: wbwhite@ucsd.edu)

A case study for the period 1982-1994 shows that a major source for the Antarctic Circumpolar Wave (ACW) is in the western subtropical South Pacific Ocean, where interannual anomalies in sea surface temperature (SST) and precipitable water (PrWat) form. Once established, these interannual anomalies, covarying with anomalies in sea level pressure (SLP), move south into the Southern Ocean. These covarying anomalies then propagate eastward around the globe as the ACW through a combination of oceanic advection by the Antarctic Circumpolar Current and ocean-atmosphere coupling (White et al., 1998). The coincidence of interannual anomalies in SST, SLP, and PrW indicates the extra-tropical ocean and atmosphere are coupled on these time scales. Significant portions of the interannual SST signal propagating eastward around the Southern Ocean as the ACW propagate equatorward into the South Atlantic and Indian oceans, ultimately reaching the tropics in each basin some 6-8 years after appearing in the western subtropical South Pacific Ocean. This constitutes a slow oceanic teleconnection that is unique in climate dynamics, made possible by the continuity of Earth's oceans via the Southern Ocean. In the tropical Indian Ocean, these interannual anomalies propagate eastward and arrive at the Indo-Pacific transition in phase with the ENSO (El Niño - Southern Oscillation) signal in covarying SST and SLP propagating eastward from the Indian Ocean to the Pacific Ocean (Tourre and White, 1997). The interannual SST and PrWat anomalies that appear initially in the western subtropical South Pacific are directly linked with ENSO on the equator through anomalous vertical convection and a regional overturning Hadley cell in the troposphere, the same cell that initiates fast planetary waves in the atmosphere (Sardeshmukh and Hoskins, 1988) that transmit ENSO signals around the southern hemisphere on much shorter time scales.

JSM18/E/03-A4 1420

EVIDENCE OF EL NINO-SOUTHERN OSCILLATION IN SURFACE METEOROLOGICAL DATA IN ANTARCTICA

Linda KELLER (Department of Atmospheric, Oceanic and Space Sciences, University of Wisconsin, 1225 West Dayton Street, Madison, Wisconsin, 53706 USA), George WEIDNER and Charles Stearns (both at Space Science and Engineering Center, University of Wisconsin, 1225 West Dayton Street, Madison, Wisconsin 53706, USA)

Meteorological measurements have have routinely been made for some 40 years in Antarctica. For about half that period, automatic weather stations (AWS) have provided additional surface measurements at remote locations in Antarctica. Within this time span, there have been four El Nino events - 1982-83, 1986-88, 1991-92, and 1997-98. Signatures of the El Nino events have been observed in the surface meteorological data by several investigators and recently there have been studies concerning the teleconnections between the atmosphere at lower latitudes and the Antarctic atmosphere. Several studies have shown variability in meteorological data (temperature, pressure, precipitation, etc.) is correlated to the El Nino-Southern Oscillation (ENSO) phenomenon. Most of these studies have focused on particular regions of Antarctica. Since the number of surface observing stations has increased dramatically since the major ENSO event of 1982-83, we examine the records at new AWS sites for ENSO signatures along with the now longer record at long established AWS sites. In particular we are interested in comparing the two strong El Nino events of 1982-83 and 1997-98. Previous data indicated the Ross Ice Shelf is anomalously cold just prior to and during the early stages of ENSO events while stations on the high plateau of East Antarctica are anomalously cold during the later phase of the ENSO event. Results from the AWS will be included with observations from manned stations. The AWS data set for 1998 will be completed in the near future.

JSM18/E/07-A4 1440

THE AGULHAS CURRENT SYSTEM: THE INFLUENCE OF EDDIES ON THE TIME-MEAN CIRCULATION DIAGNOSED FROM TWO GENERAL CIRCULATION MODELS

WELLS, N.C. (School of Ocean & Earth Sciences, Southampton Oceanography Centre, Southampton, S014 3ZH, email: ncw@mail.soc.soton.ac.uk), Ivchenko, V.O.(Jet Propulsion Laboratory, N.A.S.A., Pasadena, CA 91109, Best, S.E (formerly of School of Ocean & Earth Sciences, Southampton Oceanography Centre, Southampton, S014 3ZH)

The Agulhas Retroflection region is analysed in two ocean general circulation models, (FRAM and POP). Both models are able to resolve some of prominent time-dependent features of the region, including the Agulhas rings which are shed off from the Retroflection region. In this paper an analysis of the energy budget over a 5 year period together with a stability analysis are used to determine the relative importance of barotropic and baroclinic instability processes in the two models. It is shown that both models have two quasi-zonal jets, a northerly westward flowing jet and a more southerly eastward flowing jet, which act as the entrance and exits of the Retroflection region respectively. Both jets are shown to be baroclinicly unstable, and have growth rates and wavelengths consistent with those observed in both models. It is shown that this instability process is well resolved in the POP model, but is influenced by sub-grid scale viscosity in the FRAM model. The energy budget in POP demonstrates that the westward jet is intensified by reynold's stresses which arise from the eddies in that jet, whilst the eastward jet shows that the reynold's stresses act to diffuse the jet. In both jets the eddies are produced by a mixed barotropic- baroclinic instability, though the baroclinic instability transfers are significantly smaller than the barotropic instability. In FRAM, a similar response is observed.

JSM18/W/06-A4 1500

MODELLING INTERHEMISPHERIC VARIABILITY DUE TO FLUCTUATIONS OF THE THC

Katrin MEISSNER, Holger Brix and Ruediger Gerdes (all at Alfred-Wegener-Institute for Polar and Marine Research, Bremerhaven, Germany, email: meissner@awi-bremerhaven.de)

Freshening of high latitude surface water can change the large scale oceanic transport of heat and salt. Atmospheric perturbations over the deep water production sites thus have a large scale response, establishing a kind of oceanic teleconnection with time scales of years to centuries. In a number of response experiments with a global coupled atmosphere-ocean-sea ice model, we here investigate the connections between northern and southern hemisphere sea surface conditions due to fluctuations of the thermohaline circulation. The atmospheric component of the model consists of the vertically integrated thermodynamic energy and moisture balance equations. The two-dimensional model calculates surface fresh water fluxes and surface heat fluxes over land, sea and ice areas. The sea ice component is a simple thermodynamic model while the ocean component is a full GCM based on MOM2.

JSM18/W/04-A4 1520

HOW FORM STRESS IN THE SOUTHERN OCEAN LINKS WITH SVERDRUP BALANCE IN THE SUBTROPICS

Chris W. HUGHES (CCMS - Proudman Oceanographic Laboratory, Bidston Observatory, Birkenhead, Merseyside L43 7RA, UK, Email: cwh@ccms.ac.uk), and Beverly de Cuevas (Southampson Oceanography Centre, Empress Dock, European Way, Southampton SO14 3ZH, UK, Email: B.Decuevas@soc.soton.ac.uk)

There is a dichotomy in the way the ocean's response to wind forcing is usually interpreted, in which the Southern Ocean is considered quite separately from the rest of the world. The canonical balance for most of the world is Sverdrup balance in which the forcing is due to wind stress curl and interactions with bottom topography are ignored, coupled with viscous western boundary currents. In the Southern Ocean however, it is well established that interactions with the bottom topography are necessary to balance the zonal wind stress by topographic form stress. It will be shown here that this latter balance, which also holds in other ocean basins, implies a `spin' pressure torque which upsets the Sverdrup balance at some longitude, and balances the wind stress curl in a zonal integral. At lower latitudes the spin pressure torque is concentrated near the western boundaries, producing nearly inviscid western boundary currents. This balance will be illustrated with diagnostics from an eddy-permitting global ocean model (OCCAM)

JSM18/W/12-A4 1600

TIME-AVERAGED SUBANTARCTIC CYCLONIC ACTIVITY AS REVEALED IN A FOUR-DECADE REANALYSIS

Ian SIMMONDS and Kevin Keay (both at School of Earth Sciences, The University of Melbourne, Parkville, Victoria, 3052, Australia, email: ihs@met.unimelb.edu.au)

The high density of cyclones in the subantarctic region are known to be associated with the frequent severe weather conditions experienced over coastal Antarctic and the domain to the north. Such systems are also responsible for a large proportion of the transport of heat and moisture to the polar region effected by the atmosphere. Hence the study and documentation of the behaviour of these systems in the subantarctic is important for a number of reasons, among which is the fact that they form a 'bridge' between the Antarctic and the lower latitudes. We present a new climatology of subantarctic extratropical cyclones. This has been compiled by applying a state-of-the-art cyclone tracking scheme to the 6-hourly NCEP global reanalyses spanning the period 1958-1997. The greatest density of cyclones (exceeding 6 x 10-3 cyclones (deg. lat.)-2) is found south of 60oS in all seasons and in the Indian and west Pacific Oceans in autumn and winter. In general, there is a net creation of cyclones (i.e., cyclogenesis exceeds cyclolysis) north of about 50oS, and a net destruction to the south of this latitude. Having said this, the most active cyclogenesis takes place south of 45oS. The NCEP reanalyses indicate that most SH cyclogenesis occurs at these very high latitudes, and the axis of the maximum lies on, or to the south of, 60oS. This is in agreement with the deductions of many modern studies of SH cyclone behaviour. The region is also host to even greater levels of cyclolytic activity.
The presentation will consider measures of the importance and influence (e.g., for eddy fluxes) of cyclonic systems. It is suggested that the 'depth' of a system is a relatively bias-free and useful measure of a cyclone's status and effect on the circulation. The greatest climatological depths are seen to lie at about 60oS, well to the north of the circumpolar trough and of the region of greatest cyclone density.

JSM18/W/09-A4 1620

DIAGNOSIS OF THE EXTRAORDINARY WINTER 1982 - 1983 SEASONAL ANOMALY FORMATION USING CYCLONE CLIMATOLOGY PARAMETERS OF THE GLOBAL ATMOSPHERE

Victor LAGUN, (Arctic and Antarctic Research Institute, 38 Bering str., St.Petersburg, 199397, Russia; e-mail: lagun@aari.nw.ru)

On the base of 1981 -1991 NCEP dataset the global distribution of the extra-tropical cyclone parameters is calculated using original numerical method of spatial cyclone position determination. The estimated parameters include temporal and spatial frequencies, the depth, the cyclone center location and pressure in the cyclone center, the square, the linear size, the shape, the drift velocity, the life time and storm track variability. These parameters are presented as a global distribution as well as integral hemispheric and global estimations. For the winter 1982-1983 of extraordinary weather conditions the seasonal anomalies for mentioned above synoptic climatology parameters are calculated relative to the mean decadal values. Studied decade was characterized by the increasing number of the intensive extra-tropical cyclones, accompanied by the increasing tendency of the surface temperature. The global distribution of the seasonal anomalies for the cyclone frequency, for the cyclone depth and for the drift speed is analised. Regional features of the seasonal anomalies for Europe, North America and South Atlantic are discussed. The results are compared with the global diabatic energy source/sinks estimations and with the published results of this seasonal climatic event GCM simulations.

JSM18/W/01-A4 1640

HEMISPHERIC CONNECTIONS WITH TEMPORAL CHANGES IN CYCLONE BEHAVIOUR OFF THE ANTARCTIC COAST

Ian SIMMONDS and Kevin Keay (both at School of Earth Sciences, The University of Melbourne, Parkville, Victoria, 3052, Australia, email: ihs@met.unimelb.edu.au)

We present an analysis of the variability and trends exhibited by many aspects of high southern latitude mean sea level extratropical cyclones during the period 1958-1997. The investigation is undertaken by applying an automatic finding and tracking scheme to the six-hourly 'reanalyses' produced by NCEP. The outcome of this is arguably the most reliable and extensive analysis subantarctic cyclone variability undertaken to date.
The annual average number of cyclones per analysis in the 50-70˚S latitude band rose from the start of the period to a maximum of about 17 around 1970. Since then the numbers have shown an overall decline (by about 10%), the counts in the 1990s being particularly low. (Similar behavior was evident when the count was confined to the 30-50˚S latitude band.) Least squares best fit to the time series exhibited a significant slopes of -0.58 cyclones analysis-1 decade-1.
The overall structure of the time series of annual cyclone per analysis over 30-50˚S and 50-70˚S are similar, but their year-to-year changes are shown to be negatively correlated, and hence there tends to be an interannual compensation of cyclones density between the middle and higher latitudes.
A number of modelling studies have suggested that extratropical cyclone numbers may be expected to change under enhanced CO2. It is argued that under warmer conditions the specific humidity of the atmosphere increases and hence cyclonic eddies transport (latent) energy poleward more efficiently, and hence fewer are required. The SH mean annual surface temperature exhibits a minimum in the mid 1960s, and a fairly steady rise since then. The time series shows an out-of-phase relationship with that of the SH cyclone numbers and they possess a significant correlation coefficient of -0.79.

JSM18/E/06-A4 1700

EXTRATROPICAL INFLUENCES ON INTERHEMISPHERIC ASYMMETRY OF TROPICAL CLIMATE

Anthony J. BROCCOLI (NOAA/Geophysical Fluid Dynamics Laboratory, Princeton, NJ 08542, USA, email: ajb@gfdl.gov)

Evidence from a variety of climate simulations suggests a relationship between the latitude of the intertropical convergence zone (ITCZ) and the interhemispheric temperature contrast. To explore the role of extratropical forcing in this relationship, an atmospheric general circulation model is forced by prescribed sea surface temperatures (SSTs) in the extratropics and coupled to a mixed layer ocean elsewhere. The imposition of SST anomalies of opposite signs in the northern and southern extratropics induces substantial changes in tropical climate. The ITCZ shifts toward the warmer hemisphere, accompanied by tropical anomalies in meridional surface winds. Changes in atmospheric heat exchange between the tropics and midlatitudes are the likely cause of this shift. This linkage between extratropical forcing and tropical climate may be of importance in understanding past and future climates.

JSM18/L/01-A4 1720

INTERACTIONS BETWEEN THE LOWER LATITUDE CIRCULATION AND THE ANTARCTIC DURING PERIODS OF AMPLIFIED LONG WAVES

John TURNER (Ice and Climate Division, British Antarctic Survey, Cambridge, UK, email: J.Turner@bas.ac.uk)

Understanding the teleconnections between the Antarctic and lower latitudes is very important in interpreting correctly the global climate signals found in ice cores taken from the Antarctic ice sheets. However, the ice cores contain a wide range of signals from very local climate variations to those associated with the major global cycles. Some of the most pronounced signals are associated with periods of amplified long waves when mild, moist air masses can penetrate well into the interior of the continent giving some of the largest precipitation events found over the plateau. This talk will examine the nature of the synoptic events that can occur during periods of amplified long waves, including the occurrence of major storms in the coastal region, weather systems ascending onto the plateau and rapid warming taking place at interior locations. Selected cases will be presented using satellite imagery, model output, ice core accumulation data and synoptic observations from automatic weather stations. The climatological occurrence of such events will be considered along with their relationship to conditions at lower latitudes.

JSM18/E/04-A4 1740

HIGH LATITUDE THERMAL VARIABILITY IN RELATION TO LOWER LATITUDE

Tarzadin ULAANBAATAR (Department of Earth Sciences, National University of Mongolia, email: numelect@magicnet.mn)

A best way to show the climate teleconnection of high and lower latitudes is the creation of climate model covered Earth's surface by simple climatological parameters.
In result of my research works was born a 3D mathematical model of the air temperature regime on and near the Earth's surface. According to this model a thermal field exists near the Earth, i. e. this field includes the troposphere, earth surface and shallow layers of lithosphere, which is called heliogeothermosphere as wishing by Author. It is limited from depth of yearly thermal influences into the shallow lithosphere to tropopause. In this interval the heliogeothermosphere consists of isothermal surfaces due to decreasing the temperature by atmospheric height. Shape of the heliogeothermosphere is more ellipsoid than Earth's. So, the isotherms cut the Earth's surface at certain geographical latitudes. In order to facilitate calculation we used following approach that we do not account atmospheric turbulence and its chemical content, therefore, the temperature gradient or distance between the isotherms is not changed. The isothermal surfaces show the connection of the high and lower latitudes. Temperature gradient fluctuates only in relation of sea level.
In this paper is presented that at a little fluctuation of the isothermal surface in lower latitudes drives dramatical shift of the geographical, climate and permafrost zones at high latitudes. Furthermore, the nature of thermal regime on and near the Earth's surface by length of daylight, daily and yearly motions of the Earth, terrain height, altitude of sun, geographical latitude and albedo of different objects) are shown in forms of equations and their terms.

DECADAL CLIMATE FLUCTUATIONS IN THE ARCTIC AND CONNECTIONS TO LOWER LATITUDES

Lawrence A. MYSAK and Silvia A. Venegas, Mcgill University, Dept. of Atmospheric and Oceanic Sciences, 805 Sherbrooke St., W Montreal, QC H3A 2K6 Canada.
E-mail: mysak@zephyr.meteo.mcgill.ca

During the past two decades there has been considerable research on identifying the nature and causes of interannual and interdecadal climate variability in the Arctic and high northern latitudes through the analysis of various atmospheric, oceanic, sea ice and hydrologic data sets. With the availability of longer records, it has become clear that the dominant signal of variability in the Arctic and subarctic has a decadal timescale. For example, the time expansion coefficients of the first empirical orthogonal function modes for the sea ice concentration (SIC), sea level pressure (SLP), 500-hPa height and 850-hPa temperature north of 45 degrees each exhibit an oscillatory pattern since the 1960s, with a period of around 10 years.
To further elucidate the nature of this decadal clmate oscillation, we performed a combined complex empirical orthogonal function analysis of 40 years of SIC and SLP data which span the Arctic poleward of 45 N. The analysis indicates the over most of the duration of this climate cycle, the ice cover anomalies are created by the atmosphere (i.e., are wind generated), and change through ocean advection. However, it is suggested that during relatively short intervals the atmosphere could respond rapidly to changing sea ice conditions in the Greenland Sea, which results in reversals of the phases of the North Atlantic Oscillation, a familiar climate feature in the winter SLP. The evolving patterns of the SIC and SLP anomalies over the 10-year cycle can be succinctly described in terms of a new feedback, which has remnants of, but is quite distinct from that proposed some time ago by Mysak and his collaborators.

JSM18/W/07-A5 0940

CONNECTIONS BETWEEN AIR TEMPERATURE ANOMALIES IN THE ARCTIC AND LOWER LATITUDES: NATURAL AND GREENHOUSE COMPONENTS

N.Ye. KHARLANENKOVA, G.V. Alekseyev, R.V. Bekryayev (Arctic and Antarctic Research Institute, 38 Bering Street, St. Petersburg, Russia 199397, e-mail:alex@aari.nw.ru)

The spatial distribution of air temperature anomalies in the Arctic and adjacent latitudes at strong (exceeding RMS) deviations of air temperature means in the N 85-200 area based on the 1890-1998 data is characterized in the winter by two modes with the opposite in the sign anomalies. During the anomalously warm winter months the positive temperature anomalies occupy the Arctic region being most significant over the adjoining climatic cold sources on the Asian and North American continents whereas the weak negative anomalies are located above the temperate latitudes of the Atlantic and the Pacific Oceans (COWL structure). At strong negative anomalies of mean temperature in the winter negative anomalies are located above the Arctic region and the adjoining continental cold sources while the weak positive anomalies are observed above the oceans (WOCL-structure). Two types in the distributions of surface pressure and geopotential anomalies correspond to such temperature anomalies. In particular, the increase in the pressure difference between the centers of the Azore and Icelandic Highs (the North Atlantic oscillation index (NAO)) is obvious during winter warming with the reverse process occurring during cooling. The climatic signal from the other non-arctic impact on the Arctic atmosphere related to the ENSO phenomenon, is also noticeable, although it is much weaker compared to the NAO signal in the variability of mean winter air temperature at Arctic latitudes with a time scale of 5-6 years. The spectral analysis of relations between the air temperature anomalies in different latitudinal zones of the Northern Hemisphere revealed that both negatively and positively correlated components distributed by the periods of oscillations are present in the series of anomalies. A relative contribution of the former and the latter to the total dispersion of oscillations varies within a year with the positive correlation typically observed at low frequencies and negative at higher frequencies. It is demonstrated that the inverse relation between the air temperature anomalies in the Arctic area and in lower latitudes is mainly caused by the winter air exchange between them whereas the direct relations at low frequencies indicate the influence of global factors primarily of the increase in CO2 content. The conclusions derived from the analysis of climatic data are confirmed by the analysis of data from long-term numerical experiments using the atmospheric circulation model. This study is supported by the INTAS N 97-1277 Project.

JSM18/W/10-A5 1000

A POSITIVE FEEDBACK MECHANISM BETWEEN THE OKHOTSK SEA ICE AND THE ALEUTIAN LOW

Yoshihiro TACHIBANA (JISAO Univ. of Washington, Box 354235, 4909 25 Ave NE Seattle, WA 98195-4235, USA, e-mail: tachi@atmos.washington.edu), Meiji Honda (Institute for Global Change Research/FRSGC, Tokyo, 105-6791, Japan, e-mail: meiji@frontier.esto.or.jp), Tatsuro Watnabe (Japan Sea National Fisheries Research Institute, Nigata 951-8121, Japan, e-mail: tatsuro@jsnf.affrc.go.jp)

We found a positive feedback that the Okhotsk sea ice enhances the Aleutian low while the enhanced Aleutian low also enlarges the sea ice in the Okhotsk Sea, using AGCM and ice-ocean model separately. The AGCMs with the boundary condition of widely covered ice over the Okhotsk Sea, and with that of slightly covered ice, respectively showed enhanced Aleutian low, and weakened one because of the different heat flux from the ocean due to the difference of ice coverage. Using the results of these two AGCMs as the boundary conditions of ice-ocean models in the Okhotsk Sea, we could simulate much larger ice area with the boundary condition of the strong Aleutian low than that of the weak Aleutian low. This ice difference is mainly because of the difference of northwestern wind that brings movement of sea ice toward the southern Okhotsk Sea and that brings cold air advection from Siberia toward the Okhotsk Sea, since Okhotsk Sea is to the west of the Aleutian low. Therefore, once the ice widely covers the Okhotsk S ea, the Aleutian low will be strengthened and this will also rebound upon

the ice again. In consequence, the Okhotsk sea ice amplifies the interannual variabilities of both the Aleutian low and the ice itself.

JSM18/W/11-A5 1020

ARCTIC IMPACT ON THE NORTH ATLANTIC

MYAKOSHIN O.I., Alekseev G.V., Zakharov V.F. (The Arctic and Antarctic Research Institute Bering St. St., 38, 199347 St. Petersburg, Russia e-mail:alexgv@aari.nw.ru)

The North Atlantic region has a strong influence on Arctic climate, which is transferred through the atmospheric circulation variations connected with the dynamics of the North-Atlantic atmospheric action centers and through variations of the Atlantic water inflow to the Arctic Ocean. For the last 100 years significant natural climate fluctuations were observed in this region such as the warming of the 1930-1940s, the GSA and cooling in the late 1960s-early 1970s accompanied by the sea ice area variations. The climatic phenomenon of the GSA and the related cooling in the North Atlantic in the late 1960s-early 1970s developed under the influence of the increased inflow of freshened polar water and sea ice from the Arctic Ocean [Steffansson, 1969; Dickson et al., 1988; Mysak et al., 1990, S.Hakkinen, 1993]. However, the cause of this increase has not yet been unambiguously explained. An analysis of climatic conditions in the Arctic in the 1950s-1990s and the Soviet oceanographic survey data of the Arctic Ocean in 1955-1979 suggest the increased freshened influence of the Arctic Ocean on the North Atlantic region to be predominantly connected with more intense summer melting of snow, ice caps and sea ice in the Arctic in the late 1950s-1960s. During this period positive summer air temperature anomalies in the Arctic were observed, which were the largest in the Canadian-Greenland region where enormous snow and ice supplies accumulate. Favorable conditions for sea ice melting were observed in the Arctic Basin along with the increased river water flow to the Arctic Ocean. Since summer melting of snow and ice and the summer inflow of river water comprises the major portion of the total inflow of freshwater to the Arctic Ocean, the consequences of the increased summer inflow in the 1950s-1960s was manifested in a significant freshening of the upper layer in the Arctic Ocean in the early 1970s, especially in the region of the East Greenland Current outflow. What are the grounds to suggest a possible recurrence of the climatic scenario of the late 1960s-early 1970s in the North Atlantic? First, this is the increase of the summer air temperatures in the Arctic in the 1990s. Second, this is the increase of the sea ice export through Fram Strait [Vinje et al., 1997] and the increased sea ice cover extent in the West Atlantic in the mid-1990s. Third, there is a tendency for the decreased salinity of the upper layer in the Nordic Seas and finally a conclusion of the mathematical climate theory [Dymnikov, Volodin, 1998] about the similarity of the climatic system response to the natural and external impact.

JSM18/W/08-A5 1100

CHANGES OF THE DEPOSITION OF SOLUBLE AND INSOLUBLE AEROSOLS ON EAST ANTARCTIC ICE DURING THE TERMINATION OF THE GLACIAL PERIOD AS RECORDED IN THE DOME SUMMIT SOUTH ICE CORE (DSS), LAW DOME, ANTARCTICA.

Mark A.J. CURRAN, Vin Morgan and Li Jun (Antarctic CRC & Australian Antarctic Division GPO Box 252- 80, Hobart, 7001. Tasmania. Australia email: mark.curran@utas.edu.au) Jorgen Peder Steffensen (Dept. of Geophysics, University of Copenhagen, Juliane Maries Vej 30, DK-2100, Copenhagen Ø, Denmark)

Ice cores from polar ice sheets contain a wealth of information on past atmospheric conditions. Stratigraphical profiling of ice core impurities, along with the stable isotope ratio climate proxy *18O, make it possible to infer changes in the amount and composition of airborne material during past climate changes.
The Greenland ice core records all show that sudden climate oscillations (Dansgaard/Oeschger events) occurred during the last glacial period. The last of these oscillations was the warm Bolling/Allerod period (ca 14,500 B.P. - 12,500 B.P.) which was followed by a period of cold glacial conditions for ca 1200 years (Younger Dryas) before the final climate transition into the Holocene. Some of the fast climatic oscillations have also been recorded in Arctic ice cores, but in Antarctica they appear much less pronounced.
The *18O record shows that DSS core data extends back through the Holocene and the transition period and into the last Glacial cycle. We present dust (insoluble microparticle) and major chemical ionic species concentrations from the Law Dome Summit core, through the Last Glacial Maximum-Holocene transition period. This data will be compared with records from other Antarctic and Greenland core sites.

JSM18/P/02-A5 1120

PARTICLE FORMATION IN THE MARINE BOUNDARY LAYER OVER ANTARCTICA: IMPLICATIONS IN CLIMATE CHANGE

V.K. SAXENA (Cloud-Aerosol Interactions Lab (CAIL), North Carolina State University, Raleigh, NC 27695-8208, U.S.A., email: saxena@eos.ncsu.edu)

We have characterized particle formation during flights (LC-130 aircraft) in the marine boundary layer over McMurdo and during ground based observations at Palmer Station. The following two features were observed at McMurdo: (1) The Aitken nuclei concentration showed a steady decrease up to 300m MSL and then a monotonic increase with altitude, the maximum (~1300cm-3) was recorded at 2,500m MSL. (2) The cloud condensation nuclei (CCN) concentration varied from 50 to 325cm-3, the minimum occurred at 640 m MSL and the maximum at 830m MSL. At Palmer Station, we observed significantly different particle concentrations during January and February 1994. The January month was characterized by: (i) relatively constant temporal CCN concentrations, (ii) relatively constant equivalent potential temperatures, (iii) partly cloudy skies with respect to wind direction during the daytime, and (iv) winds predominantly from the east-southeast through the Southeast. In contrast, the month of February was characterized by: (i) relatively variable temporal CCN concentrations, (ii) variable equivalent potential temperatures, (iii) variable cloudy to overcast skies with respect to wind direction during the daytime, and (iv) winds predominantly from the northeast, southwest and northwest. Exceptionally elevated CCN concentrations were observed on Jan 17, 19, 20 and Feb 7, 1994 when the cloud base descended to the ground and dissipated under prevailing meteorological conditions. The most spectacular CCN enhancement event occurred on Jan 20 when the CCN concentrations were enhanced by factors of 4 and 7 respectively at 0.25% and 1.25% supersaturation (with respect to water) compared with the pre-event concentrations. Implications of these findings in enhancing the Antarctic cloud cover and its impact on the local radiation budget are discussed.

JSM18/W/13-A5 1140

VARIABILITY OF METHANESULPHONIC ACID (MSA) IN A 27 YEAR ICE CORE RECORD FROM LAW DOME, EAST ANTARCTICA

Mark A.J. CURRAN (Antarctic CRC & Australian Antarctic Division, GPO Box 252-80, Hobart, Tas. 7001 Australia, email: mark.curran@utas.edu.au), Katrina L. Phillips (IASOS, University of Tasmania, GPO Box 252-77, Hobart, Tas 7001 Australia), Tas D. van Ommen and Vin Morgan (Antarctic CRC & Australian Antarctic Division, GPO Box 252-80, Hobart, Tas. 7001 Australia), Anne Palmer (IASOS, University of Tasmania, GPO Box 252-77, Hobart, Tas 7001 Australia)

MSA is an atmospheric oxidation product of dimethylsulphide (DMS), and a component of Antarctic precipitation. DMS is produced by certain species of algae, via the breakdown of the algal metabolite dimethylsulphoniopropionate (DMSP). Antarctic ice core records of MSA thus provide a proxy for biological activity in the Southern Ocean, and a potential source of information on climate variability such as ENSO events and sea ice extent, and other factors influencing biological activity.
A 27 year record of MSA and other trace ions was extracted from a Dome Summit South (DSS) ice core, Law Dome, East Antarctica. The MSA record exhibited a persistent seasonality, with a distinct summer maximum usually flanked by two smaller peaks. This seasonal signal is apparently unique to Law Dome. The smaller peaks appear to occur in spring and late summer (or early autumn). The origin of the smaller peaks will be addressed by considering the seasonal and spatial variation in the source of DMS from the Southern Ocean and transport to Law Dome. The implications of using this MSA record as a proxy for ENSO and sea ice extent will be covered. The potential influence of post-depositional migration of MSA in the ice core record will be discussed.

GEOELECTRIC STUDIES IN QATAR PENENSULA

Nasser M. HASSAN (Geophysics Dept., Fac. of Sc., Ain Shams Univ., Egypt.
e-mail: aboashor@asunet.shams.eun.eg) M. Sh. Diab (Geol. Dept., Fac. of Sc., Menoufia Univ., Egypt) Latifa Sh. Al Naimi (Minst. of Agri. and water Resources, Doha, Qatar)

Twenty seven vertical electrical soundings (VES's) were conducted in Qatar Peninsula. The well - known Schlumberger configuration was chosen and applied with maximum current electrode spacing of 1 Km to detect and estimate thickness of about 200m. Three profiles were constructed dissecting Qatar Peninsula in east, west directions, and comprise parts. From the geoelectric profiles, correlation with subsurface studies dominated lithologic units and their interpretations, an attempt has been made to divide the section into three major units based on the similarities in lithology, well logs and observed sedimentary structures. These units are the dolomite unit (Upper Dammam Formation), the evaporite unit (Rus Formation) and the chalky limestone unit (Umm er Radhoma Formation). Emphasis has been given to the water aquifers in the studied sections. Water quality and suitability for different purposes was also studied.

JSA19/L/01-A5 0915

GEOPHYSICAL AND HYDROGEOLOGICAL STUDY TO DELINEATE THE GROUNDWATER AND SUBSURFACE GEOLOGIC STRUCTURES OF THE AREA AROUND THE TENTH OF RAMADAN CITY, EGYPT

Abdel-Rady, Hassaneen, Salah Osman and Tarek Abdel-Hafez (National Research Institute of stronomy and Geophysics, P.O. 11421, Helwan, Cairo, Egypt, email: arghareeb@frcu.eun.eg)

Fifty six vertical electrical soundings have been carried out to evaluate the extension of the Pleistocene aquifer and the geologic structures, which may affect the type of the groundwater. These VESes are interpreted qualitatively and quantitatively. The Pleistocene aquifer in the area is subdivided into four geoclectric zones. The first surface layer is composed of sands and gravels, with relatively high resistivity values and small thicknesses. The second zone is affected by large variations in the resistivity values, which may be due to lithologic variations within this zone. The third zone is considered to be the water-bearing horizon and composed of sands and gravels. The fourth zone is characterized by low resistivity values compared with clays, sandy clays and limestone. The area is found to be affected by about 20 faults, which may affect the extension, the thickness and the type of the groundwater, therefore twelve water samples were collected from the' Pleistocene aquifer in the area. The water samples were analyzed to obtain the major anions and cations and also some trace elements to study the effect of the industrial waste products on the groundwater. Pleistocene groundwater aquifer is considered as free to semi-confined aquifer type. It is connected from the bottom by the Miocene formation. At the west the aquifer seams to be in direct connection with the Nile-Delta with limited entrance throughout faulting system, so the freshwater is governed by the flow from Ismailia canal and from the main Nile-Delta aquifer. This aquifer is recharged mainly from the seepage of the water of Ismailia canal and from the Nile-Delta through limited entrance of connection.

JSA19/W/09-A5 0930

ESTIMATING AQUIFER PROPERTIES USING CROSSWELL GPR AND TRACER DATA

David W. HYNDMAN, Ruiquing He, and M.S. Phanikumar (Department of Geological Sciences, Michigan State University, East Lansing, MI 48824; email: hyndman@msu.edu)

Non-invasive characterisation methods, such as Ground Penetrating Radar (GPR), have the potential to provide detailed estimates of aquifer properties when used in conjunction with

solute tracer tests. Cross-well GPR tomography can provide detailed slowness and attenuation estimates along planes through an aquifer, however the relation between these properties and hydraulic conductivity is unknown. To address this problem, we are combining geophysical and hydrologic data in a joint inversion to estimate heterogeneous aquifer properties. We are estimating the flow and transport properties for the Schoolcraft aquifer in Southern Michigan, USA. This site is ideal for this investigation because a large number of direct hydraulic conductivity measurements were taken, which enables us to compare our parameter estimates with measured values. In addition, knowledge of heterogeneous conductivity values is useful for optimal remediation design at the site. At this site, joint geophysical and hydrologic inversion methods enable us to develop more accurate three-dimensional estimates of flow and transport properties in heterogeneous aquifers.

JSA19/W/13-A5 0945

DETAILED VLF-EM AND RMT METHODS APPLIED TO POROUS MEDIA AQUIFERS

K. KENNEDY and I. Müller (Hydrogeology Center, UniNeuchatel, 11, rue Emile Argand, CH-2007, Neuchâtel, Switzerland, email: kkennedy@bigfoot.com)

Detailed Radio Magnetotelluric-Resistivity (RMT 12 to 240 kHz) and Very Low Frequency-Electromagnetic (VLF-EM) geophysical surveys were interpreted to characterize high permeability porous media depositional environments and paleogeography. Existing historic data for the prolific Seeland aquifer (Switzerland, BE) were too widely spaced to determine differences in important sedimentary structures, erosion surfaces and conductivity resulting from the area's complex peri-glacial history. First, continuous VLF-EM profiles and RMT soundings data identified geologic heterogeneity regionally over 3km at six sites. 1-D VLF-EM profiles showed variable resistivity, underlying aquitard depth and topography at four sites. 2-D RMT data (20m grid) confirmed sediment variability and yielded buried river channels and aquitard patterns. Of two sites with more uniform aquitard depth and topography, one was selected for VLF-EM and RMT (>800 points, 5m to 20m grid, 8000m2) measurements. These were used for a 3-D visual model of aquifer thickness (12m to 18 m), channel and ridge structures. Data interpretation showed regions with preferred permeability pathways (high resistivity). Field work took only 3 days and interpretation about two weeks. Wells drilled at 9 locations in the same area, now a ground water research field, confirmed aquifer depth, aquitard nature and consistency. A gravel aquifer resistivity correlation applied to a site flow and transport model will include the structure and permeability from this geophysical characterization combined with borehole and tracer test results. A detailed approach using these rapid, high-resolution RMT and VLF EM methods at regional and site-specific scales is an applicable technique in hydrogeology. Increasing vertical resolution can be done by incorporating recent advances in data interpretation developed jointly with our colleagues at Sopron (HU). In this way, multiple-frequency high resolution data at points can be efficiently interpreted.

JSA19/W/12-A5 1000

COMBINED GEOPHYSICAL INVESTIGATIONS FOR MAPPING MAJOR FAULT-BOUNDED DEEP AQUIFERS IN THE VIENNA BASIN

Kay ARIC (1), Kurt Decker (2), Alexander Roemer (3), David K Smythe (4). (1) Institute of Geophysics, University of Vienna, Althanstr. 14, A-1090 Vienna, Austria, email: kayihan.aric@univie.ac.at; (2) Institute of Geology, University of Vienna, Althanstr. 14, A-1090 Vienna, Austria; (3) Geological Survey of Austria, Rasumofskygasse 23, A-1031 Vienna, Austria; (4) GeoLogica Limited, 191 Wilton Street, Glasgow G20 6DF, UK

A combined geophysical approach including seismic and geoelectric measurements, together with gravity data, is used to map a deep aquifer of great economic importance for Vienna. The aquifer is formed by up to 140m of gravels filling the fault-bounded pull-apart Mitterndorf Basin of 50km length and up to 10km width. Pull-apart formation and Quaternary basin subsidence is related to active sinistral strike-slip faulting. The aquifer consists of Quaternary gravel intercalated with conglomerate layers, overlying over consolidated Tertiary shale, silt and sand. Geophysical measurements are used to map the surface topography of the underlying aquitard and to locate hydrologically relevant faults. A 500m seismic reflection profile was observed with dynamite source at a 40m shot and 10m geophone interval, to yield 3-fold subsurface coverage at 5m interval. Strong reflectors are observed at 80, 120, 220 and 380ms TWT. A 100-channel geoelectric profile about 2000m long was also observed with an electrode spacing of 20m. It crosses one end of the seismic profile. This yielded a synthesised expanding Wenner profile with a maximum electrode spacing in the centre of the line of 660m. Apparent resistivities decrease markedly from 400ohm.m at the surface to 10ohm.m at 250m depth. Our geophysical data complement existing 2-D hydrocarbon exploration seismic data which will allow us to map the down-section continuation of potential aquifer bounding faults.

JSA19/L/02-A5 1015

SEISMIC EVIDENCE FOR OVERPRESSURE AND FLUID MIGRATION WITHIN THE BARBADOS ACCRETIONARY COMPLEX

Sheila PEACOCK, Nathan Hayward and Graham K. Westbrook (School of Earth Sciences, University of Birmingham, Edgbaston, Birmingham B15 2TT, UK, email: s.peacock@bham.ac.uk)

Seafloor sediments involved in subduction are subject to a rapid increasein lithostatic stress due to forced burial, and to tectonic stress. The clay rich sediments at Barbados are overpressured because of low permeability and release of bound water from clays. Drilling and logging in accretionary complexes are difficult so seismic techniques are used to map porosity and fluid pressure and deduce the likely escape paths of the porewater.
At our site the toe of the Barbados accretionary complex consists of an upper accreted zone of stacked thrust slices, then a thin decollement zone, then an undisturbed zone of sediments riding down (at 20mm/year) with the subducting plate. A 3-D seismic reflection survey has been shot over this area and vertical seismic profiles and P waves from ocean bottom shots recorded in ODP borehole 949C within the 400-m thick accreted zone. We deduced velocity-porosity-overpressure relations from well logs to produce porosity and overpressure sections. These show a continuous zone of overpressure (lambda - pore pressure/overburden pressure - up to 0.9) in the basal 80 m of the accreted sediments, above the decollement.
The zone has low S-wave velocity and high Poisson's ratio (up to 0.477), probably indicating loss of cohesion. Above that, the thrust faults seen in the seismic section appear to act as barriers to flow, dividing the accreted sediments into packets of distinct pore pressure. Reflections from the decollement zone are modelled by a 12.5-m thick low velocity zone indicating porosity about 55% but the anisotropy seen in cores was not resolved.

JSA19/W/10-A5 1100

COMBINING GEOPHYSICAL, GEOMORPHOLOGICAL AND HYDROLOGICAL DATA TO INVESTIGATE THE STRATIFICATION OF AN AQUIFER

Gunnar LISCHEID (BITÖK, University of Bayreuth, 95440 Bayreuth, Dr.-Hans-Frisch-Str. 1-3, Germany, email: gunnar.lischeid@bitoek.uni-bayreuth.de)

Studies of subsurface solute transport and hydrochemical processes require information of the subsurface structure. Geophysical methods have proven their potential for this task. However, additional data are required for calibration. These can be provided, e.g., by drilling cores or borehole logs at a limited number of points. On the other hand, indirect methods provide less detailed, but spatially integrated information. In this paper geomorphological and hydrological data were used to check and to refine the interpretation of ground penetrating radar (GPR) data. The study was performed in a 0.55 km2 forested catchment in the Steigerwald region, in the south west of Germany. Here biogeochemical processes have been investigated since 1994. The aquifer is about 60 m thick and consists of an interbedding of clayey and sandstone layers of several dm thickness each. To model solute transport, a detailed model of the subsurface structure is needed. To this end, a GPR survey was performed (50 and 200MHz antenna). Penetration depth was about 100ns, corresponding to 10m. Spacing of the survey lines was about 10 - 20m in the central part of the catchment.
Drilling cores were available only down to 3m depth. In addition, geodetic data were used, as the topography reflects the main features of the stratification. The same holds for the spatial and temporal pattern of groundwater discharge into the stream. Measuring discharge along the stream at different dates revealed zones of pronounced groundwater discharge. Finally, the spatial patterns of soil solution, groundwater and stream water quality data were used to check the stratigraphic model.

JSA19/W/07-A5 1115

PREDICTION OF HYDRAULIC PERMEABILITY FOR RESERVOIR SANDSTONES AND BASEMENT ROCKS BASED ON FRACTAL PORE SPACE GEOMETRY

Christoph CLAUSER and Hansgeorg Pape (both at: Joint Geoscientific Research Institute, D-30631 Hannover, Germany, email: c.clauser@gga-hannover.de Joachim Iffland (Geological Survey of Mecklenburg-Vorpommern, Pampower Str. 66/68, D-19061 Schwerin, Germany)

Estimating permeability from grain-size distributions or from well logs is attractive but difficult. In this paper we present a new, generally applicable, and relatively inexpensive approach which yields information on permeability on the core sample and on the borehole scale. The approach is theoretically based on a fractal model for the internal structure of a porous medium. It yields a general and petro-physically justified relation linking porosity to permeability, which may be calculated either from porosity or from the pore radius distribution. This general relation can be tuned to the entire spectrum of sandstones ranging from clean to shaly sandstones. The resulting expressions for the different rock types are calibrated to a comprehensive data set of petrophysical and petrographical rock properties measured on 640 sandstone core samples of the Rotliegend (Lower Permian) in northeast Germany. Permeability calculated with this procedure from industry porosity logs compares very well with permeability measured on sedimentary and metamorphic rock samples.

JSA19/W/08-A5 1130

3-D ELECTROMAGNETIC IMAGING AND SELF POTENTIAL MODELLING: HYDROGEOLOGICAL CHARACTERISATION OF FISSURED CRYSTALLINE BEDROCK

Sophie HAUTOT, and Pascal Tarits, (IUEM/UBO, UMR CNRS 6538, Place Nicolas Copernic, F-29280 Plouzané, email: tarits@univ-brest.fr)

In crystalline bedrock geological context, fractured aquifers represent the main groundwater resources. Due to the complex geological structure three-dimensional (3-D) imaging tools are necessary to characterise the geometry of the fractures network. Electrical and electromagnetic sounding techniques are well suited to localise fractures because of the large electrical resistivity contrast between the fresh rock and the fractures in presence of water.
Controlled source (EM31) and very low frequency (VLF) electromagnetic soundings were carried out in a test site in Western Brittany (France). The geological context of the area is a crystalline bedrock recovered by a few meters thick weathered layer. The 3-D interpretation of the electromagnetic data allowed us to obtain a 3-D model of the resistivity distribution down to about 50 meters. Our model suggests two structural units: an electrically resistive unit interpreted as a massive crystalline structure, and a conductive unit, interpreted as a fracture network. However, 3-D electromagnetic imaging does not allow determining if localised fractures are hydraulically active or not. A self potential (SP) survey was carried out to characterise the water flow in the weathered layer. The interpretation of the SP data allowed us to determine if the electrically conductive structures can be recharge zones or not. It is demonstrated that one of these structures is an active fracture.

JSA19/P/02-A5 1145

DELINEATION OF CORROSIVE GROUNDWATER ZONE USING RESISTIVITY METHOD

L.P, CHOURASIA (Department of Applied Geology, Dr. H.S. Gour University, Sagar, M.P. India)

Corrosion is basically an electrolytic process which severely attacks a metal surface. In order to study the effects of corrosion and incrustation characteristics of groundwater, geochemical methods are generally employed. Corrosive groundwater damages the iron pipes through which it is distributed. The use of resistivity method in corrosion related studies has been done in a part of Chambal-Sind drainage basin to demarcate the zone of corrosive groundwater. It has been correlated with the geochemical data. It is found that resistivity studies help in identifying the corrosive zone of groundwater as well as type of geologic formation and hence help in limiting the depth of well drilling.

JSA19/L/03-A5 1200

THE ATTENUATED RADAR WAVE MIGRATION WITH FINITE ELEMENT METHOD DI QINGYUN

WANG miaoyue (Institute of Geophysics, Chinese Academy of Sciences, Beijing, 100101, China)

Up to now, the GPR data is processed by means of the seismic programs. But the high frequency radar waves are different from the seismic waves in dynamic characteristics, it is strongly attenuated in earth media, and the attenuation function must be considered in inversion of ground penetrate radar wave.
First we derive the finite element equations for attenuated radar waves by Galerkin's method, especially give out thoroughly the attenuated coefficients. And second, we finished reverse time migration for no offset and offset GPR data with and without attenuated term. A series of model results show that the migration results are much better after considering attenuation. Two GPR profiles of Dynasty City in Shang Qiu of China are processed using the above method, the resolution of migration profile is improved much more. Our migration program with attenuated term processes one GPR profile for basement detection, the boundary of basement and a possible fault in middle is obvious.
It proves that our work provides a possibility to improve the resolution of GPR profile and reliability of geological interpretation as long as the attenuation of radar wave is considered in data processing.

HYDROGEOLOGICAL AND HYDROCHEMICAL STUDIES ON THE DELTA OF NUWIEBA CITY, SOUTH SINAI

Abbdel -Rady HASSANCEN, Nagy Soliman and Ayman Abdel - Latiff (National Research Institute of Astronomy and Geophysics, P.O. 11421 Helwan Cairo, Egypt email: arghareeb@frcu.eun.eg)

The delta of Nuwieba City comprises Wadi Watier, Wadi Sada El - Sainra and Wadi El Sada El -Bada deltas from north to south. These wadis outlet to the Gulf of Aqaba. In this study thirtytwo drilled and hand dug wells are present in this delta reaching to the aquifer at variable depths. The direction of water flow takes the northwest and southeast directions and the water level decreases at the same direction. In this study ten isoparamters maps are constructed to show the horizontal distribution of the concentration of major cations and anions in the Quaternary aquifer. Hydraulic parametres of the aquifer in the hand dug wells are measured and show transmissivity ranging from 19.2 to 28.5 m2/day and storage coefficient ranging from 2.8 X 10-2 to 4.4 X 10-2. The water type in the study area is Mg CL2 type of marine water genesis, except in some wells in delta of Wadi Sada El-Samra and delta of Wadi El-Sada El-Bada it is Na2S04 type of meteoric water genesis, because it lies at the same main trends of these faults which constructed Wadi Sada El-Samra and Wadi El-Sada El-Bada. The hydrochemical computer program WATEQ was carried out to calculate the saturation indices for all minerals in the water samples. The saturation indices of these minerals are used to elucidate the water-rock and water-mineral interactions phenomena in the studied area. The results of this program, gave 18 minerals for the samples with special concentration according to the chemical characteristics for these samples. These resulting minerals are classified to carbonate minerals, chloride minerals sulphate minerals and hydroxyl minerals according to acidic radical and basic radical. Two hydrochemical profiles were constructed to show the water rock interaction and water minerals interaction, which gave indication that, the concentration of salts increased with water flow direction.

JSA19/L/05-A5 Poster **1400-02**

GEOPHYSICAL STUDIES FOR THE ENVIRONS OF THE ARCHAEOLOGICAL SITE OF ABYDOS AREA, SOHAG GOVERNORATE, EGYPT.

Abdel-Rady HASSANEEN, El-Said El-Sayed and Mohamed Metwally (National Research Institute of Astronomy and Geophysics, P.O, 11421 Helwan, cairo, Egypt, email: arghareeb@frcu.eun.eg).

The Abydos locality is a famous archaeological site southwest of Balyana town, Sohag Governorate, Upper Egypt. It is located at the western boundary of the agricultural land of the Nile Valley and represents one of the most important holly burial grounds for kings and high court dignitaries in ancient Egypt, and also as a pilgrimage site for the religious Pharaohs for long time. The locality is liable to groundwater hazards on the archaeological burials due to the effect of the nearby agricultural and irrigation activities.
Vertical electric resistivity soundings were conducted. The layer resistivities were calibrated via the available boreholes data and geological information to relate them to the lithofacies units and to construct geoelectric sections across the area. The results helped to construct the isopach map for the Nile silt/clay cap (Holocene), that covers the sandy Pleistocene semiconfined aquifer and also indicated the free groundwater phreatic surface depth, which increases towards the elevated desertscarps.
The resistance geoscanning technique was applied at some localities of Abydos area. This technique proved to be a powerful mean in exploring the area for mapping the subsurface rock inhomogeneties. Excavations in the area indicated numerous tombs and temples in many parts of the area. The resistance geoscanning examination of some parts of the unexplored localities is conducted depending on the marked resistance contrast between the buried stone and brick walls and the covering fill of sand, silt and clay.

JSA19/L/06-A5 Poster **1400-03**

SHALLOW GEOELECTRICAL STUDIES FOR PALEOTOPOGRAPHY AND ARCHAEOLOGICAL INVESTIGATIONS AT EL-SIMBELAWEIN DISTRICT, EASTERN NILE DELTA, EGYPT.

Abdel-Rady HASSANEEN, Mohamed Abdalla and Ayman Taha (National Research Institute of Astronomy and Geophysics, P.O. 11421-Helwan, Cairo, Egypt, email: arghareeb@frcu.eun.eg)

The Middle Pleistocene Prenile sediments consisting of clay and silt cover the irregular surface of the Middle Pleistocene sands, as in Tell Timai locality and the environs of Tell Timai and Tell El-Ruba. These localitis were covered with 76 Schlumberger vertical electrical sounding stations. Resistivities of the Quaternary sediments were calibrated with the corresponding lithofacies of the available boreholes data in the Eastern Nile Delta. Fourteen geoelectric resistivity cross-sections and eight interpreted resistivity slice maps as well as maps of palaeotopography of the Pleistocene sands and isopach map for the Holocene Nile sediments in the area of study were constructed. Exploration of a wide sand gezira related to the big sand buried ridge in which Tell Timai is located is depicted clearly from the palaeotopography of the Pleistocene sands and from the geoelectric sections. Also, the buried Mendisian Nile branch at the area of study has been traced.
The resistance geoscanning technique using the Geoscan RM-15 Resistance Meter applying the twin configuration was conducted at three sites in Tell Timai to detect the buried archaeological features. However, resistivity mapping using Wenner configuration and the Gga-31 Geoelectric DC-equipment was applied at one site to correlate resistance images with resisitivity mapping.

JSA19/W/11-A5 Poster **1400-04**

THE HYDROGEOLOGICAL SECTIONS OF THE NORTH-EASTERN PART OF THE BUENOS AIRES PROVINCE (ARGENTINA), FROM AMT RESULTS

SAINATO, Claudia M. (Fac. de Agronomía. University of Buenos Aires. Av. San Martín 4453 1417. Buenos Aires. Argentina, email: csainato@ciudad.com.ar) Pomposiello, M. C. (CONICET. Argentina) Landini, A. M.(Fac. de Agronomía. Univ. of Buenos Aires. Argentina) Galindo, G. (Fac. Ciencias Exactas y Naturales. Univ. of Buenos Aires. Argentina)

The shallow aquifers of the north-eastern part of the Buenos Aires Province has been described in previous studies. Free ground water presents good quality at some restricted zones, allowing its use for consumption. The field irrigation requires greater flows of water, perhaps from deeper aquifers.
Below the free groundwater level the aquifers have a multilayer character (Pampeano), with clay-sand sediments with low permeability and an increase of sand component with depth. Previous Audio magnetotelluric and DC soundings have shown an increase of salinity with depth with intercalation of more resistive layers which may be sand or calcareous crust. In this work, more AMT soundings have been performed, increasing the study area, in order to have a better description of deeper aquifers and the different hydrogeological components of the basin.
The results coincide with previous hydrogeological studies. The Epiparaniana section reaches 170-260m depth, including the Pampeano aquifer with its base between 30 and 100m and the Puelches Formation , below the last one, which has variable thickness and bad quality water. Below this section, the Paraniana Formation (Green Miocene) with clay and intercalation of sands shows very bad quality water and some resistive layers, perhaps hardpan. The Red Miocene with sandstones and clay is placed beneath the 400-500m.

HYDROGEOPHYSICAL STUDY IN A PART OF THE NILE VALLEY, EGYPT

Ahmed Mohamed Sobhy HELALY and Ahmed Sayed Ahmed Abu-El-Ata (both at Ain Shams University, Faculty of Science, Geophysics Department. Abbassia, Cairo, Egypt, email:helaly@asunet.shams.eun.eg).

The purpose of this work was to investigate the shallow section of the study area with respect to its groundwater aquifer conditions. That was through the use of the integrated shallow geophysical and some geological data. The subsurface stratigraphy in the study area is ranging from the deep Precambrian rocks up to the most recent Quaternary deposits, while the outcropped geological units are ranging in age from Middle Eocene to Quaternary. There are some detectable contrasts in the physical properties of the subsoil throughout the study area. So, the integrated use of electrical resistivity and gravity methods can be applied to investigate the subsurface lithological and structural manifestations which control the potentiality of the existing aquifer. The gravity method proved to be useful in mapping the buried rock topography and groundwater exploration in some geologic conditions, e.g. the occurrence of groundwater in the sands/gravels of buried stream valleys on the bedrock surface and/or bounded by much less permeable rock types. The gravity datawas represented by the Bouguer gravity map which provided information about the general geologic conditions/structures in the study area and made possible estimates of depth to bedrock. The gravity method was devoted mainly to decipher the upper section of the study area that embraces the shallow Quaternary aquifer, through separating the residual gravity anomalies from the regional ones. These residual gravity anomalies have been subjected to further analysis to determine the extension of the water-bearing main aquiferous unit in terms of width and thickness. Furthermore, the probable paleocourse of the Nile River has been aligned. Then, for interpreting a multilayer electrical sounding curve, additional subsurface lithological information from wells/boreholes can be used for solving the problem of equivalence. But in case of absence of such data, the Dar Zarrouk parameters can be used to optimize the initial stages of resistivity interpretation. Such a procedure was…

INTEGRATION OF ELECTROMAGNETIC, S-P AND MAGNETOTELLURIC METHODS IN HYDROGEOLOGICAL INVESTIGATION.

Fernando SANTOS, Rita Castro, Rita Nolasco, and Luís Mendes-Victor (Centro de Geofisica da Universidade de Lisboa, R. Escola Politecnica, 58, 1250 Lisboa, email: dfams fc.ul.pt) and Eugénio Almeida (Instituto Pilitecnico de Tomar)

At the Vilarelho da Raia area (northeastern Portugal), the youngest formations are sedimentary of Cenozoic age, having their maximum thickness along the central axis of the NNE-SSW depression. In the same area the oldest formations consist of a schisto-graywacke complex of Siluric age. A combined survey using electromagnetic, self-potential and magnetotelluric methods was carried out to delineate shallow and deep structures associated with the mineral water reservoir in Vilarelho da Raia depression.
The compiled SP and electromagnetic (electrical conductivity) maps correlated quite well with the spatial distribution of the knowledge fracturing. Nine magnetotelluric soundings were acquired in the frequency range of 180 to 0.01 Hz. The data set was analysed using the Groom- Bailey decomposition technique. A two-dimensional model was obtained by inversion of both E and B- polarisation. The geoelectrical structure of the main geological formations as well as the deep features of the main faults were well represented in the model.

THE STRUCTURE AND EVOLUTION OF THE EASTERN NANKAI TROUGH PRISM AS DERIVED FROM MCS REFLECTION DATA

Shiguo WU, Narumi Takahashi, Hajimu Kinoshita, Yoshiyuki Kaneda, Izumi Sakamoto (Deep Sea Res. Dept., Japan Marine Science & Technology Center, Yokosuka, 3270061, Japan, Fax: +81-468-5541, email: wushiguo@jamstec.go.jp)

We performed multi-channel seismic investigation during Cruise KH96-02 by R/V Hakuho-mura in 1996. Total 454 km Ggun seismic data has been acquired in order to detect the detailed structure and evolution of the eastern Nankai Trough prism, which is characterised by important active earthquake zone and widely cold seepage activity. Preliminary results show as follows: five deformation units have been divided. The five units are upper slope prism, accretionary basin, lower slope prism, trough and Zenisu Ridge from west to east, respectively. Tokai thrust fault is east boundary of upper slope prism. The fault extended to basement are important lithofacies boundary, which is suggested the Middle Miocene to Early Pliocene subduction zone from the lithofacies distribution and regional tectonics. More recently thrust system occurred between lower slope prism and trough, which express duplicated thrust and began from Late Pliocene. Tectonics of Zenisu Ridge is considered a new following subduction zone by many scientist, but we don't find compression structure in upper layers from seismic profiles. The subduction may happen more east because of collision between Izu-Bonin and Honshu Arcs. Therefore, it still needs more data to detect the possible subduction zone. The decollement surface has varied from west to east. The bend surface is resulted in the new compression by the deep subduction of Zenisu Ridge. The inner facies of the prism over the decollement surface occur slope apron, debris sediment and axial trench wedge sand and silty turbidites derived from the seismic facies. The gas hydrate surface can be seen in the some profiles, with depth variation from 0.4-0.6 sec. (two way time) below the seafloor.

REINTRODUCTION OF PHYSICS TO HYDRAULIC CONDUCTIVITY MODELING

I. TCHIGUIRINSKAIA and F. J. Molz (E.E.&S. Dept., Clemson University, 342 Computer Court, Anderson, SC29625, USA, email: iouliat@clemson.edu)

A fairly large body of observational evidence shows that the hydraulic conductivity (K) is extremely variable over a large range of scales. Pioneering attempts to capture the Log(K) variability rely naturally on the simplest scaling model, i.e. fractional Brownian motion. A class of fractal models, based on Levy-stable pdf's, was introduced to capture the 'fat tailed pdf's'. However, all these models could lead the anomalies in the resulting K field, obtained by exponentiation of Log(K). Indeed: (i) a scaling of the log(K) field does not imply in general a scaling of the K field; (ii) finiteness of some or all statistical moments of log(K) does not prevent

the K field from having all statistical moments divergent. We demonstrate that the fundamental condition of positiveness of K fields is naturally supported by an extension of Multifractal Fractionaly Integrated Flux (FIF) models. Indeed, we propose an appropriate framework not only to interpretate the results of previous scaling analyses, but also to overcome (without artificial truncation) the fundamental problems, indicated above. Furthermore, we present an anisotropic version of this multifractal model in order to capture and to reproduce the anisotropy of hydraulic conductivity measurements. The theoretical findings are well supported by empirical evidence.

MODELLING OF SEISMIC EFFECT ON GEOLOGICAL MEDIUM

A.V. MISHIN, T.V. Guseva, Yu.P. Skovorodkin (Institute of physics of the Earth, Russian Academy of Sciences, B.Gruzinskaya, 10, Moscow, Russia, 123810, email: mishin@redline.ru)

For determination of influence of a seismic waves on geologic medium we conducted full-scale modelling. A seismic waves on different geological structures made with the help of large industrial explosions or vibrational effect. The vibrations were carried out by stationary and mobile seismic vibrators on different frequencies. The complex monitoring has allowed to record diverse modifications of deformational, electromagnetic fields and local increments of gravity caused by the artificial effect on crust. The analysis of the results of the observations has shown, that in multiphase mediums there are two kinds of fluid transitions: oscillatory - in porous and translational - in permeable layers. As result of transitions of a liquid component relative to rigid skeleton there are electric currents of electrokinetic nature: variables - on frequency of vibration and quasi-constant - during filtration. During translational fluid movement the modification in space and time of liquid / gas ratio occurs due to a difference in phase velocity of filtration. As the corollary the effective density in the certain sites varies. The development of process proceeds after seismic effect decreasing gradually within several hours, that testifies a restoring an initial condition of a system rigid phase - fluid. We have conducted a number of successful experiments with vibration effects on petroleum deposits.

METODOLOGY OF HIGH RESOLUTION COMPLEX OF ELECTRO-MAGNETIC METHODS FOR AQUIFERS STUDY

R.TURSUNMETOV Gidroingeo (64 Khodjibayev str. Tashkent, 700041 tel:(998 71) 162 74 68, fax:(998 71) 162 45 53)

Though electro-magnetic methods are for long time used for aquifers investigation, results can not always be used for study of ground water flow's filtration structure. On the other hand, methods developed for study of electro-magnetic properties of environment, connected with the real processes within this environment due to peculiarities of electro-magnetic fields distribution, were not applied sufficiently to the practical tasks resolution. In this connection, special theoretical and experimental investigations were carried out by the scientists of the GIDROINGEO institute in order to develop high resolution complex of electro-magnetic methods for aquifers study. On the base of these results the methodology of electro-magnetic investigations was developed, consisting of two stages. Within the first stage aquifer's lithology is being studied, which forms filtration characteristics of an aquifer. If on electric scanning curves an aquifer is mapped as a whole, it is possible to determine clay particales concentration. Aquifer homogenity, e.g. availability of high and low resistance layers within the aquifer can be defined by frequency electro-magnetic scanning. Within the second stage electro-magnetic investigations were aimed to filtration characteristics of singled aquifers study. As aN electro-magnetic parameters coefficient of electro-magnetic fields' heterogenity and non-linear parameters of resistance and polarity were accepted, which characterize water flow movement within the porous media. Methodology of electrio-magnetic fields space heterogenity study was applied especially in vertical direction for decoding of environment's filtration properties. Moreover, methodology for determination of non-linear parameter of resistance, which describes interrelations between artificial field and natural elecro-magnetic field, caused by ground water movement. Special installations were developed for determination of the electro-magnetic field's ellipse of heterogenity and non-linear parameters of resistance. Thus, suggested complex permits to study aquifers with high reliability.

TOWARDS AN INTEGRATED GEOPHYSICAAL TECHNIQUES FOR HYDROGEOLOGICAL INVESTIGATION

MORUFFDEEN A. Adabanija (Department of Pure and Applied Physics, Ladoke Akintola, University of Technology, P.M.B. 4000, Ogbomoso, Nigeria, email: Adebayo@Ibadan.skannet.com)

The ultimate goal of hydrogeological investigation is the exploration of aquifer. In this work, computer simulation has been designed to integrate the results of the geophysical exploration of aquifers. Templates overlaying approach vis--vis aerial photographs and satellite imagery as reconnaissance tool was used with geophysical borehole logs as reference. For the purpose of this exercise, GIS application package ARC/INFO was used as database for the templates which were obtained by synthesising the findings of the survey into Boolean grid. A new template was obtained by evaluating the resultant Boolean expressions of the overlaid templates. By this approach, the resolution of the images obtained and the capability of evealing subsurface structure was enhanced.

HYDRODYNAMIC TROPOSPHERIC WAVE SOURCES AND THEIR ROLE IN IGW CLIMATOLOGY OF THE UPPER ATMOSPHERE FROM THE MU RADAR OBSERVATIONS

Nikolai M. GAVRILOV (Department of Atmospheric Physics, Saint Petersburg, University, Petrodvorets, 198904, Russia, Email: gavrilov@snoopy.phys.spbu.ru) Shoichiro Fukao (Radio Atmospheric Science Center, Kyoto University, Uji, Kyoto 611, Japan, Email: fukao@kurasc.kyoto-u.ac.jp)

The results of measurements of generation of internal gravity waves (IGWs) in the troposphere by mesoscale dynamical processes with the MU radar are presented. Zonal and meridional horizontal nonlinear advective accelerations are estimated using 8 directions of the MU radar antenna beam. Seasonal variations of the intensity of tropospheric IGW sources are discussed using results of the observations in all seasons. A contribution of IGWs generated in the troposphere into dynamics of the mesosphere and lower thermosphere is considered by comparing the MU radar data with a theoretical model. Possible contribution of IGWs generated in the troposphere at middle and equatorial latitudes to interannual variations of the wave intensity and general circulation of the middle and upper atmosphere over the MU radar is discussed.

JSA20/E/21-A4 Invited **1000**

TROPOSPHERIC EVENTS AND RELATED GRAVITY WAVE ACTIVITY EFFECTS ON THE IONOSPHERE

Petra SAULI, Josef Boska (Institute of Atmospheric Physics, Czech Academy of Sciences, Bocni II/1401, 141 31 Prague 4 - Sporilov, Czech Republic, e-mail: Pkn@ufa.cas.cz)

Short-time variability of the ionosphere was studied during campaigns of rapid sequence (repetition time 5 minutes) ionospheric soundings measured at the Pruhonice Observatory (15E, 50N) and partly at the Ebro Observatory (0.5E, 41N) under the low solar and geomagnetic activity conditions with the aim to detect gravity wave activity at various heights and in different ionospheric parameters. The short repetition time of soundings allowed to detect significant gravity activity in the period range of 20-60 minutes. The effects of gravity waves were well expressed in the shape of electron density profile and in the differences between reflection heights at fixed frequencies. These effects display an evident height dependence. Some of the observed gravity wave events seem to be related to strong meteorological (tropospheric) events. Some details concerning the diurnal height dependence of the variation of electron concentration at the levels 150-205 km may be found in poster presented at the same session.

JSA20/W/32-A4 1025

DIURNAL-, SEMIDIURNAL- AND PLANETARY-WAVE-PERIOD MODULATION OF GRAVITY-WAVE ACTIVITY IN THE MESOSPHERE AND LOWER THERMOSPHERE

V. St.C. Howells, N.J.MITCHELL, A. G. Beard (The University of Wales Aberystwyth, SY23 3BZ, UK, email: Nick.Mitchell@aber.ac.uk), H.G. Muller (The Royal Military College of Science, Cranfield University, SN6 8LA, UK)

Meteor-radar measurements of winds in the mesosphere and lower thermosphere were made over the UK from June 1989 to October 1994. Although individual gravity waves cannot easily be detected directly, the variance of the velocities is used an indication of the overall activity of the gravity-wave field. The variances reveal a persistent diurnal cycle in wave activity with a maximum during the morning in winter and during the afternoon in summer. A time-series analysis also reveals occasions where strong modulation of the gravity-wave variance occurs at semidiurnal and planetary-wave periods. The seasonal behaviour of this modulation is investigated and possible mechanisms suggested.

LUNAR TIDES IN THE MESOSPHERE AND LOWER THERMOSPHERE OVER COLLM

Robert STENING (School of Physics, University of New South Wales, Sydney 2052, Australia, email: R.Stening@unsw.edu.au); Christoph Jacobi (Institute for Meteorology, University of Leipzig, Stephanstr. 3, 04103 Leipzig, Germany, email: jacobi@rz.uni-leipzig.de)

Winds at heights of 85-105 km have been measured at Collm for many years using the D1 total reflection method. Although data are generally available only at night time the least squares analysis method of Malin and Schlapp can be used to extract lunar tides. We have thus been able to derive the mean seasonal variation of the phase and amplitude of the lunar tide in these winds. We have also obtained an estimate of some year-to-year variations which we compare with earlier results from Saskatoon in Canada.

JSA20/W/51-A4 1128

THE SEMI-EMPIRICAL MODEL OF THE TURBULENT MESOSPHERE

Anzor R. GVELESIANI (Institute of Geophysics, Georgian Academy of Sciences, 1., M. Alexidze, Str., Tbilisi 380093, Georgia, email: vazha@excite.com)

It is discussed a mechanism of generation of the turbulence in the mesosphere and suggested its original semi-empirical theory with using the method of similarity and analysis of

dimensions. On the basis of general values: the rate of viscous dissipation of kinetic energy, the Brunt-Vaisala frequency and the rate of heat turbulent dissipation, - six parameters of fluctuations are obtaine. It is established the connections between parameters of inertial subrange and buoyance subrange and characteristics of maximal sizes of irregularities. It is also discussed the breaking problem of buoyancy waves in the mesosphere and the results of numerical calculations both of turbulent and buoyancy waves parameters in different conditions of geomagnetic activity.

JSA20/W/22-A4 1146

A SPECTRAL STUDY OF PLANETARY WAVES AND TIDAL VARIABILITY: PLANETARY WAVE / TIDAL WAVE-WAVE COUPLING

A.G. BEARD, N.J. Mitchell, P.J.S. Williams (Prifysgol Cymru Aberystwyth, Penglais, Aberystwyth, Ceredigion, SY23 3BZ; email: agb@aber.ac.uk), H.G. Muller (The Royal Military College of Science, Cranfield University, SN6 8LA, UK)

Current theory predicts that a non-linear wave-wave interaction between a planetary wave and a tide should result in cyclical modulation of the tidal amplitude with a period equal to that of the planetary wave. Four and a half years of data from a meteor radar based at Sheffield, UK representing measurements of neutral wind velocity in the meteor region above 53 deg 27 min N, 3 deg 53 min W, are analysed to produce running (dynamic) periodograms to identify both longer-period (2-30 days) neutral-wind oscillations (e.g. planetary waves) and longer-period periodic variability in tidal amplitude measurements. These are used to study the relationship between periodic tidal amplitude fluctuations and contemporaneous, collocated observations of planetary waves. A bispectral analysis is also applied to the neutral-wind time series to identify quadratic non-linear interactions present in the data.

JSA20/W/34-A4 1204

VERTICAL PROPAGATING CHARACTERISTICS OF WAVE OSCILLATIONS (FROM 2- TO 6.5-DAYS) IN THE IONOSPHERE OBTAINED FROM ELECTRON DENSITY PROFILES

David ALTADILL (Observatori de l'Ebre, CSIC-URL, Horta Alta 38, 43520-ROQUETES, SPAIN); Emil M. Apostolov (Geophysical Institute, Bulgarian Academy of Sciences, Acad. G. Bonchev Str. bl. 3, 1113 SOFIA, BULGARIA)

We present the climatology of quasi-periodic oscillations from 2- to 6.5-days in the ionosphere at the altitude range from 170 to 230 km during 1995. We investigate the characteristics of the oscillations from the true height electron density profiles obtained at the Observatori de l'Ebre (40.8N, 0.5E). We show that the oscillations are significant during time intervals when the planetary waves in the mesopause region display maximum amplitudes. We found several wave events of the oscillations, burst type, for which their vertical propagation is manifest in the ionospheric F region. Each event display different degree of dispersion and the observed changes of the electron density as function of the altitude show distinct dominant types of vertical propagation of the waves in the ionosphere. The potential mechanisms linking the planetary wave activity in the mesosphere with the wave events observed in the ionosphere are discussed in order to evaluate the most likely mechanism.

IONOSPHERE – THERMOSPHERE – MESOSPHERE INCLUDING VERTICAL COUPLING 2

JSA20/L/03-A4 Invited 1400

THERMOSPHERE-IONOSPHERE-MESOSPHERE, ENERGETICS AND DYNAMICS (TIMED) MISSON

J.H. YEE (JHU/APL, Laurel, MD 20723, USA, email: jeng-hwa_yee@jhuapl.edu)

Thermosphere, ionosphere, mesosphere, energetics and dynamics (TIMED) is a NASA mission dedicated to the study of the Earth's mesosphere and lower thermosphere (60-180 km). It is also known that the global structure of this region can be perturbed during solar-terrestrial events, but the overall structure and dynamical responses of these effects are not completely understood. In order to develop and understanding of this complex region, the TIMED mission utilises well-co-ordinated measurements by both satellite-borne and ground-based instruments. Advances in remote sensing technology employed by TIMED enable us to explore this region on a global basis. An overview of the mission and its scientific objectives will b presented, followed by a description of the instruments, remote sensing techniques, and the measurements they will provide. TIMED is scheduled for launch in May 2000 into a 625 km, 72.40 inclination circular orbit. The overall plan for the collaboration with the ground-based observers and the status of its implementation will also be presented.

JSA20/W/06-A4 1425

MESOSPHERIC SOLAR ENERGY DEPOSITION RATES AS DERIVED DIRECTLY FROM AIRGLOW OBSERVATIONS

Marty MLYNCZAK (Atmospheric Sciences, NASA Langley Research Center, Hampton, VA, 23681-2199, USA, email: m.g.mlynczak@larc.nasa.gov)

A new technique has been developed to determine directly the rates of energy deposition and atmospheric heating resulting from the absorption of solar ultraviolet radiation in the mesosphere, using measurements of the molecular oxygen airglow. This approach allows the deposition and heating rates to be derived independent of knowledge of the solar irradiance, the ozone abundance, and the temperature-dependent ozone absorption cross-sections. This technique has been applied using existing measurements of the infrared atmospheric band airglow at 1.27 um made by the Solar-Mesosphere Explorer (SME) satellite. Fifty-six months of data are analyzed and presented. The derived solar heating exhibits strong variations in altitude and season, with a semi-annual oscillation in heating present near the low-latitude mesopause and annual oscillations in heating present in the lower mesosphere. Comparisons between observed and modeled rates of energy deposition and heating are also presented.

JSA20/W/19-A4 1450

INFLUENCE OF STRATOSPHERIC WARMINGS ON THE PLANETARY SCALE DISTRIBUTION OF ATOMIC OXYGEN IN THE LOWER THERMOSPHERE

Gordon SHEPHERD, Xialong Wang (both at Centre for Research in Earth and Space Science, York University, Toronto M3J 1P3, Canada, email: gordon@windii.yorku.ca)

Marked perturbations in the global scale distribution of lower thermospheric atomic oxygen are observed in the O(1S) 558 nm emission by the WINDII instrument on the UARS mission. These appear as wave 1 planetary scale perturbations, with a maximum emission rate near the longitude of maximum warming in the stratosphere, but with the lower thermospheric perturbation occurring a few days earlier. The perturbation extends from the poleward limit of WINDII observations (72 degrees) down to about 50 degrees latitude. A similar perturbation has been detected in relation to the final warming, which has been called the springtime transition; the similarities are discussed. The dynamical response of the lower thermosphere observed by WINDII is also described and discussed.

JSA20/E/13-A4 1508

A COMPARISON OF TIDAL AND QUASI-TIDAL OSCILLATIONS IN THE LOWER THERMOSPHERE AS MEASURED SIMULTANEOUSLY BY EISCAT AT LONGYEARBYEN AND TROMSO

P.J.S.WILLIAMS (Prifysgol Cymru, Aberystwyth, Wales), M.Kunitake (CRL, Hiraiso Solar Terrestrial Research Center, Ibaraki, Japan), S.C.Buchert (STELAB, University of Nagoya, Japan), Tony van Eyken (EISCAT, Longyearbyen, Svalbard)

Incoherent-scatter measurements of ion velocity, made by the EISCAT radars observing along the magnetic field line, have been used to determine the meridional component of neutral wind velocity at a number of separate heights over the range 90 km to 120 km. Frequency analysis has been used to determine the amplitude and phase of the most prominent components at each height, including those with periodicities of 24, 12 and 8 hours. Since August 1998 such measurements have been made simultaneously at both Ramfjordmoen (69.6 degrees North) and at Longyearbyen (78.2 degrees North). For each component and at each height the ratio of the amplitudes observed at the two stations have been determined, as well as the differences in phase. The results have been compared with predicted values for tidal modes in an attempt to distinguish global modes and quasi-tidal oscillations at high latitudes.

JSA20/W/30-A4 1526

COMPARATIVE STUDY OF NEUTRAL WIND AND TIDAL VARIABILITY IN THE LOWER THERMOSPHERE ABOVE U.K. AND BULGARIA

D. PANCHEVA, Pl. Mukhtarov (Geophysical Institute, Bulg. Acad. Sci., "Acad. G. Bonchev" str., bl.3, 1113 Sofia, Bulgaria); N.J.Mitchell, A.G.Beard, P.J.S.Williams (The University of Wales, Aberystwyth, Dept. of Physics, Aberystwyth, Ceredigion SY23 3BZ, UK)H.G.Muller (R.M.C.S., Cranfield University, SN6 8LA, UK)

The localised variation of power in the period range 1.5-30 days within a time series of diurnal and semidiurnal tidal amplitudes, as well as of prevailing neutral wind, measured by meteor radar in the lower thermosphere above U.K. and Bulgaria during the time interval January, 1991 - June, 1992 is investigated by a Morlet wavelet transform analysis. There is a general coincidence between the observed dominant frequencies, however because of latitudinal and longitudinal differences between the two stations their temporal courses demonstrate some differences. By a crosswavelet transform analysis the planetary waves and the time intervals when they exist simultaneously in the both studied time series are chosen. An attempt was made to estimate the wave number of the most well expressed planetary waves.

JSA20/W/12-A4 1544

THERMOSPHERIC IN-SITU TIDES VERSUS THOSE PROPAGATING UPWARDS FROM THE LOWER AND MIDDLE ATMOSPHERE.

I.C.F. MUELLER-WODARG (A.D. Aylward Atmospheric Physics Laboratory University College London, 67-73 Riding House Street, London W1P 7PP, UK)

Purpose of this study is to investigate the relative importances of tides generated in the thermosphere at high latitudes ("auroral tides") and those originating from below the mesopause. We analyze output from the Coupled Thermosphere- Ionosphere-Plasmasphere Model (CTIP) for different levels of geomagnetic and tidal forcing which suggests that the role of in-situ thermospheric tides is often underestimated at mid- to high latitudes above the E-region.

EQUATORIAL/TROPICAL COUPLING PROCESSES 1

Introduction 0900

J.M. FORBES

JSA20/W/15-A5 Invited 0905

THE SCOSTEP/EPIC PROJECT: EQUATORIAL PROCESSES INCLUDING COUPLING

Shoichiro FUKAO (Radio Atmospheric Science Center, Kyoto University, Uji, Kyoto 611-0011, JAPAN, email: fukao@kurasc.kyoto-u.ac.jp)

EPIC (Equatorial Processes Including Coupling) is one of four post-STEP programs sponsored by SCOSTEP. The equatorial region is the source of many unique atmospheric processes that couple the entire atmosphere vertically from the bottom to the top and horizontally from the equator to the poles. Despite its importance for global change, however, the equatorial atmosphere is not well studied and its coupling processes are poorly understood. The overall scientific objective of EPIC is to understand equatorial processes on all spatial and temporal scales occurring in the middle atmosphere and upper atmosphere/ionosphere, as well as their vertical coupling with atmospheric regions above and below. Coupling in the horizontal with the atmosphere/ionosphere at extratropical latitudes and between regions around the equator also needs to be studied. EPIC should become the core

program for studies of coupling processes in the equatorial atmosphere/ionosphere. Recognizing the necessity of motivating diverse science communities to work toward an interdisciplinary goal of interest, it was decided to adopt the following theme, which is related to almost all scientific questions raised to date, and can be pursued with the collaboration of all members:"Convective Processes and Influence on the Atmosphere-Ionosphere System." EPIC will operate during the period 1998-2002. It is chaired by Prof. S. Fukao in collaboration with Co-chairmen of Dr. J. M. Forbes and Dr. R. A. Vincent. A review of the project and its future perspectives will be presented.

JSA20/W/07-A5 Invited **0930**

CHARACTERISTICS OF GRAVITY WAVES GENERATED BY DEEP CONVECTION AND RELEVANCE TO MESOSPHERE DYNAMICS

M.J. ALEXANDER (Colorado Research Associates, 3380 Mitchell Lane, Boulder, CO, 80301 USA Email: alexand@colorado-research.com)

Among the possible tropospheric sources of gravity waves, convection is a source likely to generate waves with the large horizontal phase speeds that would allow them to propagate to mesospheric and thermospheric altitudes. Measurements that directly link convection and middle atmosphere waves are still only few in number, and the parameters needed to evaluate the impact of these waves on the upper atmosphere are a challenge to determine observationally. Much of what is known about convectively generated gravity waves comes from model studies. Recent relevant model and observational results will be summarized that lead to some important constraints on the properties of convectively generated gravity waves and on their global-scale effects at tropcal latitudes.

JSA20/W/01-A5 Invited **0955**

LONG-TERM STUDIES OF GRAVITY WAVE VARIABILITY IN THE EQUATORIAL MLT AND LINKS TO THE LOWER ATMOSPHERE

Robert A. VINCENT (Department of Physics and Mathematical Physics, University of Adelaide, Adelaide 5005, Australia, email: rvincent@physics.adelaide.edu.au)

One of the most difficult problems in middle atmosphere dynamics is identifying the major sources of small-scale disturbances, such as gravity waves. Eight years of MF radar wind measurements in the mesosphere/lower thermosphere made at Christmas Island are used to study gravity wave variability on both long- and short-time scales. The location of Christmas Island in the equatorial central Pacific, remote from large landmasses, makes it ideal for investigating upward coupling from convective sources. Normally Christmas Island is located in a low-convection region, but during ENSO events convection is strongly enhanced in the central Pacific. Daily measurements of outgoing longwave radiation (OLR) are used as a measure of the strength of convection in the lower atmosphere and are shown to have a significant correlation with mesospheric gravity-wave activity. The filtering effects of the intervening wind systems, such as the QBO, are shown to be important and suggest that the wave sources are anisotropic.

JSA20/W/54-A5 Invited **1020**

NON-MIGRATING TIDES: A REVIEW OF THEORETICAL BACKGROUND AND A NUMERICAL SIMULATION

Saburo MIYAHARA (Department of Earth and Planetary Science, Kyushu University, Fukuoka 821-8581 Japan, e-mail: sbm@rossby.geo.kyushu-u.ac.jp)

In the first half of this talk, Hough functions, equivalent depth, and vertical wavelength related to non-migrating tides in the atmosphere are reviewed based on the atmospheric tidal theory. It will be stressed that it is difficult to discriminate between migrating tides and non- migrating tides only by the vertical wavelength. In the second half of the talk, output data of the Middle Atmosphere Circulation Model at Kyushu University (MACMKU) are analyzed to study behavior of non-migrating tides in the MLT region. Utilizing the S-Transform method, it is shown that non-migrating tides show strong variability of amplitudes and phases than the migrating tides. Heating sources and non-linear interactions between tidal and planetary waves which can generate non-migrating tides in the model will be also discussed.

OUTSTANDING PROBLEMS IN THE ELECTRODYNAMICS OF THE EQUATORIAL IONOSPHERE-THERMOSPHERE SYSTEM

M. A. ABDU (Instituto Nacional de Pesquisas Espaciais-INPE, São Jose dos Campo, SP, 12201-970, Brazil, email: abdu@dae.inpe.br)

Dynamic coupling of the atmospheric layers involving upward energy transport coupled with the locally active thermal tidal modes establish the wind system of the thermosphere whose interaction with the magnetized conducting ionospheric layers produces the dynamo electric fields that control the quiet time electrodynamic processes of the equatorial ionosphere-thermosphere system. Their well-known major manifestations are: the equatorial electrojet curent system and its instabilities, plasma fountain and ionization anomaly with associated neutral wind and temperature anomalies, and plasma bubble irregularities. They underlie the strong electrical coupling of E and F layer processes in ways controlled by the conductivities and spatial gradients in them. The conductivity longitudinal gradients at the terminators control the sunset electrodynamics that is of fundamental importance to the problems of equatorial plasma bubble/spread-F phenoemenon. A great deal of understanding on the quiet time/average behaviour of the different EITS phenomena are now available from past investigations. Little is known regarding the causes of their day-to-day variabilities under quiet conditions, in response to magnetospheric disturbances and forcing from lower atmosphere. Recent studies have provided evidence of significant longitudinal variations believed to be caused by the longitudinally dependent geomagnetic field configurations (such as the magnetic declination angle and the south Altantic magnetic Anomaly). This paper will focus on the roles of electrodynamic processes vis-a-vis the neutral dynamics in the variabilties of the major EITS phenomena on, including those in response to magnetospheric disturbances and as a function of longitude.

EFFECT OF SPACE WEATHER RELATED PROCESSES IN THE LOW LATITUDE THERMOSPHERE IONOSPHERE SYSTEM

R. SRIDHARAN, Alok Taori, D. Chakrabarty, H. Chandra, Som kumar Sharma, R. Narayanan (Physical Research Laboratory, Ahmedabad - 380009, IDIDA.

Though the low latitude Thermosphere – Ionosphere system (TIS) is normaly shielded by the geomagnetic fields, from the highly energetic particles from the sun, electrodynamic and neutral dynamic coupling of the high and low latitude regions enables the transfer of energy and momentum to the latter. As a consequence a variety of complex processes occur in the low latitude TIS after a time delay. The effects are generally more pronounced in the thermosphere. One of the unique data set from Mt. Abu (24.6N, 73.7E) and Ahmedabad (23N, 72.6E) a pair of low latitude stations corresponding to the 6th Jan 1997 space weather event, revealed that the OI 630.0 nm dayglow intensity registered an enhancement by a factor of 2 - 2.5 on 11th Jan in the morning hours, as compared to 9th and 12th Jan i.e. one day later than the day when the auroral activities were noticed at as low as 55 N latitudes, on the day when the magnetosphere was compressed to < 6 R_E. However the Ionosphere didn't reveal any dramatic changes for the same period. Interestingly another low latitude station Kolhapur (16.8N, 74.2E), closer to the equator, revealed an opposite trend for the 630.0 nm thermospheric dayglow for another space weather event during Feb 97. Plausible explanations for such preferential behaviour of the thermospheric dayglow would be presented and discussed.

JSA20/W/41-A5 Invited **1200**

MID AND LOW LATITUDE RESPONSE OF THE THERMOSPHERE AND IONOSPHERE TO GEOMAGNETIC STORMS

Timothy FULLER-ROWELL, G. Millward, M.V. Codrescu (all at NOAA Space Environment Center and CIRES, University of Colorado, Boulder, CO 80303, USA, email: tjfr@sec.noaa.gov, gmillward@sec.noaa.gov, mcodrescu@sec.noaa.gov)

At mid-latitudes a significant fraction of the ionospheric response to geomagnetic storms can be explained by thermospheric wind and composition effects. The electrodynamic component has yet to be quantified. At low latitude the response is complicated by stronger coupling with electrodynamics. Penetration electric fields, followed by the arrival of wind surges, changes in global circulation, and subsequent composition changes, all act to alter low latitude electrodynamics. The ionosphere responds to all these processes, but the balance between them has yet to be quantified.

GEOMAGNETIC FORCING OF THE EQUATORIAL THERMOSPHERE-IONOSPHERE SYSTEM: A STUDY OF THE DISTURBANCE PERIOD 7-13 MARCH 1994

J. Hanumath SASTRI (Indian Institute of Astrophysics, Bangalore 560 034, India); V.V.Somayajulu (Space Physics Laboratory, VSSC, Trivandrum 695 022, India); K. B. Ramesh, H. N. R. Rao, J. V. S. V. Rao (Indian Institute of Astrophysics, Bangalore 560 034, India)

We present salient features of the behaviour of the thermosphere-ionosphere (TI) system in the Indian equatorial region during the prolonged disturbance period of 7-13 March 1994. A multi-experiment (FPI, ionosonde and HF Doppler radar) database is used for the study. The average nightime (1930-0430 IST) thermospheric temperature, <Tn> varied from 701 K to 914 K on individual nights of the disturbance period.There is no evidence for any persistent change in <Tn> on disturbed nights compared to quiet nights. <Tn> is nevertheless reduced on three nights (8, 11 and 13 March) corresponding to the recovery phase of Dst index. The agreement between the measured and MSIS model Tn is better on disturbed nights than on quiet nights. The nighttime pattern of meridional winds showed several interesting features which include strong surges in equatorward winds and quasi-periodic wind oscillations with a period of about 3-hr, with a corresponding feature in Tn. The F region vertical plasma drift pattern at Kodaikanal showed unambigious effects of short-lived (2-3 hrs) electric field perturbations on some of the disturbed nights. These and other results are compared with earlier work and discussed in the light of current understanding of the disturbance-time behaviour of the equatorial TI sytem.

JSA20/W/26-A5 **1425**

MODELLING STUDIES OF THE ELECTRODYNAMIC COUPLING BETWEEN THE EQUATORIAL IONOSPHERE AND THERMOSPHERE USING CTIP

G. H. MILLWARD, T.J. Fuller-Rowell (both at Space Environment Center, 325 Broadway, Boulder, CO 80303, USA. email: gmillward@sec.noaa.gov)

The CTIP (Coupled Thermosphere Ionosphere Plasmaspere) model has undergone a significant enhancement with the addition of the equations for a full electrodynamic coupling between ionosphere and thermosphere at equatorial latitudes. The new enhanced model has been used to investigate the vertical component of the resulting equatorial ionospheric ExB drift and its changes according to season, F10.7, geographic longitude, and also the effects (in separate experiments) of the forcing from lower- thermosphere tides and a large geomagnetic storm. Results from the model will be presented and compared with the latest measurements. In addition, the causative factors for the production of a 'post-sunset enhancement' of the vertical ExB drift (seen clearly in the model) will be addressed.

JSA20/W/16-A5 **1443**

ON THE VARIABILITY OF EQUATORIAL PLASMA MOTIONS

B. G. FEJER, L. Scherliess (Center for Atmospheric and Space Sciences, Utah State University, Logan, Utah 84322-4405, USA, email: bfejer@cc.usu.edu)

We use incoherent scatter radar observations from the Jicamarca Observatory to examine the variability of the equatorial plasma drifts driven by ionospheric dynamo and disturbance dynamo electric fields. The average vertical plasma drifts during the March and September equinoctial periods are significantly different for low solar flux conditions, but are nearly identical during high solar flux periods. Our measurements suggest that over Jicamarca, the transition from the southern hemisphere summer to winter takes place over a relatively short period of time (about 4 weeks). These transitional periods are characterized by very large day-to-day variability. Since, on these occasions, the F-region dynamo contributions are expected to be identical, this effect is probably due to changes in the lower thermospheric wind forcing. The vertical daytime plasma drifts show significantly larger day-to-day variability during solar minimum that near

solar maximum. Preliminary TIEGCM results suggest than this could be explained by the effect of the (2,2) semidiurnal tidal mode. Large short term variability also occurs near sunset possibly due to gravity waves and/or changes in the relative efficiencies of the E- and F-region dynamos. During disturbed conditions, the efficiency of the disturbance dynamo electric fields near sunset is strongly season and solar cycle dependent. The evening disturbance dynamo zonal electric fields drive downward plasma motions which maximize during solar maximum equinoctial conditions over Jicamarca. We will also discuss possible seasonal and solar cycle effects on the efficiency of prompt penetration zonal electric fields at the equator.

JSA20/P/01-A5 1501

MODELING OF THE PENETRATION OF HIGH-LATTITUDE ELECTRIC-FIELD TO LOW LATTITUDES FOR NON-STEADY CONDIDTION.

A.T. KOBEA (UFR SSMT/Laboratoire de Physique de l'Atmosphère. 22 B.P. 582 Abidjan 22, Côte d'Ivoire (West Africa), email: kobeat@syfed.ci.refer.org); C.Peymirat (CETP-CNRS, Centre Universitaire, 10- 12 Avenue de l'Europe, 78140 Velizy, France); A.Richmond, R. G. Roble (High Altitude Observatory, National Center for Atmospheric Research, Boulder, Co. 80307-3000, U.S.A, e-mail: richmond@hao.ucar.edu); C. Amory-Mazaudier, J. Vassal (both at CETP/CNRS, Observatoire de Saint Maur, 4, avenue de Neptune F-94107 Saint-Maur-Des-Fossés, France, email: Christine.Mazaudier@cetp.ipsl.fr); H.Lühr (Institut für Geophysik und Meteorologie der Technischen Universität Braunschweig, Mendelssohnstrabe 3, 38106 Braunschweig, Germany)

Auroral and equatorial magnetometer data are used to study a direct penetration of polar electric field at the equator. First, an observed case of apparent overshielding is modeled with the Magnetosphere-Thermosphere-Ionosphere-Electrodynamics General Circulation Model (MTIE-GCM). Although no particular attempt was made to match the model conditions to the observations, the simulated equatorial H variation is in acceptable agreement with the observed H disturbance at the equator both for the magnitude and the duration. Subsequently to that event, a quasi-periodic DP2 fluctuations (period of 30-40 min) appears coherently at the equator with an enhancement ratio of 4 compare to the magnitude at sub-auroral latitude.
The excellent correlation coefficient(O.9) between the high latitude variation and the equator can be explained as an instantaneous extension of the ionospheric current generated by magnetospheric eletric field. The mid-latitude and the equator fluctuate coherently with the afternoon vortex which seems to extend in wide latitudinal range (67º- 120º) in regard to the twin-vortex pattern resulting from the AME procedure run. The polar cap potential variation inferred from the AMIE pattern tends to lag behind the electric field at the equator whereas it tends to be advanced in phase with respect to the auroral oval field; such behavior is expected from the dynamics of the Region 2 currents which tends to shield electric field penetration across the latitude of Region 2 currents.

JSA20/W/21-A5 1519

LOW-LATITUDE IONOSPHERIC ELECTRIC FIELD INFERRED FROM ION DRIFT MEASUREMENTS OF THE ROCSAT-1 IPEI PAYLOAD

H. C. YEH, S. Y. Su (both at Institute of Space Science, National Central University, Chung-Li, Taiwan, email: yeh@jupiter.ss.ncu.edu.tw); R. A. Heelis (William B. Hanson Center for Space Sciences, The University of Texas at Dallas, Richardson, Texas, 75803, USA)

The ROCSAT-1 satellite is scheduled to launch in January 1999 with a nominal mission time of 2 years. The Ionospheric Plasma and Electrodynamics Instrument (IPEI) onboard ROCSAT-1 consists of 4 sensors to take in-situ measurements of ion density, temperature, composition and drift velocity over a large dynamic range with high sensitivity. As ROCSAT-1 is maintained in a circular orbit with an altitude of 600 kilometers, and an orbital inclination of 35 degrees, observations with global coverage in local time and longitude are available every 52-day period. Furthermore, since the IPEI payload will normally be operated with 100% duty cycle, the ROCSAT/IPEI can provide a fairly complete set of ion drift data for the low-latitude ionosphere during its mission lifetime. In this report, we analyze four months of ion velocity data from ROCSAT-1 to compile a preliminary global electric field model at 600 km altitude. The dependencies of electric field structure on latitude, longitude (and geomagnetic field configuration), local time, and geomagnetic activity are examined in detail. Electric field mappings along the realistic geomagnetic field lines are performed for the purpose of comparing ion E x B drift with conductivity-weighted neutral wind at various altitudes along the magnetic flux tubes covered by the ROCSAT orbits. As the IPEI data are accumulated the electric field model will be improved and contribute more to studies of thermosphere-ionosphere coupling at low latitudes.

E-REGION IONOSPHERIC TOMOGRAPHY

L. KERSLEY (Department of Physics, University of Wales, Aberystwyth SY23 3BZ, UK, e-mail: lek@aber.ac.uk)

Radio tomography has matured into an established experimental technique for imaging the spatial structure of ionospheric electron density. The method uses observations recorded at a chain of receiving stations of total electron content, measured by means of radio transmissions from a satellite in low Earth orbit. The resultant data set is then inverted in a reconstruction algorithm to create an image in two dimensions of the plasma density. The bulk of the ionospheric plasma is concentrated in the F-layer and radio tomographic techniques are now well established for the imaging of F-region features. However, at high latitudes precipitation of energetic particles may result in 'auroral-E' ionisation that can make a significant contribution to the total content. With appropriate selection of the reconstruction process the structuring of this E-layer plasma can be imaged, thus providing spatial information about features in the electron density that complement results from other experimental techniques. The paper reports experimental work directed towards the imaging of the ionosphere at high latitudes, where the validity of the technique has been verified by means of independent measurements from the EISCAT and ESR incoherent scatter radars. Observations made at a chain of stations (Ny Ålesund, Longyearbyen, Björnöya and Tromsö) in the European Arctic have been used to investigate features in the cusp, polar cap and auroral ionospheres. Results are presented in which 'auroral-E' ionisation imaged by tomography is related to both optical observations and satellite measurements of precipitating particles.

JSA20/W/49-A6 0930

DETERMINATION OF E-REGION CONDUCTIVITY FROM FAR ULTRAVIOLET IMAGES

Larry J. PAXTON (email: larry.paxton@jhuapl.edu); Daniel Morrison (email: daniel.morrison@jhuapl.edu); Gerald J. Romick (email: Gerald.Romick@jhuapl.edu); Ching I. Meng (email: ching.meng@jhuapl.edu) (all at The Johns Hopkins University Applied Physics Laboratory 11100 Johns Hopkins Rd., Laurel, MD 20723, USA); Douglas J. Strickland (email: strick@euler.cpi.com); Scott Evans (email: evans@euler.cpi.com) (both at Computational Physics, Inc. 2750 Prosperity Ave Ste 600, Fairfax, VA 22031, USA)

United States High latitude inputs to the coupled thermosphere- ionosphere system are important factors in determining the response of the atmosphere at low and mid- latitudes as well as at high latitudes. Local heating by particle precipitation and Joule heating are two of the major high latitude influences on the neutral atmosphere composition. Imaging in the Far Ultraviolet (110 to 180 nm) is commonly used to provide estimates of the magnitude of these inputs. The measurements are inherently a column-integrated one since the observed radiance represents the integral of the altitude dependent source and transmission functions. To first order, observations in two wavelength regions (one wavelength interval or "color" where atmospheric optical absorption is important and one "color" where it is not) are required in order to provide some information on the precipitating particles's energy distribution and the magnitude of the flux of those particles. Broadband or single "color" imagery can yield some information on the magnitude of the incoming flux but can not provide much quantitative information. Furthermore, the choice of a single color must be considered very carefully: for example, the relatively bright OI 130.4 nm emission feature will show reduced spatial structure due to multiple scattering effects. In this paper we discuss how accurately the ionization rate profile in the E-region can be deduced using multiple "colors" (i.e. simultaneous measurements of OI 135.6, LBH short (140 to 150 nm), and LBH long (165 to 180 nm)) and the role of proton precipitation (seen using HI 121.6 nm) as a source of additional ambiguity. From the ionization rate profile, a time dependent electron density profile can be calculated. The Hall and Pedersen conductivities couple the neutral atmosphere to these calculations through collisional terms. Assumptions about the distribution function (i.e. Maxwellian or Gaussian) of the precipitating electrons or neglecting to allow for the presence of precipitating protons leads to uncertainties of a factor of two in the height-integrated conductivity and larger errors in the altitude distribution. We will discuss the implications of modeled and observed changes in the neutral atmosphere on the estimated conductivity profile.

JSA20/W/40-A6 Invited 0948

GLOBAL JOULE HEATING AND THE THERMOSPHERE-IONOSPHERE RESPONSE

G. CROWLEY (Southwest Research Institute, San Antonio, TX, USA; email: crowley@picard.space.swri.edu); C. Fesen, O.Kivanc (UT Dallas, Richardson, TX, USA); T. Immel, A. Ridley (Southwest Research Institute, San Antonio, TX, USA); R.G. Roble, A.D. Richmond, B.A. Emery (HAO-NCAR, Boulder, CO, USA); D.J. Knipp (US Air Force Academy, Colorado Springs, CO, USA)

Joule heating is a key element of thermosphere-ionosphere-magnetosphere coupling. At high latitudes, the local Joule heat input can exceed the daytime solar input. Joule heating provides more than 10 percent of the global average energy input to the thermosphere, and plays major role in determining the global temperature, wind, density and compositional structure of the thermosphere. This in turn drives the global structure of the ionosphere. Currently our knowledge of Joule heating at both a particular location and globally is uncertain by factors of 2 to 10. Numerical experiments illustrating the effect of these uncertainties on the global atmospheric structure will be discussed. Both quiet and storm conditions were simulated using the NCAR TIE-GCM. Dramatic differences result from only factors of 2 changes in the Joule heat inputs. For space weather modelling, these results illustrate the importance of accurately defining the high latitude inputs, and of fully coupling the ionosphere and thermosphere. Comparison of the Joule heating computed by the TIEGCM and AMIE versus ground- based and space-based measurements reveals some of the problems which need to be addressed in the specification of Joule heating and magnetosphere- ionosphere-thermosphere coupling.

JSA20/W/53-A6 1013

DETECTION OF GEOMAGNETIC STORM EFFECTS ON LOWER THERMOSPHERIC WINDS AT MIDLATITUDES

Joseph E. SALAH (Haystack Observatory, Massachusetts Institute of Technology, Westford, MA 01886 USA, email: jsalah@haystack.mit.edu); Larisa Goncharenko (Haystack Observatory, Massachusetts Institute of Technology, Westford, MA 01886 USA, email: lgoncharenko@haystack.mit.edu)

Several sets of observations of neutral winds in the lower thermosphere have been obtained by the Millstone Hill incoherent scatter radar (42.6N, 71.5W) during geomagnetic storms of different intensity. The reliable detection of the storm effects on midlatitude winds in the altitude region 100-130 km is difficult, and a search for such effects during the CEDAR/LTCS campaigns over the past ten years does not reveal strong evidence for a response to the storm at these altitudes until the intensity of the storm exceeds a Kp of 6 and is long lasting. Observations made during two campaigns, June 1991 and September 1998, where the disturbances were intense, illustrate this conclusion. The primary finding is that the effects are best seen in the zonal wind component with enhanced westward motions during the most intense storm in June 1991. Evidence of flywheeling of the winds in the lower thermosphere on the day following the end of the geomagnetic storm is seen, as predicted by some general circulation models. Opportunities for collecting additional observations to investigate this important topic are planned and will be discussed.

JSA20/W/17-A6 1031

LATITUDINAL AND GEOMAGNETIC ACTIVITY VARIATIONS IN LOWER THERMOSPHERIC NEUTRAL WINDS OBSERVED OVER SONDRE STROMFJORD AND MILLSTONE HILL

R. M. JOHNSON, S. M. I. Azeem (both at Space Physics Research Laboratory, The University of Michigan, 2455 Hayward, Ann Arbor, MI 48109, USA, Email: rmjohnsn@umich.edu); L. P. Goncharenko, J. E. Salah (both at Haystack Observatory, Massachusetts Institute of Technology, USA)

Neutral winds deduced from measurements obtained during Lower Thermospheric Coupling Study (LTCS) campaigns at two incoherent scatter radar (ISR) sites, Sondre Stromfjord in Greenland and Millstone Hill in U.S.A, are compared in the light of model results to examine the latitudinal variation of lower thermospheric semidiurnal oscillations. Both Sondre

Stromfjord and Millstone Hill observations indicate large variability in the tidal oscillations during winter whereas the results obtained during summer LTCS campaigns show more consistent amplitude and phase structure. Average seasonal amplitude and phase structures obtained from the radar measurements are compared with model predictions of expected semidiurnal amplitude and phase profiles at the two different latitudes of the radars. The effects of geomagnetic activity on the semidiurnal tidal oscillations are assessed and compared with model predictions and previous results.

JSA20/E/18-A6 1118

THERMOSPHERIC AND IONOSPHERIC DYNAMICS IN THE AURORAL REGION

Hiroyuki SHINAGAWA, Shin'ichiro Oyama, Satonori Nozawa, Ryoichi Fujii (Solar-Terrestrial Environment Laboratory, Nagoya University, Toyokawa 442-8507, Japan,
email: sinagawa@stelab.nagoya-u.ac.jp); Mamoru Ishii (Communications Research Laboratory, Tokyo 184-8795, Japan, email: mishii@crl.go.jp)

Dynamics of the thermosphere and the ionosphere in the auroral region is quite complicated. There have been a number of reports on strong vertical neutral winds mainly in the auroral region. The magnitude of the vertical winds sometimes exceeds 100 m/s, suggesting that particle precipitation heating as well as Joule heating could cause extremely large upwelling and downwelling of the thermosphere. Behavior of the ionosphere associated with strong neutral winds also appears to be complex. Although such small-scale variation is likely be confined in the auroral region, those events are expected to produce equatorward propagating gravity waves. It is also possible that such small-scale phenomena influence the global structure and dynamics of the thermosphere-ionosphere system. Two- and three-dimensional non-hydrostatic thermosphere-ionosphere models are used to investigate small-scale variation of the thermosphere and the ionosphere associated with local auroral activities. The results are compared with neutral and ion velocities measured by Fabry-Perot Interferometers and the EISCAT radar. In this paper, emphasis is placed on coupling of the thermosphere and the ionosphere in the auroral region. Interaction processes between the global wind system and the locally generated winds are also discussed.

JSA20/E/04-A6 1136

THERMOSPHERIC WIND FIELD OVER MAWSON AND DAVIS, ANTARCTICA; SIMULTANEOUS OBSERVATIONS BY TWO FABRY-PEROT SPECTROMETERS OF L630 NM EMISSION

P.A. GREET (1), M.G. Conde (2), P.L. Dyson (3), J.L. Innis (1), A.M. Breed (1), D.J. Murphy (1) ((1) Australian Antarctic Division, Channel Highway, Kingston, Tas. 7050, Australia. (2) Geophysical Institute, University of Alaska, Fairbanks, USA. (3) Department of Physics, La Trobe University, Bundoora, Vic. 3083, Australia)

The themospheric oxygen l630 nm emission has been observed using high-resolution Fabry-Perot spectrometers at Mawson (67.6°S 62.9°E) and Davis (68.6°S 78.0°E), Antarctica. A new technique, combining the results from the two instruments, is used to derive vector wind fields. The technique is described and applied to five nights of simultaneous cardinal point data obtained in 1997. Solar flux was low during this interval, typically F10.7 = 75. Of the five nights two were magnetically disturbed and three were quiet. The disturbed nights were compared to a TIEGCM model run and reasonable agreement was found in the first half of the night. On one of the disturbed nights a closed evening circulation cell and cross-polar jet could be identified in our data. On none of the nights was a morning circulation cell evident. Auroral imager data were used to locate the auroral oval. For several hours around magnetic midnight the auroral oval produces a doldrums in the thermospheric winds. Auroral doldrums are not described by the model. Auroral doldrums are also seen on the quiet nights which otherwise maintain approximately antisunward flow

JSA20/E/17-A6 1154

A LARGE VERTICAL WIND IN THE THERMOSPHERE AT THE AURORAL OVAL/POLAR CAP BOUNDARY SEEN SIMULTANEOUSLY FROM MAWSON AND DAVIS, ANTARCTICA.

J.L. Innis (1), P.A. GREET (1), D.J. Murphy (1), M. Conde (2), P.L. Dyson (3) ((1) Australian Antarctic Division, Channel Highway, Kingston, Tas., 7050, Australia. (2) Geophysical Institute, University of Alaska, Fairbanks, Alaska, USA. (3) Department of Physics, La~Trobe University, Bundoora Campus,Vic., 3083, Australia)

Ground-based Fabry-Perot spectrometer observations from the Australian Antarctic stations of Davis and Mawson show an upward wind >= 100 ms in the thermosphere at ~240 km altitude on the night of Day of Year 159 in 1997. The wind was from a region located to the poleward of the poleward edge of the discrete auroral oval, and is identified as a further event of the type seen at Mawson, and elsewhere, in earlier work. The upward wind was first seen over Davis station at ~22 UT. As the auroral oval moved northward the region of upward wind followed, and was seen at Mawson (some 5 degrees magnetically north of Davis) just over 1 hour later. It is shown that the presence of the large upward wind does, at times, affect the derived horizontal wind. Correcting the affected measurements for the non-zero upward wind leads to a much smoother (less divergent) horizontal wind field. The area of the region of upward wind over Mawson and Davis on this night is estimated as ~6 x 10^-11 m^2. The estimated power required to drive the upward wind over this area at 240 km altitude is of order 6 x 10^9 W. This represents a significant fraction of the power input at high-latitudes during quiet geomagnetic conditions.

JSA20/E/02-A6 1212

A STUDY OF THE STRONG MAGNETIC STORMS BY THE CLUSTER ANALYSIS

Pavlina K. IVANOVA (Geophysical Institute Bulg. Acad. Sci., Akad. G. Bonchev str., bl.3 Sofia 1113, Bulgaria, email: pivanova@geophys.bas.bg)

The problem of the Solar-Terestrial interactions is presented in the folowing manner: to find the interplanetary medium parameters, which determine Geomagnetic activity (GA) and to work out an algorith for the Geomagnetosphere storm (GMS) prediction. The GMS causal dependences on the processes running in the interplanetary environment are included in the present analysis of the problem. We should cnsider the Dst-variations of the geomagnetic field as the accumulation of a great number of disturbences which reflect different in time and space operating processes. The magnetic storms, which have occurred in 1978-1979, have been analysed, i.e. close to the maximum of the 19th cycle of solar activity. First the =D3outer environment where the storm occur has been analysed. The results obtained indicate the conditions under which it occurs. After that the main phase is considered and finally the recovery phase. The clusters obtained show not only the inner structure of the investigated SSC but also the change the functional connections between the different studied parameters participating in the SSC.

JSA20/W/52-A4 Poster 1200-01

THE THEORY OF MID-LATITUDE IONOSPHERIC LONG-PERIOD VIBRATIONS

Khantadze, Anzor GVELESIANI, Z. Kobaladze, Z. Ioseliani (Tbilisi State University, 1., Chavchavadze Ave., Tbilisi 380028, Georgia Institute of Geophysics, Georgian Academy of Sciences, 1., M. Alexidze Str., Tbilisi 380093, Georgia, email: vazha@excite.com)

Numerous ionospheric observations of mid-latitude long-period vibrations travelling horizontally allow to separate: a) background vibrations at quiet and moderate geomagnetic disturbances and b) separate splashes of magnetic storms, earthquakes and artificial explosions. The linear theory of these observations is suggested when Rayleigh and ion frictions are taken into account. From the dispersion relation are obtained two types of waves: a) slow Rossby's waves travelling to the West caused both by anisotropy of Coriolis force and geomagnetic field; b) fast planetary waves, caused only by the gradient of geomagnetic field travelling both to the East and to the West. The values of the velocities of the latter waves are more on the night side than on the day side. Parameters of these waves are in good agreement with the parameters of mid-latitude ionospheric long-period vibrations and may be attributed to the background vibrations, caused by the gradient of geomagnetic field. It is shown identity of these waves with drift waves in an inhomogeneuos magnetoactive plasma.

JSA20/W/04-A4 Poster 1200-02

A NEW COUPLED MESOSPHERE / THERMOSPHERE MODEL

M. J. HARRIS(1), A. D. Aylward(1), N. F. Arnold(2), (1) : Atmospheric Physics Laboratory, University College London; (2) : Radio and Space Science Group, University of Leicester.

The upper mesosphere / lower thermosphere is an important transition region in the coupling of the upper and middle atmospheres. In order to help study the dynamics and energetics of this system, a 3-D time dependant Coupled Mesosphere and Thermosphere model (CMAT) has been developed, extending and updating the existing thermospheric code to incorporate mesospheric dynamics, energetics and chemistry. Some general output and a preliminary study of minor constituent response to tidal forcing will be presented.

JSA20/W/39-A4 Poster 1200-03

SIMULATION OF LARGE-SCALE DYNAMICS IN THE MESOSPHERE AND LOWER THERMOSPHERE WITH THE DOPPLER-SPREAD PARAMETERIZATION OF GRAVITY WAVES

R. A. AKMAEV (Department of Aerospace Engineering Sciences, CB-429, University of Colorado, Boulder, CO 80309-0429, USA, email: akmaev@spb.colorado.edu)

The Doppler-spread parameterization of gravity wave (GW) spectra developed by C. O. Hines has been implemented into the Spectral Mesosphere/Lower Thermosphere Model. Special attention has been devoted to different ways of parameterization of eddy mixing associated with saturation and breaking of gravity waves in the mesosphere and lower thermosphere (MLT). Simulations for solstice and equinox conditions have been conducted. The role of gravity-wave imposed drag and mixing in maintaining the global-scale dynamics and structure in the MLT and their seasonal variations is discussed. The modeling results are compared with simulations using a different ("Lindzen type") GW parameterization and with empirical models and observations.

FIRST E-REGION OBSERVATIONS OF TIDES IN THE LOWER THERMOSPHERE USING THE EISCAT SVALBARD RADAR

P.J.S.WILLIAMS (Prifysgol Cymru, Aberystwyth, Wales), M.Kunitake (CRL, Hiraiso Solar Terrestrial Research Center, Ibaraki, Japan), S.C.Buchert (STELAB, University of Nagoya, Japan), Tony van Eyken (EISCAT, Longyearbyen, Svalbard)

The EISCAT Svalbard Radar made the first E-region measurements free of ground clutter in August 1998 with three days of observation with the radar pointing along the magnetic field line. This was followed by a two-day run of the common programme CP1 and a one-day run of the UK/Japan Special Programme TIDE. An analysis of the periodic components of field-aligned ion velocity provided the amplitude and phase of the meridional tides at 78 degrees North at heights between 93 and 120 km. The dominant oscillations at most heights show periods of 24, 12 and 8 hours, with height profiles of amplitude- and phase very similar to those of the corresponding tidal modes observed at lower latitudes. In addition, at heights below 100 km there is a prominent 10-hour oscillation similar to that observed near the South Pole. At the lowest heights there is also evidence of a planetary wave with periodicity between 2 and 3 days. Over the same period the amplitude of the semidiurnal tide shows a strong day-to-day variation, compatible with modulation at a period of 2-3 days.

A '30 DAY' OSCILLATION IN THE MLT WINDS: OBSERVATIONS IN EUROPE, JAPAN AND CANADA

Y. LUO, H.H. Monson, C.E. Meek (Institute of Space and Atmospheric Studies, Univeristy of Saskatchewan, Saskatoon, Canada, email: luo@dansas.usask.ca); K. Igarashi (Communications Research Lab., Tokyo, Japan); Ch. Jacobi (Institute for Meteorology, University of Leipzig, Leipzig, Germany)

A long period oscillation has been identified in the winds observed by radars (MF, LF) in the northern hemisphere. Although initially thought to be anormal mode planetary wave, spectral analysis at three sites (Sasktoon 107W, 52N; Collm 15E, 52N; Yamagawa 130E, 31N) has shown that the oscillation is a common feature of the winter atmosphere, and has strong amplitudes throughout the mesosphere (~10m/s) and lower thermosphere (~5m/s). The phase variations at the various sites are similar, and not consistent with a freely propagating wave. Comparisons with geomagnetic and solar wind parameters suggest that the oscillation is related to solar activity and the solar rotation period. Forcing mechanisms are discussed.

SPRINGTIME TRANSITION IN UPPER MESOSPHERE TEMPERATURE

Marianna SHEPHERD, Gordon Shepherd, Shengpan Zhang, Boedijanti Prawirosoehardjo (Centre for Research in Earth and Space Science, York University, 4700 Keele Street, Toronto, Ontario, Canada, M3J1P3, Email: marianna@windii.yorku.ca.), Patrick Espy (Department of Physical Sciences, Embry-Riddle Aeronautical University, Daytona Beach, FL, USA, Email: espyp@db.erau.edu)

Observations from the wind imaging interferometer (WINDII) on the upper atmosphere research satellite and three optical ground stations have revealed a 'springtime transition' in atomic oxygen. The transition is characterized by a rapid 2-day rise in the night-time oxygen nightglow emission rate by a factor of 2 to 3 followed by a subsequent decrease by a factor of 10 in the same period of time indicating a depletion of atomic oxygen that persists for days. The current study examines signatures in the upper mesosphere temperature field (70-95 km height), derived from the WINDII Rayleigh scattering observations, that are possibly associated with the springtime depletion of the atomic oxygen. Comparisons with ground-based airglow rotational temperatures and optical emissions are presented and discussed. Data from the northern springtimes of 1992 and 1993 are reported upon in detail.

SPATIOTEMPORAL DETAIL IN METEOR WINDS FROM HALLEY, ANTARCTICA

Martin JARVIS (British Antarctic Survey, Madingley Road, Cambridge, CB3 0ET, UK)

Meteor echoes have been extracted from SuperDARN HF radar data from Halley, Antarctica (76xS, 27xW) to produce an archive going back 10 years from which meteor winds can be derived. Although the SuperDARN radars provide no meteor height discrimination they have the unique advantage that their fan-like array of 16 beams gives spatial information on the derived mesospheric wind field. Examples of these wind fields are presented and, having removed the dominating semidiurnal and diurnal tides, the remaining wave signatures and intraseasonal variatons are discussed.

THE VARIABILITY IN THE AIRGLOW INDUCED BY THE VERTICAL MOTION ASSOCIATED WITH TIDES.

Tai-Yin HUANG (CRESS, York University, 4700 Keele St., North York, Ontario, M3J 1P3, Canada. Email: taiyin@stpl.cress.yorku.ca)

Varibility in the airglow was often observed and yet its origin is still not fully understood. Various studies suggest that the varibility might be induced by the vertical motion associated with tides. Green line volume emission rate data at 5577 A and meridional winds measured around fall equinox 1995 by the Wind Imaging Interferometer (WINDII) on the Upper Atmosphere Research Satellite (UARS) were analyzed. Atomic oxygen mixing ratio was derived from the volume emission rate using MSIS-90 model as the background atmosphere. Green line volume emission rate has a cubic dependence on the concentration of the atomic oxygen, thus any variation in the concentration will be amplified in the variations in the volume emission rate. Tidal amplitudes, phases and the background fields were derived using the least mean squared fitting method. Our studies show that the variations in the mixing ratio are consistent with the vertical motion associated with tides.

AN INVESTIGATION OF THE UPPER ATMOSPHERIC OPTICAI RADIATION IN THE LINE OF ATOMIC OXYGEN 557.7 NM IN EAST SIBERIA

A.V.Mikhalev, I.V.Medvedeva, A.B.Beletsky, E.S.KAZIMIROVSKY (Institute of Solar-Terrestrial, Russian Academy of Sciences, P.O.Box 4026, 664033, Irkutsk, Russia, email: mikhalev@iszf.irk.ru)

The results of photometer observations of the Earth's upper atmopsheric radiation in the line of atomic oxygen 557.7 nm that were conducted in East Siberia (52N, 103E) during 1997-1998 within the PSMOS program are presented. The seasonal and diurnal dependencies for this emission are discussed. Anomalously high values of 557.7 nm emission are recorded in the winter months (end of January - beginning of February) of 1998, which are likely to be associated with the stratospheric warming observed in the East-Siberian region during this period.

WINDS AND TEMPERATURES AROUND THE SPORADIC SODIUM LAYERS OBSERVED WITH THE MU RADAR AND SODIUM LIDARS

T. NAKAMURA, H. Miyagawa, T. Tsuda (Radio Atmospheric Science Center, Kyoto University, Uji, Kyoto 611-0011, JAPAN, e-mail: nakamura@kurasc.kyoto-u.ac.jp); M. Abo, C. Nagasawa (Graduate School of Electrical Engineering, Tokyo Metropolitan University, Hachioji, Tokyo, Japan); T. D. Kawahara, K. Kobayashi, T. Kitahara, and A. Nomura (Faculty of Engineering, Shinshu University, Nagano, Japan)

Simultaneous observation of mesopause region have been carried out with the MU radar at Shigaraki(34.9N, 136.1E) and two Na lidars in Shigaraki and in Hachioji(35.6N, 139.4E). From lidar data, 15 events of sporadic sodium layer (Nas) were detected. Dynamical parameters, such as wind shears, temperatures, and indices for stability, at around the time and height of Nas have been observed by the MU radar. There are some cases indicating the strong westward shear or temperature enhancement accompanied Nas events, as reported by previous studies, but the statistical study for the all 15 events suggested that strong total wind shear correlates well with the Nas occurred at Shigaraki and Hachioji (mid-low latitudes) but no other clear correlations are found, which is similar to the study from the lidar observations in Hawaii (22N) during ALOHA-93 campaign.

CONSTITUENT OBSERVATIONS IN THE PRESENCE OF LARGE SCALE VERTICAL MOTIONS.

William E. WARD (CRESS/CRESTech, York University, Toronto, Canada)

In the mesosphere and lower thermosphere significant vertical motions occur as the result of the large amplitude tides and planetary waves present at these heights. In addition, the mixing ratio profiles of a number of constituents have significant gradients with height. These two aspects of this region result in significant variations in the concentration of these constituents at a given height. As a result interpretation of constituent observations must be made with care taking into account the variations associated with these motions. In this paper, the effects of these motions will be described and a strategy for correctly interpreting constituent observations at these heights outlined. These considerations are particularly important for the interpretation of the atomic oxygen distribution and its associated airglow in the mesopause region because of the strong vertical gradient in the atomic oxygen mixing ratio between 80 and 100 km.

SOLAR WIND INDUCED PERTURBATIONS IN THE METEOR REGION AS DETERMINED BY SPECTRAL WIDTH VARIATIONS IN THE SUPERDARN HF RADARS

Neil ARNOLD, Terry Robinson, Mark Lester, Paul Byrne and Peter Chapman (all at Department of Physics and Astronomy, University of Leicester, Leicester, LE1 7RH, UK, email: nfa1@ion.le.ac.uk)

Near range echoes from meteors in the SuperDARN oblique HF radar network allow the Doppler shift of the neutral winds to be measured near the mesopause. Information about the spectral width of the echoes is used to infer the mean altitude of the neutral wind layer as it is related to the ambi-polar diffusion coefficient. We show that the spectral width, and hence the observed height of the meteor region, is sensitive to a number of parameters such as operating frequency, zenith angle and season. A correction parameter is needed to provide long-term wind measurements at a constant height or pressure. In addition, the mean spectral width has been found to increase significantly during an interval of high geomagnetic activity. The data was consistent with modelled temperature variations in the upper mesosphere and lower thermosphere region. The technique is thus of value in monitoring the response of the atmosphere to changes in the solar wind at a number of Arctic and Antartic stations.

SEPARATING NON-PROPAGATING FROM FRONTAL THERMOSPHERE GRAVITY WAVES

Th. Farges (LDG/DASE CEB3, France), J.P. Villain (LPCE Orleans,France), A. Bourdillon (Univ. de Rennes, France), P. VILA, (CETP/CNRS, St Maur des Fosses, France)

A re-activated Y-shaped bistatic network around Francourville (with 150 km reflection distance from the central transmitter and with zenithal probing) should contribute (from early 1999 on) to a discrimination of high latitude traveling disturbances against the ionospheric gravity wave activity generated in the local mesosphere below. High latitude sources can be composites of auroral electric and thermodynamic disturbances (K.D. Cole, 1996) with obvious DP1 origin, but also "quiet activity" source couplings (which can include large-scale stratowarm post-storm effects and local stratosphere jet-streams). Among the coupling processes, the disturbance dynamo and its fronts traveling to equatorial latitudes is of major concern for ionospherists. On the basis of recent Windii anf Hrdi average variations we also extract some particular European and Afro-Atlantic Windii data. The major solar eclipse of 11 August 1999 must provide a free special disturbance of all-levels supersonic shocks that should help testing :i)a twin dynamo and near-total sunset and sunrise noontime front, ii)the E-F near-simultaneous electric field coupling with unstable distribution above new layers, iii) the two lateral (lower midlatitude and higher latitude) "bow"-wave fronts of mesospheric origin. The perfectly defined scale and timing of the eclipse perturbation will be a great advantage for discrimi- nating among these various contributions.

THE INFLUENCE OF ION COMPOSITION ON THE SPECTRUM OF PLASMA IRREGULARITIES INDUCED BY NEUTRAL TURBULENCE IN THE MID-LATITUDE SPORADIC-E LAYER

Yurij KYZYUROV (Main Astronomical Observatory NASU, Kiev, 252650, Ukraine, email: kyzyurov@mao.kiev.ua)

In the present report an analytic expression describing the spectrum of plasma density fluctuations generated by neutral air turbulence in the mid-latitude sporadic-E layer is discussed for the cases of different ion composition of the layer. The expression was derived from the system of 3-fluid equations taking into account processes of diffusion and recombination, in assumption that plasma density is a passive scalar field and turbulence of neutral gas is a Kolmogorov type one. The analysis of the irregularity spectrum under different values of the recombination coefficient shows that the presence of slowly recombinig ions in the sporadic-E increases the slope of spectrum and the rms level of plasma density fluctuations created by atmosphere turbulence.

HORIZONTAL SHEAR FLOW AS A REASON OF FORMATION OF LARGE SCALE TIDS WITH SMALL PERIODS

Goderdzi DIDEBULIDZE, Stephan Chilingarashvili, Avtandil Pataraya (Town Department of Abastumani Astrophysical Observatory, A.Kazbegi ave.2a, 380060 Tbilisi, Georgia, email: gocha@dtapha.kheta.ge)

The ambipolar diffusion equation for the height distribution of electron density at the ionosphere F2-layer is solved by presence of neutral horizontal shear flow. By using this nonstationary solution the reaction of F2-region electron density on the evolution of atmospheric gravity waves (AGW) is investigated. The evolution of the AGW and the corresponding behavior of the height distribution of the F2-region electron density are described by characteristic time, ta, of transient development of shear waves in horizontal shear flow. For great times t>ta the gravity wave frequency tends to the isothermal Brunt-Vaisala frequency, which appears in the F2-layer by wavelike behavior of hmF2 and NmF2 with periods close to 16-20min, when the scale height of the neutral gas is H=60km. The shear wave which is due to the presence of horizontal shear flow, gives sufficient changes of the height profile of electron density for times of t< ta. The intensity of mid-latitude F-region oxygen red line OI 630.0nm emission as an indicator of the propagation of the large scale TIDs with periods of 16-20min at magnetic disturbed days is used.

INVESTIGATION OF THE NATURAL VARIABILITY IN EXOSPHERIC HYDROGEN EMISSIONS

S. NOSSAL, F.L. Roesler (Both At Department Of Physics, University of Wisconsin, 1150 University Ave., Madison, WI 53706, USA, email: nossal@wisp5.physics.wisc.edu, roesler@wisp.physics.wisc.edu), J. Bishop (Computational Physics Inc., 2750 Prosperity Avenue, Suite 600, Fairfax, VA 22031, USA, email: jbishop@euler.cpi.com), R.J. Reynolds (Astronomy Department, University of Wisconsin, 475 N. Charter St., Madison, WI 53706, USA, email: reynolds@fosters.astro.wisc.edu)

The Wisconsin H-alpha Mapper (WHAM) is a ground-based Fabry-Perot instrument which has been making extensive high resolution observations of exospheric hydrogen Balmer-alpha emission intensities over the past two years. WHAM is remotely operable and is located at the Kitt Peak Observatory near Tucson, Arizona to take advantage of its high altitude and clear sky conditions. The majority of the WHAM exospheric data are the terrestrial byproduct of WHAM observations being taken to make an all-sky map of the interstellar medium hydrogen Balmer-

alpha emission. We have been using the exospheric Balmer-alpha component, present in all of the interstellar Balmer-alpha data, to systematically investigate the natural variability in these emissions over differing solar-geophysical conditions and a wide range of viewing geometries. We are now using these data to test exospheric model predictions. A long term goal of the WHAM and similar measurements is to use them to aid in separating natural variability from anthropogenic perturbations to the Balmer-alpha emissions. Exospheric hydrogen densities are predicted to increase by about 30-50% with a doubling in the tropospheric concentration of methane. We are carefully calibrating the WHAM data and are studying small scale effects on the data so as to make the WHAM data set a resource for future long term climatic comparisons.Interpretation of the exospheric Balmer-alpha emission data is complicated by the fact that the intensity which we observe is a function of both the exospheric hydrogen density structure and the magnitude of the solar excitation flux. We have begun using the lyao_rt radiative transport model developed by one of us (JB) to untangle these dependencies in the data. At low shadow heights (below 1000 km), photoelectron impact excitation of Balmer-alpha is also important.In this presentation we will compare WHAM exospheric Balmer-alpha emission data with predictions from the lyao_rt model incorporating the contributions from photoelectron impact. We vary the solar-geophysical inputs and the MSIS90 thermospheric boundary conditions through a range of geophysically reasonable values to explore their effect on the fits to the data. The signal-to-noise of the WHAM observations is sufficient to distinguish goodness of fit between model scenarios using different geophysical parameters as inputs. Also included in this presentation will be a brief overview of the WHAM exospheric observational and analysis program as well as the Fabry-Perot annular summing technique used to acquire the data.

GEOMAGNETIC VARIATIONS CAUSED BY QUASI-TWO-DAY WAVE OF THE NEUTRAL WIND IN THE LOWER THERMOSPHERE

Manabu KUNITAKE (Hiraiso Solar Terrestrial Research Center, Isozaki, 3601, Hitachinaka, Ibaraki, 311-1202, Japan, Email: kunitake@crl.go.jp); Hiroshi Tachihara and Kiyohumi.Yumoto (both at Department of Earth and Planetary Science, Kyushu University 33, 6-10-1, Hakozaki, Fukuoka, 812-0053, Japan, email: tachi@geo.kyushu-u.ac.jp, yumoto@geo.kyushu-u.ac.jp)

Quasi-Two-Day (QTD) geomagnetic variations can be seen in globally for January, 1993. In the interval, the neutral wind in the lower thermosphere has a large activity of the Quasi-Two-Day wave. The hypothesis that the geomagnetic variations are driven by the themospheric wind is examined by comparison between the characteristics of the wind variations and those of geomagnetic variations. Three components at 20 ground stations were analyzed.
(1)The major component is Y(EW) near the equator region, contrasting to that the major is X(NS) or Z(vertical) in the low and middle latitudes. (2) The geomagnetic variation in the low latitude regions in the southern hemisphere shows some phase shifting along longitudes systematically. East squares fitting to the phase distribution results in that the zonal wave number of the variation is about three. These characteristics are consistent with the characteristics of neutral wind variation.
(3) In the western pacific longitudinal zone, the phase comparison of X(NS) component of the geomagnetic variation between hemispheres shows that the variation is not out-of-phase but in-phase. After comparing it with the wind pattern, it means that the interhemispheric coupling through geomagnetic field lines which connect both hemispheres should be taken into consideration in this case.

BEHAVIOUR OF SUBAURORAL LOWER THERMOSPHERE AND MESOPAUSE TEMPERATURE DURING POLAR STRATOSPHERE WINTER STRONG WARMINGS

S. V. NIKOLASHKIN, V. M. Ignatyev, V. A. Yugov, V. N. Alexeyev (Institute of Cosmophysical Research and Aeronomy. 31, Lenin ave., Yakutsk, 677891, Russia,
email: s.v.nikolashkin@sci.yakutia.ru)

The relationship between temperatures of stratosphere (~24 km), mesosphere (~87 km) and lower thermosphere (~97 km) on data of the Fabry-Perot interferometer temperature measurements in night atmosphere by thermal broadening of OI 557.7 nm emission in 1979--1991, and spectrograph data on intensity distribution of rotational structure of the band OH(6.1) in 1965--1970 near Yakutsk (62N, 129.7E) is studied.
It is showed that in a few days after beginning of the moment of winter strong (major) warming peak in the polar stratosphere is observed the temperature decreasing in a subauroral mesopause and lower thermosphere. The intensity and the time of beginning of these atmosphere layers cooling depends on warming magnitude in stratosphere.
The obtained result points out on existence of role of large-scale wave processes in a formation of mesosphere and lower thermosphere temperature regime in winter period.

ARTIFICIAL PERIODIC INHOMOGENEITIES: STUDIES AND OUTLOOKS

N.V.BAKHMET'EVA, V.V.Belikovich, E.A.Benediktov, A.V.Tolmacheva (Radiophysical Research Institute, Niznhy Novgorod, Russia, e-mail: natali@nirfi.sci-nnov.ru)

The review of the experiments being performed at SURA heating facility using artificial periodic inhomogeneities (API) is presented. The formation of the API and measurements of the ionospheric and atmospheric parameters using the API are discussed. The API have been studied only at NIRFI for 15 years old. Some interesting results were obtained: 1) The relative concentration of negative oxygen ions in the D-region2) A model of the D-region; 3) Irregular structure of the lower ionosphere including the separation of the regular E-layer, the sporadic layers, additional layers in the valley; 4) The neutral temperatures and densities at the height region at 100-120 km were measured; 5) Vertical motion velocities and the parameters of the internal gravity waves in the D- and E-regions of the ionosphere were obtained; 6) Seasonal-daily variation of the vertical velocity at the heights 70--120 km were studied; 7) Parameters of the internal gravity waves and its spectral characteristics; 8) N(h)-profiles in the interlayer valley between E- and F-regions were measured and the appearance sporadic layers was testified; 9) Some data of electron and ion temperatures in the F-region. Use API could make it possible to study coupling between ionospheric layers. The work is supported by Russian Foundation of Basic Research under grants N 96-05-65130 and 97-05-64392.

EARLY RESULTS FROM THE TERRIERS MISSION

S. CHAKRABARTI, D. Cotton, T. Cook, A. Stephan, J. Vickers, V. Taylor, S. Stephan, F. Kamalabadi, J. Baumgardner, M. Mendillo, W. Oliver (all at Center for Space Physics, 725 Commonwealth Avenue, Boston University, Boston, MA 02215; email: supc@bu.edu) P. Bernhardt (Naval research Laboratory, Washington, D. C. 20375) J. Foster (Haystack Observatory, Westford, MA 01886)

The Tomographic Experiment Using Radiative Recombinative Ionospheric EUV and Radio Sources (TERRIERS) is a small satellite mission whose primary goal is to understand the Ionosphere-Thermosphere-Sun coupling through simultaneous observations of Extreme Ultraviolet (EUV) emissions. It has been shown that one feature (30.4 nm) of the highly variable solar EUV emissions is responsible for approximately 50% of all photoelectron flux responsible for many airglow emissions. TERRIERS will use a newly developed optics-free spectrometer to observe solar flux in 20 - 50 nm. A single-element imaging spectrograph will observe airglow in the 80 – 140 nm range where emission features from most of the atmospheric species are present and a dual frequency radio beacon will measure Total Electron Content (TEC) simultaneously from several ground stations. In addition, ground based optical spectrograph and incoherent scatter data will be used in observational campaigns. TERRIERS will be placed in a 550 Km altitude, 8:30AM/8:30PM circular orbit. Because it will be in a sun-synchronous, polar orbit, it will have the opportunity to study many geophysical phenomena such as Equatorial Spread F, mid-latitude trough and aurora. It is scheduled for launch in April, 1999. As an example of thermosphere-ionosphere coupling, we will examine the 83.4nm dayglow which is produced primarily by photoionization of atomic oxygen. The photons undergo multiple scattering by O+ ions and are absorbed by molecular nitrogen, oxygen and atomic oxygen gas. Thus, a complete description of 83.4nm airglow requires a knowledge of the coupling between solar EUV, and thermospheric and ionospheric density profiles. In this talk we will present TERRIERS observations of 83.4nm airglow.

API TECHNIQUE AND STUDIES OF THE IRREGULAR STRUCTURE OF THE LOWER IONOSPHERE

N.V.BAKHMET'EVA, V.V.Belikovich, E.A.Benediktov, A.V.Tolmacheva (Radiophysical Research Institute, Niznhy Novgorod, Russia, e-mail: natali@nirfi.sci-nnov.ru)

The artificial periodic inhomogeneities of the ionospheric plasma (API) have been discovered in 1975 in the experiments on the ionospheric plasma modification by a powerful radio emission. More than ten new methods of the different ionospheric parameters measurements are developed. For example, API technique allows to study the irregular structure of the lower ionosphere including the sporadic layers and to determine the turbulent velocities and the turbopause height. The measurements of amplitude and phase of scattering signals from API with height resolution equal to 1.2 km have been carried out in August, 1996 using SURA heating facility. The analysis discover that the height dependence of the relaxation time of the scattering signal shows an inclination at a height of about 100 km. The height of the inclination corresponds to the turbopause height where the turbulent mixture finishes and diffusion separation begins. The vertical component of turbulent velocities below this height have been determined. Besides it was detected the inhomogeneity of some height profiles of the relaxation time above 100 km. The analysis shows that local maxima of relaxation time are accompanied by the increase of the amplitude of a scattering signal. We suppose that sporadic E layers may be caused of the local maxima. The work is supported by Russian Foundation of Basic Research under grants N 96-05-65130 and 97-05-64392.

RELATIONSHIP THE SUBAURORAL MIDDLE ATMOSPHERE TEMPERATURE WITH SOLAR ACTIVITY AND QBO PHASES

S. V. NIKOLASHKIN, V. M. Ignatyev, V. A . Yugov and V. N. Alexeyev (Institute of Cosmophysical Researches and Aeronomy, 31, Lenin ave., Yakutsk, 677891, Russia, e-mail: s.v.nikolashkin@sci.yakutia.ru)

The subauroral lower thermosphere and mesosphere temperature relationship with solar radi flux density on wavelength 10.7 cm (F10.7) and quasi-biennial oscillations (QBO) phases based statistical analysis of the optical measurements data are studied.
It is showed that (1) in winter exists the negative correlation between subauroral lower thermosphere temperature and F10.7 index; (2) in the west phase of QBO between F10.7 index and temperature variations are absorved a positive correlation at stratosphere and negative – at the mesopause and lower thermosphere. In the east phase for stratosphere and lower thermosphere is observed the negative correlation but for mesopause – weak positive one. This result points out on existence of the dynamic relationship between considered atmosphere layers.

DIURNAL HEIGHT DEPENDENCE OF THE VARIATION OF ELECTRON CONCENTRATION AT THE LEVELS 150 KM - 205 KM DEDUCED FROM VERTICAL IONOSPHERIC SOUNDING DATA

Petra SAULI, Josef Boska (Institute of Atmospheric Physics, Czech Academy of Sciences, Bocni II/1401, 141 31 Prague 4 - Sporilov, Czech Republic, e-mail: Pkn@ufa.cas.cz)

Analyses of the height dependence of the variation of electron concentration are based on the ionosonde data measured at the observatory Pruhonice (15E, 50N). The campaign was run under low solar and geomagnetic activity conditions on 27 October - 7 November 1997. Repetition time of 5 minutes of the vertical ionospheric sounding was used during the campaign. The short-time deviations from a smoothed diurnal behaviour were derived to demonstrate the short-time variability of the electron concentration at levels from 150 km to 205 km. The average deviations show expressive height and diurnal variation. A large increase of deviations with height appears to be regular feature in the range 170-185 km. Height dependence of the gradient of the electron concentration was studied, as well. This gradient reveals among others a strong diurnal variation.

PARAMETERISATION OF THE LOCAL AND NONLOCAL PROCESSES IN THE THERMOSPHERIC ENERGY BUDGET BASED ON DE-2 SATELLITE DATA

Tarun Kumar Pant and R. SRIDHARAN (Physical Research Laboratory, Navrangpura, Ahmedabad - 380 009, India)

It is known that the in situ [e.g. DE-2 (WATS)] satellite measured thermospheric temperatures over low latitudes exhibit significant deviations from the thermospheric model (MSISE-90) predictions. The existence of such deviations between the two can be due to two main factors. One is that, all the processes and energy inputs for quiet and disturbed geophysical conditions are not adequately accounted for by the model, especially so, for low latitudes. The other factor is that the low latitude thermosphere ionosphere system (TIS) is continuously under the influence of many large scale local processes which might contribute significantly to its thermal balance but are not yet accounted for by the MSIS model. The process of Equatorial temperature and wind anomaly (ETWA) is perhaps one of the most important aspect in this context. In the present study, a method for parameterisation of the energy inputs during varying geophysical conditions in terms of rate of change of magnetospheric ring current based on the characteristic thermospheric response time during different seasons has been developed. It is proposed that the various current systems operative in the ionosphere and magnetosphere at anytime could be used as an indices for the fast temporal changes occurring in the neutral temperatures. It has been found that these changes could be represented by the temporal rate of change in the ring current index i.e. Dst. Further, to parameterise the ETWA associated temperature variations, the DE-2 satellite data on composition and temperature has been made use of. Since, the process of ion-drag and chemical heating are expected to be important for the generation of ETWA, an estimation of the contributions from both these processes was made. The final exercise dealing with all the three i.e the current systems, ion-drag and chemical heating which contribute towards the low latitude thermospheric temperatures and its variabilities was performed for a representative location for more than 30 days during year 1981-82. The estimated contributions were added to the standard MSIS model which is taken as the base purely accounting for the solar controlled processes. After the inclusion of all the three terms to the model, the observed temperatures and their variabilities are reproduced fairly well on most of the occasions except for a few exceptions. Even on the very few exceptional cases, the variabilities are fairly well reproduced leaving the difference only in the absolute magnitude. This has to be necessarily due to an significantly long duration and which has not yet been accounted for. These results, first of their kind, would be presented and discussed.

A COMPARISON OF HIGH-LATITUDE THERMOSPHERIC ION AND NEUTRAL TEMPERATURES FROM GROUND BASED MEASUREMENTS

K. Cierpka, M. KOSCH, M. Rietveld, K. Schlegel and T. Hagfors (Max-Planck-Institut fuer Aeronomie, Max-Planck-Str. 2, 37191 Katlenburg-Lindau, Germany, email: cierpka@linmpi.mpg.de)

Direct measurements of neutral temperature in the lower and upper thermosphere are obtained by a Fabry-Perot interferometer (FPI) located within the Scandinavian auroral zone. The EISCAT radar, located only 50 km westward from the FPI, provides measurements of ion temperatures in the E- and F- region as well as ionospheric electric fields. FPI neutral temperatures are compared with MSISE90 model predictions and EISCAT ion temperatures for different altitude ranges. Without an external energy source, the ion and neutral temperature should be equal. Significant enhancements of the ion temperature over the neutral temperature indicate Joule heating, a parameter which EISCAT can estimate. For periods when electric field data are available, the ion energy equation is used to predict the effect of Joule heating. This is compared to measured temperature differences.

PERTURBATION OF ELECTRON DENSITY DISTRIBUTION IN THE DAYTIME MID-LATITUDE F2 REGION IONOSPHERE ASSOCIATED WITH A GIANT THUNDERCLOUD

Vitali KIM, Valeri Hegai (both at IZMIRAN, Troitsk, Moscow Region, 142092 Russia, email: kimvp@izmiran.rssi.ru)

Changes of electron density in the daytime mid-latitude F2 region ionosphere associated with dc giant thundercloud electric fields penetrated into the ionosphere are calculated. It is obtained that the F2 region electron density is noticeably disturbed within an area with horizontal dimensions of about 500 km. The horizontal distribution of electron density in the perturbed area becomes irregular in course of time. The irregularities' sizes range from 15 to 150 km one hour after thundercloud formation. The changes of electron density are stronger in the upper F2 region where their amplitude can be as large as 40% relative to undisturbed values of electron density.

RESEARCH OF TROPOSPHERIC FRONTS AND INTERIOR GRAVITY WAVES INFLUENCE ON IONOSPHERIC IRREGULARITIES BEHAVIOUR

Oleg A. Litvinenko, Roman O. KRAVETZ, Svetlana K. Panishko (URAN-4 observatory, Radioastronomical institute, Pushkinskaya str. 37, 270011 Odessa, Ukraine. Email: uran@paco.net)

The radioastronomical monitoring of ionosphere by the radio telescope URAN-4 (Odessa. Ukraine) is used for observation of mean-scale ionospheric irregularitieses. The observations were carried out in decameter radiorange. Ground-base sounding of an ionosphere on fixed frequencies was simultaneously carried out. By means of a measurement of the dopler frequency shift of reflected signals this mode allows to discover large-scale periodic ionospheric irregularitieses which are identified as interior gravity waves. The joint analysis of time series of intensity and characteristic sizes variations of ionospheric irregularitieses and time series of intensity and phase of interior gravitational waves was carried out. Correlation between these time series was not detected. In difference from gravitational waves, tropospheric fronts rendered the strong influence on a behaviour of ionospheric irregularitieses, which we has observed with the help of radio telescope.

AGW SPECTRA IN THE ELECTRON DENSITY

Joseph Boska (Intitute of Atmospheric Physics, Academy of Sciences, Bocni II cp 1401, 14131 Praha 4, Czech Republic, email: boska@ufa.cas.cz); Diego MARIN, Gloria Miro and Benito A de la Morena (all at Atmospheric Sounding Station El Arenosillo, National Institute of Aerospace Technology, Ctra. San Juan-Matalascanas km. 33, 21130, Mazagon-Huelva, Spain, email: marinsd@inta.es); Miguel Herraiz (Geophysics and Meteorology Dp., Faculty of Physics, Complutense University, 28040, Madrid, Spain, email: mherraiz@eucmax.sim.ucm.es); Edward Kazimirovsky (Siberian Institute of Terrestrial Magnetism, Ionosphere and Radio Propagation, Academy of Sciences, 664033, PB 4026, Irkutsk, Russia, email: edkaz@iszf.irk.ru)

The datasets of 5-min measurements by ionosondes in El Arenosillo, Spain (37,1˚ N; 6,75˚ W; 41,37˚ dipole geom. lat.) allow to use ionospheric parameters data for the tudying the gravity wave activity in the midlatitude upper ionosphere in the period range 5 -120 min. The comparison of data has revealed some features of the resulting AGW spectra including similarity and some distinctions possibly caused by AGW dependence on the season, latitude, and regional peculiarities of the lower atmosphere.

THE RESPONSE OF THE TOPSIDE IONOSPHERE TO THE TOTAL SOLAR ECLIPSE OF FEBRUARY 26, 1998

B. MACPHERSON, S. A. Gonzalez, M.P. Sulzer (all at National Astronomy and Ionospher Center, Arecibo Observatory, HC3 Box 53995, Arecibo, PR 00612 U.S.A. Email: bmacpher@naic.edu, sixto@naic.edu, sulzer@naic.edu); G. J. Bailey (The Upper Atmosphere Modelling Group, Applied Maths Department, The Hicks Building, University of Sheffield, Sheffield, England. Email: g.bailey@sheffield.ac.uk); F. Djuth (Geospace Research, Inc., El Sequndo, California, U.S.A. Email: djuth@netcom.com); R. Rodriguez (Plasma Physics Division, Naval Research Laboratory, Washington, D.C., U.S.A. Email: rodriguez@ccf.nrl.navy.mil)

The Arecibo Incoherent Scatter Radar was used to observe the response of the topside ionosphere during the total solar eclipse of 26 February, 1998. The path of totality passed south of Puerto Rico with the maximum degree of obscuration at Arecibo being 90%. The data were taken using an experimental technique which allows measurements from around 146 km to 2400 km altitude. This paper will present what we believe to the first observation of the response of the topside ionosphere to a solar eclipse. These results, together with the lower altitude measurements, will be used to study the coupling and energy transfer of the F-region and topside ionosphere during the eclipse.

VARIATIONS OF TOTAL ELECTRON CONTENT DURING A GEOMAGNETIC STORM IN ARGENTINA

Blas F.de Haro Barbás, Victor H. Ríos, Antonio Pérez Gómez, Marcelo Santillán (Laboratorio de Técnicas Satelitales, Av. Independencia 1800, CP (4000), S. M. de Tucumán, Argentina)

In the present work we studies the variations of total electron content (TEC) caused by a happened geomagnetic storm between days 9 to the 12 of April of 1997 by means of the analysis of data pertaining to three Argentine permanent stations: Tucumán (-26,3 Lat; -65,13 Long), San Juan (-31,4 Lat; -68,23 Long) and Tierra del Fuego (-54,4 Lat; -68,56 Long); and its corresponding comparison with the measurements of such days obtained during 1998. The determination of the TEC became from measurements of observable of code and the phase of the signals trasmitidas by the satellites of the Global Positioning System GPS.It is possible to be observed that the values obtained during the days of the storm exceed approximately in a 30% to the values corresponding to the quiet days. Also the variation of the TEC with the latitude due to the different geographic positions from the analyzed stations is observed.

PROPAGATION OF MAGNETIC STORMS EFFECTS ON IONOSPHERE FROM HIGH TOWARDS LOW LATITUDES

O.M.Pirog, N.M.Polekh, L.V.Chistyakova , and E.S. KAZIMIROVSKY (Institute of Solar-Terrestrial Physics, 664033 Irkutsk, P. O. Box 4026, Russia, e-mail: edkaz@iszf.irk.su)

Magnetic storm effects on ionosphere were investigated. Data from ionospheric stations located in the range of longitudes 90°-175° E and invariant latitudes 51°N-51°S were used in this study. The intense magnetic storms were considered, which were observed at the equinox period, but correspond to different solar activity. At all stations, one day before the storm and during initial phase (daytime), foF2 increased significantly, then at midlatitudes it was decreasing with the progression of the storm, and during the explosive phase it dropped by a factor of 1-1.5 as against the undisturbed level. Negative disturbances were also observed at night. At low latitudes, the storm maximum and the recovery phase (daytime) showed abrupt changes in foF2 relative to the undisturbed level, with an amplitude of up to 3 MHz and a period of up to two hours. A change of the character and sign of disturbances occurs at latitudes corresponding to L<1.5. Es of auroral type, was observed to L=2 in the storm maximum. The above mentioned effects are most pronounced during minimum SA. The observed variations of ionopsheric parameters were caused by a strong contraction of the magnetosphere and by the equatorward displacement of the main ionospheric trough. The ring current energy dissipation affects the global circulation rearrangement of the upper atmosphere, the neutral component at midlatitudes starts to change its composition thus affecting foF2 variations. During the main phase, a contraction of the plasmapause can lead to observed wave-like changes in electron density in the F2-layer maximum at low latitudes.

KELVIN WAVES IN THE MESOSPHERE AND THERMOSPHERE

J.M. FORBES (Department of Aerospace Engineering Sciences, Campus Box 429, University of Colorado, Boulder, CO 80309-0429, USA); M.E. Hagan (High Altitude Observatory, National Center for Atmospheric Research, P.O. Box 3000, Boulder, CO 80307, USA)

Satellite and radar observations near the equator have established the existence of "ultra-fast" Kelvin waves in the mesosphere and lower thermosphere (40 to 110 km), with periods between about 3 and 6 days and vertical wavelengths in excess of 20 km. Using the global-scale wave model (GSWM) we simulate the propagation of Kelvin waves in the presence of realistic mean winds and dissipation from the troposphere to the upper thermosphere. We consider waves with periods of 3 and 6 days and zonal wavenumbers, s=1 and s=2. By calibrating the tropospheric latent heat source to match observed amplitudes, we are able to provide realistic estimates of the penetration of these waves above 110 km and to predict their latitudinal structures. Temperature and wind amplitudes achieved by the 3-day s=1 wave exceed 20 K and 30 m/sec in the 100 to 150 km regime. Significant interhemispheric asymmetries are found and attributed to the interplay between Doppler-shifting of the wave period and the accompanying influences of eddy and molecular dissipation. The mean-flow accelerations due to dissipation of these Kelvin waves are also estimated.

COORDINATED OBSERVATIONS OF QUASI-2-DAY OSCILLATION IN EQUATORIAL ELECTROJET STRENGTH AND MESOSPHERIC WINDS

S. GURUBARAN, T. K. Ramkumar, S. Sridharan (Equatorial Geophysical Research Laboratory, Indian Institute of Geomagnetism, Krishnapuram, Tirunelveli 627 011, India,
email: gurubara@md3.vsnl.net.in) R. Rajaram (Indian Institute of Geomagnetism, Colaba, Mumbai 400 005, India, email: rrajram@iig.iigm.res.in)

The quasi-2-day oscillation (QTDO), believed to be a manifestation of the westward propagating mixed Rossby-gravity normal mode with zonal wavenumber 3, is an ubiquitous feature of the middle atmosphere. Several studies in the past indicated that the QTD type of oscillations exist in the ionospheric parameters. Though these features are thought of originating in the mesospheric QTD wind oscillation, the mechanisms for producing them are not known.
Observations of mesospheric winds with a medium frequency (MF) radar operated from Tirunelveli (8.7 degrees N, 77.8 degrees E, geographic, 0.3 degree N dip), India, since the middle of 1992, are being made use of in the present work and the characteristics of the quasi-2-day oscillation in zonal and meridional winds are brought out. The equatorial electrojet (EEJ) strength, derived from ground-magnetic field variations, is determined for the same period, and the QTDO events are identified. It is noted that there is a reasonable correlation between the occurrence times of the QTDO in the EEJ strength and the mesospheric winds, as revealed by the observations.

DAYTIME MESOPAUSE `OH' ROTATIONAL TEMPERATURES FROM EQUATORIAL AND LOW LATITUDES USING GROUND BASED OPTICAL METHODS

R. SRIDHARAN, Alok Taori (Physical Research Laboratory, Ahmedabad -380009, INDIA)

Inspite of the crucial role played by the mesopause in coupling the lower and upper atmosphere, this region is one of the least explored due to its relative inaccessibility. Mesopause temperature is one of the sensitive parameters, that gives clues to the complex processes occurring there in. Till recently, the ground based optical methods had been restricted only to clear skey, moonless periods of a night. In this paper we present some of the first of its kind results, on the daytime mesospheric OH (8,3) rotational temperatures, estimated from the measurements of the relative intensities of the rotational lines in the same vibrational band, using the unique multiwavelength daytime photometer from Tirunelveli(8.7N, 77.8E) and Kolhapur (16.8N, 74.2E). After validating the initial results using near simultaneous WINDII data, continuous data have been obtained from both the locations revealing - (1) Significant deviations (+/- 30K) from the models on several occasions and also large day to day variabilities and (2) Oscillatory features with periods ranging from 0.5 - 6.0 h. The data were subjected to spectral analysis on all the days. It is seen that periods ranging from 0.5 - 1.5h stood out prominently. These unique results would be presented and discussed.

PLAUSIBLE EXPLANATION FOR THE EQUATORIAL TEMPERATURE AND WIND ANOMALY (ETWA) BASED ON CHEMICAL AND DYNAMICAL PROCESSES

Tarun Kumar Pant, R. SRIDHARAN (Physical Research Laboratory, Navrangpura, Ahmedabad - 380 009, India)

One of the important discoveries based on the Dynamics Explorer (DE-2) data in the recent years had been the Equatorial temperature and wind anomaly (ETWA) [Raghavarao et. al. 1991], which is a perfect example for a closely coupled interacting equatorial thermosphere ionosphere system (TIS) and has important implications with regard to the overall energy budget of low latitude TIS. Earlier attempts to theoretically simulate ETWA had been with limited success. In order to fully understand the processes involved in the generation of ETWA, so as to be able to parameterise the same, a detailed exercise was undertaken using DE-2 satellite data. It has been shown that both the Chemical heating due to the exothermic reactions and the frictional heating due to the ion-drag effects, contribute significantly to the generation of ETWA. Simultaneously measured ionospheric and thermospheric parameters both during day and night time by DE-2 have been made use of in coming to the above conclusion. This enables one to quantify their contribution and paves the way for taking into account the local processes while formulating models for the equatorial thermosphere.

LONG TERM VARIATIONS IN THE EQUATORIAL F-REGION USING OI 630NM OBSERVATIONS

FAGUNDES, P.R., (Instituto de Pesquisas e Desenvolvimento, IP&D/UNIVAP, Av. Shishima Hifumi, 2911, Urbanova - S. José Campos, SP, Brazil-CEP 12244-000, email: fagundes@univap.br); Y. Sahai, A.A. Pimenta, J.A. Bittencourt, H. Takahashi (Instituto Nacional de Pesquisas Espaciais, INPE, CP 515, S.P, S. J. dos Campos -Brazil-CEP 12201-970)

The OI 630 nm nightglow emission is widely used to monitor thermosphere/ ionosphere processes as well as large scale ionospheric plasma irregularities (plasma bubbles). Simultaneous observations of the OI 630 nm emission using multi-channel tilting filter-type zenith photometers have been carried out in Brazil at Cachoeira Paulista (22.7˚S, 45.0˚W) and Fortaleza (3.9˚S, 38.4˚W) during the last solar cycle. Also, an all-sky (180˚ field of view) imaging system for observing the OI 630 nm nightglow emission is operational at Cachoeira Paulista. The observed averaged intensities changes from 60(±44) R to 223(±90) R at C.P. and from 70(±40) R to 50(±41) R at Fortaleza between years of low to high solar activity, respectively, suggesting that the equatorial ionospheric anomaly region (C.P.) is more affected by the solar flux changes than the equatorial region (FOR.). Also, it was noticed that during the solar activity maximum the frequency of occurrence plasma bubbles are larger than during the low solar activity.

DP2 ELECTRIC FIELDS IN THE MIDNIGHT DIP EQUATORIAL IONOSPHERE

J. Hanumath SASTRI (Indian Institute of Astrophysics, Bangalore, India); H. Luhr (GeoForschungsZentrum Potsdam, Germany); H. Tachihara, T. I. Kitamura (Department of Earth and Planetary Sciences, Kyushu University, Hakozaki, Fukuoka, Japan); J.V.S.V. Rao (Indian Institute of Astrophysics, Bangalore, India)

Measurements with a HF Doppler sounder at Kodaikanal (10.2N, 77.5 E, dip 4 N) revealed conspicious quasi-periodic fluctuations (period 25-35 min) in F region vertical plasma drift, Vz, in the interval 1916-2026 UT on 23 December 1991 (Ap=14, Kp < 4-). The fluctuations in F region vertical drift are found to be coherent with variations in north-south (Bz) component of interplaneatry magnetic field (IMF) and with geomagnetic H/X components at high-middle latitude locations both in the sunlit and dark hemispheres. They are also coherent with H-field variations in the dip equatorial region on the dayside. We interpret the disturbance in F region vertical plasma drift over Kodaikanal as the signature of DP2 electric field fluctuations in the midnight dip equatorial ionosphere.

EQUATORIAL PLASMA BUBBLE DEVELOPMENT AND ZONAL DRIFT DURING THE 26 AUGUST 1998 MAGNETIC STORM

M. A. ABDU, H. Talahashi, I. S. Batista, E. R. de Paula, J. H. A. Sobral, N. B. Trivedi and A. F. Medeiros (Instituto Nacional de Pesquisas Espaciais- INPE, São Jose dos Campos, Brazil)

Equatorial ionospheric plasma bubble development and dynamics during the major magnetospheric storm of 26 August 1998 are investigated based on the data collected by two digissondes, an all-sky 630nm imager, GPS scintillation recievers and two magnetometers operated in the equatorial and low latitude sites in Brazil. The disturbances in the auroral electrojet activity (represented by AE indices) and associated disturbances in equatorial magnetograms had their onsets at~11UTon the 26th . Large enhancements in these disturbances produced large equatorial F region vertical plasma drift (eastward electric field) in the evening sector over Brazil which triggered a series of intense plasma bubbles, the event lasting the entire night, as observed by the all-sky imager at Cachoeira Paulista and digissondes at the equatorial site, Sao Luiz, and at the low latitude site, Cachoeira Paulista. Under quiet conditions plasma bubbles do not generally occur over Brazil in August. A notable aspect of the dynamics of the bubbles on the night of 26-27 Aug. was their westward zonal drift, in contrast to the well-known eastward drift observed under quiet conditions. The analisis to be presented will focus on the possible causes of the bubble westward drift as arising from (a) Hall electric field arising from prompt penetration magnetospheric electric field interacting with the enhanced ionospheric conductivities produced by storm associated particle precipitation in the South Atlantic magnetic anomaly zone as recent evidences have suggested (Abdu et al., Geophys. Res. Lettrs. 25, p.4137, 1998) and/or (b) disturbance dynamo associated westward thermospheric winds resulting from the storm associated heating of the high latitude I-T.

AN EQUATORIAL AND LOW LATITUDE TIME-DEPENDENT IONOSPHERIC MODEL

Scott DANN, Robert Stening (School of Physics, University of New South Wales, Sydney, 2052, Australia, email: sadn@newt.phys.unsw.edu.au)

A new version of the Chan and Walker model has been developed, capable of running under a variety of solar activity levels and at any longitudinal sector.
The model solves the plasma continuity equation for the total ion density, as well as the equations of motion of the neutral species to obtain a self consistent estimate of the neutral wind velocities. The non-linear terms in the neutral equations of motion pose a particular problem in this type of model, which uses input thermospheric data.
By solving for the neutral wind velocities, this model lends itself to studying the symmetry of the equatorial anomaly. The effects of trans-equatorial meridional winds and the resulting interhemispheric transport of ionization, often give rise to large assymmetry in the development of the anomaly crests, the maximum crest electron densities and the latitudinal extent of the plasma fountain.

SIMULTANEOUS GPS AND OI 6300 ALL-SKY IMAGING OBSERVATIONS DURING LARGE SCALE EQUATORIAL IONOSPHERIC IRREGULARITIES

FAGUNDES, P.R. (Instituto de Pesquisas e Desenvolvimento, IP&D/UNIVAP, Av. Shishima Hifumi, 2911, Urbanova, S.José dos Campos, SP, Brazil-CEP 12244-000, fagundes@univap.br); E. R.de Paula, Y. Sahai, (Instituto Nacional de Pesquisas Espaciais, INPE, CP 515 - S.P, São José dos Campos, Brazil-CEP 12201-970)

Global Position System (GPS) is now a days the most common instrument for navigation and the coordinates of any location on the earth (latitude longitude and altitude) can be obtained using the GPS. However, it is well known that equatorial large scale ionospheric irregularities have strong influence on transionospheric radiowave communications and on GPS performance causing amplitude and phase fluctuations in radiowaves crossing these irregularities. The equatorial F-region irregularities have scale sizes from meter, or less, to large scale plasma depletions, or bubbles, extending north-south to a few thousands of kilometers (aligned to the earth's magnetic field lines) with east-west widths of few hundred kilometers. The large scale irregularities are monitored at Cachoeira Paulista (23 S, 45 W) by an all-sky (180 field of view) imaging system for observing the OI 630 nm nightglow emission and the observations provide informations about the size, position and dynamics of these irregularities. Since these irregularities affect the performance of the GPS, we carried out an analysis of the simultaneous observations of the GPS data (latitude, longitude and altitude) and all-sky imaging to estimate deviations in the GPS data during different geophysical conditions. In this paper we present the GPS performance with/without large scale ionospheric irregularities and quiet/disturbed geomagnetic conditions.

THE IONOSPHERIC PLASMA AND ELECTRODYNAMICS INSTRUMENT (IPEI) ONBOARD ROCSAT-1: MISSION OPERATION AND DATA PRESENTATION

H. C. YEH, S. Y. Su, J. M. Wu, Y. C. Yeh, C. K. Chao (all at Institute of Space Science, National Central University, Chung-Li, Taiwan, email: yeh@jupiter.ss.ncu.edu.tw) R. A. Heelis, B. J. Holt, C. R. Lippincott, and R. A. Power (all at William B. Hanson Center for Space Sciences, The University of Texas at Dallas, Richardson, Texas, 75803, USA) Y. S. Chang and W. L. Chiang (both at National Space Program Office, National Science Council of ROC, Hsin-Chu City, Taiwan)

The newly launched ROCSAT-1 is the first scientific satellite program of the Republic of China (ROC) on Taiwan. The satellite is in circular orbits at 600 km altitude with inclination of 35 degrees. The mission lifetime will be 2 years with 4 years as the design goal. The ROCSAT-1 program is managed by the National Space Program Office (NSPO) of ROC. There are two major mission objectives. The first is to successfully develop, launch, and operate a Low Earth Orbiting scientific satellite. The second is to conduct three scientific experiments using three separate instruments onboard the spacecraft in the areas of ocean color imaging, space telecommunications, and solar terrestrial physics. The Ionospheric Plasma and Electrodynamics Instrument was selected as the sole solar- terrestrial physics payload. The IPEI payload consists of an ion trap, a retarding potential analyzer and a pair of ion drift meter. These sensors are designed by the University of Texas at Dallas to measure ion density, temperature, composition and drift velocity with unprecedented spatial resolution and sensitivity. In anticipating significant contributions of ROCSAT- IPEI to the understandings of low-latitude ionosphere physics, we introduce to interested scientists, the instrument

capabilities, mission operations and data management of the IPEI payload. In particular, we will present examples that typify the IPEI data. We will also discuss procedures for campaign mode operation and the level of data access for general users.

EQUATORWARD PENETRATION OF ELECTRIC FIELDS ASSOCIATED WITH REGION-1 AND 2 FIELD-ALIGNED CURRENTS DURING DP2 AND SUBSTORM EVENTS

Takashi KIKUCHI (Communications Research Laboratory, Koganei, Tokyo 184, Japan, e-mail: kikuchi@crl.go.jp), Hermann Luehr (GeoForschungsZentrum, Potsdam, Germany), Kristian Schlegel (Max-Planck Institut fur Aeronomie, Katlenburg-Lindau,Germany), Hiroshi Tachihara, Manabu Shinohara, and Tai-Ichi Kitamura (Kyushu University, Fukuoka 812-81, Japan)

During a substorm event on April 20, 1993, a negative magnetic bay occurred in the afternoon sector at mid to equatorial latitudes. The negative bay at low latitudes is caused by a 3-D current in the magnetosphere, but the large amplitude at mid and equatorial latitudes suggests major contribution of DP currents. The temporal variations of the electric field measured by the EISCAT radar (66 cgmlat) and of the magnetic X-component at Nurmijarvi (56 cgmlat) are coherent during the DP2 fluctuation event preceding the substorm (correlation coefficient r = 0.71), while the coherency is broken during the substorm event (r=0.26). The breaking of the coherency infers a secondary electric field associated with the R2 field-aligned current (FAC) which tends to shield the convection electric field associated with the R1 FAC from the lower latitude ionosphere. From the IMAGE magnetometer array the R1 and R2 FACs are inferred at 73 and 61.5 cgmlat, respectively. Quantitative analysis is made to obtain electric fields associated with the R1 and R2 FACs basing on the EISCAT and magnetometer observation at Nurmijarvi. The R2 FAC grows in concert with the R1 FAC, with a correlation coefficient of r = 0.92 and a time delay of 17 min. The DP current component of the negative bay is primarily caused by the substantial decrease in R1 FAC, but the delayed growth of the R2 FAC contributes considerably to the enhancement of the negative bay at subauroral and equatorial latitudes.

RESPONSE FEATURES OF THE IONOSPHERE OVER FORTALEZA (DIP 3S) TO VERY INTENSE GEOMAGNETIC STORMS

J. H. A. SOBRAL, M. A. Abdu, W. D. Gonzalez, Alicia C. de Gonzalez (all four at the Instituto Nacional de Pesquisas Espaciais, São José dos Campos, S.P, Brazil), B. T. Tsurutani (Jet Propulsion Laboratory, Pasadena, California, U. S. A.)

Disturbed ionospheric F-region height drifts and peak electron density changes observed at Fortaleza, to events of very high intensity and long time duration of magnetospheric storms that occurred in December 1980, April 1981 and September 1982, are analyzed. All the magnetic storms considered here are the result of the transit at Earth of magnetic clouds. The interplanetary magnetic field (Bz) data from the ISEE-3 satellite, the auroral activity index AE, and the ring current index Dst are used as indicators of the magnetospheric condidtions, and the ionospheric response features are analyzed using the F-layer critical parameters h'F, h'F3, hpF2 and foF2. An attempt is made to identify the origin of electric fields responsible for the disturbed F-layer alterations.

EVIDENCE FOR VOLCANIC INFLUENCE ON MEXICO CITY AEROSOLS

G. B. RAGA (Centro de Ciencias de la Atmósfera, Universidad Nacional Autónoma de México, Ciudad Universitaria, 04510, México DF, México, email: raga@servidor.unam.mx); G. L. Kok (National Center for Atmospheric Research, Boulder, CO 80303, USA, email: kok@ucar.ncar.edu); D. Baumgardner, A. Báez and I. Rosas (all three at: Centro de Ciencias de la Atmósfera, Universidad Nacional Autónoma de México, Ciudad Universitaria, 04510, México DF, México, email: darrel@servidor.unam.mx)

In situ measurements of sulphur dioxide (SO2), carbon monoxide (CO) and sulphate mass provide evidence that aerosol composition in Mexico City is affected by emissions from the neighbouring volcano, Popocatepetl. The data suggest that there are two distinct pathways by which SO2 is incorporated into particulates. Periods of high humidity, fog, and rain are accompanied by elevated sulphate mixing ratios, attributed to aqueous chemistry. Similarly, elevated sulphate concentrations in low humidity periods appear to be a result of adsorption onto existing particles. These two mechanisms are important for understanding the processes associated with particle formation in this highly polluted urban area. Under the influence of volcanic emissions, SO2 concentration is more than four times the average value and particulate sulphate is a factor of 2 larger.

CURRENT AND LONG TERM TRENDS OF CFC REPLACEMENT CHEMICALS AT CAPE GRIM, TASMANIA

Georgina STURROCK and Paul Fraser (CSIRO Atmospheric Research/CRC Southern Hemisphere Meteorology, Aspendale, Victoria 3195, Australia, email: g.sturrock@bom.gov.au); Simon O'Doherty and Peter Simmonds (School of Chemistry, University of Bristol, Brsitol, UK); Ben Miller and Ray Weiss (Scripps Institution of Oceanography, University of California at San Diego, La Jolla, California, USA); Ron Prinn (Department of Earth and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts, USA); David Oram (School of Environmental Sciences, University of East Anglia, Norwich, UK)

The refrigeration/air conditioning and foam plastics industries are using HCFCs and HFCs as interim and long-term replacements, respectively, for the ozone depleting chlorofluorocarbons (CFCs). The tropospheric removal of HCFCs and HFCs by reaction with hydroxyl radicals is significant and thus they cause less ozone depletion and global warming than the CFCs they replace. Nevertheless some of the HCFCs reach the stratosphere, resulting in limited ozone destruction, especially over the next 20 years. Both HCFCs and HFCs contribute to global warming - in particular the HFCs.
Monitoring the early accumulation in the background atmosphere of the CFC replacement chemicals is important, as it ensures that any unexpected increase in their levels will be detected early, possibly avoiding a repetition of the CFC pollution problem which was not detected until there had been significant accumulation in the atmosphere, resulting in unavoidable environmental damage, for example the Antarctic ozone hole.
Tropospheric data are being collected for the CFC replacement species using identical instrumentation and methodologies at mid-latitude sites in the Northern (Mace Head, Ireland, 52N) and Southern (Cape Grim, Tasmania, 41S) Hemispheres, as part of the long-term Advanced Global Atmospheric Gases Experiment (AGAGE) program designed to determine global trends and ultimately atmospheric lifetimes or emissions of CFCs, HCFCs and HFCs. In situ measurements are achieved using state-of-the-art instrumentation with high-resolution capillary gas chromatographic (GC) separation and mass spectrometric (MS) detection.

TROPOSPHERIC CONCENTRATIONS OF THE CHLORINATED SOLVENTS, PERCHLOROETHENE AND TRICHLOROETHENE, MEASURED IN THE REMOTE NORTHERN HEMISPHERE.

Claudia H. DIMMER, Peter G. Simmonds, Graham Nickless. (School of Chemistry, University of Bristol. Bristol. BS8 1TS. UK.email: c.dimmer@bris.ac.uk); Archie McCulloch. (ICI Chemicals & Polymers Ltd. P.O. Box 13, The Heath, Runcorn, Cheshire. WA7 4QF. UK.)

A fully-automated twin ECD GC system with sample enriching Adsorption-Desorption front end was deployed on two major field campaigns - Ny-Ålesund, Svalbard, (July to September 1997), and the RRS Discovery CHAOS cruise of the N.E. Atlantic, (April to May 1998). Concentrations of an extensive suite of halocarbons were detected at 50 minute intervals at pptv levels of concentration. The results obtained for the chlorinated solvents, perchloroethene (PCE), and trichloroethene (TCE) will be presented. Trajectory sector analysis sorting, and filtering to remove local pollution events enabled baseline concentrations for each compound to be defined, and ratios between PCE and TCE for polluted air masses to be determined. Background PCE and TCE concentrations of 2.68 and 0.26 pptv respectively were recorded in Ny-Ålesund. During pollution incidences, concentrations rose to 7.41 (PCE) and 2.89 pptv (TCE). The cruise data showed average concentrations ranging from 5.71 (PCE) and 1.43 pptv (TCE) for air masses originating over the N.Atlantic and Arctic open oceans, to 11.46 (PCE) and 5.75 pptv (TCE) for polluted air masses from Northern Europe. The significance of local contamination was highlighted and the concentrations compared to data obtained at Mace Head, Ireland, and to atmospheric concentrations calculated from the audited emissions data.

REGIONAL AND BACKGROUND MEASUREMENTS OF HALOMETHANES AT CAPE GRIM, TASMANIA

Michelle COX (CRC for Southern Hemisphere Meteorology, Monash University, Wellington Road, Clayton, Victoria, 3168, Australia, email: michelle.cox@dar.csiro.au); Paul Fraser and Georgina Sturrock (CRC for Southern Hemisphere Meteorology/CSIRO Atmospheric Research, PMB1 Aspendale, Victoria, 3195, Australia, email: paul.fraser@dar.csiro.au); Steve Siems (Mathematics Department, Monash University, Wellington Road, Clayton, Victoria, 3168, Australia, email: siems@monsoon.maths.monash.edu.au)

Chlorine and bromine species are the major catalysts for the significant, anthropogenically-enhanced, stratospheric ozone destruction that has occurred over the past two decades. The synthetic chemicals that provide the major halogen sources are the chlorofluorocarbons (CFCs) and halons. However approximately 20% of stratospheric chlorine and 50% of stratospheric bromine are derived from halomethanes, largely methyl chloride (CH3Cl) and bromide (CH3Br), which have both natural and anthropogenic sources. The atmospheric behaviour, sources and sinks of these halomethanes are not well understood. In an attempt to reduce the uncertainties associated with these species, an in-situ measurement project for CH3Cl, CH3Br, CH2Cl2 (dichloromethane) and CHCl3 (chloroform) was established at Cape Grim in late 1997, using state-of-the-art GC-MS instrumentation developed at the University of Bristol as part of the global AGAGE (Advanced Global Atmospheric Gases Experiment) program. In this paper, the temporal behaviours of these species in the background atmosphere are described and low level trajectories are used to investigate the pollution episodes and to help identify possible source regions. Trajectories from two high-resolution regional climate models (DARLAM - Division of Atmospheric Research Limited Area Model (CSIRO) - and LAPS - Limited Area Prediction System (BMRC)) are compared.

JSP21/W/11-A4 **1050**

A FIRN AIR RECORD OF CHLORINATED AND BROMINATED ORGANIC COMPOUNDS AND HCFCS SINCE THE 1950'S IN TWO HEMISPHERES

WT STURGES, DE Oram, H McIntyre, SA Penkett (School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, UK, email: w.sturges@uea.ac.uk), A Fabre, J Chappellaz, JM Barnola (Laboratoire de Glaciology et Geophysique de l'Environnement, CNRS, 54 Rue Moliere, Domaine Universitaire, 38402 St-Martin-d'Heres Cedex, FRANCE), E Atlas, V Stroud (National Center for Atmospheric Research, Boulder, CO 80307-3000, USA)
R Mulvaney (British Antarctic Survey, High Cross, Cambridge, CB3 0ET, UK)

The histories of a number of HCFCs and chloro-/bromo-carbons, dating back to the 1950's, have been examined in firn air from Canada and Antarctica. Many of the replacement compounds for CFCs such as HCFC-22, HCFC-141b, HCFC-142b, HCFC-21 HCFC-123 and HFC-152a show trends dating back to the late 1950's or early 1960's. Comparisons between hemispheres for the shorter-lived species reveals evidence for changing interhemispheric ratios, suggesting possible changes in global sinks. Trends for methyl chloroform, chloroform, dichloromethane, tetrachloroethylene, 1,1,2-trichloroethane and 1,1,2,2-tetrachloroethane show clear maximum Northern Hemispheric (NH) concentrations in the early 1980's (early 1990's for methyl chloroform). The lower levels in the Southern Hemisphere (SH) can be largely attributed to transport from the NH. Current estimates of oceanic sources of these compounds appear to be too high in many instances. Methyl chloride appears to have grown slightly in the SH, possibly due to biomass burning. Organobromines are separated into those showing trends due to anthropogenic sources (methyl bromide, dibromoethane), and those which have no trend and are evidently of entirely natural origin (dibromomethane, chloro-bromo-methanes, etc.). There appears to be a significant source of several organohalogens within the firn itself.

JSP21/W/12-A4 **1110**

NEW CONSTRAINTS ON GLOBAL AND HEMISPHERIC LOSS RATES OF METHYL CHLOROFORM

Stephen A. MONTZKA, James H. Butler, and James W. Elkins (NOAA/CMDL, ms: R/E/CG1, 325

Broadway, Boulder, CO 80303, email: smontzka@cmdl.noaa.gov, jbutler@cmdl.noaa.gov, jelkins@cmdl.noaa.gov).

The atmospheric residence time for many CFC-replacements and other reduced gases is determined primarily by the abundance of the hydroxyl radical. Accordingly, an accurate understanding of the burden of OH on global and hemispheric scales is essential for gauging the environmental effects of these gases. Estimates of the global mean hydroxyl radical concentration have been made in the past by inferring residence times or lifetimes for CH3CCl3 and 14CO from consideration of global measurements and sources. As emissions of methyl chloroform become insignificant, owing to the limits outlined in the Montreal Protocol on Substances that Deplete the Ozone Layer, atmospheric measurements of this gas will allow for refined estimates of its lifetime on global and hemispheric scales. From our measurements of CH3CCl3 at 7-9 remote sampling locations, the decrease observed between 1997 and 1998 corresponds to an e-folding time of 5.7 ± 0.3 yr. Because the data suggest that industrial emissions are not yet zero, this e-folding time represents only an upper limit to the global atmospheric lifetime of CH3CCl3. This upper limit, however, is independent of accuracy associated with calibration gas standards and industrial emission estimates. Additional consideration of our data allows us to estimate an upper limit of approximately 4.8 yr to the lifetime of CH3CCl3 in the Southern Hemisphere. This limit is also quite insensitive to calibration accuracy, emission estimates, and hemispheric exchange rates. Finally, we explore the utility of our measurements to discern relative differences

JSP21/W/09-A4 1130

CHANGES IN STRATOSPHERIC OZONE INDUCED BY CHANGES IN NATURAL ORGANOHALOGEN EMISSIONS

K. KOURTIDIS, C. Tourpali, C. Zerefos and D. Balis (Aristotle University of Thessaloniki, Laboratory of Atmospheric Physics, 54006 Thessaloniki, Greece, email: kourtidi@ccf.auth.gr)

We present here model simulations with a 2-D CTM that deal with the effect on stratospheric ozone of changes in the tropospheric abundance of the natural organohalogens methyl chloride (CH3l) and methyl bromide (CH3Br). The simulations include a 5-fold increase in the tropospheric CH3Cl abundance, a 5-fold increase in the tropospheric CH3Br abundance, and combined 5-fold increases in the tropospheric levels of both substances in both the unperturbed pre-industrial atmosphere and the industrial atmosphere. Thirty-fold increases in the tropospheric levels of both substances in the unperturbed pre-industrial atmosphere have also been simulated. The simulations for a combined 5-fold increase in both substances in a pre-industrial atmosphere show significant depletion of ozone at high latitudes during the spring season, that are mostly confined in the 30-55 km altitude region, while 30-fold increases are shown to significantly affect the global ozone layer. The results for 5-fold increases are also discussed in view of the effect of the calculated ozone changes in the radiation reaching various atmospheric levels in the 10-40 km altitude region. Possible mechanisms that could have lead to changes of the simulated magnitudes in the tropospheric natural organohalogen abundance in the past are also discussed.

JSP21/L/06/A4 1140

TRENDS IN HALOCARBON RELEASES FROM ANTHROPOGENIC, NON-COMBUSTION SOURCES

A. MCCULLOCH

A large number of halocarbons are manufactured industrially and used in society to provide specific effects such as refrigeration and solvent cleaning. In many cases, release of these chemicals into the atmosphere is a fundemental part of the way that they are used and occurs in quantities sufficient to be detected remotely. In order to assist in the Advanced Global Atmospheric Gases Experiment, manufacturers have cooperated to collect production and sales data for several decades and have developed technically bases emission functions. Thus the quantities of individual halocarbons released into the global atmosphere can be estimated with comparatively small uncertainty. The compounds included in this exercise are the CFCs (11, 12, 113, 114 and 115) –, CCl2F2, C2Cl3F3, C2Cl2F4, C2ClF5, Halons (1211 and 1301) – CBrClF2, CBrF3, methyl chloroform – CHCl3, as well as the halocarbon CFC replacements, HCFCs (22, 124,141b, 142b) CHClF2, C2HClF4, C2H3Cl2F, C2H3Cl2F, C2H3ClF2, and HCFC-134a C2H2F4. In a parallel exercise , production, sales and emissions data for trichloroethene, tetrachloroethene and dichloromethane have been developed. The global and regional emissions of all these compounds will be discussed, together with methods to distribute those emissions latitudinally and longitudinally. Chloroform and carbon tetrachloride releases arise mainly as unintentional by-products and the quantities and distribution have been estimated by far less rigorous methods. Nevertheless, the values are consistent with the observations and will be discussed here.

JSP21/W/02-A4 1150

THE INFLUENCE OF DIURNAL VARIATIONS IN THE CONCNETRATION OF HALOCARBONS ON AIR-SEA FLUX CALCULATIONS

Katarina ABRAHAMSSON, Anja Ekdahl and Anders Lorén (Department of Analytical and Marine Chemistry, Chalmers University of Technology, SE-412 96 Göteborg, Sweden)

Diurnal variations in concentrations of volatile halogenated organic compounds have been studied in a rock pool and in open ocean. The concentrations were measured every hour or every other hour at six different occasions during a cruise in the Atlantic sector of the Atlantic Ocean, as well as every hour during one occasion in a rock pool at the Canary Islands. We will present results that show that the variations in concentrations of halocarbons correlate with photosynthesis and respiration. The levels of halocarbons vary considerable during a 24 hour period even in the open ocean, for example for diodomethane, bromoform and trichloroethylene the concentrations varied with a factor of 90, 8 and 10 respectively. The diurnal variations are characterised by rapid increases and decreases in concentrations, just within a few hours, and calculations of the air-sea flux cannot account for the observed losses.

ON THE FLUXES OF SHORT-LIVED ORGANOCHLORINE COMPOUNDS BETWEEN THE OCEAN AND ATMOSPHERE.

Robert M. MOORE, (Department of Oceanography, Dalhousie University, Halifax, N.S. Canada, B3H 4J1, email: rmoore@is.dal.ca)

Measurements of dichloromethane, chloroform, trichloroethylene and tetrachloroethylene were made, at the same time as several naturally-produced trace gases, in the ocean water column during cruises in the western Atlantic in 1997, and, as part of the GAS EX98 experiment, north of the Azores in 1998. While it is evident that the gases were supersaturated at the ocean surface, and that the ocean was therefore acting as a source to the atmosphere, it will be shown that it is more difficult to establish whether the gases are produced within the ocean or are, at least in part, anthropogenic. All of these compounds are expected to have seasonally varying concentrations in the atmosphere as a result of their short lifetimes (ca. 7 – 150 days) with respect to loss by reaction with the OH radical. This can, depending on the lifetime of the gas in seawater, drive a wintertime flux of a gas from atmosphere to ocean, and a reverse flux during summer. The effects of any biological production or consumption of the gas in the ocean will be superimposed on the physically driven fluxes.

JSP21/W/03-A4 1420

SOURCES AND SINKS OF HALOGENATED GASES IN THE NORTH ATLANTIC OCEAN

Denise SMYTHE-WRIGHT, Stephen Boswell and Russell Davidson (Southampton Oceanography Centre, Empress Dock, Southampton SO14 3ZH)

Following the Montreal Protocol on ozone depleting gases and continuing concern over greenhouse warming, attention is now being focused on the new anthropogenic CFC 'replacements' and other radioactively-active and ozone-depleting gases which initially were given little regard; for example, hydrohalomethanes, haloforms and methylhaloforms. Evidence suggests that the ocean is both a source and a sink of such compounds but the specific sources (and sinks) within the ocean are poorly understood. While it is possible to measure variations in the seawater concentrations, little is known about seasonal and geographical variation, or about biological production or release (ie during the growth and mortality of planktonic organisms). Results from 3 RRS Discovery cruises covering winter, summer and spring biological conditions will be presented to show that there is a direct relationship between the distribution of methyl chloride, methyl bromide and methyl iodide and biological production, depending on season and geographical location. For example up to 40% methyl bromide supersaturation (with respect to the atmosphere) has been observed off the coast of Greenland and in excess of 1000% methyl iodide supersaturation in the subtropical gyre. Speciation studies indicate that the methyl bromide production may be related to a bloom of Nitzchia ssp while the methyl iodide may result from a prochlorophyte source, but the mechanism by which the compounds are produced is still unclear.

JSP21/L/02-A4 1440

METHYL BROMIDE AND METHA CHLORIDE EMISSIONS FROM COASTAL SALT MARSHES

ROBERT C. RHEW, Benjamin R. Miller, and Ray F. Weiss (Scripps Institution of Oceanography, University of California at San Diego, La Jolla, CA 92093-0220; 619-534-2599, email: rob@gaslab.ucsd.edu)

Field measurements show that coastal salt marshes are large natural sources of methyl bromide and methyl chloride and may contribute significantly toward balancing the known global budgets of these compounds. We chose to investigate salt marshes for methyl halide emissions because they are known to be regions of high primary productivity and high halide concentrations. Flux chamber deployments were carried out between June and December 1998, in two southern California coastal salt marshes. Measured net fluxes show that methyl bromide and methyl chloride are emitted from all vegetation zones of both salt marshes, with greater emissions in the growing season than in the non-growing season. The greatest emissions of these methyl halides are from the middle to upper-middle zone of the salt marsh and are associated with high carbon dioxide respiratory emissions and high densities of above-ground green biomass. Furthermore, there is a strong correlation between the molar fluxes of methyl bromide and those of methyl chloride, pointing to a common mechanism of production and release. The average molar ratio of chloride ion to bromide ion in seawater is about 600, while the average ratio of emissions of methyl chloride to methyl bromide from the salt marsh is roughly 20. Therefore the mechanism appears to favor the production of methyl bromide over methyl chloride, an observation consistent with the biosynthesis of these compounds by enzymes isolated from certain plants and wood-rot fungi. Estimated global extrapolations indicate that coastal salt marshes represent the largest natural terrestrial source of methyl bromide and methyl chloride identified thus far. Although salt marshes comprise less than 0.1% of the global surface area, they may produce roughly 10% and 5% of the total annual fluxes of methyl bromide and methyl chloride, respectively.

JSP21/W/17-A4 1500

PRODUCTION AND EMISSION OF METHYL CHLORIDE IN THE SURFACE OCEAN

Daniel B. KING (NOAA/CMDL, Boulder, CO 80303, USA and CIRES, University of Colorado, Boulder, CO 80309, USA, email: dking@cmdl.noaa.gov); James H. Butler (NOAA/CMDL, Boulder, CO 80303, USA, email: jbutler@cmdl.noaa.gov); Jürgen M. Lobert (Center for Clouds, Chemistry, Climate, SIO/UCSD, La Jolla, CA 92093, USA); Shari A. Yvon-Lewis (NOAA/AOML/OCD, Miami, FL 33149, USA); Stephen A. Montzka and James W. Elkins (NOAA/CMDL, Boulder, CO 80303, USA)

Methyl chloride (CH3Cl) is the primary natural source of organic chlorine in the atmosphere. As anthropogenic sources of atmospheric, organic chlorine are reduced in the future, the relative contribution of CH3Cl to chlorine in the stratosphere will increase. However, there are currently significant uncertainties associated with the global budget of atmospheric CH3Cl. The oceans are a substantial source, as is biomass burning, and perhaps wood-rotting fungi. The oceanic contribution alone is difficult to rectify, and extrapolations of the known oceanic sources of CH3Cl cannot currently account for the estimated oceanic emission to the atmosphere.
In an attempt to understand the oceanic processes driving the production and emission of CH3Cl, we examined the relationship between its air-sea flux and a variety of physical and chemical oceanic properties. A total of four field campaigns was conducted in the Atlantic, Pacific, and Southern Oceans, in open ocean, upwelling and coastal environments. CH3Cl was supersaturated in most of the waters, with higher degrees of saturation in warmer waters. Data from these campaigns are used to derive a correlation between the flux and temperature, along with other physical and chemical properties. The contributions of the chemical degradation of CH3Br and CH3I to the production of CH3Cl are estimated for the four field campaigns and compared to the total air-sea flux of CH3Cl.

JSP21/W/05-A4 1520

THE OCEANIC CONTRIBUTION TO ORGANIC BROMINE IN THE ATMOSPHERE

Shari YVON-LEWIS (NOAA/AOML, Miami, FL 33149, USA, email: Shari.Yvon-Lewis@noaa.gov); James Butler, Daniel King, Stephen Montzka (NOAA/CMDL, Boulder, CO 80303, USA, email: jbutler@cmdl.noaa.gov); Jose Rodriguez (RSMAS, Univ. of Miami, Miami, FL 33149, USA); Jürgen Lobert (C4/SIO, Univ. of California San Diego, La Jolla CA 92093, USA); Malcolm Ko (AER Inc, Boston, MA 02139, USA)

The ocean delivers considerable organic bromine into the troposphere. Although many of the oceanic, bromine-containing compounds are short-lived in the troposphere, they can be convected periodically into the stratosphere, where they contribute to the destruction of stratospheric ozone. Methyl bromide (CH3Br) and the halons are recognized as being the primary carriers of bromine into the stratosphere, but contributions from other compounds may be significant. Some of these other trace gases include CH2Br2, CHBr3, CH2BrCl, CHBr2Cl, and CHBrCl2. All of these gases are produced to some extent in the ocean and their collective sea-air flux is of the same order as the total flux of CH3Br from all sources.
We have been measuring CH3Br, CH2Br2, CHBr3, and other bromine-containing compounds in air and surface seawater samples on research cruises in the Pacific, Atlantic, and Southern Oceans since 1994. Results show CH3Br undersaturations throughout much of the ocean, suggesting that the ocean is a net sink for this brominated trace gas. However, results for CH2Br2, CHBr3, and the other bromine-containing compounds show these trace gases to be supersaturated throughout much of the ocean, often with higher degrees of saturation in the tropics and subtropics. These data are presented here and will be used in conjunction with a 2-D model to examine the role that the oceans play in the cycling of atmospheric organic bromine.

JSP21/W/15-A4 1600

SEASONAL AND TEMPORAL VARIABILITY IN THE DISTRIBUTION OF METHYL BROMIDE IN THE SURFACE OCEAN

James H. BUTLER (NOAA/CMDL, 325 Broadway, Boulder CO, 80303, USA;
email: jbutler@cmdl.noaa.gov; +01-303-497-6898); Daniel B. King (University of Colorado/NOAA, CIRES; Boulder CO 80309, USA); Shari A. Yvon-Lewis (NOAA/AOML, Miami, FL 33149, USA); Jürgen M. Lobert (C4/SIO, Univ. of California San Diego, La Jolla CA 92093, USA); Stephen A. Montzka, James W. Elkins (NOAA/CMDL, Boulder CO, 80303, USA)

The ocean is both the largest known source and the second largest known sink for methyl bromide (CH3Br) in the atmosphere, yet we still don't fully understand how the ocean regulates the atmospheric burden of this gas. Consequently, we cannot predict accurately how oceanic fluxes of methyl bromide will respond to global change. First-order calculations suggest that the steady-state, net flux of CH3Br from the ocean will act in opposition to changes in the atmospheric burden. The distribution of the oceanic sources and sinks of this gas, however, lacks uniformity on both small and large scales. The open oceans are typically undersaturated in CH3Br, with coastal waters commonly supersaturated. Warm waters tend to be undersaturated and cooler waters can be super- or undersaturated, but there are significant exceptions to these generalities. Although the chemical degradation of dissolved CH3Br is predominantly a function of sea-surface temperature, production appears to be mainly biological, and there is strong evidence for biological degradation as well. Here, we examine the distribution of methyl bromide from recent studies of its saturation in the Pacific, Atlantic, and Southern Oceans to examine spatial and temporal dependencies upon its net flux and, consequently, its production and degradation.

JSP21/W/07-A4 1620

DEGRADATION OF METHYL BROMIDE IN SURFACE WATERS OF ATLANTIC AND PACYFIC OCEAN (8N TO 45N)

Ryszard TOKARCZYK, Eric Saltzman (RSMAS, Univ. of Miami, FL-33149, USA,
email: rtokarczyk@rsmas.miami.edu, esaltzman@rsmas.miami.edu)

Methyl bromide is both produced and destroyed in the surface ocean, at rates which significantly impact its tropospheric burden and lifetime. Recycling of methyl bromide within the water column limits emissions from this source into the atmosphere and enhances the removal of atmospheric methyl bromide derived from anthropogenic or terrestrial biospheric emissions. Methyl bromide is destroyed in the ocean by chemical and biological processes. In this study seawater samples were incubated with 13C-labelled methyl bromide in order to measure the degradation rate, with the goal of determining the relative importance of chemical and biological processes. Degradation rates were measured during the GASEX-98 cruise across the Atlantic and the western Pacific coast (May-July 1998). Total measured degradation rates averaged from 0.17 to 0.31 per day. Methyl bromide degradation was faster in the Caribbean Sea and the coastal Pacific waters, than in the Atlantic. Temperature seems to be the primary factor controlling degradation rates in the mid-latitude ocean. On average, biological degradation contributed only 1-5% to the total degradation rates in these waters, but its contribution increases with decreasing temperature.

JSP21/W/01-A4 1640

ARE SOILS A GLOBALLY SIGNIFICANT SINK FOR ATMOSPHERIC CARBON TETRACHLORIDE AND METHYL CHLOROFORM?

James D. HAPPELL (Department of Marine and Atmospheric Chemistry, University of Miami, 4600 Rickenbacker Cswy, Miami, Florida, 33149, USA, email: jhappell@rsmas.miami.edu); Douglas W.R. Wallace (Abteilung Meereschemie, Institut fuer Meereskunde, Duesternbrooker Weg 20, 24105 Kiel, Germany, email: dwallace@ifm.uni-kiel.de)

Evidence will be presented that suggests that soils are a globally significant sink for atmospheric carbon tetrachloride (CT) and methyl chloroform (MC). Soil gas profiles of CT and MC obtained from temperate and sub-tropical forests and lawns indicate rapid removal of CT and MC in the top 30 cm of soil. The concentration of CT and MC in the soil gas decreased by up to 75 % and 50 % relative to the respective atmospheric concentration in the top 30-cm of the soil. CFC-11, CFC-12 and CFC-113 were also measured and there was no evidence for the removal of these compounds. These data and the changes in the soil gas profile during and after a large rain storm at one site will be used to speculate on likely removal mechanisms for CT and MC.
The soil gas profiles will also be used to calculate the flux of CT and MC into soils, and the flux estimates will be scaled up to give a preliminary estimate of the global soil sink strength for these compounds. Because estimates of the ODP and GWP for CT and MC are based on their atmospheric lifetimes, which in turn are based on estimates of their sources and sinks, a globally significant soil sink would require a reevaluation of their ODPs and GWPs. Changes in the atmospheric lifetime of MC will also affect the deduced concentration of tropospheric OH, because the global mean OH concentration is estimated from the MC lifetime. If the deduced OH concentration changes so will the estimated lifetime, ODP and GWP of other radiatively and/or chemically important gases (CH4, HCFCs, HFCs, CO, NOx, SO2, etc) oxidized by OH.

JSP21/E/03-A4 1700

AN INVESTIGATION INTO THE RELEASE OF HALOCARBONS BY PHYTOPLANKTON CULTURES

Cristina F. PECKETT(1,2), Denise Smythe-Wright (2) and Duncan A. Purdie (1). (2)George Deacon Division for Ocean Processes, (1) School of Ocean and Earth Science, University of Southampton, Southampton Oceanography Centre, Empress Dock, European Way, Southampton, SO14 3ZH, email: crfp@soc.soton.ac.uk.

Halogenated methanes are known to contribute significantly to ozone destruction in the stratosphere and to play an important part in tropospheric chemistry. The oceans act as both a source and a sink for these halogenated methanes, and marine organisms are possibly a major oceanic source. This paper describes the results of an investigation into the release of a suite a halogenated methanes by a number of different phytoplankton species in culture.Cultures were grown for about four weeks in specifically designed, gas-tight glass vessels, which hold 1 litre of culture, leaving over 1 litre of headspace for gas exchange. The headspace was sampled every two days and analysed using a GC-ECD or GC-MS. Culture growth was monitored by cell counts and chlorophyll analysis. Species tested include Isochrysis galbana, Phaeocystis pouchetii, Chaetoceros sp., Emiliania huxleyi, Thalassiosira gravida and Prochlorococcus marina. Methyl chloride, methyl bromide and methyl iodide production has been detected for most species and some negative production, i.e. apparent uptake of halocarbons by the culture has also been observed. DMS production has also been detected. The mechanisms behind halocarbon production by phytoplankton are poorly understood. Further experiments are planned involving nutrient manipulation, the use of axenic cultures and grazing experiments. It is anticipated these will allow the mechanism of halocarbon production by marine phytoplankton to be investigated and results from some of these experiments will be discussed. The pattern of halocarbon production during the growth cycle will be compared between species and the significance of this halocarbon production on a global scale will be discussed.

JSP21/L/03-A4 1720

THE QUANTIFICATON OF DIMETHYLSULPHIDE

ARCHER SD, Stelfox CE , Burkill PH, (Centre for Coastal and Marine Science, Plymouth Marine Laboratory, Prospect Place, West Hoe, Plymouth PL1 3DH, UK); Malin G, Steinke M, Liss PS. (School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, UK)

Microzooplankton herbivory is one process by which dimethylsulfoniopropionate (DMSP) contained in phytoplankton, is converted to dimethylsulfide (DMS). Several previous studies have illustrated the extent of conversion of algal DMSP to DMS as a result of grazing by microzooplankton in laboratory cultures. However, few if any studies have demonstrated or quantified this process in natural waters. We have developed a new approach in the laboratory that has been applied to natural waters to quantify DMS production by microzooplankton. The model is based on the dilution technique that is used routinely to determine the impact of microzooplankton grazing on phytoplankton. The modified dilution approach provides simultaneous estimates of microzooplankton grazing rate, phytoplankton specific growth rate, grazing-mediated production of DMS and dissolved DMSP and the production/loss of DMS and dissolved DMSP in the absence of grazing.
During field studies in the southern North Sea and Iceland Basin in 1998, we found that microzooplankton were active grazers in waters containing DMSP-rich Phaeocystis spp. and autotrophic dinoflagellates. Our modified dilution technique was used to quantify this grazing impact and to estimate the production of DMS and dissolved DMSP that resulted from the grazing. Variations in the production of DMS and dissolved DMSP due to grazing reflect the differences in plankton composition between experiments. The experiments confirm the importance of bacterial processes to dissolved DMSP and DMS turnover and provide an indication of these rates in relation to grazing-mediated production. An impression of the relative importance of microzooplankton grazing to the DMS budget in each region was possible. We suggest that the technique provides a useful means by which some of the complex processes involved in the production of DMS in natural waters can be quantified and modelled.

OBSERVATIONAL CONSTRAINTS ON THE GLOBAL BUDGET OF ATMOSPHERIC NITROUS OXIDE

James W. ELKINS, James H. Butler, and Thayne M. Thompson (Climate Monitoring and Diagnostics Laboratory, National Oceanic and Atmospheric Administration, Boulder, Colorado, USA,
email: jelkins@cmdl.noaa.gov, jbutler@cmdl.noaa.gov, thompson@cmdl.noaa.gov)

Nitrous oxide (N2O) is a significant contributor to the radiation budget of the atmosphere and to the depletion of stratospheric ozone (O3). N2O is a strong greenhouse gas and it is the major source of ozone-depleting nitric oxide in the stratosphere. Increased levels of atmospheric N2O may delay the recovery of the O3-layer even though mixing ratios of the chlorofluorocarbons (CFCs) are decreasing. The relative effect of N2O in depleting stratospheric ozone also could increase in the future because methane has now reached steady state in the atmosphere; methane is the primary source of water that aids in tying up free chlorine. Our group has been monitoring N2O from ground-based stations since the mid-1970's and, in recent years, has developed small gas chromatographs for sampling N2O in the atmosphere from airborne and shipboard platforms. While trends over the past 20 years tend to be relatively constant, there have been some significant variations over short periods. This talk will focus on the observational constraints on the global budget of atmospheric N2O from measurements made from tall towers, baseline stations, aircraft, balloons, and ships.

JSP21/W/04-A5 0950

FACTORS GOVERNING THE OCEANIC NITROUS OXIDE SOURCE AND DISTRIBUTION

P. SUNTHARALINGAM (Department of Earth and Planetary Sciences, Harvard University, Cambridge, MA 02138, USA, email: pns@europa.harvard.edu); J. L. Sarmiento (Atmospheric and Oceanic Sciences Program, Princeton University, Princeton, NJ 08544, USA,
email: jls@splash.princeton.edu)

N2O is a radiatively important trace gas and also plays a significant role in stratospheric ozone depletion. The major contributors to the atmospheric budget are biological processes in soils and water. The oceanic source displays a high degree of spatial and temporal variability, making it difficult to derive reliable flux estimates from sparse surface measurements. Furthermore, the main formation mechanisms responsible for marine N2O remain subject to some uncertainty. In this study, ocean general circulation model (OGCM) simulations of the marine N2O distribution are employed to evaluate current understanding of the dominant formation processes and to estimate the magnitude of the global sea-air flux. N2O is modelled as a non-conserved tracer in a global OGCM and subject to biological sources and sinks in the ocean interior and gas-exchange at the surface. A comparison of two source presentations is presented; the first is based on observed correlations between excess N2O and AOU, and models N2O production as a linear function of organic matter remineralisation. The second parameterization incorporates, in addition, behaviour suggested in recent studies, namely, enhanced N2O production at low oxygen concentrations. Simulation results indicate that both parameterizations are able to reproduce the large-scale features of the observed distribution,

i.e., high surface supersaturations in regions of upwelling and biological productivity, and values close to equilibrium in the oligotrophic sub-tropical gyres. However, inclusion of a dependence on a depth varying quantity in the relationship between N2O production and remineralisation (as, for example, in the oxygen dependent case) is more successful in reproducing the structure of the observed deep N2O distribution. These simulations yield an estimate for the global open ocean water column N2O source of 3.8 Tg N per year (range 2.7 - 8.0 Tg N).

JSP21/L/05-A5 1010

NEW SOURCES AND SINKS OF NITROUS OXIDE

Sheo S. PRASAD (Creative Research Enterprises, P.O. Box 174, Pleasanton, CA, USA, email: ssp@CreativeResearch.org)

Nitrous oxide (N2O) is an important greenhouse gas, since it is about 300 times more efficient than CO2 on per molecule basis and its atmospheric loading is rising. The current belief is that N2O has no atmospheric sources. However, recent observations of N2O isotopic anomalies and reviews of earlier laboratory experiments suggest the existence of significant atmospheric photochemical production of N2O. The talk will review these breaking developments and the experimental study, which shows that vibrationally highly excited O3 reacting with N2 in the gas phase produces N2O at an atmospherically significant rate. Kinetically, this result closely parallels the recently reported N2O production from vibrationally highly excited ClO. If we accept the 1990 IPCC position on the N2O source-sink budget, then the new atmospheric source bridges the source deficit. On the other hand, if the current IPCC position of a nearly balanced source-sink budget is accepted, then the new source implies that either the current methodology for estimating the surface emission is over-estimating this emission, or there is a significant missing sink. It will be further argued that this missing sink, if it is really there, must be a surface sink. Laboratory experiment based speculations about its nature, and suggestions for new field and laboratory experiments will be presented.

JSP21/W/06-A5 1050

LIGHT NON-METHANE HYDROCARBONS IN THE OCEAN - AN OVERVIEW

J. RUDOLPH (Centre for Atmospheric Chemistry and Chemistry Department, York University, 4700 Keele Street, Toronto, Ontario, M3J 1P3, Canada, email: rudolphj@yorku.ca)

Emissions from the ocean into the atmosphere are a source of a substantial number of different non-methane hydrocarbons (NMHC). However, the magnitude of this source is still under debate with estimates of global emission rates ranging from a few Tg/yr to over 50 Tg/yr. Since the atmospheric residence time of most non-methane hydrocarbons does not allow for long-range transport, oceanic emissions will determine the abundance of NMHC in the remote marine atmosphere. The oceanic emission rates of light alkenes, derived from oceanic concentrations and air-sea transfer formulations are in the range of several Tg/yr. The oceanic production rates derived from laboratory experiments and field observations are somewhat higher, suggesting that emission to the atmosphere is not the sole loss process for hydrocarbons produced in the ocean, although the difference between both estimates is statistically not significant. Total oceanic emissions of all non-methane hydrocarbons are estimated to be somewhat less than 10 Tg/yr. Consequently oceanic NMHC emissions have only a minor impact on the chemistry of the remote marine atmosphere. However, oceanic emissions have to be considered if measurements of reactive in the marine atmosphere are used to study atmospheric processes.

JSP21/E/04-A5 1110

ON INTERPRETING THE SEASONAL CYCLE IN AGAGE METHANE OBSERVATIONS AND VARIATIONS IN THE METHANE COLUMN

D.CUNNOLD (School of Earth and Atmospheric Sciences, Georgia Tech, Atlanta, GA 30332-0340, USA Email: cunnold@eas.gatech.edu); P.Steele, P.Fraser, R.Prinn, P.Simmonds, R.Weiss and L.Emmons

Measurements of methane at the AGAGE sites are reported and compared against results from the CMDL network. Simultaneous measurements of the CFCs and CH3CCl3 are used to constrain the OH distribution and transport in models in order to better isolate the effects of regional sources on the observed seasonal cycle in methane. Results from a 2D model are reported and the 3D MOZART model is now being used to test the conclusions. The MOZART model is also being used together with the ground-based observations to investigate likely sources of variability in observations of vertical column methane which will be made by upcoming satellite experiments such as MOPITT.

JSP21/W/16-A5 1130

METHANE EMISSION REDUCTION IN WASTE MANAGEMENT

Percival THOMAS (Department of Environmental Management and Ecology, La Trobe University, P.O. Box 821, Wodonga, Victoria 3689, Australia)

Methane is considered as one of the main greenhouse gases because of its ability to trap much of the outgoing earth's radiated energy forming a thermal blanket around the globe, raising its temperature. It is produced in large quantities under anaerobic conditions in garbage dumps, swamps and cattle feedlots. Methane which is more potent than carbon dioxide in causing global warming has an atmospheric residence time of 10-12 years as compared to carbon dioxide's residence time of about 100 years, and reduction of methane from the atmosphere should produce an immediate beneficial effect. Solid waste landfills are found in every country where tonnes of garbage are disposed of each year. Gas produced from these sites consists of about 45-55% methane, which is also a useful source of energy, and therefore, control of atmospheric emission can have an added benefit if the energy content is utilised. In many developing countries the level of income of the people is so low that they cannot afford to pay for the conventional energy sources, and methane collected from garbage dumps can be a cheap source of energy. In most cases revenues from the sale of methane will offset the cost associated with the operation of the landfill.

JSP21/W/10-A5 1150

NON-CONTROLLED EMISSION OF METHANE, CARBON DIOXIDE, AND OTHER TOXIC GASES FROM LANDFILLS

Noemi LIMA, José M. L. Salazar, Nemesio Pérez (Environmental Research Division, ITER, 38594 Granadilla, Tenerife, Canary Islands, Spain, email: nlima@iter.rcanaria.es); Candelaria Perdigón, Ana Martinez-Zubieta (Faculty of Chemistry, Univ. La Laguna, 38206 La Laguna, Tenerife, Canary Islands, Spain); and Pedro A. Hernández (Laboratory for Earthquake Chemistry, Univ. Tokyo, Tokyo 113, Japan).

Landfills work as chemical and biological reactor where biogas and leachates are the products. CH4 and CO2 are major components of biogas, which also contains other trace gas components. These gas species are atmospheric contaminants which must be collected and either flared or utilized for the production of energy. Landfill gas extraction system recover just 35 to 50 % of the total production of biogas at landfills, but significant amounts of non-controlled emissions of major and trace biogas components could be released to the environment in the form of diffuse degassing. The goal of this study is to evaluate the non-controlled emission of biogas in Arico's landfill, where biogas extraction system is not operative yet. Arico's landfill has an extension of 350,000 m2 and 1,170 tons of urban solid wastes, which contents 48 % of organic mater, are daily deposited. Diffuse emission of CO2 levels were measured at 525 sites by means of a NDIR spectrometer and ranged from 0.8 to 32,868 g·m-2·d-1. Spatial distribution of diffuse emission of CO2 indicates that biogas degassing is not uniform all over the landfill. The total output of CO2 released to the atmosphere from Arico's landfill is about 150 t·d-1. The total output of biogas can be estimated by taking into consideration the CH4/CO2 molar ratio of the biogas; this amount is about 423 t·d-1. Trace components emission levels are 11 t·d-1 of H2O, 153 t·yr-1 of VOCs, 0.9 t·yr-1 of C2HCl3, 2.5 t·yr-1 of C2Cl4, and 1.1 kg·yr-1 of As. Significant amounts of non controlled emission of toxic gases to the surrounding environment suggest important environmental and engineering implications. In addition, generation of methane from numerous anaerobic wastewater treatment ponds, sludge digesters and artificial wetlands designed to treat wastewater needs attention, if a country has to maintain its commitment to the United Nations Framework on Climate Change.

JSP21/W/14-A5 1210

ESTIMATION OF THE METHANE EMISSIONS FROM THE WEST SIBERIA WETLANDS AND OIL AND GAS DEPOSITS BY THE 3D REGIONAL CHEMICAL TRANSPORT MODEL

Svetlana JAGOVKINA, Igor Karol, Vladimir Zubov (Main Geophysical Observatory, Karbyshev str. 7, 194021, Russia, email: karol@main.mgo.rssi.ru); Victor Lagun (Arctic and Antarctic Research Institute, Bering str. 38, 199397, Russia, email: lagun@aari.nw.ru); Eugeny Rozanov (University of Illinois at Urbana- Champaign, IL 61801, USA, email: rozanov@uiatma.atmos.uiuc.edu)

Methane is one of the most important greenhouse gases, but some its source intensities are not well known. The 3-D regional transport chemical model of the troposphere with the calculated PBL and wind fields of the above layers from data bases is used for estimation of methane fluxes from West Siberia Region (58-730N x 62-810E). The model has 0.5x10 resolution, 10 layers up to 1 km and 10 layers in the troposphere. Databases of the wind and temperature fields are created from the data from Russian meteorological stations located in the considered and adjacent areas. The estimations of the methane fluxes from gas deposits, as well as from the wetland are made on the base of the data for three periods (July 1993, June 1996 and May 1997) of airborne and ground surface methane concentration measurements. The results of the model estimations are compared with published data of the methane fluxes from Canadian and Alaska wetlands and the input of West Siberia Region into the global methane budget is evaluated.

THE USE OF CONTINENTAL FLOOD BASALTS TO PROVIDE CONSTRAINTS FOR OFFSHORE HYDROCARBON EXPLORATION: A CASE STUDY ON THE HUAB BASIN, NW NAMIBIA

Dougal JERRAM (Dept. of Geological Sciences, University of Durham, South Rd, Durham, DH1 3LE, UK. email: D.A.Jerram@dur.ac.uk); Nigel Mountney (Department of Earth Sciences, Keele University, Keele ST5 5BG, UK); John Howell (Department of Earth Sciences University of Liverpool, Brownlow St, Liverpool L69 3BX, UK); and Harald Stollhofen (Institut für Geologie, Universität Würzburg, Pleicherwall 1, D-97070 Würzburg, Germany).

Of increasing interest in the petroleum sciences is the effect and interaction of igneous rocks with petroleum reservoirs and sediments. Currently there is continued exploration interest in the Atlantic margin and offshore NW Scotland areas, where basins have been effected by the Tertiary Igneous Province, and where there is considerable difficulty in imaging under the basalt units. Continental Flood basalt provinces, e.g. the Etendeka Province NW, Namibia, can potentially be used to provide field outcrop databases to aid exploration and provide realistic numbers for geological modelling. The Huab Basin in NW Namibia, is used as a case study to highlight the use of detailed fieldwork in understanding the development of such provinces and their relation to the underlying sedimentary sequences, providing important information e.g. geometry, size and thickness of flow units etc., and enabling simple 3-D models to be produced. Here an active aeolian sand sea (erg) was progressively engulfed by lavas of the Etendeka Flood Basalt Province. This has resulted in the unprecedented preservation of large parts of the active dune system, the occurrence of a variety of sediment interlayers and examples of the dynamic interaction between lava and aeolian/fluvial sands. The stratigraphic relationship in the Huab Basin is a potential analogue for the offshore Kudu Gas Province, as well as providing many examples of how igneous rocks intrude and invade an extensional basin during passive rifting and continental break-up. The contact between the lavas and the sediments is of particular interest. These regions are indurated, often with carbonate cements, and show systematic thickness variation of the indurated zone with respect to lava flow thickness. This suggests that the lavas have a marked 'baking' effect on the sands, although at this stage the full dynamics of that effect are poorly understood. In other places strong silica cements are present, and in one example a pure quartzite layer is produced.

JSV22/W/02-A5 0920

ETENDEKA IGNEOUS PROVINCE: INSIGHTS INTO CONTINENTAL BREAKUP PROCESSES

J.S. MARSH, (Department of Geology, Rhodes University, Grahamstown, 6140 South Africa)

Eight mafic and 17 silicic and geochemically distinct magma types occur in the Etendeka Igneous Province. Mafic magmas have sources dominated by components of a plume (Tafelkop), the asthenosphere (Horingbaai) and mantle lithosphere (Khumib, Tafelberg, Albin, Kuidas, Huab, Esmeralda). Silicic magmas (60-72% SiO2) have sources in old continental crust or underplated Etendeka basalt. Geographic and stratigraphic distribution of these types gives insight into magmatic processes on a breakup continental margin. Amongst early eruptives, plume-derived magmas are localised in a narrow zone, orthogonal to the breakup margin, at least 300 km S of the plume axis as defined by its trace in adjacent oceanic lithosphere, i.e. the Walvis Ridge. Late-stage asthenospheric dykes are confined to the same zone, as are generation and eruptive/emplacement sites of large-volume, crustally-derived silicic magmas. Implications: this was a major weak or thin zone in continental lithosphere towards which plume-head material was channelled to shallow depth with subsequent melting and emplacement of melts into continental crust. Later, asthenospheric mantle was also channelled into this zone to produce Horingbaai dykes as continental lithosphere moved away from the plume head. High-Ti Khumib basalts, derived from enriched lithospheric mantle, thicken northwards towards the plume axis and dyke distributions suggest main eruptive sites over the plume axis. Thus, an importnat thermal influence of the plume, in conjunction with lithospheric thinning, is to produce significant melting of the subcontinental lithosphere. Such lithosphere is also incorporated into the plume and subsequently sourced for some Walvis Ridge basalts (DSDP 525A). Continental crust (early to late) and underplated basalt (late) are also melted to produce a number of giant (1000-10000 cubic kms) and compositionally discrete silicic magma systems. Within the continental breakup zone the flux of silicic magma into the upper crust may match that of mafic magma.

JSV22/E/07-A5 0940

UPPER MANTLE STRUCTURE OF PLATEAU-BASALTS AREAS IN THE SIBERIAN CRATON

Nina PAVLENKOVA (Institute for Physics of the Earth, B.Grusinskaja 10, 123810 Moscow, Russia, email: Ninel@Pavlenkova.msk.ru) Galina Pavlenkova (GEON Centre, Chisty 4,119034 Moscow, Russia)

One of the largest area of the continental plateau-basalt covers the eastern part of the Siberian Craton. The flood-basalt penetrate the Paleozoic sediment of the Tunguss basin. The area is characterized by specific pattern of the magnetic field and by ed with nuclear explosions, cross the area and characterize the upper-mantle structure down to depth of 700 km. Some peculiarities were determined in the lithosphere structure of this area. Two blocks with anomalous high velocities (8.5-8.6 km/s) were out tures in the crust and upper mantle structure are observed: decreasing of the velocities in the middle crust, inclined crustal and upper-mantle reflectors dipping to the north, a reflectivity zone (bright spot) at depth of 300-350 km. These structural peast transportation of fluids and flood-basalts to the surface through the cold lithosphere.

JSV22/W/06-A5 1000

INTRA-PLATE VOLCANISM IS IN RIFTS OR DERIVED FROM DEEP OR SHALLOW MANTLE PLUMES

K. BURKE (Geosci,Univ.Houston,Tx 77204-5503 ,USA email: kburke@uh.edu)

Rifts, which form where plates are locally in extension, are the sites of most intraplate volcanism. Much of the rest can be ascribed either to deep or to shallow mantle clearly recognised on the African plate which has been at rest wrt the mantle circulation for the past 30 My. Modellers have shown that a distinctive pattern of shallow mantle circulation develops under plates that are at rest. Much African plate volcanism began ~ 30 Ma when that plate stopped moving and is therefore attributable to plumes of a shallow mantle convection system. Plumes under the African plate have generated elevations and small volumes of HIMU-derived basalt with low 3 He values. Exceptions are the Afar, whose vast volume shows that it alone comes from depth, Tristan which is ancient (130 Ma), and Reunion, Shona, Bouvet and perhaps also Ascension which have 3 He values MORB. Initial eruptions of these four plumes are all < 2 My old perhaps indicating that at their initiation plumes of shallow origin may briefly tap a reservoir isolated from the MORB, HIMU, low 3 He sources that dominate the convecting upper mantle. Shallow plumes may also underlie slowly moving parts of the Antarctic, Caribbean and Eurasian plates but the occurrence of volcanism in rifts and Eurasian plates but the occurrence of volcanism in rifts within broad plate boundary zones has made shallow plume recognition harder than on the African plate.

JSV22/E/14-A5 1050

HAWAII'S HOT SPOT, AND THE "ELECTROCARDIOGRAM" OF THE EARTH ARE LIP'S ITS "HEARTBEATS"?

Giovanni P. GREGORI (IFA-CNR, via Fosso del Cavaliere 100, 00133 Roma, Italy;
e-mail: gregori@atmos.ifa.rm.cnr.it); Wen Jie Dong (Lanzhou Institute of Plateau Atmospheric Physics, Academia Sinica, Lanzhou, Gansu Province, P. R. of China, e-mail: hxy@ns.lzb.ac.cn)

The geographical location and dating of the islands and seamounts of the Hawaii - Emperor Seamount chain allow for inferring the time variation of the magma emplacement rate during the last ~70 Ma. A trend resembling an electrocardiogram is thus found, with three heartbeats, with a return time every ~27.4 Ma. The available dating of all known LIP's appears consistent with the guess that every LIP perhaps occurred on the occasion of one such heartbeat. In any case, as far as the last ~70 Ma are concerned, a detailed analysis was carried out relating such Earth's electrocardiogram with the timing of the geomagnetic reversals, and with a tide-driven dynamo (Gregori, PEPI, 77, 39, 1993), and with its Joule's heating generation and propagation up to Earth's surface. Similar analyses from other hot spot trails ought to confirm such a feeding mechanism and its respective time variation, mechanism that, provided it is correct, should hold on the planetary scale.

JSV22/E/09-A5 1110

INDIRECT EVIDENCES OF JURASSIC VOLCANICS IN NORTH ARABIAN SEA AND RELATED TECTONICS ON ADJOINING INDIAN CONTINENT

D.C. MISHRA (National Geophysical Research Institute, Uppal Road, Hyderabad 500 007, India, email: postmast@csngri.ren.nic.in)

Analysis of airborne/marine magnetic anomalies of the north Arabian sea delineates two ridges oriented NE-SW with basic intrusive rocks at depths of approximately 1.0 km and 5.0 km located offshore (Pakistan) and Saurashtra (India) respectively. The former coincides with the known Murray ridge while the latter offshore Saurashtra extending towards the owen fracture zone is known as Saurashtra ridge. The observed magnetic anomalies can be accounted only by remanent magnetisation with a direction of magnetisation corresponding to high latitudes in the southern hemisphere. Seismic velocities reported along profiles offshore Karachi, Kutch and Saurashtra indicate volcanic activities of early-Jurassic time which may constitute a part of these magnetic ridges and floor of the north Arabian sea.
This volcanic activity of Jurassic time show sea ward dipping reflectors and appears to be related to the break-up of Africa from the Indian plate and may be contemporary to Karoo and post karoo volcanics of east Africa. Saurashtra and Kutch on shore are also characterised by similar structural trends namely NE-SW and E-W respectively and depict several contemporary tectonic activities including Mesozoic sediments and intrusives of almost same period which might be related to the break-up of Africa from the Indian plate.

JSV22/E/02-A5 1130

GLOBAL TEPHRA LAYERS FROM THE ETHIOPIAN TRAPS : A CLUE TO EVALUATE TRAP CLIMATIC IMPACT

Yannick Touchard, Pierre ROCHETTE (CEREGE, BP80 13545 Aix en Provence Cdx 4, France, email: rochette@cerege.fr), Marie-Pierre Aubry (ISEM case 64 34095 Montpellier Cdx 5) and Franck Bassinot (LSCE 91198 Gif-sur-Yvette cedex)

A precise stratigraphic study of the Ethiopian traps have demonstrated that the emplacement of the main flood sequence has occurred at 30 ±0.5 Ma (Ar/Ar dating) and within magnetochron 11, with a maximum duration of either 0.8 or 1.9 Myr, depending on the magnetostratigraphic solution chosen. Four acidic tephra layers have been found in leg 115 sediments, 2600 km to the SE, with magnetostratigraphic ages synchronous with acidic layers of the traps section (in the 0.8 Ma solution). This support the "short" hypothesis, leading to magma production rate >1.6 km3/yr. The Ethiopian origin of the tephra material (glass shards) have been confirmed by distribution of major and trace elements together with isotopic studies. For the first time, trap products are found within distant marine sequences, allowing to discuss with much more confidence the climatic impact of trap atmospheric emissions. Perfectly synchronous susceptibility peaks -interpreted as the results of volcanic input- are found in the South Atlantic 522 site. Together with the characteristics of intertropical global atmospheric circulation, this strongly suggests that the glass shards have been disseminated globally, at least in the intertropical band, during explosive eruptions largely exceeding the Toba tuff eruption. A sudden global cooling should therefore be associated with each tephra layer. However the well established global cooling event Oi2 appears below the tephra layers, that is during the early flood basalts emplacement. Micropaleontological evidences and deltaO18 stratigraphy will be used to discuss these correlations.

JSV22/L/01-A5 1150

INTRUSIVE-SPLITTING OF TECTONIC PLATES AND LOG-JAM SEGREGATION OF MAGMAS: A NEW MECHANISM FOR INTRAPLATE MAGMATISM ON EARTH AND IN OTHER TERRESTRIAL BODIES

Miles OSMASTON (The White Cottage, Sendmarsh, Ripley, Woking, Surrey GU23 6JT, UK.
email: miles@osmaston.demon.co.uk)

The base of a large plate may be put into extension mechanically or by the penetration of cooling. Mantle cannot be split at low strain rates but its viscosity is highly temperature-sensitive and dependent on local composition. These may then combine to result in rapidly concentrated upward-necking of the plate. Sub-plate material thus drawn upward will undergo pressure-relief melting and eventually endow the column with net buoyancy to extend the narrow split up to the surface. Melt segregation will occur by a log-jam mechanism, well-known to grouting engineers and in other fields, in which the solids inevitably jam in the crack if they are bigger than 20-25% of the crack width. In our diapiric/intrusive column the jam will form when the solids grow again at shallower levels where wall cooling becomes important. The diapiric column will force melt through the jam. Continued opening of the crack will be offset by wall accretion; the jam will continually re-form and permit the segregation of flood basalts. Rupturing of jams provides a source of xenoliths. The self-generated diapiric capability of the column in the crack results in pressure around its base being sub-lithostatic, so low- melting and diffusible-gas mantle constituents will be drawn from a wider zone than the main melting, giving the magma a 'plume' signature (e.g. 3He and 87Sr) that is not of lower mantle origin. The mechanism offers a simple account of the alk-thol-alk-neph OIB sequence and of alkali basalts that precede or follow tholeiitic flood basalts. It also seems applicable to any terrestrial bodies with thermally shrinking global lithospheres.

COMPUTER ANIMATION OF GONDWANA DISPERSAL AND THE HISTORY OF IGENOUS EXTRUSION IN THE INDIAN OCEAN

Colin REEVES and B.K. Sahu (International Institute for Aerospace Survey and Earth Sciences (ITC), Kanaalweg 3, 2628 EB Delft, The Netherlands. email: reeves@itc.nl)

Perceptions of geological phenomena can be clarified by their visualisation in time through computer animation. Thanks largely to interpretation of the Geosat ocean-floor topography data, the spreading history of the Indian Ocean now has far fewer uncertainties. In broad lines, four distinct but individually long-lived regimes of plate tectonism can be described quantitatively and animated using appropriate Euler poles. One of these regimes, which included several minor plate re-organisations, occurred largely during the Cretaceous Normal Superchron and so left little record in the marine magnetic anomalies, adding to the uncertainties of earlier work.
Ocean floor and continental geological features have been digitised with precision, ascribed to their respective plates and programmed to appear at appropriate times using the Cambridge Atlas and Timetrek software. The animation demonstrates graphically the relation in space and time between the igneous events of (1) Karroo-Ferrar volcanism, (2) dyke injection in southern Africa, (3) Rajmahal-Bunbury-Kerguelen basalts and the Ninety-East Ridge, (4) the Etendeka-Parana-Walvis Ridge complex and (5) the Deccan-Seychelles-Reunion hotspot in relation to the several spreading regimes and their respective plate boundaries and time intervals. The appearance, progress and disappearance of suspected hotspots and mantle plumes can also be visualised schematically. The eye of the beholder may be inspired to new and better-conceived interpretations by viewing this geological pageant.

JSV22/L/05-A5 1420

THE KERGUELEN PLATEAU AND BROKEN RIDGE LARGE IGNEOUS PROVINCE: INITIAL RESULTS OF OCEAN DRILLING PROGRAM LEG 183

Millard F. COFFIN (Institute for Geophysics, The University of Texas at Austin, 4412 Spicewood Springs Road, Building 600, Austin, TX 78759-8500, USA, email: mikec@ig.utexas.edu); Fred Frey (Department of Earth, Atmospheric, and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139, email: fafrey@mit,edu); Paul Wallace (Ocean Drilling Program, Texas A&M University, College Station, TX 77845, email: Paul_Wallace@odp.tamu.edu); and Ocean Drilling Program Leg 183 Scientific Party

Most of the Kerguelen Plateau and Broken Ridge formed as a single giant oceanic plateau in Cretaceous time. During Ocean Drilling Program Leg 183 (December 1998-February 1999), we cored igneous basement rock and sediment from five sites on the Kerguelen Plateau and two closely spaced sites on Broken Ridge. Initial analyses of basalt, other igneous rock, and interbedded and overlying sediment shows that: (a) The uppermost crust of this very large igneous province (LIP) formed in several, probably discrete episodes. The southern Kerguelen Plateau formed at ~110 Ma; the central Kerguelen Plateau, Broken Ridge, and Elan Bank at ~85 to ~95 Ma; and the northern Kerguelen Plateau at £35 Ma. (b) High melt production rates of the Kerguelen hot spot formed several subaerial landmasses that gradually subsided below sea level through time. For example, terrestrial sediment containing wood fragments overlies subaerially erupted lava flows on the central Kerguelen Plateau. (c) Explosive eruptions of volatile-rich magmas marked the terminal phase of volcanism forming Elan Bank, and the central and northern Kerguelen Plateau sectors. (d) Continental crust comprises parts of the Kerguelen Plateau and Broken Ridge. For example, clasts of garnet-biotite gneiss in a braided river conglomerate are intercalated with basalt flows on Elan Bank.

JSV22/E/13-A5 1440

GEOPHYSICAL/MORPHOTECTONIC ANOMALIES ALONG THE EDGE-OF-THE-INDIAN SHIELD AND INDIAN OCEAN HOTSPOTS

U. RAVAL and K. Veeraswamy (National Geophysical Research Institute, Hyderabad, India)

During 125-60 Ma, encompassing its break-ups the 'Greater' Indian lithosphere seems to have been influenced by 2-4 hotspots lying within (20-50) S & (55-70) E, which may perhaps represent a superplume. Further a number of gravity highs could be noted along the edge-of-the-Indian-shield which, it is suggested, may have developed, at least partly, due to modification of continental lithosphere (CL) by plumes. Their occurence near continent-Ocean transition may be attributed to juxtapositioning of break-ups (at 130, 90, 64 Ma) with plumes. The gravity highs over thick sedimentary basins imply large subsidence and foundering of high density material due to say gabbro-eclogite transformation. Other density materials due to say gabbro-eclogite transformation. Other geophysical anomalies also appeared to be associated with these gravity highs e.g. a) high velocities beneath Mahanadi & Cambay, b) magnetic highs over Mahanadi on and offshore regions & western Rajasthan and c) high heatflow and seismicity along the Cambay. This emphasizes that plume-CL and plume-ridge interactions could manifest not only as magmatism but also as geophysical features due to heat & mass transfer, which may be of economic significance as well.

JSV22/E/06-A5 1500

ST. MARY ISLES OFF INDIA - REMNANTS OF MARION PLUME

K.V. SUBBARAO (Department of Earth Sciences, Indian Institute of Technology, Mumbai (Bombay) 400 076, India. E-mail:subbu@geos.iitb.ernet.in)

The 90 Ma old acid rocks of the St. Mary Isles of Western Continental Margin (off Mangalore Lat. 30 degree 20; Long. 74 degree 41) of India are characterised by the presence of highly evolved dacites and rhyolites (Mg*30), Ti-enriched (~4%) tholeiites and alkali dykes (ne- and ol-normative), with narrow range of Sr87/Sr86 (0.7053-0.7058) covering all rock types. The palaeomagnetic pole of these islands (8 degree, 45 degree West (dp = 8 degree, dm = 6 degree); ancient latitude 26 degree S) does not fall on the apparent polar wandering curve obtained for the Deccan Traps (~65Ma) and Rajmahal Traps (~188 Ma).
Based on nearly similar age (~ 90 Ma), chemical Sr isotopic composition and ancient latitudes for both the St. Mary Isles and early Cretaceous rocks of Madagascar, we propose that the former bears an important signature of the breakup of Madagascar and India around 90 Ma vis-à-vis Marion hot spot; but totally unrelated to the Deccan and Reunion activity. Thus the early Cretaceous St. Mary volcanism appears to represent amixture of Madagascar lithospheric mantle and Southwest Indian Ridge mantle.
We will discuss the effects of overprinting of three plume activities (Kerguelen-Marion-Reunion) during the past 20 Ma and related thermal effects on the Indian lithosphere.

JSV22/E/15-A5 1550

GEOCHEMICAL EVIDENCE FOR CENOZOIC MANTLE PLUME IN THE SOUTH CHINA

Jian-Ren MAO, Kui-Yuan Tao, Guang-Fu Xing, Yu Zhao and Zhu-Liang Yang (Nanjing Institute of Geology and Mineral Resources, 534 East Zhongshan Road, Nanjing, P.R.China,
email: nigmr@public1.ptt.js.cn)

The authors discuss the geochemical characteristics of Cenozoic basalts in the South China Sea basin, Hainan Island, Leizhou Peninsula and Longhai-Mingxi in Fujian Province. They may be divided mainly into two periods: mid-Miocene (20-10Ma) and Pliocene-Pleistocene (<5Ma). These basalts are almost consistent with OIB which are more enriched in HFSE, especially in Nb,Ta,U. It is considered that the Polynesian basalts are probably formed by upwelling from the core-mantle boundary superplume, and the Hawaiian basalts are probably formed by the low-velocity column of the upper mantle. The occurrence of both the Polynesian-type and the Hawaiian- or MORB-type lavas in the South China Sea basin may imply that OIB may be produced on an oceanic ridge and that entrainment of upper mantle material may be caused by a rising superplume of lower-mantle origin. The basalts in Hainan Island and Leizhou Peninsula may have a similar origin. The within plate basalts about same contemporaneity in Longhai-Mingxi have high =E2=96=B37/4Pb, =E2=96=B38/4Pb and Nb/Zr ratios=EF=BC=8Cshowing they are totally Polynesian-type basalt. The special geochemistry of Cenozoic basalts may indicate the speciality of mantle source-"quasi-OIB-type" enriched mantle. The origin of the basalts may be attributed to (1) the eclogite residue after the partial lower-mantle; (2) the continental crust contribution through delamination of the lithosphere (including the lower crust); (3)the upwelling of a deep-mantle superplume.

JSV22/E/18-A5 1610

MESOZOIC PETRO-TECTONIC ASSOCIATIONS AND RECORDS OF THE GEODYNAMIC PROCESSES IN SOUTHEAST CHINA

Kui-Yuan TAO, Jian-Ren Mao, Zhu-Liang Yang, Yu Zhao, Guang-Fu Xing and Huai-Min Xue (Nanjing Institute of Geology and Mineral Resources, 534 East Zhongshan Rd., Nanjing, P. R. China,
email: nigmr@public1.ptt.js.cn)

According to the researches on the ages of volcanic/intrusive rocks-compositions (rock series and associations), the tracing isotopic geochemistry (Sr and Nd) and the geotectonic orientation etc., the authors have summarized the petro-tectonic associations during 250-80Ma and have divided the volcanic-intrusive rocks in the region into five petro-tectonic associations and three rock provinces, then have discussed the magmatic source regions as well as the crust-mantle interaction and their contributions. The authors have proposed that the original cause for the complex nature of various rock associations in the region may be derived from the composite of the dynamic system, i.e., the Tethys tectonic regime and the Paleo-Pacific Ocean tectonic regime. The authors also considered that the study of the mechanism for the transition and continuation of the two dynamic systems would be the link for the plate tectonics and deep processes. The Southeast China would become one of the best regions for the study of the ocean-continent transitive terrain in the world.

JSV22/W/05-A5 1630

EPISODIC SILICIC VOLCANISM ALONG THE PALAEO-PACIFIC MARGIN OF GONDWANA; PLUME AND SUBDUCTION INFLUENCES

Teal RILEY, Philip Leat and Bob Pankhurst (British Antarctic Survey, Natural Environment Research Council, High Cross, Madingley Road, Cambridge, CB3 0ET, UK, email: t.riley@bas.ac.uk)

Jurassic magmatism in western Gondwana produced the most voluminous episode of continental volcanism in the Phanerozoic. During the Early-Middle Jurassic, some 2-3 million km3 of dominantly basalt and to a lesser extent rhyolite, were erupted onto a supercontinent in the early stages of break up. Ninety percent of the volcanic rocks were emplaced during a short, 2-3 Ma burst (ca. 183 Ma). The major silicic portion of the Gondwana magmatic province is exposed in Patagonian South America, and an extension into the Antarctic Peninsula would increase the strike length along the active Pacific margin by ca. 2000 km. The volcanic rocks of Patagonia have been collectively termed the Chon-Aike Province and constitute one of the world's most voluminous silicic provinces. The volcanic rocks are predominantly pyroclastic, dominated by ignimbrite units of rhyolite composition. Volcanic rocks exposed along the east coast of the Antarctic Peninsula (Mapple Formation) are also dominated by rhyolitic ignimbrite flows, with individual units up to 80 m in thickness, and a total thickness of ca. 1 km. The ignimbrites vary in degree of welding, from high-grade rheomorphic ignimbrites with parataxitic textures, to unwelded, lithic-rich ignimbrites. The silicic rocks from Patagonia and the Antarctic Peninsula are chemically and isotopically indistinguishable and have a similar Middle Jurassic eruptive age, which strongly suggests a continuum between the two regions. Granitoid plutonic rocks of similar Middle Jurassic age and with identical isotopic (Sr and Nd) characteristics are also exposed extensively along the east coast of the Antarctic Peninsula and an identical source region to the volcanic rocks seems likely.

JSV22/P/01-A5 1650

DEEP STRUCTURE OF THE LITHOSPHERE BENEATH THE BASALTIC PROVINCES IN THE TRANSITIONAL ZONE FROM EURASIAN CONTINENT TO THE PACIFIC OCEAN

A.G.RODNIKOV (Geophysical Center, Molodezhnaya, 3,Moscow, 117296, Russia,
email: gcras@wdcb.rssi.ru)

Research was carried out along tree geotraverses made on the base of complex interpretation of geological and geophysical data. The first geotraverse across the structures of the Sikhote Alin, Japan Sea, Honshu Island and Northwest Pacific Ocean was prepared jointly with Japanese scientists. The second geotraverse across the North China Plain, East China Sea, Philippine Sea and Mariana Island Arc was carried out jointly with Chinese and Japanese specialists. The third geotraverse being under preparation now runs across the Sikhote Alin, Sea of Okhotsk, kuril Island and Pacific Ocean.
Volcanic rocks in the marginal sea basins occur predominantly as pillow lavas indicating submarine eruption. Most basalts are classified as olivine tholeiites. They form a series of N-and T-type MORB to E-type MORB. The general characteristics of the deep structure of the basaltic provinces of the marginal seas in the transitional zone from Eurasian continent to the Pacific Ocean are as follows: (1) the deep basins of the marginal seas overlie the asthenospheric diapir; (2) rift structures or spreading centers are in the base of deep basins; (3) active volcanism is present at the initial stage on the formation of a deep basins; (40 the hydrothennal activity with the sulfide deposits is observed in the rift structures. Probably, the asthenospheric diapir is a channel through with the hot mantle fluids rise from the asthenosphere into the deep basin.

STRUCTURAL-AGE RELATIONS AND PETROGEOCHEMICAL DIFFERENCES OF DOLERITES AND GABBRO IN OPHIOLITES OF THE URALS (RUSSIA)

Igor V. SEMYONOV, Yuri L. Ronkin (Institute of Geology and Geochemistry Urals Branch of Russian Akademy of Sciences, Pochtovy 7, 620151 Ekaterinburg, Russia, email: root@igg.e-burg.su)

The biggest in the world the ophiolite complex stretching almost for 2500 km along the Urals presents itself the preserved fragment of the Urals Paleozoic ocean - a part of Paleo-Tethys Ocean. In different degree preserved blocks of paleooceanic spreading structure as the enclosing rocks for the sheeted dyke complex there have been served already substantially deformed and cold rocks of dunite-harzburgite and dunite-clinopyroxenite-gabbro associations. On the contact with the bodies of gabbro and other rocks of these associations everywhere dolerite dykes have the edge hardened zones. Nowhere one could observe reverse relations - reliable hardened edge parts of bodies or the massifs of gabbro and ultrabasites on the contact with paleooceanic tholeiitic basalts of any facial nature. On their chemical and rare-earth contents dolerites sharply differ from gabbro. For example, dolerites an all petrochemical parameters are compareable with tholeiites of MOR and posses tholeiitic trend of differentiation (in parameters f-SiO2), while gabbro of both gabbro-ultrabasite associations have quite an opposite trend, not characteristic to magmatic series at all. Dolerites possess REE distributions close to chondrite or with obvious lack of light rare earths , while gabbro of dunite-harzburgite association have mainly W-like distributions of REE and dunite-clinopyroxenite-gabbro - distributions of REE with gradual increase of all the more lighter REE. The work has been done with RFFI (Russia) support - grant N 98-05-64809.

CRUST MANTLE INTERACTION AND ITS CONSTRAINTS ON THE FORMATION OF GIANT DEPOSITS – A CASE STUDY OF THE SHIZHUYUAN TUNGSTEN DEPOSIT, HUNAN PROVINCE, CHINA

Zhao ZHENUA, Bao Zhiwei, Zhang Boyou, Xiong Xiaolin (Guangzhou Institute of Geochemistry, Chinese Academy of Sciences, Guangzhou, 510640, China)

In recent years, our systematic investigation and some others' on the Shizhuyuan giant tungsten deposit, Hunan Province, China, have shown that there is a strong and prolonged crust-mantle interaction in this area, and played an important role in the ore-forming processes. The main geology and geochemistry evidences are as follows: 1. The Shizhuyuan giant tungsten deposit occurs in rift-like environment; 2. The Qianlishan granite which closely associated with the ore-formation is subalkaline with high Ga/Al*10000 values (average 3.85), low (18O values (5 ~ 7!k)#, varied (87Sr/86Sr#)i (lower case) (0.7032 ~ 0.73282), high 143(upper case) Nd/144 (upper case) Nd (0.512112~0.512344) and (epsron) Nd(T) = -4~-8; 3. Apart from granite, alkaline rocks, basaltic rocks and diabase are closely associated with ore formation temporally and spatially; 4. The Sr, Nd, and Pb isotopic compositions of the alkaline rocks and basaltic rocks and spinel lherzolite inclusions in the basaltic rocks show that the regional mantle was fertilized; 5. Isotopic compositions and trace elements of the ores show that mantle material played a role in the metallogeny: (1) Pb isotope compositions of the ores and the lower initial 187Os/186Os ratios of molybdenite in the ores (2.17(0.08) show clearly mantle material input; and (2) the ores are strongly enriched in volatile components such as F, Cl, B.

MANTLE METASOMATISM AND MANTLE ZONING BENEATH THE VIRUNGA VOLCANIC RANGE (CENTRAL-EASTERN AFRICA)

A.B. KAMPUNZU (Department of Geology, University of Botswana, Private Bag 0022, Gaborone, Botswana. E-mail: Kampunzu@noka.ub.bw)

The Virunga volcanic range is the best example of extensional perpotassic igneous province around the world. It is located in the western branch of the East African Rift System and straddle the boundaries between Democratic Republic of Congo, Rwanda and Uganda. This volcanic province includes eight major volcanoes, two of them (Nyiragongo and Nyamulagira) being active volcanoes. The main rock types in this volcanic province are basanites, nephelinites, leucitites, melilitites, tephrites, K-hawaiites, K-mugearites, K-benmoreites, trachytes and phonolites.
The geochemical investigation of mafic rocks with more than 5% MgO indicates a major increase of CaO, P2O5 and rare earth elements correlated to a decrease of SiO2, Al2O3, K2O and radiogenic isotope compositions from the east to the west of the volcanic province. This variation of composition of mafic rocks is shown to be the result of a zoning of the mantle source. This zoning is inherited from a ca 800 Ma old mantle metasomatism induced by the injection of alkaline-carbonatitic melts within the Proterozoic subcontinental lithosphere. The belt of Neoproterozoic alkaline-carbonatitic complexes aligned along the western branch of the East African Rift System strongly supports this model.

ORIGIN CONDITIONS FOR VITIM BASALTS

ASHCHEPKOV I.V (United Institute of Geology Geophysics and Mineralogy, SD RASC, Email: garnet@uiggm.nsc.ru)

Liquidus thermobarometry for Vitim basalts suggest that in intial stage Bereya block hydrous OIB picrite basaltts (mgi70) came from depth of 40-60kbar heated to 1500˚C. Associated Hi-K silisic basalts differentiated in the crust. The main plateau (14-7Ma) (mgi65-60) basanites with the slighhtly convex down LMREE part originated from peridotites gently U shaped and Cpx deficient as result of melt percolation in 32-25kbar interval while more differentiated are close to Ga-Sp boundary. Subalkaline ol-basalts interacted with peridotites ascending from garnet to spinel facie with the relic garnet revaeling more gentle PT pass. Typical Quaternary OIB Ne-mela-hawaiites (25-15 kbar) and more differentiated Ne-leico-hawaites with hydrous phases demonstrate more cold conditions of differentiation. The later are contaminated in host peridotites as well as Miocene basanites mixed with the DM (MORB0 type mantle. Geochemistry of HFSE elements suggest primary OIB type magmas in 1st and last stages to be individual representing heard and tail of the small plume. Megacrystalline pyroxenite assemblages demonstrate intermediate heating conditions between basalts and iherzolites and mixing signatures being orginated in pre-eruption small magma chambers or large veins.

JSP23/C/U5/P/01-A5 Invited **0830**

ATMOSPHERIC HAZARDS ASSOCIATED WITH THE EL NINO/SOUTHERN OSCILLATION PHENOMENA: A SYNTHESIS

Madhav L KHANDEKAR (Consultant, Baird & Associates, Ottawa, Ontario, CANADA, L3R 7Z5)

The ENSO phenomenon – spreading of warm water from the equatorial central Pacific to the equatorial South American coast and associated global weather anomalies -- is now identified as the strongest signal in the global climate system after the annual cycle. The term El Nino refers to the spreading of anomalously warm water off the coast of Ecuador and Peru and associated weather anomalies over the west coasts of the Americas. The Southern Oscillation is the atmospheric counterpart of El Nino and refers to the slowly varying atmospheric pressure differential over the eastern and western regions of the tropical Pacific. The two phenomena together are now popularly known by the acronym ENSO (El Nino/Southern Oscillation).
The appearance of warm water off the coast of South America and associated changes in the regional weather patterns were known to Peruvian fishermen for over 400 years. The landmark papers of Jacob Bjerknes in the Nineteen Sixties provided a physical link between ENSO and weather anomalies over the entire equatorial Indo-Pacific basin. Several studies inspired by Bjerknes' landmark papers and reported in the last twenty-five years have documented a link between ENSO and global weather anomalies.
This paper provides an overview of global weather anomalies and associated atmospheric hazards in the context of the ENSO phenomena. The paper further presents several examples of atmospheric hazards associated with extreme weather events and their relationship to the various phases of ENSO. The importance of monitoring various phases of the ENSO phenomena through suitable atmospheric and oceanic indices will be discussed in the context of long-range weather forecasting.

JSP23/W/04-A5 **0910**

ENSO AND 'ENSO-LIKE' IMPACTS ON INTERANNUAL TO SECULAR TIME SCALES

Robert J. ALLAN (CSIRO Atmospheric Research, Aspendale, Victoria 3195, Australia, email: rob.allan@dar.csiro.au); Ian N. Smith (CSIRO Atmospheric Research, Aspendale, Victoria 3195, Australia, email: ins@dar.csiro.au).

Efforts to improve our understanding of the various types of natural variability inherent in the global climate system have included a growing focus on the El Niño Southern Oscillation (ENSO) phenomenon and lower frequency 'ENSO-like' decadal to secular scale fluctuations. Signal detection analyses applied to global historical sea surface temperature and mean sea level pressure anomalies, reveal significant climatic signals operating on quasi-biennial, inter-annual, decadal multi-decadal and secular time scales. The ENSO signal is seen to consist of quasi-biennial (QB) and lower frequency (LF) components that interact to produce important modulations of the phenomenon. 'Protracted' El Niño and La Niña episodes are found to be a consequence of the 'phasing' of quasi-decadal and inter-decadal 'ENSO-like' signals with the QB and LF ENSO components. Further climatic modulations are provided by 'ENSO-like' phenomena operating on multi-decadal time scales. The secular trend, reflecting the observed global warming signal, reveals neutral to slightly 'La Niña-like' conditions in the Pacific sector. The impact of the above climatic signals can be seen in the patterns of correlation with global precipitation and mean surface land temperatures. Significant contributions to rainfall and land temperature variability are evident, not just in known 'ENSO-sensitive' regions. In addition, El Niño and La Niña episodes on inter-annual time scales can be both synchronous and asynchronous with 'El Niño-like' and 'La Niña-like' signals on various decadal to multi-decadal time scales, resulting in the range of fluctuations seen in many rainfall and temperature impacts over time.

JSP23/L/01/A5 **0930**

HAZARD AND RISK MITIGATION BY IMPROVING THE CULTURE OF SOCIETY AND OF THE DECISION MAKERS

FABRIZIO FERRUCCI and Giovanni P. Gregori

Hazard and risk management requires a precise preliminary assessment of their respective formal definition, sources and causes. The natural environment, likewise demography, territory use, and energy consumption, are not steady in time. They rather experience a continuous transformation or evolution. Every so-called natural catastrophe is a strict need by natural reality. Neither it makes sense to search for a forerunner (that in a strict sense can be given, at most, only with some relevant error bar, that makes a forecast of little practical help). Moreover, a prevision is often useless in terms of concrete reduction of causalities and/or damages. The entire problem rather emphasises per se the great need for improving the consciousness of the specific characteristics of every type of natural catastrophe, and of the ways by which its consequences can be prevented or minimised. A forgotten aspect of human history is concerned with the epoch when mankind got the consciousness of space orientation, and much later also of absolute time. Similarly to this, at present there is a great need for educating both society and decision makers about the correct cultural approach to Nature, to environmental knowledge, and to territory management. All this appears the unique concrete viable approach for solving the threaten by the progressively stronger impact of mankind on environment, a factor that is closely and unavoidably related to the same progress of civilisation. Several case histories will be specifically discussed.

JSP23/W/31-A5 **0950**

FLOOD EVENTS IN THE RHINE RIVER BASIN: GENESIS, INFLUENCES AND MITIGATION

Markus DISSE (German Federal Institute of Hydrology, P.O. Box 309, D-56003 Koblenz, Germany, Email: disse@bafg.de); Heinz Engel (German Federal Institute of Hydrology, P.O. Box 309, D-56003 Koblenz, Germany)

The catchment of the river Rhine can be distinguished in 4 main subcatchments: the alpine region with the river Aare as the main tributary and downstream the lower mountain regions of the tributaries Neckar, Main and Moselle. These four basins clearly generate different hydrographs. Due to the geographical circumstances, the average discharge maximum shifts from summer towards winter downstream the Rhine. However, spatial and temporal precipitation patterns have a strong influence on the individual flood. The particular genesis of recent and historical floods will be discussed. Besides the climatological causes a brief overview of the manmade alterations to the river system itself (Rhine and tributaries) and to the linked catchments are given and their effect will be indicated. However, up to now the influence of land surface and river training measures on flood conditions in the Rhine basin has not exactly been quantified. Therefore, the Dutch-German project LAHoR has been established within the framework of the EU-project IRMA (INTERREG II C Rhine Maas Activities). The results of this project may give efficient advice for the "Action Plan on Flood Defence" of the International Commission for the Protection of the Rhine (ICPR), which is briefly introduced. In this plan a multidisciplinary approach to mitigate floods is suggested that can yield to synergic effects between flood prevention, water management, regional planning, agriculture, forestry and ecological demands.

JSP23/E/37-A5 **1010**

THE SUVA EARTHQUAKE RISK MANAGEMENT SCENARIO PILOT PROJECT (SERMP) - MITIGATION OF EARTHQUAKE AND TSUNAMI RISKS FOR THE CITY OF SUVA, FIJI

Jack RYNN (Centre for Earthquake Research in Australia, PO Box 276, Indooroopilly, Brisbane, Queensland 4068, Australia, email: sally.brown@uq.net.au); Poasa Raveo (Department of Regional Development and Multi-Ethnic Affairs, Government of the Republic of Fiji, PO Box 2219, Government Buildings, Suva, Fiji); Atu Kaloumaira (South Pacific Disaster Reduction Management Office, c/o UNDP, Private Mail Bag, Suva, Fiji, email: atu@sopac.com.org)

The 1953 Suva earthquake (ML 5.6) and associated tsunami is a stark reminder of the vulnerability of the City of Suva to such natural hazards. Through the UN IDNDR program, per the 1994 "Yokohama Statement", the Government of the Republic of Fiji took the challenge to counter mitigation strategies. SERMP was a co-operative effort of the Government, UNDP-UNDHA and international consultants. A specific methodology was developed to address definitive project components of hazard, vulnerability and risk assessments, mitigation measures, response planning, public awareness, policy support and dissemination of findings. Wide-ranging outcomes for both earthquake and tsunami, of risk assessments, loss estimations, disaster planning, risk management and tsunami warning, with 90 recommendations, were documented as an ""information resource:" These were implemented as "practical applications" in building codes, GIS, land use planning, disaster plans, training, emergency management and community education. A Sub-Regional Seminar and exercise "SUVEQ 97""were conducted. SERMP also demonstrated mitigation measures to decision makers in all Pacific Island Countries.

JSP23/W/19-A5 1050

THE AUSTRALIAN ENVIRONMENTAL RISK MANAGEMENT FRAMEWORK

Tom BEER (CSIRO Atmospheric Research, Aspendale, 3195, Australia, email:Tom.Beer@dar.csiro.au)

Environmental risk management deals with impacts on the environment, as well as with impacts on organisations that disturb the environment. Management options are based on a measure of the risk, which is obtained through an analysis of both the likelihood and the consequences of the impact. Many of the concepts, and much of the terminology, of environmental risk assessment have arisen from its use by the US EPA as an objective tool that provides information on which to base environmental decisions. A key step in the United States was to maintain a clear separation between risk treatment and risk assessment. Risk treatment is an activity undertaken by decision-makers and managers, whereas risk assessment is an activity undertaken by technicians. Many workers have argued that one cannot maintain such a clear distinction and a conference of the Australian Academy of Science developed an Environmental Risk Management framework. Australia has been reluctant to embrace the US-inspired clear distinction between risk treatment and risk assessment. Australia has, instead, combined risk assessment (envisaged as a combination of risk analysis and risk evaluation) and risk treatment within a generic risk management framework that has been incorporated into the Australian/New Zealand Standard on Risk Management, AS/NZS 4360. This presentation synthesises the Australian Risk Management and Environmental Risk Management frameworks.

JSP23/W/02-A5 1110

CAUSE-EFFECT MODELS OF LARGE LANDSLIDES

Ewald P. BRUECKL (Vienna University of Technology, Gusshausstrasse 27-29, A-1040 Vienna, Austria, email: ebrueckl@ luna.tuwien.ac.at)

Within the scope of IDNDR cause-effect models of large landslides are being developed to estimate potential danger. This work is based on structural exploration of the landslides mainly by seismic methods. Information about the status of deformation is got by comparison of the actual topography with a reconstruction of the original topography, GPS and SAR interferometry. Geological and geomorphological evidence, as well as relevant information from other geoscientific disciplines, is included. The Finite Element method is used to model the initial phase of a mass movement. Later on this modelling will be extended to the quasi-stationary creep phase and the transition from creeping to rapid sliding.
Three large landslides within the crystalline rocks of the Eastern Alps have been investigated since 1997. The largest one is the Koefels landslide with a total volume of 3.9 km3 and a potential energy release of 5_1016 Joule. Refraction and reflection multi-component seismic techniques were applied successfully to resolve structure and elastic parameters of the landslide masses. For the modelling of the initial phase of the landslides by the Finite Element method a strain softening behaviour of the rock mass has been assumed. The development of softened or fractured zones according to the structures obtained by the seismic measurement was simulated.

PSEUDOSCIENCE U.N. DOCUMENT: GEOMAGNETIC FORECASTING OF EARTHQUAKES AND METEOROLOGICAL DISASTERS

Wallace H. CAMPBELL (World Data Center A for Solar-Terrestrial Physics, NGDC / NOAA, 325 Broadway, Boulder, CO 80303-3328, USA, e-mail: whc@ngdc.noaa.gov)

The United Nations recently published a "Manual on the Forecasting of Natural Disasters: Geomagnetic Methods" (1998) by Chinese and U.N. authors that stretches the imagination with prediction of earthquakes and Meteorological disasters. A careful reading of this document reveals an illusionary approach to the subject with no valid supporting evidence of prediction capability. The "mathematical" section simply copied well-known formulae that provided no scientific details of any physics connecting changes in geomagnetic recordings and subsequent localized disastrous earthquakes or meteorological events. The presented data indicated that 82.3 % of the recorded earthquakes did not correspond well to predictions. The authors ignored the recommendations and testing suggestions of a 1996 international London meeting, Assessment of Schemes for Earthquake Prediction. The manual provides clear and reliable evidence of the improper use of public funds for building hopes of disaster relief with projects totally lacking in scientific merit.

JSP23/W/26-A5 1150

25 SECONDS FOR BUCHAREST

Friedemann WENZEL, Mihnea C. Oncescu, Michael Baur and Frank Fiedrich (University of Karlsruhe, 76128 Karlsruhe, Germany, email: fwenzel@gpiwap1.physik.uni-karlsruhe.de); Constantin Ionescu (National Institute for Earth Physics, P.O. Box MG-2, 76900 Bucharest, Romania,
email: viorel@infp.ifa.ro)

The Romanian capital Bucharest faces a significant earthquake hazard with a 50% chance for an event in excess of 7.6 moment magnitude every 50 years. Within the last 60 years Romania experienced 4 strong Vrancea earthquakes: Nov. 10, 1940 (Mw = 7.7, 160 km deep); March 4, 1977 (Mw = 7.5, 100 km deep); Aug. 30, 1986 (Mw = 7.2, 140 km deep); May 30, 1990 (Mw = 6.9, 80 km deep). The 1977 event had catastrophic character with 35 high-rise buildings collapsed and 1500 causalities, the majority of them in Bucharest. A group of civil engineers and seismologists from the National Institute of Earth Physics (NIEP) in Romania and Karlsruhe University in Germany propose an Early Warning System (EWS) for the capital city of Bucharest. The group studied the seismological boundary conditions of an EWS for the Romanian capital of Bucharest. The earthquakes threatening the capital are intermediate deep events with magnitudes close to Mw = 8.0 at an almost fixed epicentral distance of about 150 km. The travel-time difference between the destructive S-wave arriving in Bucharest and the epicentral P-wave is always greater than 25 s, which represents the maximum possible warning time. Moreover source mechanisms are extremely stable for larger and smaller events so that a projection of the level of ground motion to be expected in Bucharest can be based on the amplitude of the epicentral P-wave rather than on cumbersome determination of magnitude and depth. This feature allows the design of a simple, robust and fast EWS. With 25 s, a system with the largest warning time after the Seismic Alarm System for Mexico City could be established. Even this small time window can provide opportunities to automatically trigger measures such as, shutdown computers; re-route electrical power; shutdown airport operations; shutdown manufacturing and high-energy facilities; stop trains; shutdown gas distribution; alert hospital operating rooms; open fire station doors; start emergency generators; stop elevators in a safe position; issue audio alarms; maintain safe-state in nuclear facilities. The value of an EWS can be judged on the basis of an application specific costs-benefit analysis, but simple considerations suggest that it will be cost-efficient.

JSP23/E/31-A5 1210

GLOBAL VOLCANIC SIMULATOR: ERUPTION FORECASTING AND URBAN PLANNING OFDENSELY POPULATED AREAS

Flavio DOBRAN (Global Volcanic and Environmental Systems Simulation, 32-50, 34 Street, Long Island City, New York 11106, Email: dobran@idt.net)

A Global Volcanic Simulator consists of physico-mathematical models of the volcano that are effectively implemented for solution on distributed or parallel computers. Such a simulator can be used to forecast future eruptions and for studying their effects on people and infrastructures for the purpose of mitigating eruption consequences. Current simulator for Vesuvius models magma reservoir volume, temperature, and pressure changes, variable rates of magma supply into the chamber, and varying elastic, plastic, and heat transfer characteristics of magma reservoir surroundings. Different types of magma ascent models allow for time-varying and non-isothermal simulations, including magma flow regime changes and melting of conduit walls. These models have been used to forecast that a plinian or subplinian eruption of Vesuvius will occur within the next 100 years and that the pyroclastic flows from column collapses can destroy the surrounding territory in several minutes. The simulator is also being employed to study the effects of different eruption scenarios on the territory and how this territory can be protected by engineering intervention measures. Computer simulations of possible eruptions of Vesuvius are also being utilised to sensitise the population of the area.
A useful simulator requires reliable geological and geophysical data of the volcano's internal structure, whereas the verification and validation of complex physical models on computers presents both computational and physical modeling challenges that are described in: Dobran, F., Theory of Structured Multiphase Mixtures, Springer Verlag, New York, 1991; Dobran F., Global Volcanic Simulation of Vesuvius, Giardini, Pisa, 1993; Dobran, F., Etna: Magma and Lava Flow Modeling and Volcanic System Definition Aimed at Hazard Assessment, Topografia Massaroa Offset, 1995.

EXTRATROPICAL EVOLUTION OF TROPICAL CYCLONES AS AN UNEXPLORED HAZARD IN MIDDLE AND HIGHER LATITUDES

Jenni L. EVANS (Department of Meteorology The Pennsylvania State University University Park PA 16802, USA.)

A recent climatology of extreme rainfall incidence in the northeast United States (including New England) reveals that the passage of a tropical cyclone is the cause of major rainfall events every 2-3 years over most of this region. Locations such as Boston and Cape Cod are particularly susceptible, with individual events resulting in twice their monthly rainfall due to a single tropical cyclone passage every 5-6 years. At the time that these tropical cyclones are delivering such copious rainfalls, they are typically undergoing complex structural changes that are poorly understood.
The lifecycle of the tropical cyclone through to a hybrid or truly extratropical cyclone and the associated rainfall evolution will be elucidated here and a theoretical underpinning provided.

NATURAL DISASTERS: A POSTGRADUATE PROGRAM AT UNIVERSITY OF KARLSRUHE

Jens MEHLHORN, Frank Fiedrich and Fritz Gehbauer (Institute for Construction Equipment and Construction Management, University of Karlsruhe, Am Fasanengarten, 76126 Karlsruhe, Germany, email: mehlhorn@imbdec1.bau-verm.uni-karlsruhe.de)

According to the United Nations the annual financial loss as a result of natural disasters increased from 50 billion to 360 billion US-dollar during the last 35 years. This fact presents a tremendous challenge to politics, society, and the scientific community. Disaster related research has to be increased. On the basis of fundamental research new knowledge will be created and used to develop practical tools for hazard and risk assessment. More effective measures for reducing this risk can be taken and the performance of emergency response can be improved. These steps towards a better understanding of disaster causes and effects and improved disaster management have been demanded since the UN-decade IDNDR (International Decade for Natural Disaster Reduction) started in 1991. The Postgraduate Program Natural Disasters has to be seen in this context. A total of 15 institutes of different fields work together in this project involving five departments of the university.
The research projects include topics like Modelling of Hazard and Risk, Development of Disaster Scenarios, Mitigation Aspects and Economic Consequences of Natural Disasters. During the first period the activities concentrate on floods, earthquakes, strong rainfalls and land-slides. Natural sciences like physics, hydrology, meteorology and geosciences give a contribution to the basic understanding of the disaster process. Mathematics and computer sciences are used for complex models, for modelling fuzzy and imprecise information and for forecasts. With the help of economics the risk can be quantified and evaluated. In addition the institutes dealing with engineering aspects develop measures and tools for risk mitigation.

JSP23/C/U5/W/13-A5 1440

WORLD MAP OF NATURAL HAZARDS – A DEPICTION OF THE GLOBAL DISTRIBUTION OF SIGNIFICANT HAZARDS AND THEIR INTENSITY

G. Berz, S. Ehrlicher, T. Loster, E. Rauch, A. Siebert, J. Schimetschek, J. SCHMIEDER, A. Smolka and A. Wirtz (Munich Re, Geoscience Research Group, D-80791 Munich, Germany, Tel. 0049-89-3891-5291, Fax: 0049-89-3891-5696, E-mail: info@munichre.com)

For over 25 years now Munich Re's Geoscience Research Group has been looking at natural hazards throughout the world. Twenty years ago it summarised the overall results of its work

in the first edition of the World Map of Natural Hazards. The map represents a unique source of information for numerous insurance companies, engineering offices, planning authorities, geoscientists, schools and interested lay people world-wide. For the recently released third edition all the basic data was for the first time captured and analysed using Munich Re's geographical information system (GIS). The resulting maps were created using digital cartography. Four auxiliary maps have supplemented the new edition. The earthquake and windstorm zones contained in the previous editions have been updated, refined and augmented. There are also details of other significant natural hazards like severe rainfall, storm surges, hail and lightning. A particularly interesting innovation is the auxiliary map on climate change. It deals on the one hand with the effects of El Niño, which generated so much interest and concern internationally in 1997/98 and was responsible for numerous natural catastrophes. Even more important are the effects that are to be expected from the emerging phenomenon of global warming, which will be accompanied by more frequent and more dramatic natural catastrophes in many parts of the world and will lead to a distinct long-term deterioration in the risk situation. The accompanying publication provides a detailed catalogue of historic natural catastrophes that have occurred in countries all over the world, grouped by continent and listed chronologically with additional information on the number of deaths and the economic losses.

JSP23/C/U5/W/11-A5 1500

ASSESSMENT OF HYDROLOGICAL HAZARDS OF VOLCANIC ALLUVIAL FANS

Kazuo OKUNISHI (Disaster Prevention Research Institute, Kyoto University); Gokanosho Uji, (611-0011 Japan, Email: okunishi@slope.dpri.kyoto-u.ac.jp); Hiroshi Suwa (Disaster Prevention Research Institute, Kyoto University, Gokanosho Uji, 611-0011 Japan, Email: suwa@slope.dpri.kyoto-u.ac.jp)

Alluvial fans on the foot of volcanoes have high hazard potential because of frequent inundation of debris flows and floods accompanying marked topographic changes. However, the social needs for the development of such lands are ever increasing, because of their high demand for recreational and touring sites. Assessment of hazard potential and regulation of land use are thus urgent problems. We propose fundamental principles for the assessment of hazard potential on the basis of a case study carried out at the Kikkakezawa Fan on the southern foot of Mt. Yatsugatake, central Japan. Existing villages are located below a major spring zone in the alluvial fan, which is fed by the groundwater in the volcanic body. Construction of a new road stimulated land developments along it and further upstream. It has been found that the debris-flow deposits had covered the fan in three geologically distinct ages. The ages of the deposits of new-age and middle-age debris flows are estimated on the basis of aerial photographs and a field investigation to assess their recurrence interval. The three kinds of debris flows are characterized by relative height from the current stream bed and by the area of deposition. Since the hazard assessment is needed for any part of the fan for any time span of the planned land use, it is advisable to define and assess the hazard potential of a fan from which the risk is calculated taking account of the location in the fan, and the time-span and the mode of the planned land use.

JSP23/E/54-A5 1520

THE ADVANTAGES OF HOLONIC DESIGN FOR WARNING AND ALARM SYSTEMS

Gary GIBSON (Seismology Research Centre, 2 Park Drive, Bundoora, Victoria 3083, Australia, email: gary@seis.com.au)

Warning and alarm systems are near real-time monitoring systems. They may be adversely affected by the events they are seeking to detect, such as a communication failure caused by an earthquake. Holonic systems were developed in manufacturing engineering, and require that each system element involves both task performing and decision making. A holon is an intelligent system element, either human or computer based, that is normally in communication with other holons. A holon is AUTONOMOUS (it can perform tasks alone if communications fail) and COOPERATIVE (overall results are enhanced when holons help each other, and it monitors the health of neighbouring holons, providing an immediate alarm if a failure is detected, and may attempt to compensate for any loss of function).
Holonic systems are designed so that no elements or communication links are critical. It must be accepted that any particular component will fail, and the system must be designed to cope with this. The Internet is a system designed to continue in operation after individual components have failed. An holonic system is one, which self-organises and evolves to dynamically optimise survivability, adaptability, flexibility, efficiency and effectiveness.
Earthquake and tsunami warning and alarm systems are ideally suited to holonic design. They use "Event Oriented Seismology", requiring minimal data flow. Each seismograph may be event triggered, may record continuously and only transmit selected waveform segments on request, and/or may transmit minimal continuous data to facilitate event detection. They respond to requests or issue messages to other holons in the system. Communication can vary from the Internet, to slow digital radio links, or even dial-up telephone. A system is holonic if each element sends and receives information to and from other elements, but continues to function autonomously when communications fail. Any system failure should be immediately reported by one or more system elements. Holonic systems may be very economical because they only perform the tasks that are required. Compared with continuously tele-metered data from non-holonic digitisers, there is a dramatic reduction in total data flow, and usually in operating cost, with enhanced reliability and flexibility.

URBAN LOCAL EARTHQUAKE DISASTER RISK INDEX

Yang TING (Geophysics Institute, China Seismological Bureau. Now at Shanghai SeismologicalBureau, No.87, LanxiRd. Shanghai,China, 200062, Email: tyang@263.net); Zhu Yuanqing (ShanghaiSeismological Bureau,No.87,Lanxi Rd.Shanghai,China,200062)

In many modern cities, especially megacities with low seismicity, there exist a lot of hidden disadvantages, except for the frequency of historical earthquake and ground shaking level, that may amplify the influence of earthquakes and cause a catastrophe to them. The Urban Local Earthquake Disaster Risk Index (ULEDRI), which is firstly presented by authors, will highlight those disadvantages with an easily understandable form for city decision-makers, planners, organizations and individuals. ULEDRI is a variation of EDRI, which is a new approach that can directly compare the relative overall earthquake disaster of megacities worldwide, and describe the relative contributions of various factors to that overall risk. Unlike EDRI, whose study unit is the greater metropolitan area, ULEDRI uses the local area of an urban, e.g. administrative district, postal area, as its unit of study. Whats more, depended on the demand of users, ULEDRIs study unit can be a larger one (e.g. every administrative district of city), or a smaller one (e.g. several blocks). As a result of this difference between EDRI and ULEDRI, the objectives, uses and developing approach of ULEDRI will differ distinctly from those of EDRI. ULEDRI involves a large amount of knowledge about earthquake disaster of a wide range of disciplines, and the factors that contribute to overall ULEDRI of a city include those of geophysics, geology, engineering, residents, socio-economics, culture and so on. ULEDRI has the following potential uses. First, this kind of index can serve as a simple tool to directly compare the relative overall earthquake disaster risk of different local area of a city, so the decision-makers and administrators can find where the most dangerous local area is when an earthquake affects the city. Second, through disaggregated ULEDRI, the users can find the reason why a local region has a high overall ULEDRI, and which factor is the most important one that causes this. For city planner and disaster manager, the information will be significant in urban function planning and disaster mitigation. Third, any organization and individual will be able to refer to the index in allocating resources and increasing awareness of disaster. As a sample, ULEDRI of Shanghai, which is based on several districts, has been constructed, and its feasibility and potential application have also assessed.

THE GSHAP WORLD MAP OF SEISMIC HAZARD

D. GIARDINI (ETH, 8093 Zurich, Switzerland, email: giardini@seismo.ifg.ethz.ch); G. Grunthal (GFZ, Potsdam, Germany); H. Gupta (NGRI, Hyderabad, India); D. Mayer-Rosa and S. Sellami (ETH, Zurich,Switzerland); K. Shedlock (USGS, Boulder, USA); P. Zhang (SSB, Beijing, China); T. Annaka (Tokyo Electric Power Sevices, Japan); M. G.-Ashtiany (IIEES, Tehran, Iran); K. Atakan (Bergen University, Norway); S. Balassanian (NSSP, Yerevan, Armenia); P. Basham (CTBTO, Vienna, Austria); C. Dimate (Ingeominas, Bogota, Colombia);; M. Erdik (Kandilli Obs., Istanbul, Turkey); M. Garcia (CSIC, Barcelona, Spain); Giesecke (CERESIS, Lima, Peru); K. McCue (AGSO, Canberra, Australia); R. McGuire (Risk Engineering, Boulder, USA); R. Musson (BGS, Edimburgh, UK); S. Riad (Assiut University, Cairo,Egypt); D. Slejko (OGS, Trieste, Italy); V. Ulomov (JIPE, Moscow, Russia)

The Working Groups of the GSHAP regions: Central-North America, Central-Northern Europe, Eastern Asia, Northern Eurasia, Ibero- Maghreb, Adria, the working Groups of the projects: PILOTO, CAUCAS, RELEMR, SESAME, PAIGH-IDRC, EU-QSEZ-CIRPAN.
The Global Seismic Hazard Assessment Program (GSHAP) was launched in 1992 by ILP and ICSU and endorsed as a demonstration program by the UN/IDNDR. The GSHAP promoted a regionally co-ordinated, homogeneous approach to seismic hazard evaluation. Regional activities were concluded in 1992-98; the results have now been compiled in a uniform set of databases and in a world map of seismic hazard expressed in PGA. Support for the GSHAP implementation was provided by ING, Roma, by national and regional institutions, by IASPEI, UNESCO, ICSU, ILP, IDNDR, EU, NATO, INTAS and IGCP. All GSHAP materials (regional report, maps, datasets) can be retrieved on the GSHAP web site at http://seismo.ethz.ch/GSHAP/. The GSHAP world map of seismic hazard will be presented for the first time at the IUGG assembly and will be available for distribution at the assembly.

JSP23/E/33-A5 1640

RISK ASSESSMENT AND MANAGEMENT IN RUSSIA

Shakhramanjyan M.A.(1), Nigmetov G.M.(1), Larionov V.I (1), FROLOVA N.I.(2), Suchzhev S.P.(3), Ugarov A.N.(3) Agency on Monitoring and Forecast of Emergency Situations, Ministry of Emergency Situation of Russian Federation (2)Seismological Center of IGE, Russian Academy of Sciences (3) Extreme Situations Research Center

At present in Russia the new technologies and procedures of natural and technological disasters monitoring and forecast of their consequences are elaborated and implemented. they are the following: procedure for individual seismic risk and losses assessment and identification of effective response scenarios; technology of operative zonation of the territories according to the rate of forest fires and flooding hazards; procedure of complex risk assessment and mapping with taking into account different natural and technological hazards; technology od estimation of buildings and structures' stability and earthquake resistance with the help of mobile diagnostic complexes; technology of operative monitoring of the territories with the use of remote sensing. All the technologies and procedures are realised on the basis of modern geographical information systems (GIS). The main blocks of the special GIS is described. The examples of individual seismic risk computations for different earthquake prone areas and cities of the Russian Federation, as well as for other countries are given. The influence of secondary engineering geological processes (landslides and liquefaction) is considered. The procedure of acceptable seismic risk level estimation is proposed. The examples of complex risk estimations are also given for the areas where different natural hazards (earthquakes, volcanic hazard, tsunami, flooding, hurricanes and storms, avalanches, forest fires) are possible. The preventive measures plans and measures for reduction the risks from separate hazards are proposed. The maps of operative zonation of the territories according to the rate of forest fires and flooding hazards are presented for some regions of Russia and other countries. The application of the obtained results to disaster management practice may increase significantly the efficiency of measures aimed at risk reduction for population in urban areas.

JSP23/E/39-A5 1700

EARTHQUAKE RISK ASSESSMENTS AND PRACTICAL APPLICATIONS FOR EARTHQUAKE MITIGATION STRATEGIES IN AUSTRALIA

Jack RYNN (Centre for Earthquake Research in Australia, PO Box 276, Indooroopilly, Brisbane, Queensland 4068, Australia, email: sally.brown@uq.net.au)

In response to the United Nations IDNDR program, the Australian IDNDR Co-ordination Committee of Emergency Management Australia facilitated the earthquake zonation mapping of urban areas in Australia as one of its initial projects. The catalyst for this was the devastating 28 December 1989 Newcastle earthquake. A specific methodology was developed which has been expanded to address the national requirements for earthquake mitigation strategies. This involves a multidisciplinary approach integrating, both quantitatively and qualitatively, earth science, engineering, socio-economic, humanitarian, disaster planning, emergency management and community aspects. The results are compiled as an "information resource" in terms of hazard and vulnerability assessments and the integrated risk assessments, earthquake scenarios, potential ground motions and possible damage situations relative to the built and natural environments and the community. the outcomes are translated into practical applications to address awareness and preparedness for earthquake codes,

JSP23/W/11-A5 1720

HYDRODYNAMIC SIMULATION EXTREME STORM SURGES IN AZOV AND CASPIAN SEAS

Olga TIKHONOVA, Sergei Popov, Guennady Safronov, Oleg Zilberstein (State Oceanographic Institute, Kropotkinski per. 6, 119838, Moscow, Russia, email: oleg@soins.msk.ru)

Problems of storm surges description and prediction are very important because surges often lead to loss of human life and bring substantial damages to national economies. Thus for prevention their fatal consequences it is necessary to forecast storm surges according to available operative meteorological information and to calculate the storm surges characteristics. Besides of that, each extreme storm surge case is very important for determination of long return period characteristics of sea level and currents for hydrodynamic

support hydro-technical engineering and marine shelf oil and gas exploration. Design and installation of stationary shelf oil platforms require information about vertical structure of currents. These characteristics are obtained by the 3D hydrodynamic model simulation. In this paper a non-linear 2D and 3D hydrodynamic models were applied for calculation of some extreme storm surges in Azov and Caspian Seas (including the catastrophic cases). The regime of sea level variations was investigated.
GIS mapping, education and training, loss reduction, disaster planning and emergency management. Such projects have been undertaken in the urban areas of Sydney, Southeast Queensland, Newcastle and Melbourne. Particular effort is directed towards real-time simulated earthquake exercises in co-operation with emergency services authorities. Collaboration with several international organisations and other risk projects in Australia is continuing. Although Australia is a moderate seismicity active interplate regime, the record of albeit "rare" earthquake disasters pointedly attests to the need for mitigation strategies.

JSP23/E/40-A5 1740

TOWARDS REAL-TIME MONITORING OF LAVA EFFUSION RATES DURING VOLCANIC ERUPTIONS

Andrew HARRIS and Luke Flynn (HIGP/SOEST, University of Hawaii, 2525 Correa Road, Honolulu, HI 96822, USA, email: harris@kahana.pgd.hawaii.edu)

Determining volumetric effusion rates for lava flows is an important but challenging task. Effusion rates are a major consideration in considering the potential threat posed by a lava flow. For channel-fed flows, higher effusion rates produce flows that are longer, more rapidly moving, voluminous, and aerially extensive than those with low effusion rates. High effusion rate flows thus have greater potential to inflict damage on distant communities with less advance warning. To calculate effusion rates we use satellite-derived (TM and AVHRR) thermal data in a heat balance. High spatial resolution TM data are collected infrequently, but allow high precision. Using TM data for active flows at Kilauea, Hawaii, we obtain effusion rates of 1.76±0.57 and 0.78±0.27 cubic meters per second on 23 July and 11 October 1991, respectively. These rates compare with field measurements of 1.36±0.14 and 0.89±0.09. Using lower spatial resolution weather satellite (AVHRR) data collected at higher spatial resolution (>1 image per day), we obtain similar but more poorly constrained effusion rates. However, comparison with ground-based and TM data for eruptions at Kilauea, Krafla and Etna show that the AVHRR-derived time series reliably show waxing and waning phases of effusive eruptions with high temporal precision.
All of our systems are automated, and with direction reception of TM and AVHRR at the University of Hawaii we anticipate providing a web-based real-time lava flow monitoring tool. This will display current effusion rate time series, up-dated within minutes of satellite overpass at-least once every 6 hours for AVHRR, once every 8 days for TM. This system will be similar to our GOES-based real-time hot spot monitoring site at http://volcano1.pgd.hawaii.edu.

Concurrent Poster Session

SEISMIC RISK MAPS AND SCENARIOS: TOOLS FOR THE PROTECTION AGAINST EARTHQUAKES

JSP23/W/17-A6 0830

THE LONG AND WIDING ROAD FROM EARTHQUAKES TO DAMAGE

A. Ansal (Istanbul Technical University, Faculty of Civil Engineering, Maslak, Istanbul 80620, Turkey, tel: (90)-212-285 3702, fax: (90)-212-2856006, e-mail: ansal@itu.edu.tr); D. SLEJKO (Osservatorio Geofisico Sperimentale, P.O.Box 2011, 34016 Trieste, Italy, tel: (39)-40-2140248, fax: (39)-40-327307, e-mail: dslejko@ogs.trieste.it)

The impact of destructive earthquakes has two faces: one in the short term and the other in the long term. The first is given by the number of victims, damaged structures and direct economic losses. The second is given by the negative influence on the social structure in the following years. Although the direct economic loses can be absorbed by the country, especially with international support, in most cases the social structure suffers permanent damages. The recent earthquakes of Northridge and Kobe have shown the long term problems caused respectively to the insurance companies and private habitants. This is one of the reasons why in seismically active countries (e. g.: Italy), a general private insurance against natural calamities is now being implemented. The knowledge on seismic risk is, therefore, fundamental for loss reduction. Seismic hazard maps at national level are the basic tool for defining the national seismic zonation which is relevant for planning adequately new settlements and constructing properly new buildings. The choice of the hazard parameter to consider for zonation is critical when the description of the whole contents of the seismic excitation is desired. However, these maps are only valid at large scales and local effects are not taken into consideration. Seismic risk maps at national scale are strategic for planning the policy for retrofitting old buildings in the presence of limited investments: their definition in a quantitative manner remains mainly a research topic for the difficulty of quantifying properly the ingredients. Risk scenarios at regional to local scale are very popular in recent years as they have the potential to limit earthquake victims and structural damage when a dangerous event is presumed to take place. In fact, based on the information and analysis concerning earthquake resistance capacity of existing buildings and structures, strengthening and retrofitting programmes can be optimised. The good knowledge …

JSP23/E/34-A6 0850

DETERMINISTIC VS. PROBABILISTIC EARTHQUAKE HAZARDS AND RISKS

Robin K. MCGUIRE (Risk Engineering, Inc., 4155 Darley Ave, Suite A, Boulder, Colorado, 80403, USA, email: mcguire@riskeng.com)

Deterministic vs. probabilistic approaches to assessing earthquake hazards and risks have differences, advantages, and disadvantages that often preclude the use of one over the other. Factors that influence the choice include the decision to be made (i.e. the purpose of the hazard or risk assessment), the seismic environment (whether the location is in a high, moderate, or low seismic risk region), and the scope of the assessment (a single-site risk, a multi-site risk, or risk to a region).
Decisions coming from earthquake assessments include selection of design or retrofit criteria and levels, financial planning for earthquake losses, and planning for emergency response and long-term recovery. The more quantitative the decision to be made, the more appropriate is probabilistic hazard and risk assessment.
For high seismic regions (e.g. California or Japan) where the largest earthquakes occur every 100-300 years), a deterministic scenario for the largest event will allow details to be examined such as ground motion effects caused by rupture propagation. In low seismic regions, extreme deterministic scenarios will have probabilities of occurrence that are too low to be useful for most decision purposes.
Specific site analyses generally require a probabilistic approach. Multiple-site analyses (e.g. for a portfolio of exposed or insured properties, or a lifeline) often require a probabilistic analysis because of multiple variables and complexities of the system, and a deterministic check can be misleading. Regional assessments often benefit most from deterministic models.

JSP23/C/ST3/E/21-A6 0910

METHODOLOGICAL CONSIDERATIONS OF PROBABILISTIC SEISMIC HAZARD MAPPING

R.M.W. MUSSON (British Geological Survey, West Mains Road, Edinburgh, EH9 3LA, UK, Email: R.Musson@bgs.ac.uk)

The study of seismic hazard is perhaps the most practically oriented aspect of earthquake seismology. As such, it should not be treated in an idealised or academic manner, but with regard to the needs of the consumers of the final product. This has important consequences when it comes to the topic of probabilistic seismic hazard maps. Who are these for? Historically, early studies of probabilistic seismic hazard tended to be done for engineers for specific design requirements. Consequently, there has been a tendency to treat seismic hazard maps as a sort of pan-national study for engineers, who can identify the design requirements for any site by picking them from the map. A dissenting point of view argues that seismic hazard maps are by their very nature too generalised to be used in this way; that such maps provide a first indication of relative hazard and should not be a substitute for site studies. There are, therefore, a number of interesting and important methodological questions to be asked: what are the practical differences in undertaking a seismic hazard map from calculating hazard for a site? Should probabilistic seismic hazard maps have the same degree of conservatism as site studies? How can seismologists meet the needs of different audiences? An engineer may think in terms of ground acceleration, but this parameter probably means little to people in other professions who still need access to seismic hazard data, but in a form they can understand. These are questions that need to be addressed directly; one should not leave them to be answered by default.

JSP23/E/03-A6 0930

EARTHQUAKE SCENARIOS FOR SWITZERLAND

FAEH, D., Bay, F., Giardini, D., Kind, F., Mayer-Rosa, D., Sellami, S. (Swiss Seismological Service, ETH Zurich); Lang, K., Bachmann, H., Wenk.,T. (Institute of Structural Engineering, ETH Zurich); Noack, T., Huggenberger, P. (Institute of Geology, University of Basel)

The goal of our project is to develop a method for the estimation of expected damage from earthquakes. The presentation is giving an overview of the state of the project, which includes, the modelling and mapping of ground motion on a regional scale for the area of Switzerland, and on a local scale for the Basel area, the classification of the vulnerability of buildings to earthquake ground motion for some target areas, and the realization of scenarios. We will present the deterministic seismic hazard in form of scenario ground motion maps. This can be done on a regional scale or on a local (microzonation) scale. On the regional scale the scenario ground motion maps should include significant earthquakes in a regional sense. Maps will then display ground motion with different probabilities of occurrence in different locations. On a local scale, ground motion scenario maps are most appropriately computed for single possible earthquakes, and these maps can be combined with a vulnerability assessment of existing structures. In this combination the scenario maps include the level and duration of shaking. Furthermore they make it possible to identify localities where ground is likely to fail through liquefaction or landslides, and they enable us to pinpoint structures that are likely to be severely damaged and to find weak links in life-line structures. Such studies can be done with different levels of detail. The project will contribute to the necessary seismic upgrading of existing buildings, as well as to reliable earthquake resistant design of new structures, to the education of the general public, the emergency planning and it will serve as a reminder that there is a large difference between what is expected from probabilistic maps and what is a possible event.

JSP23/E/08-A6 0950

REGIONAL AND LOCAL SEISMIC HAZARD ASSESSMENT

A. MARCELLINI, R. Daminelli, G. Franceschina e M.Pagani (Istituto di Ricerca sul Rischio Sismico, CNR, via Bassini 15, 20133 Milano, Italy, e-mail: marcel@irrs.mi.cnr.it)

Site effects can produce, at a local scale, abrupt changes of the ground motion as also instability phenomena such as landslides and soil liquefaction; microzonation studies are the scientific response for the evaluation and mitigation of this kind of phenomena. Seismic microzonation generally produces on a municipal scale Landuse planning criteria and defines seismic actions for engineering purposes. Seismic codes instead, are issued on the basis of Seismic Hazard studies, that is, seismic actions and seismic zonation are a direct consequence of a probabilistic seismic hazard, generally assessed considering a 474 yr R.P. In other words seismic actions assessment is biased by the inefficiency of seismic hazard evaluation procedure to account properly of parameters controlling the ground motion, mainly due to the limited number of factors used in the attenuation laws. It should be pointed out that till now this limits appears unavoidable due to the scarcity of strong motion accordings. Microzonation investigation can overcome these limitations, but only if the reference input motion is properly assessed by adopting the same level and the same criteria of protection used to issue seismic codes at national level. The case study here presented refers to a zonation and microzonation investigation performed in the Forlì provincia (Emilia-Romagna) for the purposes of seismic prescriptions to be issued both at regional and local level and we will main focus on the importance of multiple approach for the definition of the reference input motion.

JSP23/C/U5/W/06-A6 1010

NEAR-FIELD GROUND MOTIONS

N. AMBRASEYS (Imperial College, London)

The assessment of earthquake hazard of interest to the engineer must be based on the analysis of reliable observational data than on statistics of many records and seismological parameters of questionable quality. Theoretical methods for the prediction of ground motions have become highly developed, whilst knowledge of the observational material is usually lacking. Differences between attenuation laws arise from the size and distribution of the sets of data used in their derivation and from the use of different magnitude scales, which introduce significant bias in the results. In addition, the correction of records and the modelling of attenuation laws and fitting method used to regress the data are sources of systematic errors. Taking some of these differences into consideration we find no significant variation of attenuation laws among different regions for shallow earthquakes, and a remarkable agreement between attenuation laws derived for Europe, western North America and New Zealand. They are all within the standard deviation of the determinations, which are not better than by a factor of 1.7 for accelerations. The importance of the vertical acceleration needs further investigation. However, the observation that the ratio of peak vertical zero-period or

spectral value, to that of the horizontal, can be larger than 1.0 does not necessarily imply large vertical accelerations or spectral ordinates, most certainly when these maxima occur simultaneously. Also the assessment of peak and spectral ground displacements, which is of some engineering importance, needs further investigation. Near-field ground motions from medium and large magnitude earthquakes associated with surface faulting or, from sites on low-strength deposits, contain a significant component of permanent displacement, not accounted or in standard base-line correction procedures. An answer to these question is needed in order to rank these effects among other variables, and clarify the need to include or exclude them from building codes.

JSP23/W/18-A6 1050

ASSESSMENT OF STRONG EARTHQUAKE GROUND MOTIONS FOR NEAR-FAULT CONDITIONS

Mustafa ERDIK, Eser Durukal (Bogazici University, Kandilli Obs. And Earthq. Res. Inst. 81220 Cengelkoy, Istanbul, Turkey, email: erdik@boun.edu.tr, durukal@boun.edu.tr)

Near-fault ground motions are strongly influenced by the earthquake faulting mechanism. Especially, the motions with periods above 1s may follow certain radiation patterns, predicted by equivalent double-couple source models, and exhibit distinct long period pulses with amplitudes depending on the orientation of the site with respect to the rupture direction. Widely use predictive earthquake engineering tools, such as empirical attenuation relationships and spectral shapes fail in the assessment of such near fault motions. Deterministic theoretical predictions of the ground motion can be achieved by convolution of the Green's Functions and the slip function. Such deterministic predictions cannot be extended into the frequency regions above 1Hz, since, high frequency ground motions are controlled by the heterogeneities in the fault rupture, which cannot be accounted for in a deterministic manner. This requires either the use of stochastic source models or the stochastic treatment of the high frequency components in the ground motions.
Based on these developments a state-of-the art hybrid procedure is developed for the assessment of the time history of the DBE (or SEE) ground motion for important engineering structures near major faults. The essential elements of the procedure can be listed as follows: (1) Assessment of the source parameters of the DBE motion associated with the corresponding return period for specific conditions of site and seismicity; (2) Deterministic assessment of the low frequency (DC-1Hz) ground motion, at the outcrop of a reference soil layer, due to rupture of seismic faults using numerical simulation; (3) Use of a Boore (1983) type stochastic simulation method to complement the deterministic low frequency ground motion with high frequency (1Hz- 50Hz) components; (4) Combination of the two parts of ground motion to yield a site-specific simulation for a frequency range of DC-50 Hz.; and (5) Site response analysis, if required, to include the local wave propagation effects in the soil media above the reference soil layer.
An example that illustrates the application of this procedure is provided.

MODIFICATIONS TO SEISMIC HAZARD DUE TO SITE-CITY INTERACTION

Pierre-Yves BARD, Philippe Gueguen (Laboratoire Central des Ponts- et-Chaussies and Observatoire de Grenoble, BP 53 - 38041 Grenoble Cedex - France,
email: Pierre-Yves.Bard@lgit.obs.ujf- grenoble.fr); Jean-Frangois Semblat (LCPC, 58 Bd Lefebvre, 75732 Paris Cedex 15 - France); Martin Cardenas and Francisco Chavez- Garcia (Coordinacion de Ingenieria Sismologica, Instituto de Ingenieria, UNAM, Ciudad Universitaria, Apdo. Postal 70-472, Coyoacan, 04510 Mixico, D.F)

Soil-structure interaction has long been known to significantly affect the seismic behavior of large buildings on soft soils. A few observations, and several computations as well, recently indicated the possibility for significant feed-back effects from buildings into the soil: the waves radiated back into the soil from the soil-struture interface are trapped in the surface layers when the impedance contrast at depth is large enough, so that the building is acting as a secondary source of surface waves. This phenomena has been shown to be maximum in case of coincidence between the building and ground natural frequencies: the worst case corresponds to the matching of fundamental frequencies, and induces ground motion modifications of at least 30 % in time- domain amplitudes within distances up to 5 to 10 times the building base dimensions. The question then arises of the possibility of large-scale site-city interaction due to the quasi- random superposition of such phenomena for a large number of buildings in a given city, or in a given quarter, which, in turn, raises two issues: Is the "free-field record" concept relevant in such areas? And will the construction or destruction of some buildings modify locally the hazard? The aim of the presentation is not to answer these questions, but simply to briefly review the reasons why these issues have to be addressed, and to present some preliminary, first order computations exhibiting significant effects not only for "exceptional" configurations such as Mexico City, but also for much more common situations with "ordinary" sediments and "ordinary" buildings.

JSP23/W/20-A6 1130

THE CYCLIC BEHAVIOUR OF SOILS AND EFFECTS OF GEOTECHNICAL FACTORS IN MICROZONATION

Atilla ANSAL (Istanbul Technical Uni, Civil Engng., Maslak, Istanbul, Turkey, email:ansal@itu.edu.tr)

The behaviour of soils subjected to cyclic loading is briefly reviewed. The results obtained from cyclic triaxial, simple shear and torsional hollow cylinder tests conducted on undisturbed, normally consolidated clay samples subjected to different shear stress amplitudes and different loading patterns are summarised. Results of the tests conducted under uniform cyclic stresses to evaluate "cyclic yield stress" and "threshold cyclic shear stress" are presented. The effects of cyclic loading on static shear strength and induced settlements due to pore water pressure dissipation are discussed. Cyclic tests performed to evaluate the liquefaction susceptibility of laboratory prepared and undisturbed sands and silty clayey sands are briefly reviewed in the light of the findings reported in the literature.
Geotechnical site conditions is one of the main factors controlling earthquake forces affecting structures. Therefore, in analysing the observed damage in previous earthquakes and for microzonation studies, this factor and its coupled effect with earthquake source characteristics need to be evaluated. The earthquake source characteristics induced by a tectonic source mechanism are on macro level and are not sufficient to explain the variations in structural damage observed within short distances. On the contrary, the geotechnical site conditions that can be very different due to changes in the thickness and properties of soil layers, depth of bedrock and water table, can have more dominant influence on damage distribution. In addition the effect of coupling between site and source characteristics may modify earthquake ground motion characteristics significantly. There are large numbers of instrumental field observations obtained during recent earthquakes reflecting the coupled effects of geotechnical site and earthquake source characteristics. During earthquakes soil layers are subjected to multi-directional cyclic stresses with different amplitudes and frequencies that lead to cyclic deformations and to changes in stress-strain and strength properties of soil layers. Extensive laboratory, model and field studies were conducted concerning response of soils subjected to cyclic stresses. Significant improvements were achieved in the field of insitu tests to obtain more reliable soil properties. Numerous analytical and empirical relationships were developed to model the behaviour of soil deposits subjected to earthquake excitations. From an engineering perspective, it is possible to investigate the properties of geo-technical site conditions in detail and analyse the response of soil layers with sufficient accuracy.

JSP23/E/05-A6 1150

LOCAL SITE EFFECTS AND DYNAMIC SOIL BEHAVIOUR

Erdal SAFAK (U.S. Geological Survey, Box 25046, MS 966, Denver, CO 80225, USA,
email: safak@usgs.gov)

Amplitudes of seismic waves increase significantly as they pass through soft soil layers near the earth's surface. This phenomenon, commonly known as site amplification, is a major factor influencing the amount of damage on structures. It is crucial that site amplification is accounted for when designing structures on soft soil sites. The characteristics of site amplification, at a given site, can be estimated by analytical models, as well as field tests. Analytical models require as inputs the geometry of all soil layers from surface to bedrock, their dynamic properties (e.g., density, wave velocity, damping), and the incident bedrock motions. Field tests involve recording and analyzing the dynamic response of sites to artificial excitations, ambient forces, and actual earthquakes. The most reliable estimates of site amplification are obtained by analyzing the recorded motions of the site during earthquakes.
This paper presents a review of the models and methods that are used to characterise site amplification, and introduces some new ones with better theoretical foundations. The models and methods discussed include spectral and cross-spectral ratios, response spectral ratios, constant amplification factors, parametric models, physical models, time-varying filters, methods for downhole records, single-station methods, and generalised inversion techniques. The paper also examines the validity of one-dimensional models, in comparison to 2D and 3D models, and shows the effects of surface waves and surface-to-bedrock topography on site amplification estimates. The paper concludes that probabilistically cross-spectral ratios give more reliable estimates of site amplification than spectral ratios. Spectral ratios should not be used to determine site amplification from downhole-surface recording pairs because of the feedback in the downhole sensor. Response spectral ratios are appropriate for low frequencies, but overestimate the amplification at high frequencies. One-dimensional site amplification models are not appropriate for sites in deep sedimentary basins that are susceptible to generating surface waves. The surface topography…

THREE DIMENSIONAL PLATE KINEMATICS IN ROMANIA

Georg Dinter (Department of Geodesy, University of Karlsruhe, D-76128 Karlsruhe, Germany,
email: dinter@gik.uni-karlsruhe.de); Guenter SCHMITT (Department of Geodesy, University of Karlsruhe, D-76128 Karlsruhe, Germany, email: schmitt@gik.uni-karlsruhe.de)

Since 1996 the Collaborative Research Center (CRC)461 ``Strong Earthquakes: A Challenge for Geosciences and Civil Engineering'' is funded by the Deutsche Forschungsgemeinschaft (German Research Foundation) as a German Contribution to the UN initiative ``International Decade of Desaster Reduction'' (IDNDR). A central project of this CRC is the subproject B1 ``Three dimensional Platekinematics in Romania'' which is installed to detect borders of the geotectonic plates in Romania, to quantify their three dimensional movement rates and to determine in detail the deformation of each geotectonic unit in the Vrancea Region as a contribution to the research of the tectonic cause of the intermediate depth earthquakes in this region. These aims shall be accomplished by repeated GPS-measurements in a network which has been installed in 1997 and measured until now in 1997 and 1998. This network is consisting of 26 stations, covering an area of 250 x 380 km with the Vrancea area as the centre. The frame is given by six stations of the CEGRN (Central European Geodynamic Regional Network) of the CEI-Initiative CERGOP, for which co-ordinates and velocities in a global tectonic scenario are available. The paper gives information about the tectonic background, the geodetic network, the GPS-measurements and the achieved accuracy's and first results of deformation analyses.

EVALUATION OF VULNERABILITY OF CIVIL ENGINEERING STRUCTURES

Mauro DOLCE (Department of Structures, Soil Mechanics, Applied Geology, University of Basilicata, Potenza, Italy)

The impact of earthquakes on man-built systems (buildings, groups of buildings, lifelines, cities, etc.) is usually expressed in terms of losses. Loss assessment is a highly complicated task, involving, besides structural engineering and seismology, many disciplines such as geotechnical, transport, hydraulic and electrical engineering, geology, urban planning, social and economic sciences, etc. However most of the losses results from the consequences of direct damage to civil engineering constructions, particularly buildings. The evaluation of their seismic vulnerability is then a fundamental step in the process of determining the impact of earthquakes on man-built systems. This is usually assessed in terms of seismic risk in a period of time (e.g. one year, hundred years), i.e. in terms of probability or of expectation of losses during that period due to all the possible arriving earthquakes. This representation is very general but presents many drawbacks such as the difficulty of interpreting the results in practical terms and the difficulty of expressing and quantifying losses for territorial systems. In fact they are highly dynamical systems, whose future developments are difficult to forecast, particularly after the occurrence of an earthquake. A long term loss prediction is therefore not much significant, if it is referred to the current situation or even to the current trend.
Recently the interest of researchers and operators has been focused on risk scenarios, where the impact of a given earthquake is investigated and quantified. This approach permits to better understand the behavior of the built environment under study and to take the countermeasures aimed at reducing its impact. Scenarios can be prepared considering different aspects of the earthquake consequences. Different levels of accuracy can be assumed in the preparation of a scenario, starting from the assessment of shaking intensity and characteristics, through damage prediction up to loss assessment. Obviously the accuracy levels in the different steps must be consistent.
The assessment of damage to constructions deserves a special attention. In this respect, two ...

JSP23/L/07-A6 1420

FROM VULNERABILITY OF OBJECTS TO VULNERABILITY OF SYSTEMS

Carlo GAVARINI (Universita' La Sapienza, Roma, Italy)

First of all the paper outlines the current conceptions relevant to vulnerability of constructions, describing the various approaches and the different research levels, then, in the second part,

a more global vision is developed in which the constructions belonging to an aggregate, or a centre, or a city, or a territorial area, are considered as a part of a vulnerable system, with all the complexity that it brings about, in terms of different variables that must be taken in consideration, properties and values that are in danger, disciplinary, cultural and historical aspects that must not be ignored.
Assessment of vulnerability is strictly connected with another basic problem, risk mitigation, that will be briefly considered in the third part, analysing the interrelations between vulnerability and environment aggressions. Also here we must point out how today it is a common exigency, also as regards technical codes, to abandon the sectional vision of objects considered separately and to promote instead the above mentioned 'picture in picture' vision applied to systems, better said to complex systems, specially when the areas in question are rich with particular 'objects' with a 'cultural value', such as historical buildings and monuments.
Lastly, in the fourth part, we return to deal with single objects, giving a short account of problems specific to monuments and in particular to churches subjected to seismic actions; referring to studies regarding the Cathedral of Noto, partially collapsed in 1996 and now in course of reconstruction.
The need for experiments, either real or virtual, is recognized as a key for understanding and classifying the…

LOSS ESTIMATION: A POWERFUL TOOL FOR RISK ASSESSMENT AND MANAGEMENT

Fouad BENDIMERAD (Risk Management Solutions, Inc., 149 Commonwealth Drive, Menlo Park, CA 94025, USA; email: fouadb@riskinc.com)

Earlier loss estimation studies were limited to investigating particular scenarios and were carried out by highly specialized experts. Today, loss estimation techniques are translated into efficient software applications that are accessible by a large constituency of end-users. These techniques offer a high level of analysis sophistication and enable users to perform various "if-then" scenarios to study the sensitivity of the results, to develop a better understanding of the outcomes and to gain insight on the consequences of the findings and decisions.
Loss estimation techniques have benefited from the advances in information technology. Modularity, encapsulation and a new generation of computer codes such as C++, provide a logical and flexible structure for organizing the analytical procedures involved in loss estimation. These techniques organize the multitude of analytical calculations into modules that are logically inter-related by hierarchical rules. This flexible architecture permits ease in development, testing, validation, maintenance and upgrade. The study region is divided into geographical units (Geo-Units) such as postal codes or census tracks. The data, calculations and results are then associated with the centroid of the Geo-Unit. The aggregated results from the Geo-Units yield the results for the study region. Geographical Information Systems (GIS) and Relational Database Management Systems (RDMS) are used to organize data in data warehouses, to manipulate data during analysis, and to associate results to geographical regions from which they can be queried, aggregated and/or mapped. GIS and RDMS also allow for easy display of input and output (in standard reports and maps) providing a critical functionality for communication of outcomes to end-users. Loss estimation has become a critical tool to the insurance industry and is quickly being adopted by a wide range of users including emergency managers and planners. The key to this expansion is the integration of new information technologies that gave these techniques greater analytical capabilities, flexible architecture, and user-friendliness.

GLOBAL SEISMIC HAZARD AND RISK ASSESSMENT

YONG CHEN, Qi-fu Chen, Ling Chen, Juan Li and Jie Liu (No. 63, Fuxing Avenue, China Seismological Bureau, Beijing 100036, P. R. China)

A global seismic hazard assessment was conducted using the probabilistic approach in conjunction with a modified means of evaluating the seismicity parameters. This method is applicable to both oceanic and continental regions, and for any specific duration of time. It can be used for those regions without detailed geological information or where the relation between existing faults and earthquake occurrence is not clear.
Most seismic risk studies use a probabilistic approach in which predicted damages in various categories of structure and facilities in the region in concern are estimated and added together to obtain a total loss for particular intensity ranges. We have used an alternative means of estimating earthquake losses based on several macroeconomic indices such as the gross domestic product (GDP) and population. A global seismic loss map is then compiled.
The expected losses(in USD) of selected countries and regions for the next 50 years are as follows:

World 949 (USD), Asia 563 (USD), European 184 (USD), N.America 115 (USD), S.America 60 (USD), Oceania 12 (USD), Japan 390 (USD), USA 66 (USD), China 17 (USD)

JSP23/W/16-A6 1520

SEISMIC HAZARD MAPPING FOR ADMINISTRATIVE PURPOSES

L. Peruzza (C.N.R. Gruppo Nazionale Difesa Terremoti, c/o OGS, Trieste, Italy); A. Rebez and D. SLEJKO (Osservatorio Geofisico Sperimentale, Trieste, Italy, tel: (39)-40-2140248, fax: (39)-40-327307, e-mail: dslejko@ogs.trieste.it)

Local site conditions strongly influence the seismic hazard assessment, even if done using standard probabilistic techniques, with average soil classification. GIS applications, nowadays, enhance these variations, without entering into a detailed microzonation study, that is not possible at wide, regional scale. On the other side, the administrative border of municipalities remains the basic units to face the problems of legislative measurements devoted to risk evaluation and reduction. The aim of this paper is to present maps of different hazard parameter devoted to better represent the free field shakebility in NE Italy. The dominant soil in each municipality has been classified, taking into account the location of buildings and structures: then soil dependent hazard estimates have been performed and mapped, according to the some of the criteria leading the new proposal of seismic classification in Italy.

JSP23/W/29-A6 1600

EARTHQUAKE HAZARD ASSESSMENTS FOR THE GULF OF CORINTH (CENTRAL GREECE) AND KRESNA REGION (SW BULGARIA)

Vladimír SCHENK, Zdeka Schenková and Pavel Kottnauer (all at Institute of Rock Structure and Mechanics, Academy of Sciences, CZ-182 09 Praha 8, The Czech Republic, email: schenk@ irsm.cas.cz)

The earthquake hazard calculations were realised for two seismically high-active European zones, for the area round the Gulf of Corinth (Central Greece) and for the Kresna region (SW Bulgaria). To make reliable earthquake hazard calculations all available data were collected. For the Gulf of Corinth data of the National Observatory of Athens compiled by Drakatos, Kalogeras and Papadopoulos and as well the published earthquake catalogues, geological and geophysical materials (Ambraseys & Jackson 1990, Ganas & White 1996, Hatzfeld et al. 1990, Makropoulos 1985, Papazachos 1988, Papazachos & Kiratzi 1993, 1996, Papazachos et al. 1991, 1996, Shebalin et al. 1974) were applied. Simultaneously, for the Kresna region similar available data of the Geophysical Institute, Bulgarian Academy of Sciences, were sent to us by Ranguelov and Shanov. All these data allowed seismogenic zones with respect to earthquake occurrence and main tectonic structures to be delineated, dependent events from independent ones to be identified, an earthquake regime per requested observation period and/or a size of the area to be normalised, a maximum possible earthquake to be assessed and an acceptable attenuation law to be applied. Every quantity was statistically tested in order to be possible to introduce the logical tree of the input parameters to the hazard calculations. A reliability of the earthquake hazard calculations in common practice will be discussed. The presented calculations were realised under the EC INCO-Copernicus ASPELEA Project No ERBIC 15CT97 0200.

EARTHQUAKE DISASTER MITIGATION AND EMERGENCY RESPONSESYSTEM (EDMERS) OF SHANGHAI BASED ON GIS

YANG TING (Geophysics Institute, China Seismological Bureau. Now at Shanghai Seismological Bureau, No.87, Lanxi Rd. Shanghai,China,200062, Email: tyang@263.net) Zhu Yuanqing and Song Jungao (Both at ShanghaiSeismological Bureau,No.87, Lanxi Rd.Shanghai,China,200062)

As the largest city of China, Shanghai is also under the earthquake threat. In order to understand how severe disaster Shanghai will be suffered and what should be done by government when a possible earthquake affects the city, the Earthquake Disaster Mitigation and Emergency Response System (EDMERS) has been developed based on Geographic Information System (GIS). The EDMERS mainly includes two subsystems and several databases. The first subsystem, rapid earthquake damages estimation subsystem, will provide the rapid estimation of all kinds of earthquake damages according to the real earthquake parameters, (the origin time, epicenter location and source depth) which determined by Shanghai Telemetry Seismic Network in minutes while a destructive earthquake occurs. The second subsystem is the emergency response, in which the following emergency responses should be completed in time after a shock: determining the rescue scheme, evacuating victims, coping with dangerous materials, making decisions against fire following earthquake. The databases of EDMERS include building information, lifelines, soil conditions, aerial photographs, historical earthquake catalogues and so on. The following features of EDMERS should be highlighted: first, making use of GIS can enable the system to process the spatial data in a reasonable way, for example, The overlay and buffer functions of GIS can deal with the comprehensive effect of damage of buildings and lifelines. The network analysis of ARC/INFO can be directly used in emergence response such as victim evacuation and pathfinding. Second, emergence response can carry out on the base of real damage conditions by integrating damage estimation subsystem and emergence response subsystem. Third, using remote sensing, namely aerial photograph as an auxiliary tool, make EDMERS visual, vivid and informative.

FIELD SURVEY OF TSUNAMI DISASTER IN PAPUA NEW GUINEA ON 17 JULY 1998

Yoshiaki KAWATA (Research Center for Disaster Reduction Systems, DPRI, Kyoto University, Gokasho, Uji, Kyoto 611-0011, Japan, email: kawata@drs.dpri.kyoto-u.ac.jp)

On the evening of Friday 17 July at about 7:30 p.m. a breaking wave from a massive tsunami swept across the sand bar that forms the outer margin of Sissano Lagoon, west Sepik, PNG. Initial reports claimed that the wave was between 7 and10m and that up to 3,000 persons were killed or missing. This seemed to be an unusually damaging tsunami given the size of the earthquake. Members of the International Tsunami Survey Team decided that a field survey was necessary as soon as possible to try and determine the true value of the maximum run-up and to accurately map the run-up distribution along the coast. The first surveys to the Sissano region confirmed the 7 - 10m wave reports and even found place where the waves were larger - up to 15 m. The severe damage and extreme wave heights were confined to a relatively short (30 km) stretch of coast between Aitape and Sissano Village. The survey was conducted by a multi-national team with representatives from Japan, the United States, Australia, and New Zealand. The team was broken up into two groups, the Japanese and everyone else. By the numerical estimation, it is impossible to get such gigantic tsunamis with the earthquake magnitude of 7.0. We found many marks of liquefaction at the sand bar and many residents reported that they had three earthquakes and middle one was the most severe. Therefore, we concluded that the earthquakes were not slow earthquake. Numerical simulation models of submarine landslide show good agreement with tsunami heights and their longshore distribution.

JSP23/C/U5/E/23-A6 1700

PRECISE TOPOGRAPHIC AND GEOPHYSICAL SURVEYS OFF SISSANO LAGOON, NORTHERN PAPUA NEW GUINEA

TAKESHI MATSUMOTO(1), David Tappin(2) and R/V KAIREI KR98-13 Cruise Scientific Party 1) Japan Marine Science and Technology Center (JAMSTEC), 2-15, (BNatsushima- cho, Yokosuka 237-0061, Japan (2) British Geological Survey, Keyworth, Nottingham, UK

The northern coast of Papua New Guinea suffered from a M7.1 earthquake and aftershock events which occurred on July 17, 1998. A large-scale tsunami also occurred just after the earthquakes. KR98-13 Cruise by the Research Vessel KAIREI was carried out in January 1999 in order to locate the possible seismic faults and/or underwater landslides as the source of tsunami. Precise topographic and other geophysical mapping off Sissano Lagoon, in the area of 200km (E-W) and 120km (N-S), was completed after the 9 days' survey.
The study area is characterised by enormous amount of fan sediment supply from Sissano Lagoon, deep-sea canyons on the shelf, arc-shaped slump and offshore strike-slip faults. Straight small-scale submarine canyons and valleys are eroding the shelf slope. The meandering canyon is located on the old shelf to the north of Aitape. Topographic features caused by landslides are recognised at numerous sites of the study area. Most of them are old, and the most recent is located 25km north-east off the Sissano Lagoon. The most prominent of the many tectonic faults located in the study area is E-W trending escarpment, the length of which is about 40 kilometres, recognised 25 kilometres north of Sissano Lagoon.
The result of simplified numerical modelling of tsunami propagation by use of the new bathymetric data shows that the distribution of maximum wave height is in good agreement with the observation. This suggests that the bottom topographic feature is an important factor to amplify the wave and to generate the focused tsunami runup, and that both earthquake faulting and underwater landslide should be taken into account as possible origins of the tsunami.

SUPER DENSE REAL-TIME MONITORING OF EARTHQUAKES: SUPREME

Fumio YAMAZAKI (Institute of Industrial Science, The University of Tokyo, 7-22-1 Roppongi, Minato-ku, Tokyo 106-8558, Japan, email: yamazaki@iis.u-tokyo.ac.jp); Yoshihisa Shimizu, Wataru Nakayama and Ken-ichi Koganemaru (all at the Center for Supply Control and Disaster Management, Tokyo Gas Co., Ltd., 1-5-20 Kaigan, Minato-ku, Tokyo 105-8527, Japan, email: yshimizu@tokyo-gas.co.jp)

To cope with earthquake-related secondary disasters, city gas companies in Japan have promoted several countermeasures in the last two decades: increasing seismic resistance of facilities and pipelines, segmentation of gas networks into blocks, earthquake monitoring by seismometers, installation of intelligent gas meters with a seismic sensor etc. As one of such earthquake countermeasures, Tokyo Gas Company introduced an earthquake monitoring and rapid damage assessment system, SIGNAL, with 331 SI-sensors, which measure the peak ground acceleration (PGA) and spectrum intensity (SI) at district regulator stations. The strong motion indices and the results of damage estimation are used for the decision-making whether or not to shut off gas supply.
Recently Tokyo Gas further developed new SI-sensor, having several new functions with the much cheaper price. The new SI-sensor can store acceleration time histories in its IC memory and send monitored strong motion indices to the Supply Control Center through public telecommunication lines. The new sensors will be installed at all the 3,600 district regulator stations with in the next 8 years. The new SI-sensor network is named SUPREME (Super-Dense Real-time Monitoring of Earthquakes), which may be the most dense seismic monitoring network in the world. The data from the network will significantly contribute to the strong ground motion research as well as promote seismic safety of the greater Tokyo Metropolis.

POTENTIAL OF DISRUPTION OF HUMAN ACTIVITIES ON EARTH AND IN SPACE AS A CONSEQUENCE OF THE INTERACTION BETWEEN THE SOLAR CORONA AND EARTH'S MAGNETIC FIELD

Gordon ROSTOKER (Department of Physics, University of Alberta, Edmonton, Alberta, Canada T6G 2J1, email: rostoker@space.ualberta.ca)

Over the past few decades, mankind has become increasingly dependent on various technologies which have helped greatly to improve the standard of living around the world. Two examples of such technologies that have had an enormous impact on human activities are global communications and the provision of readily available electric energy through the development of large transmission grids. Unfortunately, with the advent of new technologies comes human dependence on them. The use of satellites for communications and position finding purposes serves as a useful example of this dependence. It is now recognised that both geostationary communications satellites and the position-finding GPS satellites are vulnerable to the energetic electron environment in which they orbit. In this paper I shall outline the nature of this vulnerability and what the consequence of the loss of these satellites might be. As well, it is worth noting that large fluctuations in the geomagnetic field at auroral latitudes can induce electric currents in large power transmission grids sometimes causing them to be disabled for significant periods of time. I shall describe the nature of this problem and how space researchers are attempting to develop techniques to predict the potential for power outages. These practical manifestations will be presented in the context of the physical processes through which the solar corona interacts with the earth's magnetic field.

DESTRUCTIVE ATMOSPHERICALLY-GENERATED LONG WAVES: SEPARATION BETWEEN SOURCE AND TOPOGRAPHY

S. MONSERRAT (1), A.B. Rabinovich (2) and B. Casas (1). (1) Instituto Mediterráneo de Estudios Avanzados, IMEDEA, (CSIC-UIB), Palma de Mallorca, SPAIN, dfssmt4@ps.uib.es, (2) Tsunami Center, P.P. Shirshov Institute of Oceanology, Moscow, RUSSIA

Destructive long waves caused by atmospheric disturbances (meteotsunamis) present a significant threat for the Mediterranean coast, in particular, for the Iberian Peninsula and the Balearic Islands. Ciutadella Harbour, Menorca Island, is the place where extreme oscillations, locally known as 'rissaga waves', occur most frequently. The understanding of their origin and generation mechanism is a key scientific and applied problem. A method was first elaborated to suppress the influence of the initial source in order to isolate the general topographic function. The next step was to separate the resonant influence of the outer shelf from the local coastal features (bays or inlets). This second step allows reconstructing the corresponding admittance functions for any bay or inlet, which may be afterward used to predict amplification of meteotsunami but also of tsunami waves in a given location. The data of LAST-97 hydrophysical experiment (June-September, 1997) gave us a good opportunity to test this. A set of bottom pressure recorders were deployed on the shelf of Menorca Island, in two neighboring inlets of this island (Ciutadella and Platja Gran), and in Palma Bay (Mallorca Island); a number of precise microbarographs were working simultaneously. The first step of our analysis allowed reconstructing the open-sea source spectra for several abnormal seiche events recorded in the region of Ciutadella which, after compared with the observed atmospheric spectra, were used to estimate the so-called 'transfer function' between the atmosphere and the sea surface. This function is clearly related to the topography of the source area, but when computed for Ciutadella region, the transfer function was quite similar for different rissaga events suggesting consistency of the basic parameters (phase speed and direction of propagation) of the atmospheric waves generating large seiches. This fact can be used to predict the sea-level spectrum at a given location with the knowledge of the atmospheric pressure spectrum only. The second step of…

ASSESSMENT OF GEOMAGNETIC HAZARD TO POWER SYSTEMS

D. H. BOTELER (Geomagnetic Laboratory, Geological Survey of Canada,Observatory Crescent, Ottawa, Ontario K1A 0Y3, Canada)

During severe geomagnetic disturbances electric currents induced in high voltage power transmission systems can cause transformer saturation resulting in transformer heating, generation of harmonics and increased reactive power demand. These effects can damage transformers, cause misoperation of protective relays and, in the worst case, cause power blackouts. An extensive study has been made to assess the geomagnetic hazard to power systems in Canada. Data from the Canadian Magnetic Observatory Network and conductivity models for different parts of Canada were used to calculate the electric fields produced during different levels of geomagnetic activity. This was combined with statistics on the occurrence of geomagnetic disturbances to determine the electric fields the power systems could expect to experience, on average, once a year and once every ten years. These electric field values were then used as input to power system models which calculated the corresponding levels of geomagnetically induced currents (GIC) in each power system.

THE SATELLITE CONCEPTION FOR MONITORING OF IONOSPHERE EXCITATION BY SEISMIC OR TECTONIC PROCESSES.

Vladimir DOKUKIN, Victor Oraevsky, Yury Ruzhin and Vladimir Alekseev (IZMIRAN,Troitsk-town, Moscow Region, 142092, RUSSIA; E-mail: ruzhin@izmiran.rssi.ru)

The deep tectonic faults are known to be zones of concentration of stresses, canalisation of fluids, aerosols and gases, change of magnetisation and electro- conductivity of rocks, appearance of high electrical potentials and so on. Also the tectonic faults are associated with the geodynamical structures which form the zones of elevated seismicity (quakes or volcanic eruptions) or zones of dangerous natural hazards. The results of joint processing of the data of low-frequency emission, corpuscular flows as well as temperature and density of plasma permitted us to reveal the previously unknown effect of the generation of low frequency noises in space over the deep faults of the earth crust. The developing now in Russia method of ionosphere tomography also is very perspective for that .The system of the small satellites can be especially important for revealing and research of global and regional net of geological faults in an effort to plan searches of mineral resources and to forecast destructive earthquakes (volcanic eruptions). The first microsatellite COMPASS, weighting about 80 kg, is planned to launch to the circular orbit with height 400 km and inclination 790 for development of the methods of monitoring and forecasting of natural disasters on the base of co-ordinated monitoring at the Earth and from space the pre-earthquake phenomena. COMPASS is composed of several sensors associated to a data processing unit and a large memory in order to record the information all around the Earth independently from telemetry station. The details of the measurements, instruments and general conception of the microsatellite system based on the COMPASS mission are presented in the report.

AIR QUALITY AS A GEOPHYSICAL HAZARD

Tom BEER (CSIRO Atmospheric Research, Aspendale, 3195, Australia, email:Tom.Beer@dar.csiro.au)

Geophysical hazards are usually considered to be earthquakes, volcanic eruptions, landslides, floods, droughts, tsunamis, storm surges, wildfire, tropical cyclones and extreme weather events. Air pollution is not normally considered to be a geophysical hazard. This view has arisen because the causes of air pollution – industrial and motor vehicle emissions – are not geophysical in nature. However, as air pollution regulations succeed in reducing the amount of pollutant emissions, air pollutant episodes become sporadic in nature, and their occurrence depends on a particular combination of meteorological factors. Analyses of air pollution episodes and hospital admissions indicate that there is a significant increase in morbidity and mortality as a result of air pollution episodes. Time-series studies undertaken in Sydney have shown that particulate matter, ozone and nitrogen dioxide are the pollutants that are primarily responsible for adverse health effects. Air quality forecasting systems can play an important role in mitigating the adverse effects of air pollution. The forecasts will affect the behaviour of susceptible individuals, and thus reduce adverse health effects. The outputs from forecasting systems can also be used to provide improved estimates of the total exposure to air pollutants of the inhabitants who are at risk. Such improved estimates can then be used in conjunction with longitudinal studies of health effects to obtain better understanding of the complex interaction between air quality and health. This presentation will illustrate the manner in which air pollution depends on meteorology, review some of the data concerning the resulting health effects, and discuss the future research needed for a better understanding of the interaction between air quality and human health.

MULTIFRACTAL ANALYSIS OF TROPICAL ATMOSPHERIC STRUCTURES AND TYPHOONES GENERATION.

I. TCHIGUIRINSKAIA (E.E.&S. Dept., Clemson University, 342 Computer Court, Anderson, SC29625, USA, E-mail: iouliat@clemson.edu); D. Schertzer (L.M.M., Université Pierre et Marie Curie, 4 Place Jussieu F-75252 Paris Cedex 05, France); S. Lovejoy (Physics Dept., McGill University, 3600 University st., Montréal, Qué., H3A 2T8, Canada)

During the last past ten years numerous investigations have been lead on the tropical atmospheric structures: boundary layer coherent structures, tropical storms and typhoons. Emphasis has been often placed on the structural conditions of generation of typhoons. Contrary to other approaches, we investigate this question on a large range of scales and intensities, trying to understand the crucial relationships between extremes events (such as typhoons) and more average ones, how the latter can build up to the appearance of the former. We chose thus a universal multi-fractal approach, since in this case the mean as well as the extreme events are ruled by three fundamental multi-fractal exponents determining the infinite hierarchy of singularities of the field and their corresponding co-dimensions. We analysed data sets obtained during two aircraft expeditions over South China Sea in 1988 and 1989 (Karmazin and Mikhailova, 1991). Measurements were usually done everyday from July to October on 8 or 11 levels from 50 meters up to 5 km heights, every 125 ms along 40 km in the horizontal for each level across the largest clouds bands. In the latter case, some flights were carried at a

distance of Ed typhoon center as close as 7 km. Although variations of the estimates of the multi-fractal exponents are present, they do not seem to be significant, since these values remain close to those obtained in mid-latitude boundary layers or wind tunnel experiments (Schmitt et al. 1992). In conclusion, we discuss the rather low critical order of divergence of statistical moments qD=7 which rules the self organised criticality of extreme wind shears, temperature gradients and generation of related structures, in particular typhoons.

JSP23/W/32-B1 1130

LARGE-SCALE EVOLUTIONARY PROCESSES IN HAZARD SYSTEMS OF EARTHQUAKES, A PHENOMENOLOGICAL MODEL BASED UPON SELF-ORGANIZED CRITICALITY [SOC]

Natalia SMIRNOVA, Vladimir Troyan (both at Institute of Physics, University of St.Petersburg, St.Petersburg 198904, Russia, e-mail: nsmir@snoopy.phys.spbu.ru); Masashi Hayakawa (The University of Electro-Communications, Chofu, Tokyo 182, Japan,
e-mail: hayakawa@whistler.ee.uec.ac.jp); Thomas Peterson (TFPLAB, Cleveland, Ohio 44124-5441, U.S.A., e-mail: TFPLAB@aol.com); Yury Kopytenko (St.Petersburg Filial of IZMIRAN, St. Petersburg 191023, Russia, e-mail: galina@admin.izmi.ras.spb.ru)

The concept of self-organised criticality (SOC) is now widely used for the interpretation of the behaviour of natural hazard systems. This concept was recently introduced by the present authors as a way to search for earthquake precursory signatures. Here, we continue to consider earthquake region processes on the basis of the SOC concept. We suggest a phenomenological model for large-scale evolutionary processes that occur between violent earthquake episodes. Four principal stages of evolution are proposed and analyzed. They are: random chaos, subcritical, critical, and super-critical. External stimuli such as geomagnetic storms, sharp temporal and spatial variations in atmospheric pressure, and ULF impulses are considered as driving forces for a "cellular automata" process in active seismic regions. We discuss the possibility of using fractal characteristics of signals to study the critical dynamics of a hazard system. The important fingerprints of SOC - temporal and spatial fractal structures are analyzed using seismic and ULF electromagnetic data timed to violent earthquakes near Guam (August 8, 1993, M = 8.0) and Kobe (January, 16, 1995, M = 7.2). The research was supported by NASDA (Japan) and Russian Foundation for Basic Research (Grants No. 98-05-65554 and 99-05-NNN).

JSP23/W/10-B1 1150

ON CONNECTION BETWEEN THE SEISMICITY SPACE-TEMPORAL CHARACTERISTICS AND THE EARTH ROTATION

Boris W. LEVIN (*Shirshov Oceanology Institute of RAS and Russian Foundation for Basic Research, 32a Leninsky prosp., Moscow, 117334 Russia; levin@rfbr.ru)Yeugeny Chirkov (**Union Institute of the Earth Physics of RAS, 10 Bolshaja Gruzinskaja, Moscow, 123810 Russia; chirkov@uipe-ras.scgis.ru)

An importance of the Earth's rotation influence to earthquakes occurrence was noted by I.Kant (1756), I.R.Mayer (1893), G.H.Darwin (1908) and was often discussed by geophysicists at present time. Supposing the unpredictability of natural hazards is connected partially with our poor understanding of the planetary processes role, we investigated a geographical distribution of the earthquakes. Using the catalog NEIC, we had created the histograms of the earthquake numbers and its energy as a function of a latitude F from 90 deg. N to 90 deg. S at period of 1900-1993. We had found that the latitude distribution of the event numbers N(F) is similar to the curve describing a dependence R^2(F) or I(F) where R is a distance from the axis of rotation and I is an inertia momentum of mass unit. Also we discovered the local maximum of the seismicity on so-called "critical latitude" 35 deg. N which was first mentioned by geographer A.Veronne (1912) and was calculated by F.Krasovsky and V.Magnitsky (1941) as a specific parallel for the Earth figure theory. The preliminary analysis of the seismicity-time dependence (more than 100000 events with M>4.0) for different latitude layers showed that the seismicity varies with main period of near 6 years practically at all latitude layers of the Earth.

JSP23/E/02-B1 1210

VOLCANIC RISK ASSESMENT AND ZONATION OF THE MAIN ERUPTIVE HAZARDS IN TENERIFE (CANARY ISLANDS)

Vicente ARAÑA and Alicia Felpeto (Dept. Volcanologia, Museo Nacional de Ciencias Naturales, Jose Gutierrez Abascal 2, 28006 Madrid, Spain); Mar Astiz (Dept. Matematica Aplicada, E.T.S. Arquitectura, U.P.M., Avda. Juan de Herrara, 4, 28040 Madrid, Spain, email: civgv@pinar1.csic.es); Francisca Gomez (Centro di Studio per la Geologia Structturale e Dinamica dell´Apennino, CNR, Pisa Italy); Alicia Garcia and Ramon Ortiz (Dept.Volcanologia, Museo Nacional de Ciencias Naturales, Jose Gutierrez Abascal 2, 28006 Madrid, Spain, email: mcngg92@pinar1.csic.es and mcnor72@pinar1.csic.es)

Taking into account that the island of Tenerife is a complex case, that one unique volcano and a unique eruptive style cannot be considered, the methodology developed in this paper to define a volcanic hazard-risk zonation in the island consists of: (1) Definition of the different hazards. (2) Numerical gradation of the probability of occurrence of each phenomenon by area. (3) Selection of the areas that show the higher probability of being emission centres. (4) Numerical simulation of the effects of an eruption of the corresponding eruptive style in those areas. The steps (1), (2) and (3) are based on the extensive knowledge of the eruptive activity of Tenerife Island and structural parameters. The results obtained from these three steps and the hazard map are implemented in a GIS and also used for the organisation of the surveillance network in terms of efficiency.

STRESS CHANGES AT THE SOUTH ICELAND SEISMIC ZONE - A MODEL FROM 1706 UP TO THE PRESENT FOR BETTER HAZARD ESTIMATION

Frank ROTH (Section "Earthquakes & Volcanism", Division "Solid Earth Physics and Disaster Research", GeoForschungsZentrum, Telegrafenberg, D-14473 Potsdam, Fed. Rep. of Germany,
email: roth@gfz-potsdam.de)

The South Iceland Seismic Zone is situated between two sections of the mid-Atlantic ridge, i.e. the Reykjanes Ridge SW of Iceland and the Eastern Volcanic Zone on the island. It is a transform zone, though no typical one, as it is not connecting both rifts at right angles. Following this hypothesis, earthquakes should occur on EW-trending left-lateral shear faults, equivalent to conjugate, NS-oriented right-lateral, rupture planes. In fact earthquakes take place on NS-oriented faults, which are indicated by intensity and aftershock distributions, as well as by surface fault traces.
The stress field permanently generated in the fault zone by opening of the adjacent ridges with slightly more than 2 cm per year is computed and superimposed with the stress field changes induced by a series of 11 earthquakes (M >= 6) between 1706 and 1912. For these, different rupture depths are assumed, depending on the distance to the rifts. Finally, the post-seismic stress field of 1912 is extrapolated to the present, to see where highest stresses might have accumulated. In addition, the influence of loads at the Eastern Volcanic Zone on the stress field in the seismic area is studied.
The modelling shows that the stress is released by the series of events in the whole area, even though the ruptures planes are located on parallel NS-striking zones. The pre-seismic stress level for most events is high and pretty stable with the exception of situations when several strong shocks occur over a time span of several days, i.e. display typical main shock-aftershock patterns.

JSP23/C/U5/W/03-B1 1420

INITIAL STRUCTURES AND PACKING TRANSFORMATIONS OF LOESS DEPOSITS: IMPLICATIONS FOR THE ANALYSIS OF CATASTROPHIC MASS MOVEMENTS

Eleanor PARKER and Tom Dijkstra (Coventry University)

Gradual settlement from aeolian suspension means that loess particles generally form very open initial packing. There is less than 50% solids in a unit volume of soil - unless there is too much water or additional stress which will cause particles to settle in a much denser state. As long as the deposit remains relatively dry, cementation and other bond types will maintain the open structure; the loess is metastable. The potential of metastable loess to collapse is impressive. Rapid transformations from undisturbed packing with dry densities of about 1.3 Mg/m3 (void ratio e ~ 1), to more closely packed 'deformed' fabrics with dry densities of about 1.65 Mg/m3 (e = 0.65) after collapse. At failure, signifcant pore volume reductions (often more than 10%) result in considerable rapid increases in pore pressures (principally related to water pressures, but in loess air pressures are also important). Such pore pressures are necessary ingredients to produce very mobile mass movements, usually in the form of flowslides. In situations where pore pressure dissipation is impaired, a lowering of the shearing resistance may last long enough to allow long run-outs and high sliding velocities. The study material is Chinese loess from Gansu province, but there are important parallels with similar collapsible deposits such as the brickearths of South East England.

EARTHQUAKES PREDICTABILITY: A CASE STUDY

Valery KOREPANOV, Yevhen Klymovych and Pavlo Maltsev (Lviv Centre of Institute of Space Research, 5-A Naukova str., 290601, Lviv, Ukraine, e-mail: vakor@isr.lviv.ua); Masashi Hayakawa (Dept. of Electronic Engineering, University of Electro-Communications, 1-5-1 Chofugaoka, Chofu, Tokyo 182-8585, Japan, e-mail: hayakawa@whistler.ee.uec.ac.jp); Katsumi Hattori (International Frontier Program on Earthquake Research, Institute of Physical and Chemical Research (RIKEN), c/o Earthquake Prediction Research Center, Tokai University, 3-20-1, Orido, Shimizu 424, Japan,
e-mail: hattori@iord.u-tokai.ac.jp); Victor Tregubenko (Kyiv Branch of Ukrainian Geology Research Institute, 78 Avtozavodska str., 252144 Kyiv, Ukraine, e-mail: direct@kgou.ru.kiev.ua)

It is accepted that large earthquakes (EQ) are accompanied by different electromagnetic phenomena. They are also found to precede the EQ and the most debatable question is whether they can be used as EQ precursors. Two of such positive examples for EQ with M; 4,5 are investigated: near Matsushiro (Japan) 01.07.1998 and near Crimea peninsula (Ukraine) 16.10.1998. In both cases three components of magnetic fluctuations only were studied: for Matsushiro in frequency band from 0,01 to 30 Hz and for Crimea the DC magnetic field was sampled once per 10 seconds. For Matsushiro EQ some preceding events were extracted: short spikes with some features deviating from noisy background and also about 50% overall growth of daily averaged amplitude of ELF emission. For Crimea EQ the variations of mean longitudinal conductivity of the crust were calculated. The resulting curves excellently suit the Scholtz dilatant-diffusional model: for 15 days averaged variations of the conductivity defection from the mean value before earthquake was about 6% what was fairly beyond mean error ~ 1,2%. Still higher was the deflection for daily averaged variations: more than 25%. The peculiarities of the study and processing methodology are discussed.

JSP23/C/U5/L/01-B1 1500

MACRO SCALE MODELLING OF CATASTROPHIC NATURAL HAZARDS

Adrian STEWART, and Dr Claire McQueen, (EQE International Ltd, 500 Longbarn Boulevard, Warrington, WA2 0XF, UK. Tel:- +44 1925 838372, fax +44 121987 654, Email: astewart@eqe.co.uk, cmcqueen@eqe.co.uk.)

Economic losses from Natural disasters over the last few decades have been enormous, as demonstrated by Hurricane Andrew in the US. The impact on the Global economy can reverberate for years after a single event. Assessing the risk to regions and countries is essential in the context of enabling International Organisations, Governments a International Industry and Commerce to plan, mitigate and manage losses.
In terms of risk from damaging earthquake or windstorm events, the risk is a function of the hazard intensity combined with the vulnerability of the properties within any given unit or area. The deterministic results of such studies may also be combined With expected frequencies to obtain probabilistic estimates of risks. In order that the losses expected within an area from an event be estimated accurately, the vulnerability functions and hazard models should be representative of the scale of the are that they are located in. Scale is an important issue. The Hazard Model needs to reflect the reduced risks expected over larger areas. However, the detail needs to remain in order that the spatial resolution of the hazard across an area is accurately represented. The question is whether vulnerability and hazard models can be created for a specific scale, or whether it is possible to calculate losses on a detailed grid and aggregate consistently at any macro scale.

JSP23/W/39-B1 1520

SPACE PRECURSORS OF EARTHQUAKE REGISTERED BY SATTELLITE AT GEOMAGNETICALLY CONJUGATED AREAS

Yuri RUZHIN, Vera Larkina and Anna Depueva (IZMIRAN, Troitsk-town, Moscow Region, 142092, RUSSIA; email:ruzhin@izmiran.rssi.ru)

There is some progress in investigations of space plasma precursors of earthquake (EQ) - the magnetic conjugation of VLF pre-seismic emission on satellite orbits was found in both hemispheres. It means that some signature of precursor could be found inside the geomagnetic flux tube (shell) which connected with both conjugated ionosphere regions where the VLF precursors on satellite orbits were registered. Satellites INTERCOSMOS-18 and ALOUETTE data were analyzed from this point of view. Conjugated EQ-precursors are found in very low frequency (VLF) emission and ionosphere F2-layer plasma parameters. It should be pointed out that F2-precursors appears some days before the earthquake, manifest

themselves as an plasma anomaly like Appleton anomaly if epicenter of future earthquake is situated near magnetic equator. It is shown that the electric field less than one mV/m have to be generated in the ionosphere. Then we'll can be able to observe the above ionosphere phenomena as an equatorial earthquake forerunners. We are able to show that VLF precursors which appears some hours before the earthquake are localized close to magnetic shell corresponding to future earthquake epicenter and have a belt-like structure (longitude aligned on more than some tens thousands kilometers) in bot hemispheres. In the presented work relationship of VLF fields intensity and spectra with energetic electrons flux density are investigated over epicentral zone of the prone earthquake. On the base of our estimations and phenomenological development of the event in the ionosphere (plasmasphere) over the seismic region and over magnetically conjugated region the possibilities of the seismoionospheric anomalies (space precursors of EQ) generation are discussed.

JSP23/C/U5/W/10-B1 1600

THE CENTRAL POSITION OF GEOPHYSICS FOR THE EVALUATION OF THE NEAR-FUTURE AND ESPECIALLY THE DISTANT FUTURE

Nils-Axel MÖRNER, (Paleogeophysics & Geodynamics, S-10691 Stockholm, Sweden, email: morner@pog.su.se)

Geophysics and its paleogeophysical expresions over past periods will always play a central role for all types of predictions and estimations of the future. This applies for the near-future and its evaluation based on our understanding of the natural variability in environmental parameters on a decadal-to-century time scale, and its interaction with induced anthropogenic factors. On the 104-105 year time scale, the selestrial mechanical calculation of the so-called Milankovitch variables form a strong basis in climate prediction. Distant predications and evaluations are, in general, neither simple nor straight-forward. Still, there is a desperate need for safity predictions over 104-106 year time scale when it concerns the long-term stability and safity of high-level nuclear waste repositories. This has added a completely new dimension to geophysics. For a "safe" final bedrock deposition of high-level nuclear waste, we need guarantees for the immense time period of "hundreds of thousands of years". No one can, of course, give meaningful guarantees over such long time periods. The Fennoscandian crystalline bedrock is, by no means, as stable and reliable as sometimes claimed. Only some 10,000 years back in time, the seismic activity was (as a function of the extreme rates uf glacial isostatic uplift amounting as much as some 10 cm per year) tremendously high; in amplitude as well as in frequency. In such an environment – to be repeated at the next future ice age – we can, of course, give no guarantees for a waste disposal in the bedrock; on the contrary, most facts suggest that it would be seriously damaged. In the absence of a true long-term safity, we can only propose that the waste produced: (1) is kept at a minimum, (2) is stored under constant control, and (3) is kept accessible for reparations as well as possible future innovations of how to render the waste harmless.

JSP23/E/14-B1 1620

LONG-TERM HAZARD FROM RIVER-BED AGGRADATION FOLLOWING VOLCANIC ERUPTIONS

Thomas C. PIERSON (U.S. Geological Survey, Cascades Volcano Observatory, 5400 MacArthur Blvd., Vancouver, WA 98661, USA, email: tpierson@usgs.gov)

Explosive volcanic eruptions can provide immense volumes of readily erodible volcaniclastic sediment to drainage basins on or near source volcanoes. Posteruption rainfall, or other types of rapid runoff, mobilizes sediment from hillslopes or from source deposits in upper valleys, episodically moving it downstream during periods of high discharge (probably as long, slow-moving sediment waves). Depending on the volume of sediment added to a fluvial system, this sediment mobilization can result in dramatic and hazardous vertical aggradation of river beds. Data from recent historical eruptions at Mount Pinatubo (Philippines), Mount St. Helens (USA), and other volcanoes demonstrate that river-bed aggradation can occur rapidly (at varying rates as high as 0.4 m/day) in channels up to hundreds of meters wide over extensive downstream reaches in the first year or two following an eruption. Although periods of aggradation may be interrupted by irregular periods of degradation (channel downcutting), river-bed elevations may show net rises of as much as 20 to 30 m within only a matter of months within 50 km of source, and net aggradation of at least 8 m has been documented as far as 280 km from source. Under these conditions, floods and lahars need not have extraordinarily high discharges to be able to reach and inundate previously safe homes, roads, and farmland.
Aggradation may continue for decades before sediment supply from the disturbed areas decreases enough to allow rivers to incise back down to previous bed levels. Tree-ring data from terraces along the Sandy River, 80 km downstream from Mount Hood (USA) indicate that significant reincision (about 8 m or nearly 50 percent) occurred within about 40 years of the ~200 yBP eruption of Mount Hood, and the river nearly regained its original bed level within about 60 years. Efforts to mitigate river-bed aggradation hazards, such as has been done at Mount St. Helens, should be planned with knowledge of this potentially long-term impact on fluvial systems.

JSP23/C/U5/W/17-B1 1640

A SEA LEVEL-WAVE JOINT DISTRIBUTION FOR SEVERE STORM SURGE HAZARD ASSESSMENT USING OFFSHORE PLATFORM DATA

Le KENTANG (Institute of Oceanology, Chinese Academy of Sciences, Qingdao 266071, PRC, email: ktle@ms.qdio.ac.cn)

Generally speaking, the direct economic losses from a severe storm surge disaster consist mainly of that from sea water flooded over land and that from damage caused by high sea. However, the traditional method for storm surge hazard assessment in China is to construct one or two single-parameter distributions by using historical sea level and/or wave data at some coastal stations and/or ocean stations. In this case, apparently, both sea level data and wave data at these stations must be long enough to estimate the return periods needed for mitigation. However, the existing data of sea levels and waves at most of these stations can't meet the needs of the estimation. In this paper we presents a method to construct the sea level-wave joint distribution for severe storm surge hazard assessment by using a couple of years data on such a stations. Using a one-year platform data in the Bohai Sea, an example is given to illustrate the capabilities of this methodology.

STATISTICAL METHODS FOR SLUSHFLOW SITUATIONS RECOGNITION, MONITORING AND FORECASTING

Pavel CHERNOUSS and Olga Tyapkina (Center of AvalancheSafety,"Apatit" JSC, 33a, 50 years of October St.,Kirovsk, Murmanskregion184230, Russia, e-mail: P.Chernous@apatit.murmansk.su); Erik Hestnes and Steinar Bakkehoi (both at NorwegianGeotechnicalInstitute, P.O. Box 3930 Ullewal Hageby, N-0806, Norway, e-mail: eh@ngi.no)

Slushflows - flowing mixtures of water and snow - are a hazardous phenomena in mountainous regions all over the world. They are most frequent in higher latitudes, i.e. in Norway, Iceland, USA(Alaska),Canada and Russia (northern and eastern parts). Slushflows exert high destructive forces and they are almost unpredictable due to inadequate studies. The work is an attempt to classify meteorological situations at different heights above sea level on "slushflow" and"non-slushflow" with linear discriminant analysis and Bayes'formula. Standard meteorological observations were used as primary parameters to describe the situations. Classification was made on daily base. Data for the mountain regions of Norway and the Khibini Mountains in Russia were taken to derive the classification rules and to carry out a verification of the methods. Different sets of parameters were tried to find out most informative ones. Two parameters have been chosen -daily water income (designed parameter) and snow cover thickness. Classification accuracy, obtained with independent data, was better than 75% for both types of the situations. For more detail slushflow danger monitoring one day moving average values are used. There are two ways to transform the diagnostic methods into forecast ones- by using of forecasted parameters as predictors or by extrapolation of situation probabilities. The methods are an effective tool for slushflow forecaster and realized as software package for the real-time work at the Center of Avalanche Safety of "Apatit" JSC.

JSP23/W/23-B1 1720

PRESEISMIC ELECTROMAGNETIC SIGNALS GENERATED IN ATMOSPHERE

Yuri RUZHIN (IZMIRAN, Moscow, 142092,RUSSIA; E-mail: ruzhin@izmiran.rssi.ru); Costas Nomicos (Technological Educational Institute of Athens, GREECE); Filippos Vallianatos (Technological Educational Institute Chania branch, Crete, GREECE)

Electromagnetic (EM) precursors of Earthquakes (EQ's) are modern possibility to monitor pre-earthquake situation and to improve the EQ forecast. Its nature up to now is under the question. The EM signals registrated (before the EQ) onboard of satellites is the object of intensively investigations during last decade. Here we overview of EM seismo precursors and present situation with its explanation but the high frequency (HF) precursor (43MHz and 51MHz) is main point of our presentation. It is showed that precursor type HF signals are appeared before the EQ for one-three days and the some new peculiarity is found. This is under horizon epicenter position for main part of events under question. It means that emitted volume must be located at some altitude in atmosphere or ionosphere. The another unusual result is that such pre-seismic signals are responsible for seaquakes (not, as usually, for the earthquakes!). In result, we made conclusion about existing of some thunderstorm type activity above the sea level before the seismic event. It means that above sea level (up to 3-8 kilometers) the space charge cloud would be generated at one-three days before the active seismicity (under sea floor). Based on above mentioned we can supposed that probably this is new pre-seismic signature which will be used in future EQ forecast. Some additional experimental facts and mechanisms are discussed to explain this HF precursor (EM signals) generation above the epicenter of future seismic activity.

MONITORING THE CURRENT SUMMIT ERUPTION OF MOUNT ETNA USING INFRARED SATELLITE DATA FROM THE ERS ATSR-2

Rob WRIGHT, David Rothery, Stephen Blake (Department of Earth Sciences, The Open University, Milton Keynes MK7 6AA, UK, email: r.wright@open.ac.uk); Martin Wooster (Department of Geography, King's College London, Strand, London, WC2R 2LS, UK)

After the unusually quiet period that followed the end of the 1991 to 1993 eruptions, magmatic activity resumed within Etna's summit crater complex in July 1995. All four summit craters have been characterised by strombolian activity while between July 1997 and July 1998 the South East crater was also the site of sustained lava effusion. Intense paroxysmal explosions have also occured intermittently from the North East crater and La Voragine.
In March 1998, at the request of the Italian Civil Protection Authority, the European Space Agency commissioned the "Empedocles" project. This aim's to assess the role that satellite remote sensing can play in monitoring the volcano, and understanding the nature and future evolution of the current activity. Using data acquired by the ERS-2 along Track Scanning Radiometer (ATSR) we show how the amount of short-wave infrared radiance emitted from the summit crater complex has fluctuated since July 1996. The data reveal patterns that correlate well (on a weekly time scale - ATSR acquires data ~ every 3 days) with Etna's general level of activity as documented in field reports. Examining the amount of radiation emitted at different wavelengths allows us to distinguish activity associated with high temperature vents from that associated with lava flows. By applying rank order statistics to the ATSR data-set we have inferred changes in the level of activity on Etna that may reflect changes in the eruptive state of the volcano.

THE SPACE VOLCANO OBSERVATORY (SVO) PROJECT

Pierre BRIOLE (Institut de Physique du Globe, 4 Place Jussieu, F-75005 Paris, email: briole@ipgp.jussieu.fr) and the SVO science team

1500 volcanoes on the earth are potentially active. One third of them have been active during this century and about 70 are presently erupting. At the beginning of the third millennium, 10% of the world population will be living in areas directly threatened by volcanoes. Presently, in spite of the efforts of many countries, only a few volcanoes are monitored by modern observatories. Even in the best equipped of them, real-time data acquisition on the active parts of the edifices during crisis is an extremely difficult and risky task. The only way to provide global, continuous, real–time and all–weather information on volcanoes is to combine observations from space and from the ground. Spaceborne observations (with satellites, helicopters, drones, balloons,…) are mandatory and complement the ground ones that can be implemented on a limited set of volcanoes. A project called SVO (Space Volcano Observatory) has been proposed to the European Space Agency to remotely monitor the deformations and thermal changes of the highest active areas of the volcanoes (lava lakes, lava domes, lava

flows, eruptive vents…). These zones are unstable and often deform significantly prior to paroxysmal events (sudden collapses, flank pyroclastic flows, …). They are also remote and dangerous and cannot be easily equipped with ground equipment. We propose to map at high resolution (1.5m pixel size) the topography and the thermal changes (for pixels above ~ 450°C) of active volcanic areas with a return time of one to three days and an image size of 6 x 6km. Those variations will put constraints on the physical and dynamic processes of the system. Other applications like landslide monitoring, will be possible. The requirement of fast data processing and interpretation imply the set up of several ground-based stations for data collection. The 12-15 major volcanological observatories of the world could host those receiving stations.

JSP23/E/42-B2 1010

VOLCANIC RISK AND EMERGENCY PLANS OF THE NEAPOLITAN VOLCANOES

Lucia CIVETTA (Co-ordinator of the thecnical committee for preparation of the emergency plans Osservatorio Vesuviano, via Manzoni, 249, 80123 Naples, Italy e-mail:civetta@osve.unina.it)

The volcanoes of the Neapolitan area, Vesuvius, Campi Flegrei and Ischia, have generated more than 100 explosive eruptions in the past 10 ka. However, they can lie dormant for many centuries and the great risk posed by volcanic activity in the region was, therefore, not always apparent. Vesuvius has exhibited various types of activity in the past 25 ka. Plinian and subplinian explosive eruptions occurred every few millennia or few centuries, respectively. Strombolian activity, lava effusions and phreatomagmatic eruptions usually follow the plinian and subplinian eruptions until conduit closes. Since the last eruption of 1944, Vesuvius has not shown signs of unrest. Only moderate seismicity and fumarolic emission testify the current state of activity of the volcano. The Vesuvius eruptive history however suggests that the longer is the quiescent period, the more violent is the renewal of the activity. The last eruption of the Campi Flegrei caldera occurred in 1538 AD, at the north-western edge of the. La Starza resurgent block. Since that time, after hundreds of years of subsidence, two bradyseismic events occurred in 1969-70 and 1982-84, which totalled a net vertical uplift of 350 cm of the central caldera block, at the harbour of Pozzuoli. The last eruption of Ischia occurred in 1302 AD, at the edge of the resurgent Mt. Epomeo block. Since that time intense fumarolic activity, hot springs and seismicity characterise the island current state. Intense urbanisation and inadequate planning of the Neapolitan territory have significantly contributed to the increment of the volcanic risk since the fifties. In response to the increasing volcanic risk, in 1993 the Minister for Civil Defence appointed a commission to prepare the emergency plan of the Vesuvian area that was completed at the end of 1995. In 1996 the Minister of Civil Defence appointed a new Commission to update the emergency plan of Vesuvius and prepare the scenario of the expected eruption at the Campi Flegrei Caldera and define the guidelines for the Campi Flegrei emergency plan.

JSP23/E/26-B2 1050

VOLCANIC HAZARD MAPS OF TENERIFE ISLAND (CANARY ISLANDS)

Alicia FELPETO , Vicente Araña (Dep. Volcanology, Museo Nal.Ciencias Naturales, CSIC, J. Gutiérrez Abascal, 2, 28006 Madrid, Spain, email: mcnaf66@pinar1.csic.es); Mar Astiz (Dep. Matametica Aplicada, ETSA, Universidad Politécnica, Avda. Juan de Herrera 4, 28040 Madrid, Spain); Francisca Gómez (Centro di Studio per la Geologia Structturale e Dinamica dell'Apennino, CNR, via Santa Maria, Pisa, Italy); Alicia García , Ramón Ortiz (Dep. Volcanology, Museo Nal. Ciencias Naturales, CSIC, J. Gutiérrez Abascal 2, 28006 Madrid, Spain)

The first steps for the generation of volcanic hazard maps of Tenerife consists of the definition of the most significant hazards and the selection of the most suitable areas for containing emission centres, taking into account all the data of the eruptive history of the island. Then, for the evaluation of the effects of an eruption, a numerical model for each hazard has been chosen. The application of the different models allows the computation of the probability of each point of the island being affected by each type of eruption, and so, building up the volcanic hazard maps. The methodology proposed, integrated on a GIS framework, allows the automation of the generation of hazard maps for more specific studies of smaller areas of the island or specific risk scenarios. It also represents the starting point for developing risk maps.

MAPPING AND MONITORING OF VOLCANOES USING SPACE-BORNE SAR

Woolil M. MOON, Lanying Feng and (Geophysics, The University of Manitoba, Winnipeg,Canada R3T 2N2 (email: lfeng@gis.geop.umanitoba.ca, wmoon@cc.umanitoba.ca); DUK-JIN>KIM , K.H. Choi, C.W. Lee and Woolil M. MOON (Earth System Science, Seoul National University (email: wmoon@eos1.snu.ac.kr, djkim@eos1.snu.ac.kr); J. L. Lizeca (SERGEOMIN, La Paz, Bolivia ("Jose Liuseca "abtema@coord.rds.org.bo

In this study, we have investigated several active volcanic areas (Baiktu-san (China-Korea border), Cerro Caquella (Bolivia), and Halla-san (South Korea)) using RADARSAT and JERS-1 SAR data for their geological characteristics and for their application criteria in view of natural hazard monitoring. Baiktusan is located at the junction of northeastern edge of Huabai tectonic block of the Eurasian continent and mid-Cenozoic off-shore Pacific volcanic zone, and have gone through several stages of crustal evolution. According to historical records, Baiktusan had a major eruption in 1002 AD, and several minor eruptions in 16th and 18th century. However, the strategic location of Baiktusan at the political boundary between P. R. China and North Korea, has resulted in a situation with rather poorly surveyed geology maps and inconsistent geological interpretation of recent volcanic activities. The Halla-san volcano has not been active during the histrocial time, but it is the main feature of the Jeju Island (a volcanic island), which has recently been rapidly developed for increasing human settlement. In the Cerro Caquella region, which is a remote barren Andean range, a detailed DEM could be extracted to investigate morphological changes associated with active volcanic activities, in addition to correlation of the DEM with respect to several other geological and geophysical data collected over the study area. Several sets of JERS-1 SAR and RADARSAT data are acquired for this study with the objectives of investigating the surface geology of Baiktu-san and Halla-san volcanoes and the surrounding area to delineate consistent geological and volcanic characteristics. Both traditional geological remote sensing approach and the space-borne InSAR (SAR interferometry) approach were used (i) for structural geological interpretation of the study area using the pre-processed SAR data, and (ii) for correlation of the interferogram fringe pattern…

THE MONTSERRAT VOLCANO ALERT AND WARNING SYSTEM

Lloyd L. LYNCH (Seismic Research Unit, University of the West Indies, St. Augustine, Trinidad W.I., email: sru@wow.net)

From the onset of the Soufriere Hills volcano eruption on July 18, 1995, to the waning stages of the eruption almost three years later most areas of the more developed half of the island of Montserrat faced the threat of devastation. The relatively small size of the island, its complex political and governance structure, and the demographic setting in relationship to the threatening volcano were factors which all combined to make the management of the crisis one of the most challenging of the twentieth century. Compounding matters, was the fact that the eruption followed a style for which there was no well-documented precedent. As in most volcanic crises, an alert and warning system was instituted primarily to facilitate risk and emergency management. The system employed was an adoption of the generic alert and warning system popularised by the UN Volcanic Emergency Handbook. In this article the Montserrat volcano alert and warning system is modelled as network of closely interrelated functional entities comprising of a management subsystem, a detection subsystem and a response subsystem. This provides a comprehensive abstraction of the functions and interaction between the administrative authorities, scientists and the public during the eruption. With aid of this model a detailed analysis of the strengths and shortcomings of the system is performed and presented. Attempt is also made to document the major changes within the subsystems during the crisis. There were several. Among the most remarkable were the many changes in the management personnel such as chief minister, governor and chief scientists. Throughout the crisis key institutions such as the Montserrat Volcano Observatory and the Emergency Operation Center also endured constant evolution. Operational and decision-making policies and procedures within these institutions encountered numerous revisions. Generally, these changes were intended to facilitate the tacit objective of local authorities to maximise life safety while retaining a sustainable level of functionality on the island. In the absence of…

JSP23/W/24-B2 1150

A DEVELOPING VOLCANIC CRISIS IN DOMINICA, LESSER ANTILLES

John B. SHEPHERD, Lloyd L. Lynch, Mark Stasiuk, Joan L. Latchman (Seismic Research Unit, UWI, St. Augustine, Trinidad, e-mail: johnbshepherd@hotmail.com); Joseph M. Devine (Brown University, Providence, R.I. USA)

The island of Dominica is in the centre of the volcanically active Lesser Antilles island arc. The island is approximately 35 km long by 12 km wide and is composed entirely of Pleistocene to recent volcanoes. Earthquake swarms have been reported from Dominica since it was first settled by Europeans. These originate in all parts of the island but are most common in the southwestern part of the island where there are at least three volcanic vents which have erupted in the last few thousand years.
The most recent swarm began in September 1998 and is continuing. By January 10 1999 over 1,000 shallow volcanic earthquakes had been recorded by a nine-station digitally recording short period seismograph network. Over 300 earthquakes had been felt in the southwestern part of Dominica causing significant damage. Epicentres were initially located close to Morne Plat Pays volcano but during the swarm have spread to the most of the southwestern region. Focal depth are in the range 1-5 km and are becoming shallower as the swarm progresses. GPS measurements have detected widespread inflation of the epicentral region. An extensive programme of geological mapping is in progress and a response plan has been developed by the civil authorities.

THE SEISMIC ALERT SYSTEM IN MEXICO CITY AND THE SCHOOL PREVENTION PROGRAM

ESPINOSA ARANDA J M, A Jimenez, G Ibarrola, F Alcantar, A Aguilar, M Inostroza, S Maldonado Director, (Centro de Instrumentacion y Registro Sismico, A.C. Anaxagoras #814, C.P. 03020, Mexico, D.F. E-mail: cires@cires.org.mx Home page: http://www.cires.org.mx;); R Higareda (Director, Direccion de Emergencia Escolar Subsecretaria de Servicios Educativos del Distrito Federal Secretaria de Educacion Publica Callejon de Torresco #12, C.P. 04010, Mexico, D.F. E-mail: rhigareda@yahoo.com)

The Seismic Alert System (SAS) is a public service developed with the sponsorship of the City Government Authorities, with the aim to mitigate seismic disasters. Since August, 1991, after 88 months of continuous operation, the SAS has being capable to detect 714 seismic events in the Guerrero Coast; 12 of them so strong to trigger general alerts in Mexico City, 34 restricted, and one false general alert. The warning ranges strong or restricted correspond to seismic magnitude forecasted great than 6, or great than 5. During the "Copala" M7.3 earthquake, in September 14, 1995 the SAS was activated and issued a general warning signal in Mexico City, 72 seconds prior to the ``S" ground motion first arrivals. This earthquake warning reached an estimated population of more than 4 million citizens. The response of children in schools was massive because of the application of an earthquake hazard reduction program. The Copala earthquake helped us to identify the societal response strengths and weaknesses to the earthquake early warning signal. The long-term plan of hazard mitigation of the National Ministry of Public Education, Secretaria de Educacion Publica (SEP), has created awareness to earthquakes in the children that have assisted in these years to various school levels. Even though they did not suffered the disastrous consequences of the 1985 earthquake, they are more aware than the average people that lived through that disastrous event, who still are not trained.

SEASONAL WARNING FOR CLIMATIC HAZARDS: PROSPECTS AND RESPONSES

T.DOWNING (Environmental Change Unit, 1A Mansfield Road, Oxford, OX1 3TB,
Email: tom.downing@ecu.ox.ac.uk)

With climate change, there is increasing concern that climatic hazards will become more frequent and more severe. One of the most promising developments is seasonal climate forecasts. Already forecasts are operational in many parts of the tropics and sub-tropics, and particularly for droughts and floods associated with ENSO events. Prospects for further development of seasonal forecasting for a range of climatic hazards are reviewed, illustrated with case studies in Africa and Europe. A critical evaluation of the utility of seasonal forecasts centres on vulnerability, communication channels, and effective responses. In contrast to short-term prediction, seasonal forecasts raise new issues of preparedness and the use of information.

JSP23/E/10-B2 1420

CHANCES FOR A LONG TIME FORECAST OF SEVERE STORM EVENTS IN WESTERN EUROPE WITH RESEPCT TO THE NORTH ATLANTIC OSCILLATION

Mattius KLAWA, Uwe Ulbrich and Johannes Wefers (Institut fuer Geopyhsik und Meteorologie, Kerpener Str. 13, 50923 Koeln, Germany, e-mail: mklawa@meteo.uni-koeln.de, phone: 49 (0)221/470-3689)

The North Atlantic Oscillation is the dominant variability pattern in sea level pressure over the North Atlantic. Spectral analyses of the variations of this pattern show peaks on seasonal,

yearly or decadal time scales. Also research proved influence of the NAO on the North Atlantic Stormtracks and on the European climate e.g. rainfall rates, winter temperatures in western Europe. In this presentation extreme storm events in western Europe are evaluated with respect to the NAO. Probabilities for extreme storm events on time scales of 5-10 years dependent on the NAO are estimated. In combination with daily weather regimes (since 1881) the long time series of the NAO pattern (since 1865) is used for a more detailed analyses on European weather events. In a first step damaging storms named by reinsurance companies and meteorological extreme events are compared. Weather regimes associated with these events are used for a description for the atmospheric circulation over Europe and to find out common features of periods around storm events. In a final step the probabilities for storm events are evaluated and interpreted.

JSP23/E/29-B2 1440

FRACTURE CRITICALITY: A NEW CRITERIA FOR MONITORING THE ONSET OF EARTHQUAKES AND FRACTURING

Stuart CRAMPIN (Department of Geology & Geophysics, University of Edinburgh, Edinburgh EH9 3JW, UK; email: scrampin@ed.ac.uk)

Seismic shear-wave splitting, diagnostic of distributions of stress-aligned fluid-saturated grain-boundary cracks and low aspect-ratio pores is seen with very similar characteristics in almost all igneous, metamorphic, and sedimentary rocks with a few well-understood exceptions. There is a minimum shear-wave velocity anisotropy of about 1.5% and a maximum of about 4.5% in intact un-fractured rock below about 1km in the crust. Theory and both field and laboratory observations suggest that this maximum value is close to the level of fracture criticality, associated with the percolation threshold, where rocks are so heavily fractured that shear-strength is lost, through-going fractures propagate, pore-fluids disperse, and earthquakes and fracturing occur. The evolution of such fluid-saturated rock can be modelled with anisotropic poro-elasticity (APE), where the driving mechanism is fluid migration by flow or diffusion along pressure gradient between neighbouring grain-boundary cracks and pores at different orientations to the stress field. APE shows that shear-wave splitting is controlled by the same parameters as control pre-fracturing deformation so that shear-wave splitting can be used to monitor directly the approach of fracture criticality before earthquakes or other failures by fracturing. The high seismicity of SW Iceland and the extensive SIL seismic network now allow changes in shear-wave splitting before earthquakes to be observed routinely with hindsight. A real-time "stress-forecast" in a narrow magnitude/time window was made with forecasts 17, 15, and 3 days before a M=5 earthquake on 13 November 1998. The key feature is monitoring the increase of stress in the relatively-undisturbed rockmass away from the complications of the earthquake source, and estimating the time at which induced cracking reaches the level of fracture criticality. By monitoring the build-up of stress, such stress-forecasts can give (potentially reliable) estimates of time and magnitude of future earthquakes but cannot give estimates of location. However, forecasts may well stimulate local studies, as was the case in Iceland, where investigations by the Icelandic Meteorological Office correctly identified the rupturing fault.

JSP23/W/01-B2 1500

THE COASTAL OCEAN MONITORING AND PREDICTION SYSTEM FOR WEST FLORIDA

MARK E. LUTHER, David Burwell, Meredith Haines, Nan Schmidt, Mark Vincent, Robert Weisberg, and Huijun Yang (University of South Florida Department of Marine Science, 140 Seventh Avenue South, St. Petersburg, FL 33701; Tel: 727/553-1528; Fax: 727/553-1189; E-mail: luther@marine.usf.edu)

Florida is the United States' fourth most populous state, with 80% of the population living in a coastal county. Several recent storms have brought large, unpredicted flooding to Florida's west coast. The coastal sea level response to tropical and extra-tropical storms results from wind forcing over the entire continental shelf. Much of the local response may actually be due to storm winds quite distant from the local area of concern; a case in point being tropical storm Josephine, a modest storm that nevertheless caused extensive flooding in the Tampa Bay area. The University of South Florida is implementing a real-time Coastal Ocean Monitoring and Prediction System (COMPS) for West Florida that will provide additonal data needed to give more accurate predictions of ocean storms and coastal flooding by storm surge. This system consists of an array of instrumentation both along the coast and offshore combined with numerical circulation models and builds upon existing in-situ measurements and modelling programs funded by various state and federal agencies. This observing system fulfils all of the requirements of the Coastal Module of the Global Ocean Observing System (CMGOOS). Data and model products are disseminated in real-time to federal, state, and local emergency management officials via the internet (URL http://comps.marine.usf.edu).

JSP23/W/03-B2 1520

EARTHQUAKE PREDICTION AND EARTHQUAKE PREPAREDNESS: CURRENT POSSIBILITIES FOR THE PACIFIC RIM

Vladimir KOSSOBOKOV, Vladimir Keilis-Borok, (International Institute for Earthquake Prediction Theory and Mathematical Geophysics, Russian Academy of Sciences, 79-2 Warshavskoye Shosse, Moscow 113556, Russia, E-mail: volodya@mitp.ru); John Healy (USGS, Menlo Park, CA 94025, USA, E-mail: jhhealy@aol.com); Donald Turcotte (Department of Geological Sciences Cornell University, Ithaca, NY 14853-1504, USA, E-mail: Turcotte@Geology.Cornell.edu)

The recent results of real-time testing in the Pacific Rim, 1992-1998, have established the high statistical significance of intermediate-term predictions of the largest earthquakes by algorithms M8 and MSc. Among predicted are all earthquakes of magnitude 8 or greater. Predictions are completely reproducible and use precursory activation of seismic static at different space and time ranges to reduce consecutively time and space where disastrous earthquake has to be expected. Although the predictions are of limited accuracy they do create a possibility to prevent part of the damage. This encourages a multi-scale approach to mitigate earthquake disaster. In general, earthquake predictions range from a zero-approximation of seismic zoning through long- and intermediate- to short-term ones. Accordingly, the preparedness measures range from building code, to simulation alarms and reinforcement of high-risk facilities, to the imminent "red alert" (e.g. evacuation of population and introduction of martial law). Different time from decades to seconds is required to undertake different measures; having different cost, they can be realistically maintained during different time periods and in the territories of different size. The key to damage reduction in the area of concern is escalation or de-escalation of preparedness measures depending on the current state of alert. That is the standard practice for mitigation of other major disasters, wars included. The interface between prediction and preparedness is delivered by the recent development of optimal strategies based on a trade-off between total volume of alert and rate of failures-to-predict. We demonstrate case histories of intermediate-term predictions that would have led to preventing a considerable part of losses by low-key safety measures.

JSP23/E/06-B2 1600

SANARIS PROJECT: A SATELLITE NETWORK FOR NATURAL RISKS MONITORING

Marta TARRAGA (Dept. Volcanologia, Museo Nacional de Ciencias Naturales, Jose Gutierrez Abascal 2, 28006 Madrid, Spain, email: mcnt184@mncn.csic.es); Alicia Garcia, Ramon Ortiz, Rafael Abella and Javier Peña (Dept. Volcanologia, Museo Nacional de Ciencias Naturales, Jose Gutierrez Abascal 2, 28006 Madrid, Spain, email: mcnp182@mncn.csic.es)

A new satellite communication system specifically designed for low-rate data applications has been developed and prototyped. A validation project is proposed to install a pilot network to be operated during 6 months. One of the target markets related to volcanoes has been selected, so a group of users is integrated in the project. A specific application for this market will be developed regarding data acquisition, processing, storage and dissemination to distant users. The feasibility of using the new satellite system to provide a new Eutelsat service for low-rate data applications will be evaluated from the pilot network performance. According to the Department of Volcanology (M.N.C.N.-C.S.I.C.) experience on the development of systems for volcano monitoring, its role in the project will be: -Co-ordinate the definition of users requirements for the pilot application. Installation of the digital seismic stations. –Maintenance of Teide and/or Timanfaya stations (Canary Islands).

JSP23/C/U5/E/06-B2 1620

EFFECTIVE EARTHQUAKE MONITORING PROCESS FOR EMERGENCY RESPONSE ON RESCUES (EMPEROR)

Yutaka NAKAMURA (System and Data Research Co. Ltd., SDR Bldg., 3-25-3 Fujimidai, Kunitachi-shi, Tokyo, 186-0003, JAPAN, E-mail: yutaka@sdr.co.jp)

It has been widely recognised that systematical and continuous monitoring of earthquakes is necessary for the early warning. In this presentation an effective earthquake monitoring process is proposed. DI, Damage Intensity of seismic motion, is defined as an inner product of acceleration vector and velocity vector at each time step dt. The multiplication of DI with mass received seismic motion, indicate the power of the motion act to the object. DI-value, defined as maximum of DI, is generally appeared after S-wave arrival. When P wave arrives, DI increases drastically, and after S wave arrival DI reaches to its maximum value, DI-value, soon. P wave Index, PI-value, is defined as maximum DI of P wave part. This value is suggested to be used for P wave alarm. DI-value is related with seismic intensity. DI-value has a very important practical advantage, since it can be calculated in real-time soon after the P wave arrives. Additionally, DI-value has a clear physical meaning and it is strongly related with the earthquake damage. This can be concluded as, with the continuous observation of DI, earthquake alarm can be issued efficiently and damage can be estimated precisely. According to combination of S wave and P wave alarms, early and/or reliable alarm is realised. P wave alarms can be issued when PI-value over the pre-set level, and S wave alarm can be issued when ordinary monitored values or DI-value exceed pre-set level. Combining PI, DI values together with K values is promising for the future early warning systems, since it has been clarified with both methods that it is possible to estimate the vulnerabilities of all ground and structures concerned and it is possible to issue the alarm before the real damage occurs.

JSP23/W/06-B2 1640

HIGH RESOLUTION AEROMAGNETIC SURVEY FOR CONCEALED FAULTS IN THE FUKUI PLAIN, CENTRAL JAPAN

Shigeo OKUMA, Masahiko Makino and Tadashi Nakatsuka (Geological Survey of Japan, 1-1-3 Higashi, Tsukuba, Ibaraki, 305-8567 Japan, email: okuma@gsj.go.jp)

Geological Survey of Japan (GSJ) has conducted a helicopter-borne high-resolution aeromagnetic survey in the Fukui Plain, Central Japan, to better understand concealed faults associated with the 1948 Fukui Earthquake (June 28, 1948, M=7.3) which brought disastrous damages to this area. The survey was flown along east-west flight lines at an altitude of 150 m above terrain and spaced 300 m apart with a Cesium Vapour magnetometer with a sensitivity of 0.01 nT at a sampling interval of 0.1 second and a differential GPS system. The compiled total intensity map of IGRF residuals shows interesting magnetic features as follows: 1) A broad magnetic high area occupies the western half of the plain with a sharp NNW-SSE trending boundary to the east, which corresponds well to the assumed location of the concealed Fukui Earthquake fault. 2) Three distinctive dipole magnetic anomalies lie in the magnetic high area, two of which lie at the northern edge of the area, implying the existence of intrusions associated with the Awara Hot Spring. 3) Magnetic lows are dominant along the coast line of the Sea of Japan and in its offshore areas, suggesting the existence of reversely magnetised volcanic rocks which lie offshore and maybe outcrop along the coast line.

JSP23/E/27-B2 1700

LAND SUBSIDENCE OF JAKARTA (INDONESIA) AND ITS GEODETIC-BASED MONITORING SYSTEM

Hasanuddin Z. ABIDIN , I. Meilano, M. A. Kusuma , J. Kahar (Department of Geodetic Engineering, Institute of Technology Bandung, Jl. Ganesha 10, Bandung, Indonesia, email: hzabidin@indo.net.id and hzabidin@gd.itb.ac.id); Rochman Djaja (National Coordinating Agency for Survey and Mapping, Cibinong, Bogor, Indonesia); Samsul Hadi (Jakarta Provincial Agency of Surveying and Mapping, Jakarta, Indonesia)

Jakarta is the capital city of Indonesia with population of about 12 million peoples, inhabiting the area of about 25-km by 25-km. It has been reported for quite sometimes that several places in Jakarta are subsiding at different rates from place to place. Up to the present times, however, there has been no definitive, detail, and comprehensive information about the characteristics and pattern of land subsidence in Jakarta areas. Usually the land subsidence in several places of Jakarta is estimated using their geological parameters or inferred from the ground water level observations. In order to give a better picture about these land subsidence phenomena in Jakarta, the geodetic-based land subsidence monitoring system has been implemented. The system is based on GPS and levelling measurements.
In this paper the land subsidence study in the city of Jakarta using repeated GPS and levelling surveys will be described and discussed. The land subsidence characteristics of Jakarta and its surrounding area are investigated using the data from three repeated GPS surveys conducted in 1994, 1997, and 1998 and four repeated levelling surveys performed in 1982, 1991, 1993, and 1997. The main goal of this land subsidence study is to understand the characteristics of land subsidence in Jakarta area and their generating forces and factors. Therefore, in this paper, the geological, geophysical, and hydrological aspects of Jakarta area would also be investigated and correlated with the geometrical changes information obtained from geodetic based systems. The paper would be sum up with some closing remarks.

JSP23/W/38-B2 1720

INTERNATIONAL TECTONIC REAL TIME RADON OBSERVATION AND TRANSMISSION - RELIMINARY RESULTS OF GEODYNAMIC MONITORING.

G.SOBOLEV (United Institute of Physics of the Earth, RAS, Moscow, Russia,
email: sobolev@uipe-ras.scgis.ru); S.Balassanian (National Survey for Seismic Protection, Yerevan, Armenia, email: presidnt@nssp.yerphi.am); A.Belayev (Vernadsky Institute of geochemistry and analytical chemistry, RAS, Moscow, email: abelyaev@chat.ru); S.Bushati (Center of Geophysical and Geochemical Exploration, Tirana, Albania, email: bushati@cgge.tirana.al); E.Lagios (Department of Geophysics and Geothermy, National & Kapodistrian University of Athens, Athens, Greece, email: elagios@atlas.uoa.gr); R.A.Nicholson (British Geological Survey, Keyworth, Nottinghamshire, NG125GG, United Kingdom, email: RAN@wpo.nerc.ac.uk); A.Ponomarev (United Institute of Physics of the Earth, Moscow, email: avp@uipe-ras.scgis.ru); A.Pronin (Geological-technological Scientific Inductional Enterprise "Geotechvims", Naro-Fominsk, Russia); G.Sideris, F.Zervos (GeoMentor, European Economic Interest Grouping, Athens, Greece, email: geomen@otenet.gr).

Seismic activity is a potential threat to populations and commerce throughout the world. Geophysical-geological research institutes and commercial companies in Greece, France and the UK are collaborating with similar organisations from Russia, Armenia and Albania, under the EU-funded Inco-Copernicus (Framework IV) programme, to develop new techniques for the automatic acquisition of gas geochemical data from remote sites using gas-sensing probes and telemetry. The data are being integrated with seismic information acquired in parallel, and used to determine whether or not the technique is a suitable method for monitoring ground disturbance associated with tectonic events.A number of data loggers (transducers/detectors) have already been installed since 1998 at specific locations (base stations) selected by the Project scientists in Caucasus (Southern Russia and Armenia), Greece, Albania and Scotland (UK). The seismic and gas-hydrogeochemical maps as the results of geophysical prospecting were used to select eligible sites for radon monitoring. Each base station includes two data loggers with the latest version of the Barasol MC radon probe incorporating sensors for barometric pressure and temperature combined with local rainfall measurements. These parameters are being transferred to attached cordless modems and are transmitted via INMARSAT global satellite communication system to Greece (Project co-ordinator) where all data are collected for joint processing. Signal processing software has been developed on the base of standard and original approaches. The spectral composition and structure parameters of obtained time series are determined by applying descriptive statistics, causal analysis and methods of the dynamic theory systems. The first stage realisation of Project indicates that telemetry systems are operating satisfactorily and the data are collecting, but that longer-term monitoring is necessary to link seismic measurements to radon exhalations and consider mentioned data acquisition-broadcasting system as real warning system.

JSP23/C/U3/W/21-B2 1740

DEVELOPMENT OF SEISMIC RAPID REPORTING AND EARLY WARNING SYSTEM IN TAIWAN

Yih-Min WU, Jen-Kuang Chung, Tzay-Chyn Shin (Central Weather Bureau, 64 Kung Yuan Road, Taipei, Taiwan, email: ludan@ss2.cwb.gov.tw); Yi- Ben Tsai (Institute of Geophysics, National Central University, Chung-li, Taiwan); William H.K. Lee (862 Richardson Court, Palo Alto, CA 94303, USA)

In 1994, two prototype seismic early warning systems have been implemented in Taiwan: (1) a rapid reporting system using a tele-metered network of digital accelerographs spread over the entire island, and (2) an alert system exploring the use of modern technology for the highly seismic area of Hualien. After four-years operation, the rapid reporting system was successfully operated in the seismic monitoring system of the Central Weather Bureau (CWB) for felt earthquake observation (Taiwan Rapid Earthquake Information Release System, TREIRS). It has achieved in the determined of precise earthquake location and magnitude computation about in one minute after the earthquake origin times. On the other hand, the Hualien alert system was phased out in 1998 due to large uncertainty of source parameters determination caused by small station coverage and only using P signal in determining the magnitude. Although it performed a very well reporting time (less than 10s after the earthquake origin time). Recently, the Hualien alert system stations were equipped with the digital accelerograph and combined to the TREIRS system. By adding the Hualien alert system stations to the TREIRS system, we have obtained a good precision for source parameter determination and a well reporting time for Hualien area earthquake monitoring. During the experiment in the past several years, we benefited from these two prototype seismic early warning systems and optimised the TREIRS system. We are encouraged forwards in the development of seismic early warning system based on the successful experience

HAZARD AND RISK ASSESSMENT, RISK MITIGATION AND MANAGEMENT

JSP23/W/30-A5 Poster 0830-01

MISLEADING SIGNALS IN HAZARD CATALOGS

Allen M. HITTELMAN (NOAA's National Geophysical Data Center (NGDC), World Data Center-A (WDC-A for Solid Earth Geophysics, 325 Broadway, Boulder, CO 80303, U. S. A.,
email: ahittelman@ngdc.noaa.gov); Lowell S. Whiteside and James F. Lander (Co-operative Institute of Research in Environmental Sciences, NOAA, 325 Broadway, Boulder, CO 80303, U. S. A.,
email: lws@ngdc.noaa.gov)

The primary purpose of natural hazard data catalogs is in the mitigation of future disasters. It is hoped that future natural disasters can be anticipated and populations warned if long term catalogs, which record the regional periodicity of events, are available. While such long-term variations in hazard are possible, we show that many current catalogs of natural hazard data may not be satisfactory to determine whether they actually occur.
Most hazard catalogs cover periods of less than 200 years and are reasonably complete and accurate for only the past 20-50 years. Such catalogs are not sufficient to investigate long term hazard variations. Earthquake, tsunami and volcanic catalogs, acquired and integrated at NGDC, illustrate artificial long-term variations created by cultural and scientific reporting changes, which can introduce unanticipated cyclical variations in the catalogs. These inconsistencies are often related to changes in the way magnitudes are calculated, evolving network equipment, network discontinuities of operation and personnel.

DISASTERS CAUSED BY CATASTROPHIC STORMS AND THEIR PREVENTION IN SMALL CATCHMENTS IN THE QIN MOUNTAINS

Guozhang FENG (College of Water Resources and Architectural Engineering, Northwestern Agricultural University, Yangling, Shaanxi, 712100, China, e-mail: gfeng@public.xa.sn.cn)

Catastrophic storms often cause flash floods and corresponding geophysical hazards in the Qin Mountains in Shaanxi Province, China. The disasters are difficult to be prevented due to their rare occurrence, extremely high severity, non-predictability and too short warning time. The 980709 storm, occurred in a small area in the southeast of the Qin Mountains on 9 July 1998, is the maximum storm event in the records in the region and has an investigated maximum point storm rainfall of approximately 2122 mm during 6 hours and 40 minuets at one of two storm centers, and 1511 mm during 11 hours and 30 minutes at another center. The areas involved inside the isohyets of 1500 mm, 1000 mm, 500 mm and 50 mm's storm rain, are 31.4 km2, 45.5 km2, 86.8 km2 and 847.1 km2, respectively. The storm formed enormous flash floods, landslides, mud-rock flows and aggradation of the riverbeds. As a combined consequence of the storm related disasters, 82 people and over 2000 thousands livestock were lost, over one hundred families were homeless, and most of the farmlands with growing crops were destroyed in the disaster involved two small catchments, especially in their densely populated valleys. Similar disasters with relatively lower severity frequently occur in the Qin Mountains even during the periods of general storms.
Reconstruction and protection of the areas both under and facing the damages are considerably important. Based on the natural and sco-economic features in the damaged and relevant areas, some integrated reconstruction and protection strategies for mitigation of the disasters and sustainable development of the region as an optimal eco-sco-economic system are proposed. The strategies consist of appropriate flood control standards, optimal land uses, reasonable economic structures, and safe residences and environments, in which some detail measures of engineering and non-engineering are involved. The strategies may be suitable to the similar catchments in the Qin Mountains.

JSP23/W/08-A5 Poster 0830-03

VOLCANIC HAZARD ASSESSMENT FOR A PROPOSED HIGH-LEVEL RADIOACTIVE WASTE REPOSITORY AT YUCCA MOUNTAIN, NEVADA, USA

Charles CONNOR and Brittan Hill (CNWRA, Southwest Research Inst., 6220 Culebra Rd, San Antonio, Tx, 78238, USA, e-mail: cconnor@swri.org); Andrew Woods and Steve Sparks (Centre for Geophysical and Environmental Flows, University of Bristol, Bristol, UK,
e-mail: a.w.woods@bristol.ac.uk)

The proposed high-level radioactive waste repository at Yucca Mountain, Nevada, USA, is located within a geologically active basaltic volcanic field. Probabilistic volcanic hazard models for future eruptions through the proposed repository depend heavily on spatial controls on basaltic volcanism, including: Pliocene-Quaternary vent clustering, development of volcanic vent alignments, and localisation of vents along normal faults. When these spatial controls on past volcanism are considered, the probability of volcanic eruptions through the repository is estimated to be 10^(-7) to 10^(-8) annually, or 1:1000 during the 10,000 yr performance period for the repository. This estimate is greater than some previous estimates that do not consider structural controls on basaltic volcanism explicitly, primarily because of the location of the proposed repository within a broad density low produced by a half-graben. Modification of spatial hazard models to include this structure, which appears to have controlled past volcanism, provides a mechanism to link patterns in basaltic volcanic activity and crustal extension in a quantitative hazard assessment for the first time. This technique may be widely applicable to assessment of volcanic hazards resulting from small-volume basaltic volcanic fields.

JSP23/P/05-A5 Poster 0830-04

A SEISMIC HYDRAULIC BEARING

Federico BARTOLOZZI (Civil Engineering an Independent Researcher, via dei carracci 4, 21100 varese, Italy, email: ciuciuzza:iol.it)

The proposed bearing consists of two parts. The fixed part, connected to the building is a steel sliding surface in the shape of a spherical bowl with a safety side spandrel. The movable part, connected to the foundation-soil complex, consists of a movable steel ball (rolling friction) in direct contact with the overhanging spherical bowl; alternatively, the ball may be fixed and coated on the top with Teflon (sliding friction). The lower part of the ball is linked to a movable cylindrical piston housed in the central chamber of a hydraulic device, also having two lateral symmetrical chambers with movable pistons, subjected to the elastic reactions of pre-stressed springs. Two holes connect the lateral chambers with the central one. During an earthquake, the horizontal displacement of the foundation-soil complex slightly affects the rest state of the building and the corresponding seismic energy in the building is negligible. The vertical displacement of the foundation-soil complex does not notably alter the rest state of the building, where there is no danger of resonance occurring due to the damping action of the liquid contained in the hydraulic device. The main advantages of the seismic insulation system, characterised by this type of bearing, are: 1. self-catering of the building after an earthquake; 2. possibility of application to modern and old buildings with any planimetric shape; 3. negligible pendulous effet in the building; 4. economical competitiveness with the existing aseismic systems both with partial and total absorption of seismic energy; 5. negligible psycho-physical effects for the inhabitants.

JSP23/P/04-A5 Poster 0830-05

SELF-CENTERING ASEISMIC SYSTEM WITH ELASTIC BEARINGS AND HYDRAULIC DAMPERS

Federico BARTOLOZZI (Civil Engineer and Independent Researcher, via dei Carracci 4, Varese, Italy, email: ciuciuzza@iol.it)

The theoretical and experimental analyses emphasise the following characteristics of the proposed system: 1. the self-centring of the building after an earthquake; 2. the undulatory seismic energy in the building is constant and about 1% of the weight, by using bearing with sliding friction (pure Teflon). It is negligible, by using bearings with rolling friction (steel balls). In addition, it is independent on the seismic frequency and the soil displacement; 3. the vertical seismic energy in the building is minor and it increases both with the increase of the ratio between the frequencies (phase opposition) and with its decrease (phase); 4. the building remains almost motionless (negligible displacement) with respect to the horizontal translation of the foundation-soil complex for all values of the direction angle of the motion, of the soil displacement and acceleration; 5. in the interval of emergency vertical seismic frequencies, including the resonance frequency, the automatic starting of the dampers occurs. They progressively decrease the dynamic strain of the springs, which are integral parts of the bearings; 6. because of the sub-undulatory shock, the total load on the bearings increases for upward soil displacements and it decreases in the contrary case, both in phase and in phase opposition conditions; 7. the experimental tests, executed with reference to th undualtory shock, confirm the theoretical results.

MARABINI

Abstract not available at the time of going to press

JSP23/W/37-A5 Poster **0830-07**

ABOUT THE ENSO IMPACTS IN NORTH-EASTERN ARGENTINE

Norberto O. GARCIA and Maria del Valle Venencio (Facultad de Ingenieria y Cs. Hidricas - Univ. Nac. del Litoral, CC 495 - (3000), Santa Fe, Argentina. E-mail: nogarcia@ fich.unl.edu.ar)

Frequently the North-eastern Argentine Republic is affected by floods on the riversides of the Paraná river, originated in the precipitation on the High Basin, and/or floods caused by the local rainfalls. With the same recurrence characteristic, drought situations take place that also affects the region, going from an extreme to the other in a short time generating emergencies totally different, but equally serious.
The present work makes an analysis of the extreme situations of the Paraná River associating them with the development of the sea surface temperatures on the Pacific Equatorial Ocean (EL NIÑO, LA NIÑA and neutral years). In this sense was found, as it was hoped, that most of the EL NIÑO events were associated with extraordinary floods of the Paraná river; although there were some floods that they were associated with the neutral phase (1959). The phase LA NIÑA (cold events) not always was associated with notable low waters of the river.
The behaviour of the precipitations over the region was non-homogeneous, and not always coincident with what it was hoped from a statistical point of view (Ej. 1983). The situation of EL NIÑO 1997/98 was permanently scanned and climatologically predicted through several models. So much in the river such as in the region the forecasts were completed acceptably. While, the socio-economic impact of the extreme events was very graphically shown in the means of communication.

ESTIMATION OF SEISMIC INTENSITY ATTENUATION LAWS FOR BANAT REGION

AURELIAN PANTEA and Iren-Adelina Moldovan Ivan (National Institute for Earth Physics, P.O. Box MG-2, Bucharest-Magurele, Romania, e-mail: pantea@infp.ifa.ro and iren@infp.ifa.ro)

An attenuation relationship for macroseismic intensities for Banat (Romania) crustal earthquakes has been developed. We have used a data base including macroseismic maps from 21 earthquakes occurred during the period 1900 to present with MGR>4.0. The general form of the attenuation relation used is: log (I)=f1(M)+f2(r,E)+f3(r,M,E)+f4(F)+e (where: I is the macroseismic intensity, M is the earthquake magnitude, r is the hypocentral distance, E is the tectonic environment, f4(F) is a function of fault type and "e" is a random variable representing the uncertainty in log(I). Comparison with other attenuation relationships have been made.

TROPICAL CYCLONE RISK ASSESSMENT

M.V.RODKIN (Geophysical Center, Russ. Ac. Sci., 117296 Moscow, Molodezhnaya 3, rodkin@wdcb.rssi.ru); G.S.Golitsyn (Inst. of Physics of Atmosphere, Russ. Ac. Sci., Moscow); V.F.Pisarenko (Intern. Inst. of Earthquake Prediction Theory and Math. Geophysics, Russ. Ac. Sci., Moscow); M.I.Yaroshevich (NPO Taifun, Rosgidromet, Obninsk, Russia)

A method of statistical estimation of tropical cyclone hazard is suggested. Probabilities of exceeding of certain levels of wind velocity (quantiles of distribution function) at a given area for given time intervals T are evaluated. The evaluation is based on the following velocity/distance relation: V(R)=Vmax*(Rmax/R)**2, where Rmax is the radius of central part of tropical cyclone where maximum of wind velocity Vmax at given moment is observed. Accuracy of this relation is estimated by an error with standard deviation 7 knots. Suggested method is applied to typhoons in the Western Pacific, 1950-1988. The used catalog contains 1013 events. The 50%-quantiles (medians) and 90%- and 95%-quantiles of maximum possible wind velocity for time intervals T=1, 2, 5, 10 and 20 years at 4 areas were evaluated: Tokyo, Hong-Kong, Taiwan Isl., and Vladivostok. Problem of possible temporal change in the typhoons regime is discussed in connection with the solar activity and El-Nino regime. The suggested typhons risk assessment method can be useful for insurance industry and administration in areas subjected to tropical cyclones.

LARGE SCALE DESTRUCTIONS OF BUILDINGS, THEIR CONNECTION WITH GROUNDS SPECTRAL PECULIARITIES DURING THE SPITAK EARTHQUAKE OF 12.07.1988 IN LENINAKAN (NOW GIUMRY), ARMENIA

Hrachya ABRAHAMYAN (Institute of Geophysics & Engineering Seismology, NAS RA, Leningradian 5, Gyumri, 377515 Armenia, email: iges@shirak.am)

Severely consequences of Spitak catastrophic earthquake force us to carry out the investigations revealing the causes of much more in quantity destructions. The most interesting aspect of testing the possibility of microvibrations using for prediction the grounds frequency characteristics is the comparision of buildings destructions measure by the grounds frequency elective property giving through the microvibrations. During the earthquake of December 7, 1988 with M=7.0 the full destruction of frame-panel 9-storey buildings (from 138 buildings in Leninakan were undamaged only 6) and frame-stone 5-storey buildings (from 335 buildings were undamaged 87) was observed.
Registrations of buildings natural oscillations before the earthquake and grounds dominant periods by microvibrations after the earthquake showed that statistically the largest amount of destructions were obtained on the parts of town where the grounds natural dominant periods T were approximately of 0.5-0.6 sec for five-storey frame-stone buildings. On the grounds with T=0.2-0.38 for nine-storey buildings and T=0.2-0.3 for five-storey buildings damages were been of least amounts. Natural periods of nine-storey buildings are of 0.5-0.6 and of five-storey buildings are of 0.25-0.4. The high damages may be explained by strong influence of oscillations due to resonance phenomenon when the ground natural dominant periods tally with the buildings natural periods.
In seismic microzonation of region the possible spectrum of disastrous earthquake must be assessed. By this assessment only the grounds frequency peculiarities may be compared with buildings frequency characteristics. Such a complex approach only enables us to solve correctly the task of connection of possible damages by grounds frequency characteristics. Neglect of this factor will bring to tragic consequences such that were been in Leninakan.

MINERAL PATHOGENIC DEPOSITS INTO A HUMAN ORGANISM AS A SIGN OF NATURAL HAZARDS

Nadezhda PAL`CHIK (United Institute of Geology, Geophysics and Mineralogy of Siberian Branch of RAS, Koptjug prosp. 3, Novosibirsk 630090, Russia; email: nadezhda@uiggm.nsc.ru)

It is known that minerals exist not only into the Earth's crust but also into all human organisms. The physiogenic minerals contained into tooths and bones (as an apatite) are discovered also into pathogenic formations which can be found into different organs and tissues of a human body. We show, using the X-ray diffraction and the infra-red spectroscopy methods, that the apatite is present into urinary calculi, gallstones, dental stones, salivary calculi and also calcified cardiac valves as only phase of a mineral formation. Observations show that the full pathogenic mineralization of all living tissues of an organism occurs in some cases. Such peculiar natural hazard and its geographical distribution require a special attention and further investigation.

ASSESSMENT OF LANDSLIDE HAZARDS USING GEOPHYSICAL TOMOGRAPHIES

Simeon KOSTYANEV, Petar Srefanov and Peshka Stoeva (University of Mining & Geology, Sofia-1100, Bulgaria, e-mail: skost@staff.mgu.bg)

Landslides and unstable slopes are among the major natural and man-made hazards affecting mankind and yet their causes, their consequences for human life and property, and possible strategies for mitigating their effect are not very well understood. We will note, that only in Bulgaria there are over thousand active landslides on populated and health resort areas. The material and social losses have not been calculated yet. But in preliminary data they are enormous. Numerous and dangerous are the landslides and unstable slopes in open-cast coal-mines too.
In this paper we offer methods for combined application of high-resolution electrical tomography and seismic ray tomography for characteristic of landslide hazards and unstable ones. The major aim here is to predict where and when landsliding will occur, establishing their variability in space and time, and appraising their impact on the natural and socio-economical environment.
The above methods are applied for the studying of concrete landslide in Bulgarian Black sea coast and on some unstable slopes in an open-cast coal-mine of Maritza-Iztok area. This combined application of electrical and seismic tomography for assessment of landslide hazard is very useful.

SEISMICITY AND SEISMIC HAZARD STUDIES IN EGYPT AND SURROUNDING COUNTRIES

Samir RISAD (Geology Department, Assiut University, Egypt), Mahmoud Ghaleb (Geophysics Department, Cairo University, Egypt)

The tectonic setting of the Eastern Mediterranean Region is complicated because of the interacting effect of the principal plates: Africa, Eurasia and Arabia. The highest level of activity occurs at the northern margin of the Arabian plate, where it collides with Turkey and Iran. Strong earthquakes also occur along the western edge of the plate, along the Sea rift and the axis of the Red Sea Gulf of Aden. Egypt has a historical record of earthquake activity extending over the past 4,800 years. The most devastating earthquake in the recent history of Egypt, Dahshour earthquake, occurred some kilometers south of Cairo on the 12th of October 1992 damaged over 1,000 schools and other buildings, ed and injured over 7,000 people. In addition, other significant earthquakes occurred during this century interrupting the socio-economic development process of Egypt. Vulnerability to earthquakes increases steadily as urbanisation and development occupy more areas that are prone to the effects of significant earthquakes. The uncontrolled growth of cities in such areas are often associated with the construction of seismically unsafe buildings and infrastructures, mostly due to the insufficient knowledge of existing seismic hazard. Moderate and even small earthquakes may turn catastrophic in highly populated areas with poor building construction practice. In addition to the direct socio-economic impact of an earthquake, the long-term effects (the disruption of the economic chain, human resettlement, the reconstruction to modern standards) may last decades and absorb a considerable part of the national budget. In the absence of strong motion records a possible alternate method for seismic risk evaluation is the study of the attenuation of intensity with distance. For this purpose isoseismal maps for 17 historical and instrumental earthquakes that occurred in different parts of Egypt were analysed. Relations for intensity attenuation in different direction for different regions were obtained and have been used to calculate maximum intensity values all over Egypt. In addition, peak ground acceleration maps were produced for exposure time 10, 25, 50, 100 and 250 years, making use of an updated earthquake catalogue for Egypt. More than 20 seismogenic zones in and around Egypt were involved in the calculations. Hazard studies in Egypt have been carried within the framework of the regional IGCP Project 382, entitled "Seismotectonics and Seismic Hazard Assessment in the Mediterranean Basin (SESAME)", and in co-ordination with the activities of RELEMR Project. The results on Egypt were integrated with other available data for the surrounding countries.

JSP23/E/55-A5 Poster **0830-16**

DIRECT AND INDIRECT LOSSES DUE TO EARTHQUAKES

KOFF G.L (1), Lobatskaya R.M. (2), Frolova N.I. (3). (1) Institute of Lithosphere, Russian Academy of Sciences, Moscow, Russia, (2) Irkutsk University, Irkutsk, Russia, (3) Seismological Center of IGE, Russian Academy of Sciences, Moscow, Russia

The stability of urban area development is strongly depended on the hazardous natural processes. In order to secure the stable development of the territory the expected losses due to future events should be estimated. Direct and indirect economic losses are distinguished.

We understood direct economic losses due to natural processes as losses in economy within the current reproductive cycle which are expressed in terms of annual indexes of social economic development. All other losses are referred to indirect ones. They do not influence directly on the achieved results in the economy in the current year. The indirect losses is an estimation of negative consequences resulted from secondary effects. In contradiction to direct losses, indirect ones may arise and manifest within the long time interval. The indirect losses may not have a definite place in space and are usually characterised by cascade effects. Four main groups of factors, which influence upon direct and indirect economic losses due to earthquakes and other natural processes are distinguished; they are the following: origination, susceptibility, cycles and state. Different factors and their influence on losses due to earthquakes are analyzed. For different urban areas it is possible to construct in advance the index system which will allow to estimate the value of mentioned factors. Than it is possible to identify zones according to the weights of different factors which may be used in order to improve prevention, mitigation and response from future events. The system analysis of existing connections of urban areas with other regions will allow to estimate the rate of possible instability of the territory in the case of emergency and to obtain more reliable estimations of acceptable level of economic and ecological risks.

RECENT ANOMALOUS GEODYNAMICS OF PLATFORM FAULTS AS THE NEW ECOLOGICAL RISK FACTOR

CHURIKOV V.A., Kuzmin Yu.O. (both at United Institute of Physics of the Earth, Recent Geodynamic Lab., B. Gruzinskaya Str. 10, Moscow, Russia, email: vt.churik@relcom.ru)

New data on the existence of recent superintensive deformations (SD) of the ground surface are obtained for fault zones in aseismic regions (Russian platform, Pripyatskaya depression (Belorussia), Turanskaya platform (Turkmenistan) and etc.).
These deformations have amplitude approximately 20 - 50 ppm, extension 0.1-1.0 km, velocity of vertical and horizontal displacements up to 5 - 7 cm per year. They have a pulsating character (the duration of the impulses of the activity of 0.5 - 1.5 year). These anomalous deformations call into existence the ecological risk of two types. 1. Direct - by the plums of anomalous fluids during the periods of activating fault zones; 2. Indirect - by the casualties of ecologically dangerous objects (wells on oil field and gas deposits, pipelines, underground depots of gases and toxic wastes, atomic power stations and etc.). The mechanism of SD-processes is suggested based on the parametrical excitation (the induction) of anomalous deformations in fault zones. In this case, the induction is evoked by small disturbances with nature and technogenic origins.

DISASTER MITIGATION PROGRAMMES FOR EARTHQUAKES, CYCLONES, DROUGHTS AND LANDSLIDES

H.N. SRIVASTAVA (India Meteorological Department, New Delhi-110003, India, email: snb.imd.ernet.in)

Peninsular India earthquake of September 1993 (Latur, Magnitude 6.3) which caused the death of about 10,000 persons and major damage to stone built mud houses led to the development of a World Bank aided project for relief and rehabilitation work besides reconstruction of cheaper but safe dwellings in the area. Under this project, broad band digital seismographs (GSN) were installed in India to improve earthquake risk assessment.
Issue of warnings about the land fall of tropical cyclones through INSAT based disaster warning system have helped in saving the lives of people living in coastal areas of peninsular India. Improvement of the rainfall measurements through another World Bank Project for the peninsular India will enable us to study agricultural droughts with greater reliability.
Recent landslides and floods in Garhwal and Kumaon regions during May, 1998 in Himalaya which have taken a heavy toll of life and property during August, 1998 have focussed the need for a coordinated approach for landslide zonation integrating seismological, meteorological, remote sensing and other observations.

TOWER OF PISA: STABILITY RESTORATION PROPOSAL TO SAFEGUARD AGAINST SEISMIC RISK

Federico BARTOLOZZI (Civil Engineer and Independent Researcher, via dei Carracci 4, 21100 Varese, Italy, email: ciuciuzza@iol.it)

The proposed technique includes the solution of two problems. The former immediately provides to the removal of the instability due to the rotation in the north-south direction. The second problem consists in preserving the stability against the occurrence of two different phenomena: 1. the restarting of the instability, caused by a possible uneven subsidence of the foundation soil; 2. the instability consequent to an earthquake. Both phenomena could be avoided with the following complex operations: 1. planning and laying of a sub-foundation with geometrical and structural characteristics which ensure the stability of the foundation soil; 2. operation for preserving or decreasing the present inclination and, even, operation for conferring the perfect verticality, as well as, if wanted, the counter-inclination; 3. interruption of the solidarity between the building and the sub-foundation-soil complex, by using multidirectional movable bearings with low sliding or rolling friction, with or without dissipators of sub-undulatory seismic energy and laying laterally or rigid connections with alternative function of elastic linkages. This technique has two important advantages: 1. possibility to remove a future rotation of the Tower, due to an eventual subsidence of the soil; 2. easy maintenance of the sub-foundation structural elements, of the movable bearings and the side connections. The technique permits the removal only of the present instability, disregarding the seismic risk. In this case it is evidently less complicated and expensive. In addition, all operations for preserving or decreasing the present inclination and, even, for conferring the verticality and the counter-inclination are possible.

SEISMIC RISK MAPS AND SCENARIOS: TOOLS FOR PROTECTION AGAINST EARTHQUAKES

JSP23/C/U5/E/09-A6 Poster **0830-01**

THE PREDICTABILITY OF EARTHQUAKE: TWO RECENT CASES IN YUNNAN, CHINA

Lin RONGHUI (Seismological Bureau of Yunnan Province, Kunming 650041, CHINA); Tel: 86-871-3312339 Fax: 86-871-3315049 E-mail: ydj@public.km.yn.cn

China is one of few countries, which have the stipulation for issuing earthquake prediction and put it in practice. In the past three decades, the Chinese scientists did predict a few events of a certain type and with obvious characteristics. Though on a largely empirical basis such experience is a wealth, as the standpoint of practice should be first and fundamental in the theory of knowledge. The Menglian M7.3 earthquake occurred in the Sino-Burmese border (21¡ã59¡äN; 99¡ã04¡äE) at 05:46¡ä41.2¡åon July 12, 1995. Predictions of the intermediate-term(>1 year), short-term(3 months) and immediate-term (1 day before the mainshock) were made by analyzing in detail the observed seismic and precursory anomalies. The outcome of the prediction effort was only really significant when the immediate-term prediction was made at site just one day ahead of time. The Lijiang M7.0 earthquake occurred in 27¡ã18¡äN; 100¡ã13¡äE at 19:14¡ä18.1¡åon Feb. 3 1996. The observed precursory signals laid bases for making the intermediate- and short-term predictions. Yet, at the time of impending stage, a failure was made to locate the event, due to the superposition of post-precursors caused by Wuding earthquake (M=6.5) which occurred in central Yunnan in later October 1995.

JSP23/C/U5/E/07-A6 Poster **0830-02**

CHARACTERISTIC PRECURSORS OF THE 1996 LIJIANG, YUNNAN, EARTHQUAKE (M=7.0)

Lin RONGHUI (Seismological Bureau of Yunnan Province, Kunming 650041, CHINA); Tel: 86-871-3312339 Fax: 86-871-3315049 E-mail: ydj@public.km.yn.cn

The Lijiang M7.0 earthquake occurred in Yunnan (27¡ã18¡äN;100¡ã13¡äE) at 19:14¡ä18.1¡åon Feb. 3, 1996. Before the event, precursory anomalies in the regional seismicity pattern were characterized as the absence of moderate-strong and small events around the source area. Since 1925, an average interval between M¡_6.0 events was 6.4 years in the Lijiang area, northwest Yunnan, with the longest lasting 15 years. The latest Yanyuang M6.7 and Ninglang M6.4 events in the area occurred in 1976, surpassing the longest interval. Along the northern segment of the Zhongdian-Dali seismic belt M¡_5.0 events were absent form 1983 to 1993, forming a gap of 150 km long. From 1990 to 1995, small events of M¡_3.5 were also absent in the source area (¡÷¡Ü60km). Activity of small events began to increase in the Yhongsheng earthquake window (¡÷=77km) in Dec.1995 and Jan.1996. Around the Eryuan area (¡÷=122km), a foreshock swarm with the maximam magnitude 3.6 occurred on Dec.10, 1995. In addition, in the short and impending stage from Dec.1995 to Jan, 1996, 6 items of abnormal precursors were observed at 7 stations, namely the water level at Jianshui; water temperature at Liuku, Gangyuan, and Lincang; tilt at shiping; water quality (ion of HCO3-1) at Longling; and short leveling and short base line at Yongsheng. Besides, anomalous variations were also obtained from a synthetic analysis of precursory network data in the Lijiang area (which is consisted of 17 deep wells, 20 Radon points, 6 mercury points and 28 hot springs), and from the mobile gravity measurements in the networks of Western Yunnan Test Site before the event. Together with the seismic anomalies, all laid bases for making the intermediate (1-3 years)-, medium-short (1 year)- and short-term (months) predictions. Yet, at the time of impending stage, a failure was made to locate the event, due to the superposition of post-precursors caused by Wuding earthquake (M=6.5) which took place in later Oct. 1995.

RECENT CRUSTAL MOVEMENTS AND SEISMIC ACTIVITY STUDIES IN THE ASWAN REGION, EGYPT

Abdel Monem S. MOHAMED (National Research Institute of Astronomy and Geophysics, Helwan, Cairo, Egypt, email: mooonm98@yahoo.com)

Aswan region is one of the most important regions in Egypt and because it encompasses the vital engineering structure of the High Dam, it has been selected as a pilot project for the present study. Such a chose has been motivated by the fact that both geodetic and seismic data needed for the current investigation have been collected and become available from the Aswan region. So, the main objectives of the current research is to unify the results of the crustal movements and seismic studies which have been made in the Aswan region. This has been done for reaching the best understanding about the geodynamics of the area through investigating the relation between the crustal movements, seismic activity and earthquake occurrence and also for detecting the precursory events associated with earthquake occurrence. For the purpose of monitoring earthquake activity continuously around the Aswan Lake, a radio-telemetry network of 13 seismic stations was established. For monitoring the recent crustal movements several local geodetic networks were established around active faults in the area. Regional geodetic network covering the whole area of the northern part of Aswan Lake was established.
These studies use the seismicity recorded by the Aswan network from December 1981 to December 1997 and analyses different aspects of the data. Geodetic data were collected from local and regional geodetic networks. These studies were initiated to obtain an improved understanding of the seismotectonies in the Aswan region because this information is of importance in assessing the seismic risk.

SEISMICITY OF IRANIAN PLATEAU AND ITS BORDERING REGIONS

Arezou DOROSTIAN (Department of Geophysics, Azad University, North Tehran Branch); M. R. Gheitanchi (Institute of Geophysics, Tehran University, email: mrghchee@chamran.ut.ac.ir)

During the 20th century, from Jan.1, 1900 to Dec.30, 1998,nearly 5100 earthquakes of magnitude 4 And above occurred in the region of 20-40 N and 40-75 E. The area lies Along the Alpine-Himalayan belt and surrounded by active seismic faults. This study shows a general aspect of seismicity of different parts of Iranian plateau and bordering regions. Historical and Instrumental data have been collected from several different sources. In order to minimize the uncertainty in magnitude estimation we present a uniform magnitude scale for the calculation of earthquakes. Seismicity maps for periods of time before 1965 and after that in five-year intervals were constructed. Seismic activity in some areas has changed with time. Within major seismic zones, large earthquakes fill gaps in the seismicity pattern. A grid interval of 0.5-degree in Lat. and Lon. covered the whole area. The seismic energy and strain release in each quadrangle were computed for each interval up to 29 years from 1970 to 1999. Maps of tectonic flux and two and three dimensional energy maps were constructed to define the distribution of seismic zones in the area and to give a dynamic measure of their variation. The a and b values for 99 years period are same for some seismotectonics provinces of area and the regions of homogeneous seismicity were constructed. The frequency distribution of earthquakes of different magnitude is discussed. Recurrence curves support a high level of activity for the Zagros zone and they indicate a lower rate of activity for northern Iran faults zone than for other areas in the region. Recurrence curves for central Iran area Indicate that the rate of activity in a given region may remain practically constant over periods at least as long as a century, whether or not large earthquakes occur in the region during those periods. Comparisons between seismic hazard, energy maps, faults location and earthquake epicenters distinguish areas which will be damaged or have a heavy casualty.

EXPERIENCES GAINED IN THE RESPONSE TO THE EARTHQUAKE EARLY WARNING SIGNAL IN THE UNIVERSIDAD AUTONOMA METROPOLITANA, CAMPUS IZTAPALAPA IN MEXICO CITY

Delfino LASCARES. Universidad Autonoma Metropolitana, Iztapalapa Av. Michoacan y Purisima, Col. Vicentina, Delegacion Iztapalapa, C.P. 09340, A.P. 55-535, Mexico D.F. Tels. 724-46-98, FAX 724-46-88, email: held@xanum.uam.mx.

Since June 1997 a radio receiver of the Seismic Alert System of Mexico¸ City (SAS) was installed in the Universidad Autonoma Metropolitana, Campus Iztapalapa and an integral program for hazard mitigation has been applied in the campus. The population reached by the early warning signal is about 17,000 students and academic personnel, with an average near-by population of 45,000 people. To date 7 early warning signals have been received. During these early warning that occurred in working hours, evacuation has been carried out in an average time of 30 to 60 seconds. Surveys show that, since the SAS warning operation the attitude of the near by population toward earthquake prevention has changed. To date 90 percent of the population respond to the early warning signal. The Seismic Alert System (SAS) was developed by the Centro de Instrumentacion y Registro Sismico (CIRES). The alerts have provided as much as 30 to 60 seconds average in advance warning, before the ground motion sake reach Mexico City.

PRECURSORY SEISMIC SIGNALS DURING THE 1998 GUAGUA PICHINCHA CRISIS

HUGO A., Mario C. Ruiz, Minard L. Hall, Monica Segovia, Alexandra Alvarado, Acinoe Calahorrano, Darwin Villagomez, Diego Viracucha, Patricia Mothes, Andres G. Ruiz, Daniel Andrade; (Instituto Geofisico, Escuela Politecnica Nacional, P.O. Box 17-01-2759, Quito, Ecuador;
e-mail: geofisico@accessinter.net)

The Geophysical Institute in Quito, Ecuador, began the instrumental monitoring of Guagua Pichincha volcano in 1981. Until 1988, activity was characterized by a small number of earthquakes and sporadic phreatic explosions, which generated an explosion crater approximately 200 meters in diameter in the bottom of the caldera. In 1988, a swarm of VT earthquakes occurred 9 km southeast of the caldera at a depth of 8-12 km. Moderate phreatic explosions were detected in 1990, 1993, 1995, and 1997 during periods of rain. Between December 1997 and April 1998, three VT earthquake swarms were registered underneath the caldera, and in June 1998, an important swarm of VT earthquakes began 15 km northeast of the caldera. This swarm lasted until October, and at its height more than 100 earthquakes per day with a magnitude between 2.5 and 4.0 were noted. Furthermore, since June 1998, there have been hybrid earthquakes at depths less than 9 km.
A subduction earthquake with a magnitude of 7.1 occurred on the Ecuadorian coast 220 km from the volcano on 4 August. On 7 August, almost continual explosive activity began at Guagua Pichincha. This activity was characterized in the initial weeks by explosions followed by various days/hours of tremors. Between 7 October and 22 November, the tremors were shorter, with frequencies between 1.8 and 2.0 Hz. Between 22 November and 19 December, the number of explosions diminished with cycles of tremors between 28 and 32 hours. A new cycle of activity began on 19 December with spasmotic tremors and strong explosions followed by short episodes of tremors (<10 minutes) with frequencies of 1.6 Hz.
In addition, earthquakes characterized by narrow spectrum (between 2 and 5 Hz) have been registered since 10 September. These earthquakes have originated at shallow depths under the caldera and have accompanied periods of intense phreatic activity. Guagua Pichincha's continuing activity is attributed to various pulses of intrusion of small magmatic bodies, a process, which could ultimately result in a volcanic eruption.

THE HYDROPHYSICAL METHOD OF TSUNAMI ESTIMATION

Yury KOROLYOV and Alexander Poplavsky (Institute of Marine Geology and Geophysics, Sakhalin Scientific Centre, Nauki st., Yuzhno-Sakhalinsk 693002, RUSSIA,
email: tsunami@sakhmail.sakhalin.ru)

The estimation of tsunami danger is based on seismological data at present. It doesn't take into account inhomogeneity of tsunami source, directivity of tsunami, diffracting effects, which may both amplify and attenuate tsunami waves, and duration of tsunami. Therefore it gives some erroneous forecasts. Information of some level gauges placed on sea may confirm or refute tsunami danger. The hydrophysical method of tsunami estimation using information of some remote level gauges is based on well-known reciprocity principle. This method needs in minimal seismological data (time of beginning and co-ordinates of earthquake), data on sea level in three points and numerical "mareograms" in these points and in point to be warned. These "mareograms" must be obtained by tsunami simulation from some model tsunami sources placed on earthquake epicentre. This method takes into account inhomogeneity of tsunami source, directivity of wave radiation, different difracting and resonance effects. As a result the time of tsunami attack, form, heights and number of tsunami wave and duration of tsunami alarm are determined. This hydrophysical method will improve the reliability of tsunami warning and allow a creating of networks of local tsunami warning systems. This work was supported by grant 97-05-96625 from Russian Foundation for Basic Researches.

HISTORICAL DOCUMENTATION OF THE SEISMICITY OF LESVOS ISLAND (E. AEGEAN, GREECE) IN THE SECOND HALF OF THE 19TH CENTURY: COMPARISON WITH THE INSTRUMENTAL PERIOD DATA

Vicki KOUSKOUNA (Department of Geophysics & Geothermy, University of Athens, 157 84 Athens, Greece, email: vkouskou@atlas.uoa.gr); Kostas Taxeidis (Psichari 20, Mytilini 81 100, Greece); Kostas Macropoulos (Department of Geophysics & Geothermy, University of Athens, 157 84 Athens, Greece, email: kmacrop@atlas.uoa.gr)

A total number of 32 earthquakes from Lesvos island for the period 1851-1899 are listed in the existing published catalogues, five of which were destructive and were felt in the Eastern Aegean and Minor Asia. A detailed investigation carried out on the island revealed new, local sources of information (manuscripts, newspapers, etc.) reporting the earthquakes of Lesvos. These sources, together with the existing ones, present a more complete seismic picture of the island, and almost double the total number of its earthquakes, i.e. 34 new single earthquakes (or series of earthquakes) were located, one of which (in 1882) was damaging. The seismicity of the island in the 20th century, as derived from instrumental data, for a time window of 50 years, was compared to the above mentioned period, in an effort to: a) re-evaluate the parameters of the known, major destructive earthquakes by adding the new sources of information, and b) answer to certain questions of tectonic character, i.e. the existence of foreshock/aftershock activity and its characteristics. In this sense, the catalogue of earthquakes of the area is extended backwards up to 1850, and the completeness of its seismicity is tested. This enables the creation of an artificially complete data set, which will therefore contribute to more realistic local seismic hazard assessment and microzonation studies.

MODULE AND GRADIENT HIGH-SENSITIVITY MEASUREMENTS OF GEOMAGNETIC FIELD VARIATIONS AT THE SEISMIC RESEARCHES

Oleg KUSONSKI (Observatory Arti, Institute of Geophysics, Urals Branch of Russian Academy of Sciences, Geophysics Str., 2a, Arti, Sverdlovsk region, 623350, Russia); Vladimir Sapunov and Olga Dekusar (Ural State Technical University, Quantum Magnetometry Lab, Mira St., 19, Ekarerinburg, 620002, Russia)

The researches are carried out at the observatory Arti (WDC's mnemonic is ARS, coordinates are 56˚25.8¢ N, 58˚33.7¢ E) that is located on the Preduralsky pericratonice trough of the East-European platform. This area is seismically active. Observable here earthquakes have both natural and industrial origin. The last is connected with production of minerals and oil. The magnetic field of this region is characterized by presence of anomaly up to 1200 nT. The module and gradient variations are measured by the proton Overhauser's magnetometer POS-1 with resolution 0.001 nT (sensitivity up to 0.02 nT and 0.01 nT/meter at single measurement). At the same time a registration of super-long-period seismic oscillation (SSO) are made by the ARU IRIS station. A gradiometer allows to control the real measurement sensitivity for absolute value of magnetic fields and to locate geological and technogeneous effects caused by a near zone. The submitted methods and equipment allow to study geoblocks movements creating intensive deformations of mountain breeds, geoblocks response to tectonic factors, SSO excitation mechanism, trigger factors of earthquakes. The data can essentially soften dramatic and economic consequences of earthquakes at the mining enterprises of Ural.

OBSERVED AND PREDICTED INDUCED SEISMIC IMPACTS IN PREADRIATIC COASTAL AREA OF ALBANIA

Siasi KOCIU (Seismological Institute, Tirana, ALBANIA, email: kociu(sizmo.tirana.al)

Albania, situated on Western Balkans, with a coastal line of 470 km long, represents an attractive area for the future development of tourism. Adriatic seacoast of Albania with many , as one of the most populated areas of the country (where more than 70% of the population is concentrated, with many inhabited centers as those of Durres and Vlora towns in seacoast and Shkodra, Fieri and Tirana (capital), not far away (20-40 km), from the seacoast), represents one of the most hazardous seismic zones of the country, where many seismic impacts were observed during the past earthquakes and may be developed during expected future earthquakes.
Preadriatic area as a flat area filled mainly by recent very poor Quaternary sediments of thickness down to 100-150 m, with shallow underground water level, represents an area where a lot of soil in stabilities were observed during past earthquakes and can be observed in the future. Based on seismic hazard assessment procedures at local level for two of the biggest coastal cities of Albania (Durres and Vlora) it is shown that during the expected strong earthquakes induced seismic impacts as liquefaction of sands , new and induced landslides and appearance of fault rupturing on free surface can be observed not only along Adriatic seacoast, but especially within urban areas of these two cities.

THE RISK OF LARGE VOLCANIC ERUPTIONS AND THE IMPACT OF THIS RISK ON FUTURE OZONE DEPLETION

Howard ROSCOE (British Antarctic Survey/NERC, Madingley Rd, Cambridge CB3 0ET, UK,
email: h.roscoe@bas.ac.uk)

Ozone depletion at mid-latitudes due to reactive halogens from man-made halocarbons is enhanced by the increase in stratospheric sulphate aerosol, which follows large volcanic eruptions. Mid-latitude ozone depletion due to halocarbons almost doubled for the two to three years following the eruption of Mt Pinatubo in 1991. Although the Montreal Protocol is expected to reduce amounts ofhalocarbons in the atmosphere during the next century, the predicted reductions are such that stratospheric ozone will be at risk from such depletion enhancement for the next 50 years. Vulcanological mechanisms, models, and measurements in ice cores, suggest that large volcanic eruptions are random and that their global rate is constant over periods of a few centuries. From the rate of large eruptions observed in ice-cores, the probability of one or more eruption, the size of Pinatubo or larger, is 58% in 50 years. This probability is large enough that it should be taken into account in predictions of future ozone loss. Several of the eruptions in the ice-core record were many times larger than Pinatubo, so that a more comprehensive analysis, which also included the probability of eruptions as a function of size, would be beneficial.

STATISTICS OF EARTHQUAKE HAZARDS

M.V.RODKIN (Geophysical Center, Russ. Ac. Sci., 117296 Moscow, Molodezhnaya 3, email: rodkin@wdcb.rssi.ru); V.F.Pisarenko (Intern. Inst. of Earthquake Prediction Theory and Math. Geophysics, Russ. Ac. Sci., Moscow)

Earthquake tolls and economic losses in 1900-1996 years are examined in connection with earthquakes regime and economic conditions in different regions. It was shown that while the number of events with small and moderate number of victims and losses increase with time in a non-linear manner the large losses that constitute the major part of the total number of victims and losses have a linear increase with time. The non-linear increase with time of the total number of victims and losses is caused mainly by the Pareto-law distribution of losses from earthquakes, thus a high non-stationarity of regime of hazards assumed by a few authors is apparent. The limitations inherent to the Pareto-law distribution of losses are discussed and the value of maximum possible seismic hazard is evaluated. The connection of regime of seismic disasters with regional economic situation is discussed also. It was shown that while the losses from earthquakes have a tendency to increase with time, the number of victims and losses we normalised with the national income per capital have a tendency to decrease. A prognosis of number of victims and losses from earthquakes till 2020 year is presented.

INTERNATIONAL GPS TEST-AREA FOR DEFORMATION FORERUNNERS OF EARTHQUAKE STUDY

Mikhail PRILEPIN (United Institute of Physics of the Earth, B.Gruzinskaya Str., 10, 123810 Moscow, Russia, email: prilepin@uipe-ras.scgis.ru)

One of the reasons why the problem of earthquake prediction is far away from the solution stipulated is the lack of real international co-operation on experimental study and evaluation of significance of different forerunners. Many scientists today share the opinion that deformation forerunners are primary and their study can help in understanding the processes of preparation of earthquakes and prediction of event. The favorable factor nowadays is the availability of very effective GPS technology for the study of deformation forerunners on large territory with high accuracy and with the possibility for automatization of gathering and processing of the data. The next step in instrumentation is combining GPS with SAR interferometry, which is making the first but a very successful step toward the study of geokinematics. In the report discussed, the items dealing with the determination of the epicenter position, magnitude and time of shock using the data accumulated on GPS networks of different levels developed in seismically active areas. The consideration about the selection of place for a test-area, its status, sequence of development of the GPS networks, transition of data, gathering of auxiliary data and activity of the center for processing and analyzing the data are discussed. The consideration about the possibility of united study of different kinds of forerunners: seismic, geoelectromagnetic, variation of ground water level and emanation of noble gases are also presented shortly.

THE THREE STRONG EARTHQUAKES, NORTH CHINA, CHINA AND ITS STRUCTURAL SIGNIFICANCE

Lu PEILING (Centre for Analysis and Prediction, CSB, Beijing (l00036), China, Tel: 010-88015557, Fax: 010-68218604)

Abstract The seismic activities before and after strong earthquakes, the source mechanism of mainshocks, and the geological structure of the epicenter area of three strong earthquakes (the 1976(M7.8) Tangshan, the l989(M6.1)Datong-Yanggao and the 1998 (M6.2)Zhangbei-Shangyi earthquake) have been investigated. The structural significance of the three strong events is also discussed. The results show that 1. In according to the seismic activities before and after mainshocks, three strong events occurred in the north margin of North China faulting block area. The occurrence of three events was resulted from the most recent abrupt slip on a NE-trending Changdong fault zone, a NE-trending Shanxi grabon zone and a NWW-trending Zhangjlakou-Bohai fault zone, respectively. 2. In according to the mainsbock location, the events was in the intersecting area of the faults, therefor its sequences have the rich aftershock action, the most of strong aftershocks and the energy attenuation slow. 3. The source mechanism solutions of mainshocks are in agreement with the regional stress field with the P axis in the NEE-SWW direction of North China, but there are a difference in the fault motion type, 1976 event shows the northeastern striking high-angle strike-slip faulting mechanism, 1989 event has the strike-slip with the normal faulting motion, and 1998 quake is the thrust fault type. Those might correspond upon the structure of the epicenter area. 4. The epicenters is in or near Cenozoic-aged faulting basins with the Cenozoic -aged baselts, the genesis of the strong earthquakes which are derived from baselts may is the rising model of the hot material. Due to an action of the local hot stress the earthquakes occurred. 5. the mainshock faults are not at a great active structure, even there is not active fracture in the surface of the epicenter area.

SEISMIC HAZARD ASSOCIATED WITH SUBMARINE NEOTECTONIC FAULTS IN GREECE

Joanna PAPOULIA (National Center for Marine Research, Agios Kosmas, Hellinikon, 16604 Athens, GR)

Seismic hazard analyses are associated with large uncertainties when historical data are insufficient to define seismicity rates. These uncertainties may be decreased however in areas where seismicity is shallow, and produced by Quaternary faulting, by incorporating geological data in the analysis of seismic hazard. A tool towards the integration of the so-called prior information of seismicity, obtained from geological data, with historical observations is the Bayesian probability theory. This theory is tested here to estimate the seismic hazard associated with submarine active fault zones in the area of Greece. Prior estimates of seismicity are developed from slip rate measurements obtained from offsets of geological formations. The analysis demonstrates the importance of uncertainty in the Bayesian estimate of seismicity, and subsequently in the estimate of seismic hazard.

GUAGUA PICHINCHA: MANAGING THE CRISIS

HUGO A. YEPES; Instituto Geofisico, Escuela Politecnica Nacional, P.O. Box 17-01-2759, Quito, Ecuador; e-mail: geofisico@accessinter.net

Guagua Pichincha is a dacitic volcano located 12 km west of Quito (pop. 1.2 M.), the capital of Ecuador. It has erupted five times in the last 1,030 years (970, 1560, 1575, 1582, and 1660), with a recurrence period of approximately 500 years during Holocene. In July/August 1998, there was a commencement of seismic and explosive activity at levels superceding those seen since the installation of the monitoring network in 1988. The increased activity, which peaked during late September, precipitated the declaration of a yellow alert by the city of Quito on 1 October.
The Geophysical Institute, drawing on its experience and expertise, acted as a catalyst for the city's actions given the city's lack of preparedness and inability to initially grasp the gravity of the situation. The initial step for the government in dealing with the crisis was the designation of the mayor of Quito as the overall response coordinator. The city established an operations/information center; determined populated areas at risk; identified public sectors likely to be affected; and cleared debris from flow areas and potential evacuation routes. Contingency planning included one evacuation drill; periodic meetings of governmental entities; solicitation of heavy equipment and medical supplies from foreign governments and NGOs; the development of ways to minimize impact to the water supply, power grid, and telecommunications; and the planning for ash removal, police deployment, evacuation of aircraft, ingress/egress of the city, and procurement of food and fuel. Educational efforts comprised press conferences, briefings, and press bulletins.
Any crisis has its difficulties. Some problems are unavoidable, some can be mitigated by adequate funding, and others are preventable. Problems encountered by the city have included the inability to control rumors, inability of the government to ameliorate the public's linkage of the alert declaration to local political events, poor management of the initial alert declaration, confusion over alert level definitions, difficulty in maintaining public interest over the long term, the release of overly technical information to the public, delays in developing contingency/evacuation plans, reluctance to disclose all available information on potentially affected areas, the ill-defined role of the operations center, inadequacies in the call-down list, a failure to publicize an alarm system, and insufficient funding. Yet despite these problems, the city has made great progress in recognizing the hazard and addressing the risk.

VOLCANIC HAZARD ASSESSMENT AT THE DENSELY INHABITED ISLAND OF ISCHIA

Sandro de VITA, Giovanni Orsi (Osservatorio Vesuviano, 80056 Ercolano -NA- Italy, email: devita@osve.unina.it) Fabio Sansivero (Dip. Geofisica e Vulcanologia. Un. "Federico II", 80138 Napoli, Italy)

Ischia is a volcanic island located in the north-western corner of the Gulf of Naples. Volcanism begun more than 150 ka B.P. and the last eruption took place in 1302 A.D. The largest caldera forming eruption generated the Mt. Epomeo Green Tuff and occurred 55 ka B.P. Resurgence of the central part of the caldera begun around 28 ka B.P. and caused a net uplift of about 900 m of the Mt. Epomeo block. It occurred through a simple-shear mechanism that determined the conditions for magma to rise to surface only along normal faults within the eastern sector of the resurgent block. Almost all the volcanic vents of the last period of activity (10 ka B.P.-1302 A.D.) are located in the eastern part of the island. During this period 46 eruptions, effusive and explosive, occurred mainly between 2.9 ka B.P. and 1302 A.D. Effusive eruptions produced lava flows and domes; explosive eruptions formed tuff-rings, tuff-cones, and variably dispersed pyroclastic deposits. Eruptions were separated by periods of quiescence that lasted up to few centuries. Slope instability, likely triggered by resurgence dynamics, generated landslides and mud-flows shortly before and after eruptions. The magmatic system is still active, as testified by the intense historical, volcanic and seismic activity, and by widespread thermal springs and fumaroles. The island is inhabited by about 50,000 peoples that greatly increases during summer. Farming, wine industries and a complex network of commercial exchanges with the near city of Naples, contribute to determine a high volcanic risk in this area.

EVIDENCE FOR VOLCANIC INFLUENCES ON MEXICO CITY AEROSOLS

G. B. RAGA (Centro de Ciencias de la Atmósfera, Universidad Nacional Autónoma de México, Ciudad Universitaria, 04510, México DF, México, email: raga@servidor.unam.mx), G. L. Kok (National Center for Atmospheric Research, Boulder, CO 80303, USA, email: kok@ucar.ncar.edu), D. Baumgardner, A. Báez and I. Rosas(all three at: Centro de Ciencias de la Atmósfera, Universidad Nacional Autónoma de México, Ciudad Universitaria, 04510, México DF, México, email: darrel@servidor.unam.mx)

In situ measurements of sulfur dioxide (SO2), carbon monoxide (CO) and sulfate mass provide evidence that aerosol composition in Mexico City is affected by emissions from the neighboring volcano, Popocatepetl. The data suggest that there are two distinct pathways by which SO2 is incorporated into particulates. Periods of high humidity, fog, and rain are accompanied by elevated sulfate mixing ratios, attributed to aqueous chemistry. Similarly, elevated sulfate concentrations in low humidity periods appear to be a result of adsorption onto existing particles. These two mechanisms are important for understanding the processes associated with particle formation in this highly polluted urban area. Under the influence of volcanic emissions, SO2 concentration is more than four times the average value and particulate sulfate is a factor of 2 larger.

SAN SALVADOR, EL SALVADOR, A HIGH RISK, MULTIPLE HAZARD MEGACITY

D J SOFIELD, J W Vallance, and W I Rose (Geological Engineering and Sciences, Michigan Technological University, Houghton, MI, 49931, email:djsofiel@mtu.edu)

Volcanism and earthquakes are the most dire geological hazards that threaten San Salvador, El Salvador's largest city (population, 1.7 million), with a rapidly growing population, and few plans or resources for hazard mitigation. Financial, transportation, and governmental centers of El Salvador all reside within San Salvador. The city lies on a plain within severe hazard zones of two active volcanoes (San Salvador to the W and Ilopango to the E) and also lies in a zone of major subduction earthquakes.
In the past 60 Ka, a caldera 12 km E of the city now occupied by Lake Ilopango erupted at least four significant pyroclastic deposits, each of which blanketed the valley that San Salvador now occupies. The last of these eruptions devastated all El Salvador in AD 260 and drove pre-Classic Mayan civilization northward into the jungles. A dome eruption in 1880 and small seismic swarms beneath the lake indicate continuing unrest. Neither San Salvador volcano nor its numerous flank vents has erupted catastrophically since European colonization, however numerous explosive eruptions occurred prior to that. San Salvador volcano erupted ash-rich tephra and pyroclastic flows 800 years ago and caused mudslides that would likely kill many thousands today. Because of the frequency of earthquakes, the people of San Salvador are much more aware of seismic risk than volcanic risk. The city has had to rebuild 7 times after earthquakes since 1712. The most recent devastating earthquake in 1986, killed 1500, injured 10,000 and left 100,000 homeless. Thick unconsolidated pyroclastic and tephra deposits amplify the effects of shallow-focus, moderate magnitude earthquakes beneath the city. Timely international involvement could provide the impetus that San Salvador needs to begin effective hazard-assessment, monitoring, and educational programs. A significant part of this work will be to make the population of a volcanic country more aware of its vulnerability to volcanic hazards. The recent occurrence of hurricane Mitch offers an opportunity to advance all hazard work in Central America.

METHODS OF EXTREME SEA LEVEL AND CURRENTS VALUES CALCULATION

Oleg ZILBERSTEIN, Guennady Safronov, Sergei Popov, Mikhail Chumakov (all at State Oceanographic Institute, Kropotkinski per. 6, 119838, Moscow, Russia, email: oleg@soins.msk.ru)

Hydrometeorological support for marine branches of the economy and safety of human activities on offshore regions requires knowledge of the main marine parameters (in particularly sea level and current extreme values). As a rule long-term observations in offshore regions are absent. The most dangerous rise and fall of sea level and also extreme currents are result from the combined effect of tides and storm surges. A special automated technology including hydrodynamic and probabilistic modelling was developed. On the basis of historical information and observation series analysis for region of interest, extreme storm cases with corresponding weather maps are selected. Following computation of earth-surface level wind and atmospheric pressure gradients are produced. On the base of this information the hydrodynamic calculation of storms and summary (accounting tides) sea level oscillations and currents are calculated with help of verified 2D and 3D hydrodynamic models. Baroclinic models are actively used last years. With the help of produced probability models, which are based on Gumbel low and Langbein relationship, the results of numerical modelling are processed and long-return period characteristics of sea level and currents at different horizons are determined. Produced complex of models and methods is successfully used within

researches and survey for number of designing objects in Barents, Kara, Baltic, Caspian, and Sea of Okhotsk. This approach allows us to produce computer maps of long return period characteristics of sea levels and current

SEARCH FOR THE EARTHQUAKE PRECURSORY SIGNATURES BASED ON FRACTAL ANALYSIS OF THE ULF GEOMAGNETIC DATA

Natalia SMIRNOVA (Institute of Physics, St. Petersburg University, St. Petersburg, 198904, Russia, e-mail: nsmir@snoopy.phys.spbu.ru); Masashi Hayakawa and Tetsuya Ito (The University of Electro-Communications, Chofu, Tokyo 182-8585, Japan, e-mail: hayakawa@whistler.ee.uec.ac.jp)

An attempt to use fractal methods of time series analysis for searching the earthquake precursory signatures is fulfilled on the basis of ULF geomagnetic data obtained during Guam earthquake (EQ1) on August, 8 1993 (M=8) and Biak earthquake (EQ2) on February, 17 1996 (M=8). The observing places were situated both near the epicenters (Guam, 65 km off EQ1 and Biak, 100 km off EQ2) and far away (Darwin, 1200 km off Biak EQ). The chosen period covered a few months before and after the earthquakes in order to reveal the large-scale dynamics of scaling (fractal) characteristics of the pulsations. It is revealed that in the seismoactive region the ULF spectrum of emissions exhibits a power law behavior which is typical for self-organized critical dynamics. For Guam EQ the slopes of spectra and the fractal dimensions of ULF time series manifested stochastic fluctuations between values 2.5-0.7 with pronounced tendency for slope to decrease and for fractal dimension to increase in the process of the earthquake preparation.Taking into account the certain value of the critical slope we suggest that the gradual increase of the intervals with slopes less than this critical one prior to the earthquake may be considered as an earthquake precursory signature. The peculiarities revealed on the basis of ULF data of Guam EQ is verified on the materials of Biak EQ. The fractal properties of ULF emissions in seismoactive and seismoquiet regions are compared. The research was supported by Grant 98-05-65554 from Russian Foundation for Basic Research.

RESEARCH ON CORRELATION OF ASTRONOMIC FACTORS AND EARTHQUAKES

Hu HUI; Li Yongsheng (Yunnan Observatory, Academia Sinica, Kunming, 650011 China)

The effect of astronomical factors on the major earthquakes in China and the world is discussed in detail in this paper. The results show that the major earthquakes, especially the ones of above magnitude 7.0 are evidently affected by the astronomical factors, such as the Earth rotation, solar activities and lunar orbital motion. Only different seismotectonic belts or zones have different responses to an astronomical factor. The node of the lunar orbit with the earth's orbit regresses towards the west on the ecliptic, with a period of 18.6 years. The precession of the lunar ascending node causes the inclination between the moon's path and the equator to change continuously from 18.28 to 28.58 degrees. The seismic activities of the main seismic belts in the world are obviously affected by the period of 18.6 years and only their active periods appear alternately, which shows that different locations of the moon correspond to different seismic belts or regions on the Earth. This bears analogy to the fact that the change Earth's climate with a period of a year is caused by the different quantities of arrival of solar radiation due to the inclination of the ecliptic to the equator.
In China, 8 seismic events over M 8.0 occurred since 1820 happened to be during the acceleration of the Earth rotation(DAER). Among the 106 events over M 7.0 occurred in the 20th century, 72% were during the DAER and 71% happened when the inclination changed from the maximum to minimum. Most of the events happened in the descending phases of solar activities.

POINT-LIKE PROCESSES AND CATASTROPHE PREVISION

Giovanni P. GREGORI (IFA-CNR, via Fosso del Cavaliere 100, 00133 Roma, Italy; e-mail: gregori@atmos.ifa.rm.cnr.it)

A frequent approach when attempting at managing a natural catastrophe is in terms of a numerical model, by which we try at forecasting its occurrence in space and time. Sometimes this results to be difficult or even unrealistic. On a more pragmatic ground we can rather appeal to a formal analysis of the historical time series of every catastrophe of concern. Only approximately, however, such series can be likened to a point-like process, because the "detector-mankind" experienced substantial changes vs. time. Nevertheless, such algorithms can be approximately applied by means of a few suitable assumptions. Four basic viewpoints can be considered: (i) either by assuming that phenomena are periodic; (ii) or by assuming that an event occurs only whenever so m e energy threshold is attained (calorimetric criterion); (iii) or by assuming that it occurs only whenever the system experiences some abrupt change of its boundary conditions; or (iv), whenever no such algorithm is viable due to scanty observational inf o rmation, just by applying the box counting method, or some other more or less related and/or equivalent fractal algorithm. The mutual relations, advantages, and drawbacks of either one such approach are briefly discussed, with a few applications. They al r eady lead to an apparently successful long-range forecast of a large flood in northern Italy occurred in 1994, and to the prevision of the next explosive eruption of Vesuvius. But, the success of every such application is closely determined by the quality of the historical database, or by the physical information that is fed into the analysis, rather than by mathematics that per se have only to be concerned with avoiding that some arbitrary non-physical input is added, based only on the human need for simplicity.

PHASE OF MOON, INCLINATION OF MOON'S PATH WITH EQUATOR AND STRONG EARTHQUAKES IN YUNNAN

Li XIAOMING (Yunnan Observatory, Chinese Academy of Sciences, P.O.Box 110, Kunming; Yunnan Province, 650011, P.R.China)

Yunnan Province lies in the southwestern part of china, adjoining the juncture of the Eurasian plate and Indian plate, with the complicated geological structure, frequent seismic activities and the Mediterranean seismic belt passing through the province itself. It is found from the analyses that the rate of recurrence of earthquakes has close correlation to the position of the Moon at the last quarter and especially near the new Moon and the last quarter of the Moon earthquakes occur frequently. In the 19th and 20th centuries the rates of recurrence of the earthquakes with M 6.2 near the two phases of the Moon are respectively 6.2 times and 4.5 times as frequent as the average rate of recurrence, having a stripe-shaped distribution and the major earthquakes with M 7.0 almost occurred in the maximum and minimum year of the inclination and within two years after or before it in particular. As for the solar and lunar tidal forces, most of the earthquakes occurred in the time interval when the horizontal component of the tidal force made the greatest change. This shows that an earthquake can be excited by the position of the Moon and the tidal forces of the Sun and the Moon.

IMPACT OF THE HYDROLOGIC EXTREMES OVER THE WATER TABLE IN THE "PAMPA HUMEDA" (ARGENTINA) AND ITS RELATIONS WITH THE ENSO

Maria del Valle VENENCIO and Norberto O. Garcia (Facultad de Ingenieria y Cs. Hidricas - Univ. Nac. del Litoral, CC 495 - (3000) Santa Fe, Argentina. - E-mail: mvv@fich.unl.edu.ar)

This paper aims to create the bases in order to carry out, starting from seasonal and interannual climate prediction, a seasonal and interannual prediction of availability of groundwater resources coming from the unconfine acuifer in the productive areas of the "Pampa H=FAmeda" in the Argentine Republic.
The regional averages of the depth of the unconfined aquifer get rid suppose affected only for climatic variations. Also, the use of the groundwater resource is considered constant. Keeping in mind that the several water resources states in the region obeys several relationships between the variables precipitation, evaporation and evapotranspiration, it was carried out a serial water balance and correlations between the variability of the precipitation and the depth of the unconfined aquifer.
So, we can say that the precipitation produces decreasing or rising water level. As it was demonstrated the relationship between the ENSO and the precipitation on the Southeastern South America (SSA) by several authors, presently work was aimed to establish relationships between the water table and the ENSO. This correlation also provides useful information about the predictability of the future piezometric levels for sustainability of groundwater resources.
Then, the main conclusion of this work is that the water table level is predictable in function of a predictor like El Nino.

LONG REPOSE PERIODS IN THE ERUPTIVE HISTORIES OF RECENT KAMCHATKA VOLCANOES: WHAT VOLCANO CAN BE RECOGNIZED AS EXTINCT?

Vera PONOMAREVA, Olga Braitseva, Ivan Melekestsev (Institute of Volcanic Geology and Geochemistry, Piip Ave., 9, Petropavlovsk-Kamchatsky, 683006, Russia, email: ponomareva@geology.ru) Leopold Sulerzhitsky (Geologic Institute, Pyzhevsky per., 7, Moscow, 109017, Russia, email: suler@ginran.msk.su)

Detailed studies of the eruptive histories of Kamchatka volcanoes, based on geologic mapping, tephrochronology and radiocarbon dating, allowed us to document main repose periods in the lives of most Holocene volcanoes and monogenetic volcanic fields, and to determine their duration. It appeared that dormant periods as long as 500-1000 years were common in the lives of the volcanoes of various morphology, types of activity, and composition of eruptives. The best known example is Bezymianny volcano which was silent for about 1000 years before the 1955-56 large eruption. Longer repose periods up to 2000-3000 years were not rare. The longest repose periods - about 3500 years - were recorded at Kikhpinych and Dikii Greben' volcanoes; after a long dormancy both volcanoes were able to resume their activity. These data suggest that at least in Kamchatka a volcano should be considered potentially active (and thus, potentially hazardous) if it was proved to produce at least one eruption within the last 3-4 thousand years. This approach has allowed us to add some more names to the list of active volcanoes: Taunshits, Khodutka, Dikii Greben', Khangar volcanoes, which have been considered extinct and were not included in any catalogues of active volcanoes, appeared to have large eruptions within the last 3000 years, as well as Tolmachev Plateau and some other volcanic fields.

THE CELLULAR AUTOMATA MODEL SCIARA FOR LAVA FLOW SIMULATION: APPLICATIONS AND RESULTS

G.M. CRISCI, A. Di Francia, S. Di Gregorio, F. Nicoletta*, R. Rongo, W. Spataro (Dip. di Scienze della Terra Dip. di Matematica *Dip. di Chimica ersità della Calabria, I 87036 Arcavacata, Italy)

Cellular Automata (CA) represent a parallel computational method in alternative to differential equations, for modelling very complex phenomena, whose evolution can be considered based exclusively on local interactions. The CA model SCIARA for the simulation of lava flow was developed and subsequently improved several times by our research group. A lava flow is described in SCIARA as a system with discrete time and space; the space is represented by regular cells (square or hexagonal) two-dimensional cells, whose specifications (substates) describe the main physical characteristics of the corresponding portion of space: altitude and, for each lava layer, lava thickness, temperature, lava outflows toward the adjacent cells; furthermore a division in lava layers can be considered in a refinement of the model. The CA evolves changing the state of all cells simultaneously at discrete times. Input for each cell is given by the states in the adjacent cells; the evolution of the phenomenon is mainly given by the computation of the outflow from the cells and the change of the remaining substates. SCIARA was applied in different times to 1986/7 and 1991/2 Mount Etna eruptions. The results were satisfying within limits to forecast the lava flow path, according to the surface covered by lava. The main parameters of the model for Etnean lavas were found; then simulations were performed in order to evaluate the risk in some inhabited Etnean area (the towns of Nicolosi, Pedara and S.Alfio) considering future catastrophic events. We consider the evolution of SCIARA, the main results and a critical discussion for a further improvement of the model, its limits in the application.

LAVINA - A COMPUTER TOOL FOR AVALANCHE FORECASTER

Pavel CHERNOUSS and Evgeny Mokrov (Center of Avalanche Safety, "Apatit" JSC, 33a, 50 years of October St., Kirovsk, Murmansk region 184230, Russia, e-mail: P.Chernous@apatit.murmansk.su);

Alexander Perlikov (Institute of Ecology, Kola Science Centre of the Russian Academy of Sciences, 14a, Fersmana St., Apatity, Murmansk region 184200, Russia)

LAVINA is a software package which assist avalanche forecaster to evaluate avalanche risks. It is an integrated system consist of two main units permitting evaluate probabilities of avalanche occurrence and dynamical parameters of possible avalanches. Probability of avalanche occurrence is evaluated for a whole region or for a separate starting zone. In the first case standard meteorological data and snow drift measurements are used for different types of discriminant analysis and pattern recognition algorithms. Diagnostics is carried on each third hour as current measurements have being made. Probabilistic and categorical conclusions on avalanche releases are the results of data treatment. There is an opportunity to display ten situations closest to current one from archive. Statistical simulation applied to snow thickness, density and shear strength is used for evaluation of snow cover stability in a separate starting zone. The areas of instability of different probabilities are displayed at a computer monitor. The dynamical parameters of a probable avalanche – maximal speed and impact pressure, are calculated at any given point of the avalanche path. LAVINA as a part of computer assisted work place of an avalanche forecaster is in operation at the Center of Avalanche Safety since 1991. The results of its exploitation are discussed and the ways of its improving are considered.

INFLUENCE OF MACROSEISMIC INTENSITY ATTENUATION IN SEISMIC HAZARD EVALUATION FOR FAGARAS (ROMANIA) CRUSTAL SOURCES

IREN-ADELINA MOLDOVAN (IVAN) and Aurelian Pantea (National Institute for Earth Physics, P.O. Box MG-2, Bucharest-Magurele, Romania, e-mail: pantea@infp.ifa.ro and iren@infp.ifa.ro)

An important step for the correct assessment of seismic hazard is the interpretation of the macroseismic effects distribution from a given seismic zone, as well as the good evaluation of seismic intensity attenuation laws. The attenuation was analysed as a function of distance and azimuth, using nine attenuation laws.
The present paper is a study of macroseismic intensity attenuation laws, using 5 crustal earthquakes (MGR>4.0) occurred in Fagaras(Romania) seismic zone, along the following azimuths: E, W, N,S,NE,SW,NW,SE. The evaluation of macroseismic intensity attenuation laws for Fagaras region was imposed by the necessity of seismic hazard assessment in this high seismic potential zone the largest event occurred in this zone: MGR =6.4; Io=IX).

COMPARISON BETWEEN TWO SYSTEMS OF BASE SEISMIC INSULATION

Federico BARTOLOZZI (Civil Engineer and Independent Researcher, via dei Carracci3, 21100 Varese, Italy, email: ciuciuzza@iol.it)

One of the proposed systems is with four rigid movable bearings and the other one with four elastic bearings. The two systems share the following characteristics: 1. self-centring of the building after an earthquake; 2. extreme economical competitiveness with all the existing anti-seismic systems, due to the considerable decrease of the seismic energy in the building, which makes possible the use of slenderer carrying structures. The differences between the above systems are: 1. a pendulous effect in the building, during an earthquake, in the system with rigid bearing. It is characterised by a very small vertical rotation of the building, which varies in average from a few seconds to some minutes with soil displacements included between some millimetres and about 150 mm. In addition, this effect is extremely limited and has no repercussions of psycho-physical character for the inhabitants of the building; 2. the verticality and the immobility of the building with respect to the horizontal translation of the foundation-soil complex n the system with elastic bearings. The vertical elastic strain of the springs compensates the variations of rigid deflection relative to the bearings, due to the inclination of their sliding surfaces. The vertical component of the of the motion, due to the sub-undulatory shock, varies only partially the building behaviour because of two phenomena: minor vertical translation of the building and resonance possibility. In order to prevent the resonance danger, each bearing is equipped with two or four frequency converters automatically started up when the emergency situation, defined by the equality between the vertical component of the earthquake frequency an the building vertical natural frequency, becomes imminent.

HIMALAYS CRUST DEFORMATION REGION, RADON EMANATION AND SEISMO WAVE EFFECTS

Vladimir ALEXEEV, Yury Mikhailov (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation of Russia's Academy of Science, Troitsk, Moscow region, 142092, Russia,
e-mail: yumikh@charley.izmiran.rssi.ru)

The Himalays form is available region for study of the deformation processes of continental crust during collision orogeny. Simple shear dominant strains have developed new fabrics parallel to the main thrust zone. Radon fields [1] and aerosols create anomalous electric fields, which may change properties of upper wall of wave-guide earth ionosphere. This process leads to change of penetration of ELF-VLF waves through lower ionosphere and evolution of spectral characteristics of electromagnetic emissions, registered on satellites [2].

PHENOMENOLOGICAL MODEL OF THE LARGE-SCALE EVOLUTIONARY PROCESSES IN A HAZARD SYSTEM OF THE EARTHQUAKE BASED ON THE SOC (SELF-ORGANIZED CRITICALITY) CONSIDERATION

Natalia SMIRNOVA, Vladimir Troyan (Institute of Physics, University of St.Petersburg, St.Petersburg 198904, Russia, e-mail: nsmir@snoopy.phys.spbu.ru); Masashi Hayakawa (The University of Electro-Communications, Chofu, Tokyo 182, Japan, e-mail: hayakawa@whistler.ee.uec.ac.jp); Thomas Peterson (TFPLAB, Cleveland, Ohio 44124-5441, U.S.A., e-mail: TFPLAB@aol.com), and Yury Kopytenko (St.Petersburg Filial of IZMIRAN, St. Petersburg 191023, Russia,
e-mail: galina@admin.izmi.ras.spb.ru)

The concept of self-organised criticality (SOC) is now widely used for interpretation of the natural hazard system behaviour. That concept was included as one of the principal point in a complex approach proposed recently by the present authors for searching the earthquake precursory signatures. Here we develop consideration of the processes in the earthquake regions on the basis of SOC concept. We suggest a phenomenological model for large-scale evolutionary processes occurring between two violent earthquakes. Four principal phases of the evolution: random chaos, subcritical, critical and supercritical stages are proposed and analysed consistently. The external stimuli such as geomagnetic storms, sharp temporal and spatial variations of atmospheric pressure, ULF impulses and others are considered as a driving force for "cellular automata" process in a seismoactive region. The important fingerprints of SOC - fractal structures in space and time are analysed using seismicity data and the ULF electromagnetic data timed to violent earthquakes near Guam (August 8, 1993, M = 8.0) and Kobe (January, 16, 1995, M = 7.2). A possibility to use the fractal characteristics of signals to study critical dynamics of a hazard system is discussed.
The research was supported by NASDA (Japan) and Russian Foundation for Basic Research (Grants No. 98-05-65554 and 99-05-NNN).

DYNAMICS OF SELF-DEVELOPING NATURAL PROCESSES AND PROSPECTS OF ITS USE FOR THE FORECAST OF GEOPHYSICAL CATASTROPHES

Alexander I. MALYSHEV (Institute of Geology and Geochemistry, Urals Branch of RAS, Pochtovy per 7, Ekaterinburg, SU-620151, Russia, email root@igg.e-burg.su)

Study of patterns of fore-culmination activizations present a great interest for the forecast of geophysical catastrophes, such as disastrous earthquakes, strong volcanic eruptions, rock bumps, landslides etc. During the study of Bezymyannyi volcano eruptions in 1980-1987 the fact of hyperbolic activization before explosive-effusive eruptions was established. Further studying of the revealed regularities and their comparison with empirical dependencies of the development of various natural processes allowed to conclude that there is a wide class of self-developing natural processes, the dynamics of which is described by non-linear differential equation of the second order. The attempts of using these regularities for the forecast of eruptions were quite successful, however the accuracy of the forecast for the time of eruption did not exceed a semi-quantitative level. At present the methods, allowing confidently to reveal the laws of the development of natural processes, have been developed. As it is shown on the example of a number of Bezymyannyi and Shivelutch volcanic eruptions, for the class of eruptions, having stable fore-culmination preparation, this technique allows increasing accuracy of paroxysm time forecast up to a quantitative level.
The forecast of destructive earthquakes is more complicated. Ivan Tikhonov and me have analyzed the fore-shock-aftershock sequences of destructive earthquakes in southern Kuril arc area. It was established that the development of both of fore-shock, and aftershock sequences corresponds to the equation of the dynamics of self-developing natural processes. However the fore-shock sequences are more poorly expressed. Probably, some updating of seismic observations is required for getting more stable results. The obtained results make it possible to assume that the methods are a perspective for the forecast of these geophysical catastrophes.

EXCESS AND DEFICIENT RAINFALL YEARS OVER INDIA DURING 1871-1996: A BRIEF APPRAISAL

A. A. MUNOT (Indian Institute of Tropical Meteorology Dr. Homi Bhabha Road, Pashan, Pune-411 008, India, e-mail: munot@tropmet.ernet.in)

India, being an agricultural country has its economy closely linked with the performance of the summer monsoon (June-September) which gives 75-90 % of the total annual rainfall. Timely onset and normal distribution of rain in the summer monsoon season generate good amount of food production whereas erratic behavior of monsoon which leads to drought/flood over the country has an adverse effect on the food production and in turn on the economy of the country. Because of this, year to year variation of monsoon rainfall becomes the subject of immense importance. In view of this in this paper an attempt is made to study the inter-annual variability of summer monsoon rainfall for the period 1871-1996. On an average India as a whole receives 852.4 mm of monsoon rainfall with a standard deviation of 84.7 mm and coefficient of variation of 9.9 %. Excess and deficient rainfall years over the country are identified using suitable criterion. There are 22 deficient and 19 excess rainfall years during 1871-1996. The total area of the country under deficient rainfall conditions as well as under excess rainfall conditions have been computed for all the deficient/excess rainfall years. The mean area of the country under deficient rainfall condition in a deficient rainfall year is found to be 42.8% whereas the mean area of the country under excess rainfall condition in a excess rainfall year is found to be 35.7 %. Out of 22 deficient rainfall years, during four years viz. 1877, 1899, 1918 and 1987 more than 60 % area of the country suffered from deficient rain. Similarly out of 19 excess rainfall years during four years viz. 1892, 1917, 1961 and 1988 more than 40 % of the total area of the country was under excess rainfall conditions. Conditional probabilities have been computed for all-India rainfall to be deficient or excess on the basis of June, July and June + July rainfall. It is observed that by the end of July it is possible to anticipate with reasonable degree of accuracy how the performance of the monsoon will be at the end of September, whether it will be normal, deficient or excess. Based on these assessments precautionary measures can be taken in case of monsoon being abnormal.

SHORT-TERM EARTHQUAKE PREDICTION: METHODOLOGICAL ADVANTAGES AND WARNING SYSTEM.

Vitali A. MORGOUNOV (Institute of Physics of the Earth, Moscow 123810, B.Grusinskaya 10, Russia, email vam@uipe-ras.scgis.ru)

What is preferable: to use a chance to win or full ignorance of impending hazard?! Are the cases of real predictions only a blind luck or it is a step to solve the problem? At what extend the uncertainty relation Cognoscibility/Unpredictability of Earthquakes could be improved? Between polar opinions like the dismal prospects for real improvement of the unpredictability (London, November. 7-8, 1996) and unique practical success in China in 1975,1997 there exist a optimum way to solve the most important part of the problem. Progress in the study of short/immediate precursors could be one of the possible path to get over the obstacle due to the following advantages. 1. The final stage of preparation of impending earthquake is characterised by a substantial activation of the process while it's strain rate increase by the orders of magnitude and considerably increase signal-to-noise ratio. That is favourable for identification of critical state of the focal zone through the ground measurements of geophysical fields, in particular by electromagnetic emission, generated by the stress-strain rate of the rock. 2. The avalanche creep process and the worked out instrument make possible to advance the effectivity of the method in relatively short period of time in seismic active areas during the background seismicity (M=3-4). 3. The short-term methods suggest the practical utilisation to prevent the casualties and ecological catastrophes. The EM method, experimental results, and Hardware-Software System "Alarm-Seismo" as an acceptable warning instrument are discussed. The System consists of the network of N slave controllers and master station, where in a real time regime the data is processing by PC computer. The

distance between the slave stations is defined by the magnitude of expected earthquake, tectonic and geological peculiarities of the region, relief.

MONITORING OF NATURAL HAZARDS USING MULTI-SENSOR DATA

Ramesh P. SINGH, Sudipa Roy and N.C. Mishra (all at Department of Civil Engineering, Indian Institute of Technology, Kanpur - 208016, India, email: ramesh@iitk.ac.in)

The data recorded by the Special Sensor Microwave Imager (SSM/I), IRS-P3 MOS, IRS - LISS and NOAA AVHRR Data over India have been analysed. The brightness temperature deduced from SSM/I data over snow covered region show distinct behaviour which is attributed to the variable snow thickness and snow melting. The routine analysis of SSM/I data will give fairly good idea of snow avalanches and flooding of the river as a result of snow melting. The daily or weekly variations of brightness temperature, liquid water path (LWP) and total precipitable water (TPW) over Arabian sea and Bay of Bengal has given an anomalous characteristics of a tropical cyclone which hit the coast of Bangladesh. The normalised vegetation index (NDVI), vegetation condition index (VCI) and temperature condition index (TCI) deduced from NOAA-AVHRR give information about the vigor of the vegetation which can be used in monitoring of drought conditions. The IRS-P3 MOS data in 14 bands along path 95 of winter and summer seasons have been used in classifying water bodies. The spectral reflectance deduced in 14 bands give information about the water quality> The characteristic peaks in the spectral reflectance data give idea about the type and distribution of contamination in water bodies. The IRS-LISS data has been used for mapping of the lineaments which can be used for the evaluation of seismic hazards of any region. In the present paper the use of multi sensors data will be illustrated and discussed in monitoring various types of natural hazards.

GEOPHYSICAL HAZARDS: MITIGATION AND WARNING SYSTEMS IN INDIA

K.S. MURTY (E-3 Vishnukamal Apts., 160 Shivajinagar, Nagpur, 440 010 India)

In the last two decades, India was hit by several natural disasters of which the Andhra cyclone of 1977, the Uttarkashi earthquake of 1991, the Latpur earthquake of 1993 and the Andhra cyclone of 1996 are typical geophysical phenomena that caused destruction of property and loss of life on a large scale. Relief measures were taken up by government and non-government agencies, while long-term measures like construction of cyclone shelters and new villages to house the affected population were intiated. Cyclone warning systems, flood warning systems, and seismological network in areas that are prone to these geophysical hazards have been set up. Besides, improved infra-structures like road construction have been made part of the development programmes of the concerned areas. These steps have considerably reduced loss of life in some of the more recent natural disasters the country faced.

AN EMPIRICAL DISPERTION RELATION FOR SEISMIC SIGNALS AND EARTHQUAKE PREDICTIONS

Boris W. LEVIN (Shirshov Oceanology Institute of RAS and Russian Foundation for Basic Research, 32a Leninsky prosp, Moscow, 117334 Russia email: levin@rfbr.ru); Elena V. Sassorova (State Oceanographic Institute, 6 Kropotkinsky per., Moscow, 119838 Russia; sasor@geoph.ioras.msk.ru)

We show that faint seismic signals radiated from an earthquake source and acoustic signals foregoing a compression failure of laboratory rock samples can be written by common empirical relationship for waves of period T and length L, as follows T^2 = d L, where d is dimension coefficient. This leads us to some empirical dispersion relation for seismic signals that is defined by expression W^2 = 2*3.14* A k, where W is frequency, k – wave number, A-acceleration of stress force. The attempt to find such dispersion relation with theoretical way was made by L.Brevdo (1998) because similar function may, on his opinion, lead to an effective method of some earthquake prediction. We used special developed software package for data processing of 200 earthquake records and had found more than 30 events in which digital records the seismic foregoing signals were discovered. The period-length relation for these signals was well described by presented expression. Although the expression should been studied for using in condition of real seismic region, the presented method can sometimes be used to further improve earthquake disaster mitigation practices.

A VOLCANO MONITORING AND TSUNAMI WARNING SYSTEM FOR GRENADA AND THE SOUTHERN GRENADINE ISLANDS

Lloyd L. LYNCH, John Shepherd, and Chandradath Ramsingh (Seismic Research Unit, University of the West Indies, St. Augustine, TRINIDAD, email: sru@wow.net).

We propose to develop and establish a volcano monitoring and tsunami warning system for Grenada and the southern Grenadine islands. This region is located close to the Kick 'em Jenny (KeJ) submarine volcano, which has erupted ten times since it, was first identified in 1939. Studies that have been done to assess the explosive potential of this volcano and to assess the vulnerability of the East Caribbean Islands to tsunamis, have identified it as a prime tsunami-genic source with Grenada and the southern Grenadines being most vulnerable to its hazards. The studies have also revealed that East Caribbean islands are exposed to tsunamis from other potential sources but to a lesser extent and that the existing regional seismograph and volcano monitoring efforts could be extended and reinforced to mitigate the effects of hazards from KeJ and tsunamis.
The primary aim objective of the volcano monitoring and tsunami warning system is therefore to maximise life safety by providing some level of advanced warning to the vulnerable population. The system is composed two critical components. The first is an integrated network of instruments to detect and rapidly evaluate the nature of increased volcanic activity at the KeJ and events of tsunami generating potential (such as sub-marine landslides or large earthquakes). An array of tide gauges will also be used to track the progress of any sea wave that may be generated. The second component of the system is a set of definitive procedures on how to respond to a tsunami-genic event. All data from the network will be tele-metered to a permanently manned monitoring and warning center to be established near the north coast of Grenada. Warning and alert activities will be co-ordinated through this center. Selected data channels will be relayed to the headquarters of the regional earthquake and volcano-monitoring agency - the Seismic Research Unit (SRU). This agency will widely support the warning center in the areas of equipment installation and maintenance, data processing and interpretation, and staff training. The SRU also plans to assist in educating vulnerable communities about other mitigation techniques that can be used to complement the proposed system.

TOWARDS UNDERSTANDING LAHAR-TRIGGERING MECHANISMS AT RUAPEHU

Vincent NEALL and Jerome Lecointre (Institute of Natural Resources, Massey University, Private Bag 11 222, Palmerston North, New Zealand, email: V.E.Neall@massey.ac.nz); Katy Hodgson (Natural Resources Engineering/Environmental Management and Design Division, Lincoln University, P.O. Box 84, Canterbury, New Zealand, email: Hodgsonk@kea.lincoln.ac.nz)

Over 20 major lahar deposits have been mapped and described from the past 2,000 year B.P. record at Ruapehu. In historical time, a number of different lahar-triggering mechanisms have been observed, so it is pertinent to ascertain how the prehistoric lahar record originated and how this relates to lahar magnitude. We are beginning to recognise specific signatures in the lahar/tephra record that fit models for lahar generation at this volcano. Lahar deposits immediately preceding tephra eruptions are consistent with volcanic activity emptying the crater lake until dry eruptions can occur with resultant ash showers as exemplified by the 1995 eruptions. Lahar deposits immediately following tephra eruptions are consistent with post-eruptive rain-triggering events mobilising tephra accumulations high on the cone. Lahar deposits containing fragile volcanic bombs are clearly indicative of explosion events and eruption-generation of the lahars. Others will be non-eruptive collapse events due to failure of the crater lake wall for a variety of reasons. Currently our programme seeks to: (1) use all sedimentological parameters to characterise the lahar deposits; (2) use petrological matching of lahar clasts to lava flows on the edifice; (3) integrate the complex lahar and tephra record and; (4) provide further precise dating, to elucidate how prehistoric lahars over the last 2,000 years were generated. We thereby hope to understand the environmental conditions one may expect to lead to, or cause any future laharic event.

ERUPTION FORECASTING AT CERRO NEGRO VOLCANO, NICARAGUA, USING TIME-VOLUME RELATIONSHIPS

Brittain HILL, Charles Connor (CNWRA, Box 28510 San Antonio TX USA 78228,
E-mail: bhill@swri.edu)

At the scale of sub-duction-zone tectonics, magma production rates appear constant relative to eruption recurrence rates. Differentiation and mixing processes obscure magma production rates in the mantle, making time-volume relationships complex at differentiated volcanic systems. Cerro Negro (CN) volcano in Nicaragua, however, has erupted relatively homogeneous high-Al basalt 22 times since forming in 1850 A.D. Small petrogenetic variations at CN are produced through minor crystal fractionation+accumulation. Waxing activity from 1850-1900 is followed by a steady-state eruption rate of 1.8x10^6 m^3/yr. Relatively constant petrogenesis of CN basalt suggests eruption rate is controlled by the mantle replenishment rate and thus may follow simple time-volume predictable patterns. Empirically, large-volume eruptions at CN since 1900 are followed by long quiescence, whereas short quiescence follows small-volume eruptions. The timing of CN eruptions >5x10^6 m^3 has a linear relationship (r^2=0.97) with cumulative volume at the time of each eruption. Eruptions in 1992 and 1995 are successfully forecast within 1 yr of the actual eruption using these relationships. The 1971 eruption occurred 12 yr earlier than expected, also earlier than forecast using a 95% confidence interval (1973-1996). The 1968 eruption occurred 8 yrs

GEODETIC MONITORING OF FOGO ISLAND (CAPE VERDE ARCHIPELAGO) FOR VOLCANIC HAZARD REDUCTION

Sandra I N HELENO, Joao L Matos and Joao F B D Fonseca (IST, Av Rovisco Pais, 1, 1049-001 LISBOA, Portugal, email: sisilva@alfa.ist.utl.pt); Jos N P Lima and J P Osorio (Centro de Geodesia, Instituto de Investigacao Cientifica e Tropical, Rua da Junqueira, 534, 1300 LISBOA, Portugal,
email: cgeod@www.iict.pt); Inocencio J M Barros and Arlindo Rosario (LECV, CP 114, Praia, Republic of Cape Verde, email: lec.mit@mail.cvtelecom.cv); Antonio Berberan (LNEC, Av. Brasil, 101, 1799 LISBOA, Portugal, email: berberan@lnec.pt); Simon J Day, Benfield Greig Hazard Research Centre, UCL, Gower Street,London WC1E6BT, UK, email: s.day@ucl.ac.uk)

As part of a broader hazard reduction project in Fogo Island, N Atlantic, (Fonseca et al., this issue), a programme of periodic GPS and levelling observations was initiated, with a view to the forecasting of impending eruptions by the detection of associated anomalous crustal deformations. In addition, the data will be used in the characterization of the possible flank instability of the volcanic edifice (Day et al., this issue), which may in itself constitute a significant hazard to the population of the island (33000 inhabitants).This poster describes the observational infrastructure built in the island (23 observation points), emphasising the volcanological criteria behind its design, the care taken in the selection of sites with adequate geology, and the stability requirements of the monuments. Results from the Zero Epoch campaign (September 98) are presented and discussed earlier than forecast, but within a 95% confidence interval (1967-1994). Several intervening small-volume eruptions before the 1968 and 1971 events likely triggered the larger eruptions before source replenishment was complete. The 8x10^6 m^3 of basalt erupted during 1995 activity at CN indicates the next significant eruption is most likely in 2000+/-1, with a 95% confidence interval to 2006 in the absence of intervening small-volume eruptions.
The work reported here was supported by the U.S. Nuclear Regulatory Commission (Contract NRC-02-97-009). This work is an independent product of the CNWRA and does not necessarily reflect the views or regulatory position of the NRC.

GLOSEISRISK: A SIMPLIFIED APPROACHING TOOL FOR GLOBAL SEISMIC RISK

QI-FU CHEN and Jie Liu (P. O. Box 166, Center for Analysis and Prediction, CSB,Beijing 100036, P. R. China, email: cqf@ip.cap.ac.cn); Yong Chen (No. 63, Fuxing Avenue, China Seismological Bureau, Beijing 100036, P. R. China, e-mail: yongchen@public.bta.net.cn); Ling Chen (Institute of Geophysics, CSB, Beijing 100081, P. R. China)

A simplified methodology of seismic hazard and risk assessment has been developed by IASPEI working group chaired by Prof. Yong Chen. The new approach includes two analysis methods: One is the seismic hazard analysis method by using earthquake catalogs as basic data and taking area model as potential earthquake sources. A technique is also developed providing the method for integrating individual influences of area sources, near and far, more active or less, into the probability distribution of seismic intensity or peak ground acceleration. Second method addresses exposure bypasses the data collection problems of the traditional method by employing a macroscopic indicator to represent the total exposure directly. The earthquake losses are assessed quickly and approximately by using social wealth represent by Gross Domestic Product and population data.
GloSeisRisk is application software based on Geographic Information System, which is designed to perform analysis and demonstration of seismic hazard and risk with the simplified methodology. The GIS-based GloSeisRisk offers a simplified approach modeling earthquake

hazard assessment, loss estimation and earthquake scenario analysis. The GloSeisRisk includes the data analysis and processing programs for seismic catlogue, GDP and population and the seismic risk estimation functions respectively. It can also illustrate the data distribution and seismic risk maps for different print output. The data can be updated readily from available resources in this application tool and easy to update seismic risk analysis.

SCIENCE OR CHANCE? SCORING THE CHINESE ANNUAL EARTHQUAKE PREDICTION FROM 1990 TO 1997

Yaolin SHI (Graduate School, University of Science and Technology of China, Academia Sinica, Beijing 100039, China, email: shiyl@sun.ihep.ac.cn); Jie Liu and Guomin Zhang (Center for Analysis and Prediction, Chinese Seismological Bureau, Beijing 100036, China, email: liujie@cap.ac.cn)

China is the only country in the world that has an official institution dedicated to precursor monitoring and earthquake prediction. About 800 observational stations spread over China, where more than 1700 pre-cursorial elements are monitored on regular basis. Every January, the Chinese (State) Seismological Bureau holds a national consultation meeting on prediction of major earthquake of the year. Deterministic predictions are made in the meeting. Possible risk areas for the year are circled out. These predictions are reported in official documents to the State Council, though kept confidential during the predicted year to avoid unnecessary social panic. In this study, we apply a scheme of success rate score (R-score) to evaluate the disclosed annual predictions in the 90s. A random guess leads to an R-score of 0 and a complete successful prediction has an R-score of +1. The average R-score of the annual prediction in China in the 90s is about 0.10. The probability in achieving equal or better results by random guess for an averaged year is quite high, about 1/3. However, the probability for random prediction to get equal or better scores in 8 successive years is very low, only 1.5X10^-4. In conclusion, we believe that earthquake prediction in China is not by chance, even though it is still in a very preliminary stage to fit the definition of science.

CONTRIBUTION OF GEOPHYSICAL INVESTIGATION TO SOLVE AN ENGINEERING PROBLEM, SOUTH EL-KHARGA OASES, EGYPT

Maher A. MESBAH (Department of Geological and Geophysical Engineering; Faculty of Pet. and Min. Eng., Suez, Suez Canal University, e-mail: mmesbah@frcu.eun.eg)

A severe subsidence in the ground has been occurred during the passing of heavy machines which are used in the foundation processes of the base and the sub-base of El-Kharga-Paris railway proposed site. The current geophysical study is directed to determine the causes of this civil engineering problem. Therefore, geoelectric resistivity measurements were done by measuring 25 vertical electrical soundings (VESes) along the proposed line. Also, the previous regional gravity and magnetic surveys were examined in order to obtain the maximum information content from the measured resistivity soundings. In the light of the previous geological, geophysical and geotechnical studies in the area, the measured VESes were manually and automatically processed and interpreted in the light of the drilled boreholes. The analysis and the interpretation of the obtained results should that the maximum monitored depth is 42 m. The resulted geoelectrical models reflects that 3 to 4 geoelectric layers can be determined. A dry surface inhomogeneous layer formed from alluvium deposits covers the investigated site. This surface layer is followed by a soft to hard clay layer. The second geoelectric layer is followed by a hard and compacted clay layer and it was monitored at the most of VESes and didn't at some of them. Therefore, the bedrock layer needed to be a sub-base (or a base) for foundation didn't monitored along the investigated site and special construction requirements are necessary to overcome this conditions of the base.

AUSTRALIA'S IDNDR PROGRAM FOR MITIGATION OF GEOPHYSICAL HAZARDS

Jack RYNN (Member Australian IDNDR Co-ordination Committee, Centre for Earthquake Research in Australia, PO Box 276, Indooroopilly, Queensland 4068, Australia. email: sally.brown@uq.net.au); Alan Hodges (Chair Australian IDNDR Co-ordination Committee, Director General Emergency Management Australia, PO Box 1020 Dickson, ACT 2602, Australia. Email: ahodges@ema.gov.au); Pip Marks, (Manager Australian IDNDR Coordination Committee, Emergency Management Australia, PO Box 1020 Dickson, ACT 2602, Australia. Email: pmarks@ema.gov.au)

Following the proclamation by the United Nations of the International Decade for Natural Disaster Reduction (IDNDR) 1990 - 2000, the Australian Committee was established within Emergency Management Australia (EMA) to pursue the ideals and goals of IDNDR pursuant to mitigation measures of natural disasters in Australia. More than 120 projects were successfully undertaken directly relating to the IDNDR targets of risk assessment, mitigation measures (awareness, disaster planning, education, dissemination of information, community involvement) and warning systems, natural hazards. The multi-disiplinary approach involved government agencies (national, state and local), NGO's, academia and the private sector. The Australian projects include tropical cyclone workstation, risk assessments for storm surge and tsunami, earthquake mitigation of cities, flood and landslide awareness, wildfire prediction and warnings, economic guidelines for loss reduction, medical training package, media campaigns, education curricula and community awareness campaigns. Co-operative efforts with 7 Pacific Island countries through the Pacific Region IDNDR (per 1994 Yokohama Statement) completed projects on cyclone, flood, earthquake, tsunami, landslide and volcano. Planning is in progress to continue the IDNDR concept into the 21st century.

VIGIL - A WARNING SYSTEM FOR VOLCANIC ERUPTIONS IN FOGO ISLAND, NORTH ATLANTIC

Joao F B D FONSECA and Sandra I N Heleno (both at Physics Department, IST, Av Rovisco Pais, 1, 1049-001 LISBOA, Portugal, email: fonseca@alfa.ist.utl.pt) Peggy Hellweg and Horst Rademacher (both at Geo Enterprises Orinda, 57 Overhill Road, Orinda, CA 94563-3122, USA, email: HRademacher@compuserve.com) Steve Pauly and Bruce Pauly (both at Digital Technology Associates Inc, USA, 1330A Galaxy Way, Concord, CA94520, USA, email: dta_pauly@compuserve.com) Nicolas dOreye (ECGS, Walferdange, G.D.L., email: nicolas.doreye@ecgs.lu) Inocencio J M Barros and Arlindo Rosario (both at LECV, CP 114, Praia, Republic of Cape Verde, email: lec.mit@mail.cvtelecom.cv)

The low-energy strombolian eruption of April 95 in Fogo Island (North Atlantic), following 44 years of quiescence, enhanced the awareness of the risk posed to its 33.000-strong population by the volcanic activity (average interval between eruptions of about 20 years). This created the conditions for the implementation of a volcanological monitoring routine, presently being tested.
This presentation will describe the main components of the monitoring instrumentation, namely, a combined network of broad-band (Guralp CMG-40T) and short-period (Guralp CMG-40T-1) seismic stations, and a network of resistive tiltmeter (AGI702) stations. All the data collected, both in Fogo Island and in the neighbouring Brava Island, are transmitted in realtime to the data acquisition and processing laboratory (located in Praia, Santiago Island) using spread-spectrum transceivers and combiner-repeater modules. Aditionally, a network of 23 high-precision geodetic monuments was built in Fogo Island to allow the periodic surveying with GPS receivers and EDM.

SPACE - GEODETIC MONITORING OF LANDSLIDE MOVEMENTS USING GPS TECHNIQUES

P.RUTIGLIANO, F. Vespe (Centro di Geodesia Spaziale P.O. BOX Aperta, 75100 - Matera ITALY, email: rutigl@asi.it); F. Cafaro, C. Cherubini (Politecnico di Bari - Istituto di Geologia Applicata e Geotecnica, Via Orabona 4, 74100 Bari, Italy)

The use of GPS techniques in monitoring natural hazards like volcanic deformations or landslide motions can be a powerful way to improve disaster mitigation. In this work the experimental setting up of a GPS-based system able to monitor landslide motions is reported. The first step of this work consists in evaluating how much a small simulated landslide movement can be mirrored by GPS data. The landslide simulation has been necessary to calibrate the hardware and the software used in this analysis. The experiment has been done using an array of six receivers placed in a small area around the CGS (Center of Space Geodesy) near Matera, Italy. One receiver has been assumed as reference, working permanently during the whole campaign. The other sites have been occupied for eight hours three times each, in order to obtain an evaluation, of the baseline length between all the receivers and the reference one before and after the displacement of the antenna of a known quantity (few cm). The main topics under investigation in this step have been:
a) The minimum observation time needed to obtain an estimation accuracy level suitable to this application (2-3 cm)
b) The possibility of using one frequency (L1) instead of two frequency (L1/L2) GPS receivers without loss of accuracy in the estimation of the movements
The second step of the work consists in the planning of a system to constrain solidly the GPS antenna to the ground, necessary to be sure that the possible motions detected with the GPS are representative of the real motion of the landslide.

QUANTITATIVE TESTING OF HYPOTHESES OF PERCURSORS

ST1/W/67-A1 1050

CO- AND POSTSEISMIC GROUND WATER CONDUCTIVITY ANOMALIES RELATED TO DISTANT EARTHQUAKES

Heiko WEITH, Claus Milkereit, Rongjiang Wang and Jochen Zschau (all at GeoForschungs Zentrum Potsdam, D-14479 Potsdam, Germany, email: radon@gfz-potsdam.de); Valerie Igumnov, Ashot Avanessian and Serguei Balassanian (all at National Survey for Seismic Protection, Yerevan, Armenia, email: ird@nssp.yerphi.am); Ulrike Maiwald and Asaf Pekdeger (both at FU Berlin, FR Rohstoff- und Umweltgeologie, Malteser Str. 74-100, D-12249 Berlin, Germany, email: rike65@zedat.fu-berlin.de)

In 1996, 1997, and 1998 three co/post-seismic conductivity anomalies were observed at an artesian well in southern Armenia related to earthquakes with epicentral distances of 30, 185, and 205 km, corresponding MB magnitudes of 4.8, 5.6, 5.8, and depths of 61, 10, 33 km, respectively. In all cases the conductivity sharply dropped between 20 and 60 minutes after the event by 12, 12, and 23 µS/cm. We call this drop "co-seismic" to distinguish it from a nearly exponential decay during the succeeding 4 weeks, which is observed for the first two events (no data for the last event). The total conductivity drops - from the beginning of the anomaly until the start of the recovery about 1 month later - are 120 and 60 µS/cm for the first two events. The co- and post-seismic strains calculated for the site Kajaran are between 10-9 and 10-8 for the three mentioned seismic events, they are below 10-9 for all other earthquakes between December 1995 and August 1998. The strains were calculated for a model with an elastic upper crust overlying a Maxwellian lower crust using the dislocation theory. How can strain events below 10-8 reduce the specific electrical conductivity of a mineral water by 5 to 10 %. To our present knowledge the answer might be related to the special site conditions. We propose a mixture process between different water types, which is obviously very strain sensitive.

ST1/W/42-A1 1110

STATISTICAL ASSESSMENT OF SEISMICITY PATTERNS IN ITALY: ARE THEY PRECURSORS OF SUBSEQUENT EVENTS?

M. MURRU, R. Console, C. Montuori (Istituto Nazionale di Geofisica, Roma, Italy, email: Murru@ing750.ingrm.it)

The variations of seismicity rate in Central Apennines prior to the event of 26 September 1997 (at 00:33 UTC) with ML=5.6 have been analysed by statistical methods, with the purpose of pointing up eventual periods of quiescence. The analysis was carried out on the instrumental catalogue of the National Institute of Geophysics, covering the period from 1 January 1975 up to the date of the above mentioned event. In a preliminary phase, the catalogue was declustered using the Reasenberg algorithm. After that, eventual magnitude shifts due to variations in the modalities of observation have been individuated and corrected. The subsequent analysis, carried out making use of the Zmap software package, has put in evidence that the main shock of 26 September was preceded by a 2.5 years period characterised by absence of events of magnitude larger than 3.2, in an area approximately 20 x 40 km wide, including the epicentre of the main shock. The statistical methodology shows that only 1/103 of the space-time volume analysed in this study, exhibited quiescence of the same level. The study of seismicity rate change correlated to previous main shocks in a larger area of Central Apennines shows that none of them was preceded by a seismic quiescence, specially close to the epicentre of the main shock, and lasting until the time of occurrence of the main shock as in the 1997 case. Actually, we found other patterns of precursory quiescence with different time or space distribution. We conclude that precursory quiescence is a real feature of Central Apennines seismicity, but it is difficult to define a simple hypothesis, which applies to the generality of cases and can be tested before implementation in a system of earthquake risk mitigation.

ST1/W/23-A1 1130

PERFORMANCE AND SIGNIFICANCE OF AN EARTHQUAKE PREDICTION MODEL

David RHOADES (Institute of Geological and Nuclear Sciences, P.O. Box 30-368, Lower Hutt, New Zealand, email: d.rhoades@gns.cri.nz) Frank Evison (School of Earth Sciences, Victoria University of Wellington, P.O. Box 600, Wellington, New Zealand, email: Frank.Evison@vuw.ac.nz)

The performance of a prediction model can be compared to that of the stationary Poisson model, or any other well formulated model, using a likelihood ratio test and an independent catalogue. The significance and power of a test can be determined by means of Monte Carlo simulations. Under the precursory swarm model, major shallow earthquakes are predictable, with respect to time, location and magnitude, by means of prior earthquake swarms. In New Zealand, an early form of the model failed the performance test, which showed that the model should have allowed for the clustering of swarms and of major earthquakes. The revised model performed inconclusively, the test showing that the swarm precursor is a characteristic of subduction zones. This led to the discovery of the precursory quarm, which is a more protracted, quasi-swarm phenomenon, in the region of continental collision. As a result of these tests, the New Zealand model is now similar to that which had been formulated earlier for Japan. In Japan, a performance test is proceeding satisfactorily. Two separate major earthquakes have occurred, both proceeded by swarms. Monte Carlo simulations were carried out after the second New Zealand test, and revealed the significance and power of the test as a whole, as well as the significance of the individual major earthquake occurrences. These results confirmed the need to revise the hypothesis. In the Japan test, Monte Carlo simulations show that the results as a whole are already statistically significant.

HYDROGEOCHEMICAL SEISMIC PRECURSORS IN KAMCHATKA

P.F. BIAGI (Physics Department, University of Bari, Via Amendola 173, 70126 Bari, Italy) A. Ermini (Department of Physics and Energy Science and Technology, University of Roma Tor Vergata, Via diTor Vergata, 00133 Rome, Italy); S.P.Kingsley (Sheffield Centre for Earth Observation Science, University of Sheffield, Hicks Building, Hounsfield Road, Sheffield S3 7RH, UK); Y.M.Khatkevich and E.I.Gordeev (Experimental and Methodical Seismological Department, Geophysical Service Russian Academy of Science, Pijp Av. 9, Petropavlovsk-Kamchatsky 683006, Russia)

For many years, hydrogeochemicals have been collected with a mean sampling frequency of three days in the form of the pH value and of the most common ions and gases in the groundwater of three deep wells in the south area of the Kamchatka peninsula, where the capital city Petropavlovsk is located. In the last decade five earthquakes with M>6.5 occurred at distances less than 250 km from the wells. These earthquakes were powerful enough for them to be considered as potential precursor sources. Having filtered the hydrogeochemical data, we considered each signal having an amplitude three times the standard deviation to be an irregularity and we defined as an anomaly the existence of an irregularity occurring simultaneously in more than one parameter at each well. Then, on the basis of past results worldwide and of the time recurrence of the previous earthquakes, we chose 158 days as the maximum temporal window between a possible anomaly and the subsequent earthquake. We identified 12 anomalies with 8 possible successes and 4 failures as earthquake precursors and we obtain a probability of 67% that any given hydrogeochemical anomaly is an earthquake precursor. Out of five earthquakes considered capable of producing precursors we obtained precursors in all the cases. A very few probability exists that the precursors signals are by chance.

ST1/E/85-A1 1210

STATISTICAL EVALUATION OF PRECURSORS: BACK TO BASICS

PASCAL Bernard, (Institut de Physique du Globe de Paris, 4 Place Jussieu, 75252 Paris, Fance, email: bernard@ipgp.jussieu.fr)

The aim of this paper is to show that a significant part of the controversial arguments on the statistical evaluation of precursors and predictions and in particular for the VAN method are due to the semantic fuzziness of what is a valid prediction method, and on the inadequation of the proposed evaluation of significance levels. Some of these points are well known, but they seem to be too often forgotten, and thus need to be recalled in their simplest form. First, it is well known that in a prediction method, one should distinguish the first step, i.e., the statistical validation of precursory phenomena (existence of the precursor), from the second step , i.e., statistical validation of the method (cost-benefit evaluation): consequently, a number of recent discussions on the number of missed events are pointless, as the latter is not directly relevant to the first problem. Second, in the first step, for evaluating the significance level of observed successfull alarms, the probabilities of a chancy result are often calculated after selecting alarm subsets for different magnitude thresholds, the lowest magnitudes providing the less significant results. This is usually not appropriate, and one should instead select alarm subsets according to their probability of success, with various probability thresholds. Third, still in the first step, the standard probability gain of the alarm sequence is often provided, but its meaning in terms of significance level of precursors is usually not given. This however can be done by evaluating the statistical properties of its distribution, which is easily achieved when the individual probabilities of success of all alarms are known. This later approach has the advantage of been only weakly sensitive to the maximal probability threshold defining the alarm subset selected for evaluation.

GENERAL EARTHQUAKE MODELS: PROCESSES, PATTERNS AND PREDICTABILITY

John B. RUNDLE, (Department of Physics, C4/CIRES, University of Colorado, Boulder, CO. email: rundle@cires.colorado.edu); William Klein (Department of Physics, Boston University, Boston, MA); Geoffrey Fox (Department of Physics, Syracuse University, Syracuse NY)

The General Earthquake Model (GEM) paradigm is directed towards the development of realistic, high performance computational simulations of earthquake processes on individual and systems of faults within the earth's crust. As a part of this project, it will be necessary to push forward ideas and technologies that will allow large groups of scientists to interact within an object oriented, collaboratory software environment on a geographically diverse set of computational hardware. As a part of the development of these models, advances in a number of areas will be necessary. These technologies, which have in general not been contemplated for use in earthquake related problems, include: Fast Multipole Methods, that have been used extensively in gravitational N-body problems and in computational fluid mechanics; Karhunen-Loeve Expansions, and other pattern recognition, feature extraction, mode shaping and "data mining" techniques; Data Assimilation Methodologies, that permit "model steering" and model adaptation; Analysis Techniques, that originate from statistical field theoretic analyses of random field systems; Computational, Web-Based Collaboratory Software, whose development will be driven by the advent of web-based computing approaches. In this talk, we describe these approaches, as well as the need for coarse-grained models and simulations that capture the basic physical processes. We present a summary of ideas that describe the nucleation, growth, and arrest of earthquakes on individual faults, and the space-time patterns they produce on systems of faults. Finally, we describe how some of these methods might be used in the future to forecast the progression of patterns through pattern state space.

EARTHQUAKE NUCLEATION TO DYNAMIC RUPTURE

ST1/E/02-A1 1400

QUANTUM MODEL OF SEISMIC CODA WAVES GENERATION

Marius ANGHEL (National Institute for Earth Physics, P.O. Box MG-2, 76900 Bucharest, Romania, email: anghel@infp.ifa.ro); Olivia Bazacliu (National Institute for Earth Physics, P.O. Box MG-2, 76900 Bucharest, Romania, email: olivia@infp.ifa.ro)

The quantum model of the tectonic seismic source (Anghel, 1998 - Ph. D. Thesis) is applied to the study of the interaction of the phonon flow (radiated during the earthquake process) with the heterogeneities of the medium between the focus and station. The quantum model starts from the quantum coherence of the atoms in the source before the Megascopic Quantum Tunneling. The quantum coherence is also characteristic for the phonon radiation. The coda waves are formed at macroscopic scale (observatory scale) by the secondary phonons that result from the interaction of the primary phonons with the atoms composing the medium heterogeneities. As a consequence of these interactions, the quantum coherence of the phonons is destroyed and the seismic energy is attenuated, due to both the absorption of a part of phonons by the atoms in the medium and inelastic collisions with them during the propagation. From the analysis of the phonon number - frequency distribution we can deduce several properties known from observations, such as coda spectrum independence of the source- station distance, coda wave envelope stability and dependence of the coda absolute amplitude of the total number of phonons radiated by the source (which is equivalent with the radiated seismic energy).

ST1/W/68-A1 1420

SIMULATIONS OF SPONTANEOUS RUPTURES ON INHOMOGENEOUS FAULTS

Ruth A. HARRIS (U.S.G.S., M.S. 977, 345 Middlefield Rd, Menlo Park, CA 94025; email: harris@usgs.gov), Steven M. Day (Dept. of Geological Sci., San Diego State University, San Diego, CA 92182)

Although 2D and 3D numerical simulations of spontaneous (unforced) earthquake ruptures are becoming more common, most of these simulations still assume that the earthquake occurred on a single fault plane, in a homogeneous medium. However, observations show that many earthquakes do not occur on single fault planes, or in homogeneous rock. For example, the 1992 Landers, California earthquake was a multi-fault rupture, as shown by geological and seismological data
[Sieh et al., Science, 1993], and the fault material was heterogeneous [Li et al., Science, 1994]. We have assumed a slip-weakening fracture criterion and investigated the 2D and 3D cases of a rupture encountering a stepover in a strike-slip fault, and of a rupture in a bi-material setting. Among our observations: (i) For simple, uniform stress drop configurations, 3D model predictions of the likelihood that a rupture jumps a wide stepover are similar to those obtained in 2D by Harris et al., GRL, 1991 and Harris & Day, JGR, 1993. ii) When a rupture does jump, rupture of the second fault occurs preferentially at very shallow depth for compressional stepovers, and at shallow to moderate depths, depending on S value and previous earthquake history for dilational stepovers. iii) Repeated earthquakes on faults similar to those at Parkfield, CA and at Landers can produce events that jump across a stepover alternating with those that do not, similar to the pattern observed in these two earthquake-prone regions. iv) For the bi-material case, ruptures can propagate bilaterally, with the rupture velocity depending on both the direction of propagation and the material-velocity contrast. v) There can be a reduction in the normal stress, but its absolute value is not yet resolved. vi) Complexity is produced in the seismograms, but there is no healing. These examples show how basic features observed in the field add major complexity to dynamic simulations.

ST1/W/08-A1 1440

USING OF STAGES OF THE EARTHQUAKE SOURCE PREPARATION TO REVEAL POTENTIAL SOURCES

G.A. SOBOLEV (United Institute of Physics of the Earth, Russian Academy of Sciences, Moscow, 123810, B.Gruzinskaya, 10, Russia, email: sobolev@uipe-ras.scgis.ru)

The results of the laboratory monitoring presume that a macrorupture is preceded by the characteristic stages of acoustic emission. Among them are acoustic quiescence, migration of activity to the place of the future macrorupture accompanied by the appearance of clusters, foreshock activation. These stages indicate the development of mechanical instability in the area of the macrorupture. In the laboratory experiments, the duration of these stages falls within the minute range; under mine conditions with destruction of rock massifs it reaches hours and days. During the strong earthquakes preparation in seismoactive regions it is likely that the instability stages may take months and years. We have tested the validity of these propositions by analysing the seismic regime of Kamchatka earthquakes with magnitudes more than 7 that occurred during the last seven years. We used the regional catalogue, which was uniform for this period, starting with energy class K >= 8.5, i.e., magnitude M >= 2.5. The occurred earthquakes were preceded by seismic quiescence and foreshock activation, which were revealed by using the RTL prognostic and the DS localisation parameters. The quiescence areas appeared in the time intervals ranging from 35 to 16 months before the corresponding earthquake and covered the areas with linear dimensions of about 200 km. The earthquake epicentres were located on the edge of the quiescence anomalies. The areas of foreshock activation occurred in the time interval from 23 to 4 months before the corresponding earthquake and covered areas with linear dimensions of about 50 km. The earthquake epicentres were located within the areas of foreshock activation. A year prior to all these earthquakes, there also appeared, in their epicentral areas, single clusters of two and more earthquakes of energy class K >= 10, i.e., of magnitude M > 3.5. The anomalies of the phenomena indicated above, not accompanied by strong earthquakes, were also recorded. Their analysis implies that though the study of these stages of seismic regime does not guarantee against false anomalies and missing the individual earthquakes, still their combination is helpful in establishing potential sources and keeping track of their development.

DYNAMIC TRIGGERING OF SEISMICITY IN GRANITE

R. Paul YOUNG, Calum Baker, James Hazzard, Dave Collins and Will Pettitt (all at Department of Earth Sciences, University of Keele, Staffordshire, UK, email: r.p.young@keele.ac.uk)

There is a growing body of evidence that spatial and temporal patterns of seismicity can be influenced by static and dynamic stress changes arising from other earthquakes, both local and distant. Such influences have important implications for seismic hazard but the key factors are hard to assess due to a lack of instrumentation in key areas and problems in distinguishing these triggered seismic events from those that would have occurred anyway. In this paper we show new evidence for dynamic triggering from modelling studies, laboratory experiments and field investigations. Dynamic modelling of wave interaction from microcracking, using the Particle Flow Code, is shown to trigger new cracks and seismicity. These results are compared to experimental acoustic emission studies of rock mechanical tests of granite samples, which were used to validate the modelling results. In the field, induced seismicity from excavations at the Underground Research Laboratory in Canada are shown to interact/communicate with acoustic emission activity at the grain boundary/microcrack scale.

ST1/W/46-A1 1520

GROUND ROTATIONAL MOTIONS RECORDED IN NEAR-SOURCE REGION OF EARTHQUAKES

Minoru TAKEO (Earthquake Research Institute, University of Tokyo, 1-1-1, Yayoi, Bunkyo, Tokyo 113-0032, Japan, email: takeo@eri.u-tokyo.ac.jp)

Large rotational motions excited by earthquakes are recorded during two earthquake swarms at offshore Ito in Izu peninsula, Japan, which occurred in March, 1997 and in April, 1998. The purpose of this paper is to report the characteristics of the rotational ground motions excited by the earthquakes, and to estimate spatial changes of slips for small earthquakes. The largest rotational velocity recorded at KAW is 2.6x10-2 rad/s around the north-south axis during an earthquake of magnitude 5.2 at 14:09 (GMT) on March 3, 1997. The largest earthquake with a magnitude of 5.7 occurred at 3:51 on March 4 (GMT), 1997, whose rotational motions around the vertical axis was 3.3x10-3 rad/sec. Considering a spatial variation of slip velocity which directly relates to excitation of a rotational motion, we apply simple point source models to the largest event and the second largest event in the swarm of 1997, and succeed in explaining the observed rotational motions around the vertical axis. These results suggest that the fault slip of the at a shallower part (about 3km deep) of the fault during the second largest event.

ST1/E/33-A1 1600

ON THE PRELIMINARY RUPTURE OF THE EARTHQUAKE

Yasuhiro UMEDA and K. Kitada(both at Disaster Prevention Research Institute, Kyoto University, 611-0011, Gokasho, Uji, Kyoto, Japan, email: umeda@rcep.dpri.kyoto-u.ac.jp)

For the large shallow earthquakes, the preliminary rupture process precedes a large complex rupture called " an earthquake bright spot ". The preliminary rupture differs from the nucleation process which is aseismic process observed on the rock experiment. The preliminary rupture is normal earthquake and it produces the seismic waves. On the surface of the earthquake bright spot, severe shaking dislodges almost all of boulders. Sometimes an initial faulting steps over to another faulting accompanying with a lot of cracks. Aftershock gap is also found in this spot. The duration time (T sec) of the preliminary rupture proportion to the earthquake moment (M0 : N_$B!&_(Bm). The relationship of LogM0 = 3LogT + 18.1 shows that the longer duration time of the preliminary rupture induces the larger earthquake. However, this relationship holds on the large earthquakes or the main shocks. Almost of the earthquake swarms, aftershocks and micro-earthquakes have not the preliminary rupture process. The earthquake having the clear preliminary rupture phase is found only 9 percent in the earthquake, swarm (2.5_$B!e_(B M_$B!e_(B 4.7 _$B!K_(Bin the east of Izu peninsula, Japan. They distribute a little apart from the earthquake swarm area.

ST1/E/90-A1 1620

A UNIFIED COMPREHENSION FOR FRICTIONAL SLIP FAILURE, SHEAR FRACTURE OF INTACT ROCK, AND EARTHQUAKE RUPTURE: SIGNIFICANCE OF THE UNDERLYING PHYSICAL LAW

M. OHNAKA(1), A. Odedra(1,2), and L.-f. Shen(1) (1)(Earthquake Research Institute, The University of Tokyo, Yayoi 1-1-1, Bunkyo-ku, Tokyo 113-0032, Japan, email: ohnaka-m@eri.u-tokyo.ac.jp) (2)University College London, and BG plc Exploration and Production, 100 Thames Valley Park Drive, Reading, Berkshire RG6 1PT, UK, email: odedra.a@bgep.co.uk

There are increasing amounts of circumstantial evidence that the earthquake rupture at crustal depths is a mixed process between what is called frictional slip failure and fracture of intact rock mass. In fact, what is called a 'barrier' or 'asperity' on earthquake faults can be a local patch of high rupture growth resistance whose strength equals the strength of intact rock. In addition, a large earthquake tends to nucleate at depths corresponding to the brittle-plastic transition regime where the frictional strength conforms to the shear fracture strength of intact rock, since the lithostatic pressure and temperature are high enough at these depths. Hence, if there is a constitutive law that governs the earthquake rupture, the law should be formulated as a unifying constitutive law that governs both frictional slip failure and shear fracture of intact rock mass.
Two kinds of laboratory experiments have been performed to reveal the constitutive property of frictional slip failure on a preexisting fault, and that of shear fracture of intact rock at lithospheric conditions. Combining these data on constitutive properties of friction and fracture leads to the conclusion that the constitutive law should be formulated primarily as a slip-dependent law, and also leads to an important finding that the slip-dependent constitutive law parameters are mutually not independent, but related to one another by a universal relation, which plays a fundamental role in unifying shear fracture of intact rock and frictional slip failure, and as a consequence, earthquake rupture. The relation found here specifically prescribes the relation between the scale-dependent constitutive parameter Dc (critical slip displacement) and the characteristic length representing geometric irregularity of the rupturing surfaces, and allows to scale scale-dependent physical quantities (such as the shear fracture energy, the nucleation zone size and its duration) consistently in quantitative terms, because the characteristic length in general increases with an increase in the fault size for natural earthquakes. A unified comprehension can thus be provided for the shear rupture of any size scale - from small scale in the laboratory to large scale in the crust as an earthquake source.

ST1/W/69-A1 1640

SOURCE PARAMETERS OF SMALL EARTHQUAKES ALONG ATOTSUGAWA FAULT ZONE, CENTRAL JAPAN

ANSHU Jin(1, 2), Cesar Moya(3), Masataka Ando(2) (1) Geoscience Center, JNC, Japan; (2) RCEP, DPRI, Kyoto University, Japan; (3) University of Costa Rica, Central America.

Site response and source parameters are determined, simultaneously, for 102 events along Atotsugawa Fault zone recorded at 9 stations, in Hida region, central Japan by applying a Genetic Algorithm. To avoid the high frequency leaking, multi-taper technique is used for FFT for a 5 s time window starting at 0.1 s before S-onset. We adopt the circular crack model (Brune, 1970) to describe the source in frequency domain by 3 parameters, namely, the flat level of the displacement spectrum, Wo, the corner frequency, fc, and the high frequency decay rate, n. The source parameters of 102 events and site response for each of the 9 stations are determined by using a GA approach running up to 600 generations. We divided the earthquakes into 10 subgroup, and apply the GA approach to each subgroup in order to check the stability of the solutions. The results show that (1) the site amplification for each station varies within a factor of 4; (2) for the source parameters, the variations of Wo, fc, and n are 4-6%, 4 Hz, and 0.5, separately. The resultant source parameters show that the events located on Mozumi fault tent to have higher stress drop and the events located on the creep section and the southwest ends, where the fault dismissed into an inactive volcano, have lower stress drop. After carefully check on the effects from using different Q model, the seismic scaling is discussed by combining with some previous estimation.

ST1/W/56-A1 1700

RELATIONS OF THE HARD-CORE ALLOMORPHER ROCK FRACTURES AND THE EVOLUTION CHARACTERISTICS OF THE DEFORMATION DYNAMIC IMAGES

ZHENGYUAN Li, Shuoyu Zhou and Yun Wu (all at Institute of Seismology, China Seismological Bureau, Xiao Hong Shan, Wuhan, China 430071) Zhaoyong Xu (Seismological Bureau of Yunnan Province, Kunming, China 650041)

The fracture processes of the deformation dynamic image can directly reflect the rock evolution situation under pressure, which is the effective method for monitoring the fracture process. It has been spreadly applied in the earthquake prediction. Since the rock samples of the hard-core allomorpher under pressure display more complicate evolution image than the homogeneous one, it is much closer to the real generating earthquake process. From the experimental results of the rock samples, this paper gives the following recognitions for the characteristic of the deformation image.
1. display twice linear-nonlinear elastic variation. After the process, the rock will be fracture.sixty percent, the deformation stability will be weak, namely the empty space of deformation. If the pressure loading is more than a ninety percent, the deformation stability is

variable on the different gradient strips, and then gets into fracture situation. The process of the hard-core allomorpher sample rock is similar with the micro-fracture, from the image of the empty space to strip.
2. Comparing with the generating earthquake model of the hard-core allomorpher rock and the solid model, this paper proves the coincidence with the real earthquake cases happened in Tangshan (Ms=7.8, 39˚ 38¢ N, 118˚ 11¢ E) and Lanchang-Gengma (Ms=7.6, 22˚ 54¢ N, 100˚ 06¢ E). Therefore, we suggest three characteristic stages of the deformation dynamic images: the structure stage, loading stage, and fracture stage, and also explain the behavior of the image of the generating earthquake and the theory of the fracture.

MICROMECHANICS OF CHANGES IN TRANSMISSION WAVES ACROSS A FAULT WITH APPLICATION OF SHEAR LOADS AND PRECURSORY SLIPS

Naoto YOSHIOKA and Akihiro Suzuki (both at Yokohama City University, Seto 22-2, Kanazawa-ku, Yokohama, 236-0027, Japan, email: yoshi@yokohama-cu.ac.jp) Koji Iwasa (Earthquake Research Center, Association for the Development of Earthquake Prediction, Sarugaku-cho, 1-5-18, Chiyoda-ku, Tokyo, 101-0064, Japan, email: iwasa@erc.adep.or.jp)

We have performed an observatory experiment to detect precursory slips prior to a dynamic rupture (stick-slip event) by transmission waves across a simulated fault. The results have been reported elsewhere (GRL, 25, 3907, 1998), which show two distinctive features: (1) the amplitude of the first arrivals of transmitted waves significantly increases with application of shear stress, and (2) the increasing rate of seismic sequences there. The last seismic swarm occured in 1997. More than 170 events were located in a very narrow area. The wave forms and earthquake recurrence graph were investigated. Great similarity exists in the wave forms for most of the swarm events. Nevertheless, the old sequences in this region were reviewed and an attempt to find a probable relation between them and the strong events was made.

ST1/W/01-A1 1740

COMPLEXITY IN RECURRENCE OF LARGE EARTHQUAKES IN AND AROUND THE JAPANESE ISLANDS: A SIMULATION WITH INTERACTING FAULT SYSTEM MODEL

MANABU Hashimoto (DPRI, Kyoto University, Uji, Kyoto 611-0011, Japan,
email: hasimoto@rcep.dpri.kyoto-u.ac.jp)

I present the results of simulation of large earthquakes in and around the Japanese islands with a model incorporating interactions between inter- and intraplate faults. I adopt a back-slip model obtained by the inversion of geodetic data by Hashimoto and Jackson (1993) for the fault system model. There are 104 faults and each fault is divided into 2 x 2 segments along the length and width directions, respectively. I also made a simulation with original fault system model and compared the results. Interaction between these segments are calculated as changes in Coulomb Failure Function for preferred slip of each fault due to forward- / back-slip of all faults in the model under the assumption of purely elastic half space. Back-slip is assumed to be constant, so that CFF of each fault increases linearly. When cumulative CFF of a particular fault reaches its threshold, that fault slips forward and stress is redistributed until no more forward slip occurs. In this model threshold is assumed to be 0.5 MPa and 2 MPa for interplate and intraplate faults, respectively. Initial stress of each fault is given randomly between 0 MPa and its threshold. I also deviate initial stress and back-slip rate by 1 % and 10 %, respectively, of all faults in order to investigate dependence of resultant seismicity on these two parameters. Results of simulation suggest (1) Recurrence interval of large events which rupture whole fault area is longer (~1000yrs) than that in case of the model with undivided faults. (2) Amplitude of CFF changes on some faults fluctuate with as long period as 2000 yrs. (3) Small errors in initial stress and back-slip rates cause significant difference in simulated seismicity after hundreds of years, which cast a serious problem on long-term forecast of earthquake occurrence.

ST1/E/43-A2 1400

MEDIUM TERM FORECAST OF 1988 NORTHEAST INDIA EARTHQUAKE REVISITED

Harsh K GUPTA, (National Geophysical Research Institute Hyderabad-500007, India)

Northeast India is seismically one of the most active intra-continental regions in the world. It has been a site of several earthquakes including four earthquakes exceeding magnitude 8 during the last 100 years. Gupta and Singh (1986) systematically analyzed the time series of earthquakes associated with several main shocks in an area bound by 20 deg N and 32 deg N latitude and 88 deg E and 100 deg E longitude and found "1. Moderate magnitude to great earthquakes in the northeast India region are found to be preceded, generally, by well defined earthquake swarms and quiescence periods. 2. On the basis of an earthquake swarm and quiescence period, an area bound by 21 deg N and 25 1/2 deg N latitude and 93 deg E and 96 deg E longitude is identified to be the site of a possible future earthquake of M 8 +/- 1/2 with a focal depth of 100 +/- 40 km. This earthquake should occur any time from now onwards. Should it not occur till the end of 1990, this forecast could be considered as a "false alarm". This medium-term earthquake forecast came true with the occurrence of a M 7 1/2 earthquake on August 6, 1988. Table 1 gives the parameters of forecast and occurrence.

TABLE 1. Forecast of August 6, 1988, Earthquake

Earthquake Parameters	Prediction, (Gupta and Singh, 1986)	Occurrence NEIS, (Preliminary Determination),
Epicenter	21 deg N-25 1/2 deg N 93 deg E-96 deg E	25.116 deg N 95.171 deg E
Magnitude(M)	8 +/- 1/2	7 1/2
Depth	100 +/- 40 km	115 km
Time	February 1986 – December 1990	August 6, 1988, (00:36:26.9 G.C.T.)

The original paper by Gupta and Singh was published in 1986. This was also presented at the 19th IUGG General Assembly at Vancouver in 1987. The forecast of this earthquake was based on the concept of precursory swarms and quiescences preceding main-shocks. It is worthwhile noting that in the entire region under study the only place where an earthquake exceeding M 7 occurred since 1952 is in the area where forecast was made. At the time of writing this abstract, more than 10 years have passed after the occurrence of August 6, 1988 earthquake of M 7.5. In this paper the details of making this forecast and possible use of such medium-term forecasts are presented.

ST1/W/41-A2 1420

THE STATIONARY POISSON RATE AT WHICH INTERMEDIATE DEPTH EARTHQUAKES ARE PRODUCED CONTRASTS SHARPLY WITH PRE- AND POST MAIN SHOCK SEISMIC QUIESCENCE

Max WYSS, Yozo Toya and Stefan Wiemer (Geophysical Institute, University of Alaska, Fairbanks, 99775, email: max@giseis.alaska.edu.)

We investigated the question of how stationary the production of the background seismicity is for deep and intermediate earthquakes. For shallow earthquakes it is difficult to reliably separate the independent (background) seismicity from the dependent component (fore-, aftershocks and swarms), but the majority of the deep seismic zones are free from obvious earthquake clusters. Using data from local, regional and global seismograph networks we selected earthquakes in about 100 volumes at depths deeper than 60 km, of which only approximately 10 to 15 % contained obvious clusters. We used 500 events per sample and divided the time covered by the catalog (10 to 30 years) into 100 intervals. Chi square tests applied to the distribution of the seismicity rates within these volumes revealed that for most of them one cannot reject the null hypothesis that the production rate is a stationary poissonian process. For a number of data sets we attribute the deviation from a poissonian process to changes in the re-porting procedure. Like aftershock sequences clearly deviate from the stationary production of seismicity, the phenomenon of after-quiescence is obvious in some cases. For example the De-cember 1994 off-Sanriku M7.5 earthquake induced a quiescence down-dip from its rupture area that lasted several years, and a 1993 M4.8 Parkfield earthquake induced a quiescence lasting several years in the northern part of its rupture area and north of it. Similarly precursory quiescence is a phenomenon not unlike foreshocks, both due to redistribution of stress during the preparation process for the main rupture. There are now approximately a dozen main shocks for which we mapped statistically uniquely significant precursory quiescence in great detail. The tectonic settings of these include strike-slip and thrusting along plate margins, as well as normal and reversed faulting in mountain belts. Not all significant quiescence are followed by main shocks, and not all main shocks are preceded by significant quiescence.

ST1/W/43-A2 1440

EARTHQUAKE PREDICTION: RECENT RESULTS AND WHAT COMES NEXT

Vladimir KEILIS-BOROK, Vladimir Kossobokov, Irina Rotwain, Alexandre Soloviev (all at International Institute for Earthquake Prediction Theory and Mathematical Geophysics, Russian Academy of Sciences, 79-2 Warshavskoye Shosse, Moscow 113556, Russia,
E-mail: volodya@mitp.ru); Andrei Gabrielov (Departments of Mathematics and Geophysics, Purdue University, W. Lafayette, IN 47907-1395, USA, E-mail: agabriel@math.purdue.edu)

The worldwide test of several algorithms for intermediate-term earthquake prediction validates the underlying paradigms derived from phenomenology and modeling: 1) The area where premonitory phenomena are formed is much larger than the source of a subsequent large earthquake. 2) These phenomena include specific transformations of background seismic static. 3) They are partly similar in a wide range of conditions - from fractures of samples in laboratory experiments, through earthquakes to starquakes. 4) Some of premonitory phenomena that we encountered in seismology are universal symptoms of critical transitions, common for a wide class of chaotic systems.
The accuracy of the existing earthquake prediction algorithms is limited and allows only a partial damage reduction. However, the accumulated experience suggests a way to develop a next generation of prediction methods with about fivefold increase of accuracy and transition to short-term prediction The following possibilities emerge: integration of modeling with phenomenology; combination of universal and Earth-specific premonitory phenomena; use of a multitude of relevant fields with common scaling and common symptoms of critical transition; identification of the current state of criticality of an active lithospheric volume; prediction of transition from one state of criticality to another ("prediction of predictability"). The theoretical base and practice in linking prediction and preparedness are discussed. EARTHQUAKE-PREDICTION RESEARCH IN A NATURAL LABORATORY-PRENLAB

RAGNAR Stefansson (Geophys. Dep.of Geophysics, Icelandic Met. Office, 150 Reykjavík, Iceland email: ragnar@vedur.is) Reynir Bodvarsson (Dep. of Geosciences, University of Uppsala, Sweden, email: rb@geofys.uu.se)

The PRENLAB project is a multidisciplinary and multinational project in earthquake prediction research, focussing at crustal processes in the seismic and rift zones of Iceland. The idea is that various conditions prevailing in Iceland, ranging from well exposed geology to frequent short term variations in strain rate can be utilized to obtain significant understanding of crustal processes leading to large earthquakes.
Results of various approaches of the PRENLAB project will be described. Mapping of faults by

microearthquake technology with 10m relative accuracy, and by geologists of surface exposures. Results of deformation studies by GPS and SAR are presented. Build up of stresses approaching breaking strength, observed by S-wave splitting, by seismicity and based on fault plane solutions will be presented. Results will be presented of various studies, seismological and geological related to the effects of fluids in fault zones. Modelling of earthquakes based on defomation measurements as well as on studies of the related small earthquakes will be described, also observations of stress changes and instability related to the earthquake nucleation process.
The application of the results for warning purposes is discussed.

ST1/W/63-A2 1520

GLOBAL EARTHQUAKE FORECASTS: HYPOTHESES AND TESTS

David D. JACKSON and Yan Kagan (both at Department of Earth & Space Sciences, UCLA, Los Angeles, CA 90095-1567, USA; email: djackson@ucla.edu)

We present a global model of earthquake potential, defined here as the probability of occurrence per unit area, magnitude, time, and focal mechanism parameters. The model is based on the occurrence of past earthquakes only, with no information, at present, on plate tectonics, faults, earth structure, etc. We assume that the earthquake potential is separable into factors depending on location, magnitude, and time respectively. The magnitude distribution is assumed fixed (a Gamma distribution with a corner magnitude of about 8.5) and the time function is constant within yearly intervals, so that for a given year the earthquake potential is uniquely defined by a spatial function. That spatial function is assumed to be a weighted average of previous earthquake occurrence, where the weighting kernel decreases with distance and increases in proportion to magnitude. There are only three variable parameters in the model, corresponding to a distance scale, the rate of decrease with distance of the spatial function, and an aspect ratio defining the degree of directionality of the spatial kernel. Once the parameters are specified, the model can be tested unambiguously against future earthquake occurrence using a likelihood test. After successful retrospective tests, we began forward testing at the beginning of 1999. Testing will be based on a likelihood value obtained by evaluating the earthquake potential function at the site of each qualifying earthquake.

ST1/W/53-A2 1600

A SIMPLE AND TESTABLE EARTHQUAKE FORECAST HYPOTHESIS

R. CONSOLE and M. Murru (both at Istituto Nazionale di Geofisica, Via di Vigna Murata 605, 00143, Roma, Italy, email: Console@ing750.ingrm.it , Murru@ing750.ingrm.it)

Earthquakes are regarded as the realization of a point process modeled by a generalized Poisson distribution taking into account the past history. No hypothesis is evoked on the physical model of such a process. We assume that the Gutenberg-Richter law describes the magnitude distribution of all the earthquakes in a sample, with a constant b-value. We model the occurrence rate density of earthquakes in space and time as the sum of two terms, one representing the independent, or spontaneous, activity, and the other representing the activity induced by previous earthquakes. The first term depends only on space, and is modeled by a continuous function of the geometrical co-ordinates, obtained by smoothing the discrete distribution of the past instrumental seismicity with a suitable kernel function. The second term depends also on time, and it is factorized in two terms that respectively depend on the space distance (according to an isotropic normal distribution) and on the time difference (according to the generalized Omori law) from the past earthquakes. Under this hypothesis, all the earthquakes may potentially induce subsequent events, and all the earthquakes are subject to induction from the previous ones, so that the distinction between foreshocks, main shocks and aftershocks is meaningless. Knowing the expected rate density, the likelihood of any realization of the process (actually represented by an earthquake catalogue) can be computed straightforwardly. In the first application of the model on a computer code, we assume that all the parameters involving time dependence are space-independent. This algorithm can be used in two ways: (a) during the learning phase, for the maximum likelihood estimate of the few free parameters of the model, and (b) for hypothesis testing. The latter should be carried out on a new and independent set of data, having fixed the values of all the parameters. The test can be run in real time. Few months of seismological observations in an active region proved to be usually sufficient for showing the superior significance level of this time-dependent model with respect to a simple time-independent Poisson distribution.

ST1/E/57-A2 1620

A "STRESS-FORECAST" EARTHQUAKE IN ICELAND

Stuart CRAMPIN, Theodora Volti (both at Department of Geology & Geophysics, University of Edinburgh, Edinburgh EH9 3JW, UK, email: scrampin@ed.ac.uk) Ragnar Stefansson (Iceland Meteorological Office, Bustadavegur 9, 150 Reykjavik, Iceland; email: ragnar@vedur.is)

Stress-aligned shear-wave splitting is seen with similar behaviour in almost all rocks below about 1km-depth. Shear-wave splitting is very sensitive to microcrack anisotropy and the splitting is a result of propagation through the effective anisotropy of the stress-aligned fluid-saturated grain-boundary cracks and low aspect-ratio pores present in almost all sedimentary, igneous, and metamorphic rocks. These fluid-saturated cracks are very compliant and the evolution of fluid-saturated cracked rock can be modelled by anisotropic poro-elasticity (APE), where the driving mechanism is fluid migration along pressure gradients between neighbouring grain-boundary cracks and pores at different orientations to the stress field. APE-modelling matches observations in both field and laboratory and suggest that small changes in stress modify crack geometry and the consequently modify shear-wave splitting. In the past, changes in shear-wave splitting before earthquakes have been seen (with hindsight) on five occasions worldwide. Changes in shear-wave splitting before earthquakes are now observed routinely (with hindsight) before larger earthquakes in the highly seismic transform zone of the Mid-Atlantic Ridge onshore in SW Iceland. Consequently, it was only a question of time before a real-time stress-forecast could be made. Changes before an earthquake were recognized at three seismic stations in a 70km line in SW Iceland and stress-forecasts were issued to the Icelandic authorities on 27th and 29th October and on 10th November. The final forecast was that a M>=5 earthquake could occur soon or a M>=6 event before four months if stress continued to increase. Three days later, on 13th November 1998, a M=5 earthquake occurred near the middle of the three stations where changes had been observed. Local investigations approximately identified the source location. Note that routine stress-forecasting for a vulnerable location, without such a high level of swarm activity, would require cross-well seismics between deviated boreholes. We shall present the theory and assumptions for stress-forecasting earthquakes, and present the data for this the first stress-forecast event.

ST1/E/81-A2 1640

TOWARDS THE PREDICTION OF THE TOKAI EARTHQUAKE

Naoyuki Kato (Department of Environmental Geology, Geological Survey of Japan, Ibaraki, Tsukuba, Higashi, 1-1-3, 305-8567 Japan, email: nkato@gsj.go.jp); Shozo Matsumura and Shin-ichi Noguchi (both at Earthquake Research Center, National Research Institute for Earth Science and Disaster Prevention, Ibaraki, Tsukuba, Ten-nodai, 3-1, 305-0006 Japan, email: shozo@geo.bosai.go.jp; shin@geo.bosai.go.jp);, Takeshi Sagiya (Geographical Survey Institute, Ibaraki, Tsukuba, Kitasato, 1, 305-0811 Japan, email:sagiya@gsi-mc.go.jp);, Stefan Wiemer (Geophysical Institute, University of Alaska, Fairbanks, USA, email: stefan@giseis.alaska.edu); Akio YOSHIDA (Seismological and Volcanological Department, Japan Meteorological Agency, Tokyo, Chiyoda, Ote-machi, 1-3-4, 100-8122, Japan, email: akio.yoshida-a@met.kishou.go.jp)

Since 1976, when Ishibashi stated that the expected Tokai earthquake should be impending and advocated the necessity of countermeasures against the anticipated disaster, dense networks of seismographs, volumetric strainmeters, tiltmeters, extensometers, tide gauges and ground water monitors were deployed in the Tokai region. The various geophysical data are telemetered to the headquarter of JMA, and are continuously monitored. Because the expected Tokai earthquake is a great interplate earthquake, we think it is vitally important to elucidate the coupling state between the oceanic and the continental plates. So far we estimated the region where the two plates are strongly coupled by investigating the characteristics of the spatial distribution of source mechanisms and the hypocentral distribution of earthquakes in the subducted slab and in the upper crust. Moreover, it has now become possible to estimate changes of the back slip between the two plates using the data of GPS stations densely distributed in the Tokai region. Our strategy for a successful prediction of the Tokai earthquake is the following: First, we study the evolution of the interplate coupling state. Then, by comparing our estimate on the coupling state with the results of computer simulations of the subduction process, we try to estimate how far the plate interface has matured towards the occurrence of the Tokai earthquake. Finally, based on the evolving understanding of the coupling state, we endeavor to identify short-term precursors in real time.

ST1/W/54-A2 1700

QUANTITATIVE TESTING WORLDWIDE SEVERAL EARTHQUAKE PREDICTION ALGORITHMS

Vladimir KOSSOBOKOV, Irina Rotwain, Olga Novikova, Inna Vorobieva, Leontina Romashkova (all at International Institute for Earthquake Prediction Theory and Mathematical Geophysics, Russian Academy of Sciences, 79-2 Warshavskoye Shosse, Moscow 113556, Russia, E-mail: volodya@mitp.ru)

We summarize our experience in predicting of large catastrophic earthquakes worldwide. Our approach is based on theoretical implications that come from non-linear dynamics of chaotic systems. The prediction algorithms were designed mainly by using generic pattern recognition methods. The predictions by such algorithms are completely reproducible and scale with the magnitude of the incipient earthquake. Their spatial accuracy is limited although could be improved significantly by additional analysis, in some cases, to the size of incipient earthquake as exposed by distribution of aftershocks. Their temporal accuracy is intermediate term, i.e. of the order of years. Although of limited accuracy, the predictions create a possibility to prevent part of the damage. The interface between prediction and preparedness is delivered by the recent development of optimal strategies based on a tradeoff between total volume of alert and rate of failures-to-predict. We briefly discuss a novel understanding of seismic process as an essential part of dynamics of a hierarchical system and outline how the predictions of the current limited accuracy could be implemented on practice.

ST1/E/89-A2 1720

ANALYSIS OF SEISMICITY AROUND THE WESTERN KANAGAWA, CENTRAL JAPAN FOR EARTHQUAKE PREDICTION

Toshikazu TANADA(Hot Springs Research Institute of Kanagawa Prefecture, Iriuda 586, Odawara, Kanagawa, JAPAN (B0031: email: read35@mail.dddd.ne.jp)

It has pointed that the M7 class earthquake might occur in near future around western Kanagawa Prefecture, southwest Kanto district, central Japan and named after the place of this hypothetical earthquake as the "Western Kanagawa Prefecture Earthquake(WKPE)". In order to investigate the mechanism of WKPE, we have carried out continuous monitorings of seismicity and crustal deformation(borehole tilt meters, GPS and EDM instruments, groundwater levelling) since 1989, which covers the anticipated rupture zone estimated from historical data.
Analysis of seismicity are summarized as follows. (1)The cutoff depth of seismicity varies 6-16km from the center to the eastern flank of Hakone volcano. According to tomographic image, the relative low velocity zone extend to a depth 5-10km in this eastern flank, but high velocity zone to depth 10-15km. As large crustal earthquakes around volcanoes were reported to occur at the steeply changing zone of cutoff depth or in the periphery of low velocity zones in Japan, these relationship between seismicity and crustal structure are important to reveal the place where M7 class earthquakes might occur. (2)A seismic quiescence had been continued since the end of 1930's to early 1990's. But a remarkable seismic recovery has been recognized since the early 1990's with a successive occurrence of M4-5 earthquakes in the area surrounding the eastern flank of Hakone volcano. (3)In 77 years, the 1994 earthquake(M4.8) with focal depth of 6km occurred at the southern part of the Hakone volcano where Kita-Izu fault systems cross the somma. The focal area was clearly separated from the volcanic earthquake swarm area. As Hakone volcano is supposed to be a possible indicator of crustal stress, this event can be interpreted as caused by a stress increase with collision of the Philippine Sea plate. These analyses of seismicity would provide us with important information for forecasting crustal activity.

ST1/E/38-A2 1740

MONITORING SEISMICITY IN THE TOKAI AND KANTO REGIONS OF JAPAN - THE SEISWATCH APPROACH

Kohji HOSONO, Kenji Maeda, and Akio Yoshida (Seismology and Volcanology Dept., JMA, Tokyo; e-mail: hosono@eqvol.kishou.go.jp); Shozo Matsumura and Shin-ichi Noguchi (Earthquake Research Center, NIED, Tsukuba, Japan); Stefan Wiemer (Institute of Geophysics; ETH Hoenggerberg, CH-8093, Zurich, Switzerland;)

Modern seismic networks such as the JMA and NIED networks in Central Japan record tens of thousands of earthquakes every year. To continually and efficiently monitor this seemingly overwhelming stream of data we have designed an advanced seismicity analysis software package, SEISWATCH. The two primary objectives of our project are: (1) To monitor the health of the entire recording system by identifying artificially introduced changes in reporting and temporal changes in the magnitude of completeness; (2) To identify unusual patterns in seismicity which may be related to precursory processes. From numerical simulations and

selected case studies we expect characteristic anomalies in seismicity patterns, such as seismic quiescence and neighboring rate increases, to occur in the years to months before a large and potentially disastrous interplate earthquake. However, these precursory changes are likely to be spatially and temporally complex in appearance. We therefore regularly and automatically map several seismicity parameters in three dimensions and monitor the spatial and temporal variations of the seismicity rates in different magnitude bands, the magnitude of completeness, and the earthquake size distribution. By comparing the largely independently compiled seismicity data sets of JMA and NIED in real time, we have a unique opportunity to identifying artificial rate changes in either catalog. In addition, having two independent data sets greatly improves the reliability of potentially observed precursors. SEISWATCH identifies anomalous patterns, establishes their significance in comparison to the background, and will send out automatic alert messages. SEISWATCH also provides an interactive interface to further analyze seismicity. Observed anomalous seismicity patterns are then interpreted in conjunction with the dense geodetic observations and with numerical simulations of the subduction process.

TRIGGERED/INDUCED EARTHQUAKES

ST1/E/63-A3 0830

PROBLEMS OF INDUCING SEISMICITY, CONTROLLED RELEASE OF TECTONIC ENERGY AND SEISMIC HAZARD REDUCTION

Alexei NIKOLAEV and Nikolai Tarasov (both at Joint Institute of Physics of the Earth, Bolshaya Gruzinskaya 10, 123810 Moscow, Russia, email: alex@nikavs.msk.su)

Influence of underground nuclear explosions and powerful electric pulses on seismic flow shows that during the very last period of the strong earthquake preparation process, source zone is getting more and more sensitive to external impacts of different nature. This create a favorable conditions for triggering strong earthquakes using controlled seismic and electric sources like explosions, powerful seismic vibrators and electric generators.
The other way is to initiate systematically an activity of weak and moderate earthquakes to speed up the release of tectonic energy and mitigate the magnitude of strongest earthquakes. The regime of artificial impacts on the Earth crust must be in concordance with natural processes like Earth tides, changes of atmospheric pressure, variations of the Earth rotation speed and others.
Problem of controlled release of tectonic energy and seismic hazard reduction is realistic both from point of view of specific instruments - powerful seismic vibrators and electric generators which are already designed, and from point of view of theoretical and experimental experience. It should be one of central seismological problems of the next century.

ST1/W/58-A3 0850

INDUCED SEISMICITY IN THE NETHERLANDS; ROSWINKEL A CASE STUDY

Bernard DOST, Hein Haak (KNMI, Postbus 201, 3730 AE De Bilt, the Netherlands)

Since 1992 the region around Roswinkel (Dr.) experienced 23 earthquakes of magnitudes between 0.8 and 3.4. Most locations and magnitudes are determined using a network of 8 borehole seismograph stations in operation since 1995. The depth of these earthquakes is 2 km and their origin is related to local gas exploitation. Since waveforms of all events show a high correlation at each seismograph station, a high resolution technique of relative locations could be applied.
The last five events were recorded in a triangular network of accelerometers, installed in the region in 1997, 2-4 km from the epicenter. These data enable an absolute high resolution location and relative locations could be anchored. The recorded peak horizontal accelerations for the largest event amounts to 0.3g at a dominant frequency of 10 Hz. This last event caused damage to buildings in the region. Results will be shown of a magnitude calibration within the region, determinations of relative locations and source parameters of events around Roswinkel.

ST1/W/10-A3 0910

CHANGES IN EFFECTIVE STRESS DUE TO DIFFUSION OF METEORIC WATER - LARGE ENOUGH TO TRIGGER EARTHQUAKES?

Malte WESTERHAUS, Birger-G. Luehr, Jochen Zschau (all at GeoForschungsZentrum Potsdam, Telegrafenberg, Haus E, 14473 Potsdam, Germany, email: tilt@gfz-potsdam.de)

Data sets from the interdisciplinary Turkish-German Project on Earthquake Research indicate that the state of deformation along a 200km long segment of the North-Anatolian Fault Zone is not stable over time. A dominant feature of various (quasi-) continuously recorded parameters and derived transfer functions, including microseismic activity, are variations with annual periodicity. We assume that these variations are induced by pore pressure disturbances that are caused by the annual recharge of groundwater and propagate downwards by diffusion. The relation between the tectonic loading rate as obtained from geodetic measurements, and the background seismicity gives the opportunity to check whether the small annual changes in crustal stress/strain are sufficient to induce earthquakes. Taking stream flow as a measure of the pressure time function at the surface, pore pressure transients at depth are calculated. Units of stream flow are converted into units of pressure by a linear regression to variations in the hydraulic head of a confined aquifer. A phase lag of 5 months exists between the rate of the surface water input and variations of microseismic activity. With a mean hypocentral depth of 8 km, the best fitting pore pressure curve at depth yields a hydraulic diffusivity of 0.75 sq.m/s, which is close to the results obtained from studies on reservoir induced seismicity and hydroseismicity elsewhere. The pressure amplitude variations in this depth correspond to about 12% of the tectonic strain rate. Assuming that seismicity is a function of strain rate, the hydrologically induced changes in strain could explain 40% of the observed annual rate changes in the microseismic activity. We conclude that the crust might be in a critical condition, and even small changes in the state of deformation potentially have a strong influence on its physical properties.

ST1/W/51-A3 0930

SCALING RELATIONSHIPS FOR INDUCED SEISMICITY IN THE FREQUENCY BAND 1-250KHZ

Will PETTITT, James Hazzard, R. Paul Young and Dave Collins, The Department of Earth Sciences, Keele University, Staffordshire, UK. Email: w.s.pettitt@keele.ac.uk

We investigate the scaling relationship between high-frequency acoustic emissions (AEs), at frequencies between 30 and 250KHz and lower frequency microseismic events (MS) at frequencies between 1 and 10KHz. Induced seismicity data from the Underground Research Laboratory (URL) in Canada are used for this investigation. At the URL, similar volumes have been monitored from grain boundaries to induced microcracks and fractures. We have analysed AEs occurring in very tight spatial and temporal clusters. Each cluster is associated with failure along a fracture plane and is coincident with a much more energetic MS event. The source mechanics of both the MS event and AEs have been analysed using a moment tensor inversion technique allowing a comparison of the mechanics of failure observed on the same fracture but at widely different source scales. Dynamic numerical modelling has been used to model the failure process and has been related to the in situ results. The models simulate blocks of granite made up of thousands of individual particles bonded together at points of contact. This micromechanical modelling approach allows for a direct comparison between small-scale AEs, associated with individual bond breakage, and larger scale ruptures caused by the interaction of these. It is found that the AEs show similar mechanics to the MS events even though the MS events exhibit a much larger magnitude and source dimension. Larger scale failure is shown to be an interaction of much smaller failure on the same fracture. It is proposed that the AEs are created as the fracture plane weakens preceding an MS event and then occur afterwards as the fracture returns to equilibrium.

ST1/E/75-A3 0950

EVALUATION OF FAILURE MECHANISMS FOR MINING INDUCED MICROSEISMICITY

C-I. TRIFU, V. Shumila, and T.I. Urbancic (Engineering Seismology Group Canada Inc., 1 Hyperion Court, Kingston, ON, Canada, K7K 7G3)

Moment tensor inversions are calculated for over 100 microseismic events (M = -2 to 0) recorded at Kidd Creek Mine, Ontario, based on time domain equivalent low-frequency spectral displacements and first motion polarities as determined from wave energy functionals (P- and S-waves) and polarization criteria (S-waves). The mine has an underground 64 channel microseismic array, including 8 triaxial accelerometers located within 200 x 200 x 300 m volume at depth. Previous studies have shown that failure mechanisms can be robustly evaluated from 6 to 8 triaxial recordings. This study, consisting of work in progress, attempts to analyze the relationship between the shear and tensile components of failure and the presence of large fault structures at depth. The dependence of source parameters (e.g., source radius, Es/Ep, stress release, seismic efficiency) on resulting failure mechanism is also studied. Finally, the possibility of using the above approach for the automatic characterisation of event mechanisms is investigated.

ST1/E/67-A3 1010

STUDY OF WATER LEVEL CHANGES IN DEEP BORE WELLS IN SEISMICALLY ACTIVE KOYNA-WARNA REGION OF WESTERN INDIA

R K CHADHA, H K Gupta (both at National Geophysical Research Institute, Uppal Road, Hyderabad-500 007, India, email: postmat@csngri.ren.nic.in), H J Kumpel (University of Bonn, Nussallee 8, D-53115,Bonn, Germany, email: kuempel@geo.uni-bonn.de), I.Radhakrishna and Subhash Kushwaha (both at National Geophysical Research Institute, Uppal Road, Hyderabad-500 007, India)

Twenty one bore wells were drilled in the seismically active Koyna-Warna region in western India to study causal relationship between water level fluctuations in the wells and earthquake occurrences in the region. A clear steplike change of the order of 3 to 7 cm was observed after an earthquake of M 4.4 on April 25, 1997, 5 km from two observation wells situated within the active seismic zone, identified in this region. The influence of earth tides, barometric pressure, rainfall and groundwater exploitation on the observed water level change was considered to rule out nontectonic causes related to this earthquake. Since most of the wells which are being monitored respond to earth tides, they are considered sensitive indicators to crustal strain and hence to tectonic strain due to earthquakes. Long-term monitoring of these wells thus provides useful input to identify the possible medium and long term precursors for earthquakes. In this paper, we present the water level data from the observation wells in Koyna-Warna region and discuss tidal, barometric and earthquake related signatures.

SPACE-TIME PATTERNS OF SEISMICITY AND RELATED FIELDS

ST1/E/17-A3 1050

THERMAL WATERS MONITORING OF THE 1997-1998 CENTRAL ITALY SEISMIC SWARM

G. MARTINELLI (Regione Emilia Romagna, Serv. Cartogr. e Geologico, v.le Silvani 4/3, 41100 Bologna, Italy); email: gmartinelli@mo.nettuno.it F. Italiano and S. Francofonte (both at Istituto di Geochimica dei Fluidi, C.N.R., via U. La Malfa 153, 90146 Palermo, Italy);
Email: italiano@igf.pa.cnr.it P.M. Nuccio (Dipartimento C.F.T.A., Università di Palermo, via Archirafi 36, 90123 Palermo, Italy).

A seismic sequence struck Central Italy starting on September 26,1997. The sequence began on September 4 with a Ml 4.4 foreshock and some of the following earthquakes were characterized by magnitudes between 5 and 6. A possible clue of the reactivation process is also recognizable in a seismic swarm occurred at about 40 Kms. during May 1997. On the basis of previous studies the May 1997 swarm renewed the interest on chemically and thermically anomalous waters of Umbria Region and allowed the collection of samples before the September 1997 swarm. Thermically and chemically anomalous spring waters were collected in previously identified sites during the period 1997-1998. Seismogenic process influenced chemical composition and temperature of thermal waters allowing to distinguish anomaly patterns induced by seismic events occurred at different depths. Analytical patterns recognized in local gaseous emissions support the hypothesis that changes in crustal permeability occurred. Crustal permeability changes were found influenced by focal mechanism and/or depth of seismic events. Possible precursory geochemical patterns are discussed.

ST1/W/57-A3 1110

MONITORING OF FAULT MOVEMENTS BY USE OF MICROEARTHQUAKES

Ragnar SLUNGA (Dep. of Earth Sciences, Uppsala University) Reynir Bodvarsson (Dep. of Earth Sciences, Uppsala University) Bjorn Lund (Dep. of Earth Sciences, Uppsala University)

Fault slip may be stable and not only unstable as in earthquakes. The commonly observed time clustering of microearthquakes, often over distances large compared to the earthquake sizes, is probably sometimes related to deformation expressed by stable brittle aseismic slip on faults. The SIL system produces absolute and high accuracy relative locations for selected groups of events. Fault plane solutions and dynamic source parameters for all detected microearthquakes are estimated in near-real time (within a few minutes of the earthquake). Based on both the

relative locations and the fault plane solutions one can conclude on which fracture the earthquake slip occurred. This makes it possible to monitor the movements of the faults and fractures, identified by the multievent locations if detectable microearthquakes are generated by the fault slip. This is one of the ideas behind the PRENLAB project, as it has been suggested that slip weakening may be important in the geomechanical process leading to major earthquakes. This means that in such cases a major earthquake will be preceded by a phase of accelerating stable fault slip. If this slip is indirectly detected and followed by the microearthquake activity it opens a possibility for earthquake warning before a major earthquake. Examples of this analysis will be given in this presentation. The results support the well known observation that fault slip on part of a fault increases the probability for slip on neighboring parts ("domino" effect).

ST1/W/24-A3 1130

QUANTITATIVE REPRESENTATION AND EVALUATION OF SEISMIC ACTIVITY AROUND ACTIVE FAULTS

Ryohei NISHIDA, Jun'ichi Ozaki, Michiru Asai (these at Faculty of Engineering, Tottori Univ., Koyama-cho, Tottori, Japan, e-mail: nishidar@cv.tottori-u.ac.jp), Kunihiko Watanabe, Yukihito Imada (both at Disas. Prev. Res. Inst., Kyoto Univ., Gokasho, Uji, Japan)

A quantitative method for evaluating seismic activity along active faults is proposed. By applying GIS, an objective evaluation of the seismic activity of the fault can be done without difficulty. (A) How widely an active fault affects the seismic activity of its surrounding area. Procedure is as follows;1)Si is defined as the area whose distance from the fault ranges from i-1 to i kilometers. Ri (=i km, discrete value) is defined as the representative distance of area Si.2)Ei, whole seismic energy released in Si area, can be obtained.3)D(Ri), defined by Ei/Si, is the seismic energy density of area Si. D(Ri) is a function of Ri.4)Re is defined as the distance that D(Ri) first becomes to be independent of Ri. Re is the important value that the influence of the fault reaches. As a result, Re values of active faults in southwestern Japan are ranging from 3 to 6 km, not depending on the fault length. Namely, active faults generate seismic activities in the area less than 6 km from the fault. (B) Quantitative evaluation of seismic activity of an active fault zone. Earthquake generating capabilities of active faults can be evaluated by comparing seismic energy density D(Ri). We obtained D(Ri)s of more than 20 active faults in southwestern Japan and b-values of G-R's of these areas. This analysis is carried out by considering fault types, magnitude ranges and hypocenter depths. This method can be used as an objective parameter which represents the seismo-generating capability of an active fault. Furthermore, it may represents the condition of tectonic stress accumulation of an active fault zone.

ST1/W/39-A3 1150

ABOUT NATURE OF CALDERA LONG VALLEY (NORTH CALIFORNIA)

V.I. LYKOV, A.O. Mostryukov, V.F. Ruban (Geophysical observatory Borok, Branch of the United Institute for the Earth's Physics, RAS.)

The authors developed a method for assessment the rigidity of seismoactive rock massifs according to a primary type of seismogenic destruction. Background seismicity was used as a source of information. In present work the method has been tested on an object which is a magmatic epicentre. Monitoring of its activity is conducted by geodasic, hydrochemical and seismic measurements.

ST1/W/26-A3 1210

SEISMICITY PATTERN DYNAMICS FOR CALIFORNIA FAULT SYSTEMS

K. F. TIAMPO, J. B. Rundle and S. J. Gross (all at CIRES, University of Colorado, Boulder, CO, USA; Email: kristy@fractal.colorado.edu); W. Klein (Dept. of Physics, Boston University, Boston, MA)

The California fault system demonstrates complex space-time seismicity patterns that include repetitive events, precursory activity and quiescience, as well as aftershock sequences. Our research suggests that a new pattern dynamic methodology can be used to define a unique, finite set of seismicity patterns for a given fault system. Similar in nature to the empirical orthogonal functions historically employed in the analysis of atmospheric and oceanographic phenomena (Preisendorfet, 1988), this method derives the eigenvalues and eigenstates from the diagonalization of the correlation matrix using a Karhunen-Loeve expansion (Fukunaga, 1990). This pattern dynamic technique has been successfully applied to the study of numerically modeled seismicity for fault networks similar in character and extent to those found in California (J.B. Rundle, et al, submitted to Phys. Rev. E, 1998). We implement this same methodology in order to analyse historical seismicity in California in an attempt to derive space-time eigenvalue patterns for the San Andreas fault system. The data has been converted to recognized fault segments for central and southern California. The significant eigenstates for this relatively short period of time can be directly correlated with the known California faults and associated events.

ST1/E/45-A3 1230

SPATIAL-TEMPORAL-ENERGY CHARACTERISTICS OF SEISMICITY OCCURRING DURING THE SEISMIC CYCLE: A REAPPRAISAL

Omar J PEREZ, (Dpt. Earth Sciences, Simon Bolivar University, Baruta, Apdo. 89000, Caracas 1080A, Venezuela, e-mail: ojperez@usb.ve)

We analyze the spatial-temporal-energy distribution of seismicity (Ms>6; h<70 km) occurring in the focal and adjacent regions of all the eleven great (Mw>7.8; Mo>5*1020 N-m) pure shallow thrusting interplate events that occurred along simple plate boundaries in the Circum-Pacific from 1985 to 1997, in the decades preceding and following every main shock. For this purpose we revised and constructed a new world seismicity catalog (1950-1997; Ms>6; h<70 km) by removing a series of heterogeneities in the earthquake reporting and magnitude determination through time (Perez, O. J., Bull. Seism. Soc. Am., 1999, in press), including a heavy overestimation of the Ms assigned to shocks in the range 6< Ms<7 in the period 1950 to 1963, with respect to the Ms calculated since 1964. This new catalog lists nearly all and only those shallow shocks with Ms>6 that occurred in the world since 1950. Our findings indicate that, contrary to what predicted by the seismic gap theory, significant seismic activity occurs inside or close to the rupture of a forthcoming great shock during many decades prior to it, whereas little or no activity occurs in the adjacent segments of the plate boundary. Observations corresponding to two complete seismic cycles in the period 1950-1997 in the Kurile Is. (1969-1994; 1963-1991/95) indicate that this significant (Ms>6) activity is fairly continuos or random in time and takes place during large portions of the cycle. In some cases a small period of quiet is observed prior to the main shock. It appears that those seismic gaps showing significant activity for many decades are more likely to break in the near future than those not showing it. Finally, we also observe that also contrary to the seismic gap theory, the main epicentral regions of giant (Mw>8.5) shocks are in general the location of events with Mw = 7 to 8, in the decades following their occurrence.

SPACE-TIME PATTERNS OF SEISMICITY AND RELATED FIELDS

ST1/W/28-A3 1400

THE EARTHQUAKE: A CRITICAL, PREDICTABLE PHENOMENON

Frank EVISON (Institute of Geophysics, Victoria University of Wellington, P.O.Box 600, Wellington, New Zealand, email: Frank.Evison@vuw.ac.nz) David Rhoades (Institute of Geological & Nuclear Sciences, P.O.Box 30-368, Lower Hutt, New Zealand, email: d.rhoades@gns.cri.nz)

A three-stage model of seismogenic faulting - crack formation, fracture and healing - represents a major earthquake as part of a complex, long-term seismicity anomaly. Within the affected space, conditions of self-organised criticality are maintained on a medium scale during the seismogenic process, compared with a small scale before and after. The process begins with a major crack formation, which activates a medium-scale fractal set of faults, and raises the level of seismicity accordingly. Earthquake triggering is also facilitated, producing swarm-like anomalies of seismicity, interspersed with relative quiescence. The completion of this episode of medium-scale faulting satisfies Mogi's uniformity criterion, and enables the large-scale earthquake to occur. This occurrence again activates a medium-scale fractal set of faults, and aftershocks occur in rapid sequence, triggered both by the mainshock and by one another. Finally, the scale of seismicity reverts to the original low level. Observed occurrences of the long-term seismicity anomaly are well displayed by the cumag statistical technique, which is a form of the cusum technique, modified to indicate magnitudes. Both sets of medium-level earthquakes are closely related to the mainshock. Thus the precursory set is a long-range predictor of the mainshock, with respect to location, time and magnitude, just as the mainshock is a short-range predictor of the set of aftershocks.

ST1/W/44-A3 1420

WHAT PARAMETERS CONTROL THE RECURRENCE INTERVALS FOR GREAT SUBDUCTION EARTHQUAKES?

MASATAKA ANDO and Sou Nishimura (Disaster Prevention Research Institute, Kyoto University, Uji, Kyoto 611-0011, Japan email: ando@rcep.dpri.kyoto-u.ac.jp)

Along the Nankai trough of subduction boundary between Philippine sea plate and Eurasian plate, off the coasts of Honshu and Shikoku, Japan, great subduction earthquakes (M>8) occurred with an interval of about 100 years. We found 10 great earthquakes in historical documents in past 1300 years. The seismic coupling rate, seismic moment release relative to the relative plate motion along the subduction boundary, is calculated to be 70 to 100% for the area between 132E and 139E, estimated from the recent GPS observation. However, the seismic coupling rate suddenly decreases at 132E from east to west. The seismic rate east of 132E is estimated to drop down to 10 % from the analysis of GPS displacement and the recurrence intervals of subduction earthquakes. A remarkable difference between the tectonic boundary is found in seafloor sediments on the subductied slab: muds are dominant to the west and coarser volcanic sediments to the east. The sediments in the seismogenic zone may controls the seismic coupling of the inter plate earthquakes. This is due to Kyushu-Palau ridge, occupying in the western Philippine sea plate, meets obliquely with the subduction boundary at around 132E. It plays a role of a barrier for separating the sedimentary basins.

ST1/W/22-A3 1440

AFTERSLIP FOLLOWING THE 1978 MIYAGI-OKI, NORTHEAST JAPAN, EARTHQUAKE REVEALED FROM TIDE-GAUGE AND LEVELLING DATA

Hideki UEDA, Masakazu Ohtake and Haruo Sato (Graduate School of Science, Tohoku University, Aoba-ku Sendai 980-8578, Japan, email: ueda@zisin.geophys.tohoku.ac.jp)

The Miyagi-Oki earthquake of June 12, 1978 (M=7.4) ruptured a portion of the plate boundary of the subducting Pacific plate in the region east off northeastern Honshu. Based on the analysis of tide-gauge observation and precise levelling data, we found a significant post-seismic crustal deformation following the earthquake. The post-seismic deformation, which lasted at least 4 years, is successfully interpreted by the occurrence of aseismic afterslip following the main shock. Our inversion analysis indicates that the area of afterslip nearly coincides with the main shock fault plane, but the afterslip area is further extended to shallower portion of the plate boundary. The total moment release including the afterslip amounts to 5*10^20 Nm, which is roughly twice the co-seismic moment release. Similar afterslip have been reported for the 1994 Sanriku-Oki earthquake (M=7.5), and two other large earthquakes which occurred to the north of the 1978 Miyagi-Oki earthquake. These observations suggest that the occurrence of large afterslip may be a common nature for the subduction plate boundary in the northeastern part of Japan.

POSSIBLE SEISMICITY AND ELECTRICAL EARTHQUAKE PRECURSORS IN A SOC SYSTEM: THE 17-1-1983, M7 KEFALLINIA EVENT, GREECE

A. TZANIS, K. Makropoulos (both at Dept. of Geophysics & Geothermy, Univ. of Athens, 157 84 Zografou, Greece, E-mail: atzanis@atlas.cc.uoa.gr) and F. Vallianatos (Technological Educational Inst. of Crete, Chania Branch, Crete, Greece, E-mail: fvallian@teihan.gr).

A characteristic signature of the earthquake preparation process, (assuming it is a self-organised critical point system), is power-law acceleration in regional seismic energy release strongly diverging towards the main event. In a SOC system this would include all scales of fractures. At the very terminal phase, a crack propagation avalanche may be expected, after which the system has reached the critical point and instability is imminent. The time function of crack propagation processes may be modelled with a limited class of characteristic transient bay-like shapes, featuring a corner frequency and inverse power energy distribution law. Electrification processes due to crack propagation may generate electrical precursors with similar characteristics. Such phenomena may have preceded the M7.1, 17-1-83 Kefallinia earthquake. These included stable and persistent increase of the regional b-values, indicating changes in the stress state of the crust via long range interactions, reversing immediately after the event. A power law acceleration of seismic release was also observed, which could be modelled to yield a time-to-failure of 1983.0. On 15-1-83 a transient ULF electrical signal was independently observed approx. 120km from the epicentre, consistent with the crack propagation model above. The aftershock sequence was also associated with a number of (alleged) electrical precursors following a fractal-like amplitude-magnitude relationship, which may theoretically be shown to result from the fractal geometry of their sources. In this case, a set of diverse 'precursors' could be accommodated within the model of SOC crustal processes. We discuss whether the same may be possible in the general case.

ST1/E/83-A3 1520

THE LIMITATION OF H/V RATIO IN ESTIMATING THE SITE RESPONSE OF LAYERED MEDIUM

Hung-Chie CHIU, (Institute of Earth Sciences, Academia Sinica , P.O. Box 1-55 Nankang, Taipei, Taiwan, R.O.C., email: chiu@earth.sinica.edu.tw); Ta-liang Teng (Department of Earth Sciences, University of Southern California, Los Angeles, CA 90089-0740, email: lteng@coda.usc.edu); Xiaofei Chen (Department of Geophysics, Peiking University, Beijing, China, email: xfchen@pku.edu.cn)

Spectral ratio between horizontal and vertical components (H/V ratio) has been widely applied to site response estimation recently. However, the physical basis behind this ratio is still unclear. Furthermore, most studies indicated that the H/V ratio only can predict the fundamental resonant frequency but very few researchers claimed that this ratio could estimate the amplification factor. Although many researchers have attempted to verify this method, none of them have fully explored this problem. This paper presents an extensive analysis of the H/V ratio and gives one possible approach to verify the controversial assumptions that made for developing the H/V method. We also give a reasonable explanation to the observations. According to our analyses, the H/V ratio can well estimate the fundamental resonant frequency for a simple layered model with a simple source, and this method may fail in all other cases because of noise, multi-layered-medium or complicate-source effects. Numerical validation based on synthetic seismograms also supports our assessment.

NONRANDOM PATTERNS IN THE OCCURRENCE OF THE WORLD STRONGEST EARTHQUAKES

W. MARZOCCHI (Osservatorio Vesuviano, Via Manzoni 249, 80123 Napoli, ITALY)

For a long time, the spatiotemporal independence of the world largest earthquakes was a paradigm in seismology. Even if in the last years some researchers raised doubts on its validity and suggested the existence of triggered seismicisity at great spatiotemporal distances, the lack of convincing and statistically significant phenomenological evidence lead to a long standing scepticism about this issue.
The aim of this work is to fill this gap by searching for non-random patterns in the occurrence of the strongest shallow earthquakes of this century. A new multivariate approach, which simultaneously accounts for the spatial and temporal aspects of the earthquakes occurrence is developed.
The results indicate that the strongest earthquakes do not occur randomly. Besides to influence the seismicity at small distance and time, the strongest events extend their reach even to 5000-10000 km, and 20-25 years later. These non-random patterns have a very low probability to be observed by chance. This behaviour is discussed and interpreted in terms of the post seismic stress transfer through a viscous asthenosphere in a planet lying in a critical state. This result provides new insights, which could be profitably used, at least in principle, in the seismic risk mitigation of many areas of the world.

ST1/E/46-A3 1620

SOURCE PARAMETERS AND AFTERSHOCK CHARACTERISTICS OF THE 1997 STRONG EARTHQUAKES IN GREECE

G.N.STAVRAKAKIS (Institute of Geodynamics, National Observatory of Athens, 11810 Athens, Greece, E-mail: g.stavr@egelados.gein.noa.gr); N. Voulgaris (University of Athens, Dept of Geothermy and Geophysics, Athens, Greece); G.Chouliaras and G. Drakatos (both at the Institute of Geodynamics, National Observatory of Athens, 11810 Athens, Greece)

In 1997, strong seismic activity took place in different seismotectonic regions of Greece (13-10-1997, Ms=6.6 in southern Greece; 5-11-1997, Ms=5.6 in Central Greece; 14-11-1997, Ms=5.8 in the northeastern Aegean Sea; 18-11-1997, Ms=6.4 in the Ionian Sea). Broadband waveforms recorded by the IRIS network for these main shocks, have been used to compute the far-field displacement spectra and the source parameters (fault dimensions, stress drop, seismic moment, average displacement and seismic energy). In addition digital short period waveforms recorded by the Greek National Seismographic network have also been analysed and the computed source parameters are compared to those computed from the broadband data. The relationship of the seismic source parameters and the aftershock pattern regarding its spatial and temporal characteristics is also investigated.

SEISMOTECTONIC DEFORMATIONS ON THE REGION TAVR-CAUKASUS

GYODAKYAN Naira, (Institute of Mechanics, Moscow State University, I ichourinskiy ave, Moscow, Russia), GYODAKIAN Eduard,(Institute of Geophysics and Engineering Seismology of the National Academy of Sciences of the Republic of Armenia, Leningradian 5, Giumry, 377515 Armenia

In the present work the seismotectonik processes connected with the unelastic deformations arising in the Earth`s crust large blocks on areas of strong earthquakes are examined. On a basis of the analysis the knowledgements about the seismic flow of mountain mass are fixed. The estimation of deformation processes is done by the data of focal mechanisms of the strong earthquakes taken place on investigated region for the period from the period from 1970 to 1996. In this work the analysis of deformations relative speed is carried out using the tensor of seismic moments, of occurring on the investigated region strong earthquakes. Components of deformations and deformations speeds are determined both for region as a whole and for separate elements with the equal area on the Earth's surface. The intensity of deformations and speed of deformation are calculated as well as the class of the environment tense condition for separate elements. It is revealed the orientation of the main axes of deformation tensor is various for different elements that testifies to the complicated geodynamic structure of the region under investigation.

ST1/E/70-A3 1700

SEISMICITY VARIATIONS UNDER ELECTROMAGNETIC IMPACT USING MHD-GENERATOR

N.T.Tarasov and N.V.Tarasova (both at Joint Institute of Physics of the Earth, Russian Acad. Sci., 10 Bol. Gruzinskaya Str., Moscow, 123810 Russia, E-mail: tarasov@uipe.uas.ru)
A.A.Avagimov and V.A.ZEIGARNIK (both at Institute for High Temperatures - Association, Russian Acad. Sci., 13/19 Izhorskaya Str., Moscow, 127412 Russia, Email: zeig@termo.msk.su)

The analysis is presented of the seismicity variations within a seismoactive region of the Northern Tien Shan and adjacent areas; the variations are connected with the impact of high-power electrical pulses produced by MHD-generator. The data are engaged of long-standing earthquake prediction monitoring based on regular deep electrical soundings by high-power single pulses. Pronounced spatial and temporal variations of the seismic regime are detected; after the MHD-runs, the seismicity level (in terms of quake number) becomes distinctly higher than the same before the runs. The total energy release in the form of weak earthquakes after all 85 runs is estimated to be 5-6 orders of magnitude more than the total energy inserted by the MHD-generator into its load. Instant seismicity activation occurs on the 2nd-4th day after the run and lasts for several days. The most distinct is the effect within the upper 5-km layer of the earth crust. The results obtained are similar to those for a seismoactive region of Pamirs. The electromagnetic impact serves as a trigger initiating the seismic energy release, which is accumulated in the media during the tectonic processes.
The principal result lies in the possibility of controlled external impact on natural seismic process and triggering the release of accumulated energy in the form of relatively weak quakes. The possible physical model of the phenomenon is under discussion.

ST1/P/13-A3 1720

RESEARCH ON TEMPORAL AND SPATIAL DISTRIBUTION, EVOLUTIONARY CHARACTER AND MECHENISM OF CRUSTAL DEFORMATION FIELD BEFORE AND AFTER THE TANGSHAN EARHQUAKE

Shuoyu ZHOU, Shunying Shi, Ping Shuai (all at Institute of Seismology, China Seismological Bureau, Wuhan, 430071, China)

According to the data of precise relevelling and deformation measurement across faults, the temporal and spatial evolution process of crustal deformation field in the focal and peripheral regions of the Tangshan earthquake (1976, Ms=7.8), from 22 years before the earthquake to 9 years after, is described with the method of crustal deformation pattern dynamics. The crustal unstable zones first occur in the exterior, and then surround the focal region by contracting from the exterior to the interior, when the focal region appears to be unstable but does not lose stability. After the transient stable state, the second unstable process from the exterior to interior appears, which results in the instability of focal region. "Deformation gap", "earthquake gap" and "locked fault zone" occur before instability, and their spatial distribution overlap, but their occurrence times have little difference. The earthquake occurs after the impending pre-slide of the faults in the focal region. The studied results of the evolution process of crustal deformation field are identical with each other and with that of numeric simulation of crustal stress field, which supports the evolution model of seismogenic system with a strong body as its core.

FORESHOCK DISTRIBUTION OBTAINED BY SYNTHETIC SEISMICITY BASED ON A STATISTICAL MODEL

Kenji MAEDA (Meteorological Research Institute, 1-1, Nagamine, Tsukuba, 305-0052, JAPAN; e-mail: kmaeda@mri-jma.go.jp);, Rodolfo Console (Istituto Nazionale di Geofisica, Via di Vigna Murata, 605, Rome, ITALY; e-mail: console@ing750.ingrm.it); and Yasuhiro Yoshida (Meteorological Research Institute, 1-1, Nagamine, Tsukuba, 305-0052, JAPAN; e-mail: yyoshida@mri-jma.go.jp)

It is well known that the space-time distribution of foreshocks obtained by superposing many foreshock-mainshock pairs within a few days before a mainshock shows that the number of foreshocks increases acceleratively as the time and the location approach a mainshock (e.g. Jones, 1985). Two different explanations are possible to interpret the distribution (Maeda, 1999). The first one is that the accelerative increase of instability or stress in the region causes the accelerative increase of foreshocks, and the other one is that a foreshock is the cause of a stress change in the region and it triggers a mainshock. The second explanation, which may be a little hard to understand, is compatible with the relationship between a mainshock and aftershocks, when an aftershock happens to become larger than the mainshock. To show the second explanation more explicitly, we analysed the synthetic seismicity data produced by a statistical model (Console, 1998). The statistical model used in this study assumes a random occurrence of events with the Poisson distribution and an induced seismicity with a circular normal space distribution and the Omori time distribution, combined with the Gutenberg-Richter frequency-magnitude distribution. Note that the model does not assume an increasing time distribution before an event. The results show that the synthetic data also exhibits the accelerative increase of time distribution of superposed foreshocks.

QUANTITATIVE TESTING OF HYPOTHESES OF PERCURSORS

ST1/E/60-A2 Poster 0930-01

POTENTIAL PRECURSORS OF 1998 ZHANGBEI M=6.2 EARTHQUAKE IN CHINA

QI-FU CHEN (P. O. Box 166, Center for Analysis and Prediction, China Seismological Bureau, Beijing 100036, P. R. China, email: cqf@ip.cap.ac.cn)

The 1998 Zhangbei M6.2 earthquake occurred on northwest of Beijing on January 10 with 49 death and 816 million RMB losses. Its focal mechanism shows a NNE-striking right-lateral faulting or EW-striking faulting at a depth of 10 km. There are some potential precursors are identified from various earthquake-monitoring networks in north of China for the Zhangbei earthquake. A swarm event with magnitude 4.0 which belongs to breaking out earthquake occurred in Beijing on Dec. 16 of 1996 maybe a symptom for a magnitude 6 or above in a future. Then an isolated earthquake with magnitude 4.2 occurred in Zhangjiakou on May 25 of 1997. The interval of earthquake quiescence with ML? 4.0 in north of China is beyond 90 days found on Dec. 31 of 1997. The quiescence is also identified by SEISMOLAP. The water table of Wuliying located on Beijing showed notable anomaly, which maybe classified into medium and short-term precursory variation. It is also observed other anomaly variations of CO2 and electromagnetic radiation from Huailai station, and ground tilt from Chicheng station. Specially, there are clear demarcation lines of shift time from the lowest Z-value in geomagnetic stations around China on Dec. 17, 18 and 19 in 1997.
Those potential precursors were examined with long term data. The probability increase of earthquake occurrence is tens with those potential precursors. It is very difficult, even now, to make an exact prediction for this earthquake with those potential precursors, especially for its location. The reason is that the earthquake occurred in the Tertiary basaltic region without recognized active faults.

APPLICATION OF TIME-TO FAILURE MODEL TO PRECURSORY SEISMIC ACTIVATION ON KAMCHATKA AND IN ITALY

R. Di Giovambattista (Istituto Nazionale di Geofisica, Via di Vigna Murata, 605, I-00143 Roma, Italy. E-mail: digiovam@marte.ingrm.it);G.A.Sobolev (Institute of the Physics of the Earth, B/Gruzinskaya 10 123810 Moscow, Russia. E-mail: sobolev@uipe-ras.scgis.ru.);Yu. S.TYUPKIN(Geophysical Center, Molodezhnaya 3, 117296 Moscow, Russia E-mail: tyupkin@wdcb.ru)

Suppositions that potential sources of earthquakes form a fractal manifold and that the process of seismic release is accelerated before a strong earthquake and is concentrated in the neighborhood of its hypocenter lead to a time-to-failure model of precursory seismic activation. Log-periodic time-to-failure model is used for analysis of a process of a strong earthquake preparation. A cumulative sum of square root of seismic energy Q(t) of events preceded time t, is used for the study. Log-periodic term is considered as perturbation. The application of the model to a retrospective precursory seismic activation on Kamchatca and in Italy give a scattering of predicted time of main shocks from few days to a half of year and an error of predicted energy class <0.5. A real time application of the model for prediction of strong earthquake is labored if the location of predicted event is unknown. The model may be useful in combination with other earthquake prediction approaches. The work was supported by Russian Basic Research Foundation.

ANALYSIS OF NON-TYPICAL SEISMIC MOMENT TENSORS AS A POSSIBLE PRECURSORS OF STRONG EARTHQUAKES

YUNGA S. (Institute of physics of the Earth, Moscow, 123810, B.Gruzinskaya, 10, Email: syunga@uipe-ras.scgis.ru)

The temporal-spatial variations of focal mechanisms and seismic moment tensors are studied retrospectively in a set of points corresponded to the epicentres of strong earthquakes. The study focuses on the local variation of the state of stress in a region of strong earthquake preparation where stress state disturbances theoretically evaluated as a result of re-activation of localised deformation bend or large-scale faults.
Investigation of numerous seismic moment tensors in terms of seismotectonic strain rates in Kuriles-Kamchatka region is performed. Seismotectonic strain rate tensor is determined as a normalised sum of local seismic moment tensors for a representative number of seismic events within 1.3 degree vicinity of each point. Analysis is based on scalar product of tensors under investigation. Temporal variations are investigated on the basis of comparison individual seismic moment tensor and seismic strain rate tensor obtained through this averaging procedure. This technique, together with the construction of classification diagrams of fault plane solutions enables us to rapidly examine the stress-field pattern and further discuss the deformation modes of faulting and fracturing, which may take place at a local scale. Local variations of stress field may be considered as an additional tool in solving earthquake prediction problem. It is found that foreshocks source mechanisms were untypical for the zones of two recent large earthquakes with M=8: the October 4, 1994 Kurile Islands earthquake and the December 5, 1997 Kamchatka earthquake. A geologic interpretation of the temporal-spatial focal mechanism variations is proposed to highlight the role played by major structural discontinuities in the local variations of the stress regime. This research was partly supported by R.F.B.R., grant N 98-05-65159.

ABOUT THE PROBLEM OF THE CORRESPONDENCE OF DATA USED FOR THE ANALYSIS OF PHYSICAL STATE OF THE EARTH

Anatoly DYCHENKO, (Department of Mechanical Engineering, Ukrainian State University of Food technologies, Volodymyrska St., 68, Kyiv, 252610, Ukraine, tel.: 380 (44) 558 8313, fax.: 380 (44) 212 4267, E-mail: dychenko@uduft.niiit.kiev.ua)

The natural processes and phenomena, proceeding on the Earth are caused by the influence of global space surrounding the Earth. The physical state of global space changes continuously, which leads to continuous changes in geometric and physical parameters of the Earth as a part of the uniform global system. Therefore all natural processes, proceeding on the Earth, are connected with each other in time by cause-and-effect relationship.
To investigate physical state of the Earth it is necessary to use a great many real input data. Obtaining such data is often connected with significant difficulties and material expenditures and frequently requires long-term research work. The problem is, that the input data used for studying the state of the Earth should correspond to one certain moment of time. Otherwise the cause-and-effect relationships between phenomena can be lost, which leads to the complexity of their detection and to the initiation of essential errors in the analysis of physical state of the Earth corresponding to the moment of time considered.
The calculations carried out using a mathematical model, describing the geometric shape of the Earth, show, that even minor changes in exterior action in the scale of the Earth can lead to the results appreciable for the mankind.

PROBABILISTIC FILTERING USING STOCHASTIC MODELS OF EARTHQUAKE PRECURSORS ANOMALIES: CASE STUDIES AND RESULTS

Stefan SHANOV (Geological Institute of Bulgarian Academy of Sciences, Acad.G.Bonchev Str., bl.24, 1113 Sofia, Bulgaria, email: shanov@geology.bas.bg)

The published data for the behavior of the known earthquake precursors (phenomenological approach) have shown the complexity of the clamed prognostic anomalies and their variations in amplitude and length, as well as their deformation by irregular noises of different genesis. For increasing of the quantity of forecasting it can be used the probabilistic filtering. The Method of Inverse Probability needs of stochastic model of the expected prognostic anomaly. This method is applied in order to detect a comparatively weak efficient signal against strong, disturbing noises. The stochastic model could be created using the data records of the precursor before earthquakes above chosen magnitude level and inside given territory around the monitoring point. The imposed restrictions to the stochastic anomaly model are: 1) The noise correlation time interval has to be at least two times shorter than the length of the anomaly model; 2) The anomaly should faded several days (or months) before the earthquake; 3) The anomaly model needs to have a variation equal to 1. The data for comparing are normalized by their standard deviation. The correlation is obtained by interval, constant step multiplication of the observed values by the ordinates of the stochastic anomaly model, and by summarizing the product obtained. For the purpose of the prediction this amount is attributed to the final measurement. The curve plotted, using the values of the cumulative function, will contain the entire information of effective anomalies. The final result is given as a probability for the existence of the expected precursor anomaly on the records. Results from monitoring of thermal water level variations in a borehole (short-term prediction) and extensometric measurements on active fault (intermediate-term prediction) show the high performance of the method used.

IMPLICATIONS OF MOMENT RELEASE RATES FOR SEISMIC SOURCES

L. R. JOHNSON and R. M. Nadeau (both at Center for Computational Seismology and Seismological Laboratory, University of California, Berkeley, CA 94720 USA)

Measurements of moment release rates for sequences of small repeating earthquakes are used to estimate the seismic parameters source area, slip, and recurrence interval. Such parameters exhibit a systematic dependence upon source size over a range of ten orders of magnitude in seismic moment that can be described by three simple scaling relationships. These scaling relationships have implications for the repeat time of earthquakes, average stress drop, strength of the fault, and heat generated by earthquakes. They suggest a model for earthquakes that involves a highly heterogeneous fault on which the earthquake process is controlled by small strong asperities that occupy less than 1% of the area. Such heterogeneity helps to explain many apparent contradictions about earthquakes, such as their apparent weakness, the absence of heat flow anomalies, and the presence of pseudotachylites. Field data from exhumed fault zones are used to complement the seismic measurements, provide further constraints on the fine scale features in the earthquake source region, and constrain the energy budget of the earthquake process. Numerical calculations are used to study the dynamic interaction of a heterogeneous stress field and simulate the radiated elastic waves.

PRECURSORY GEOCHEMICAL SIGNATURES OF RECENT EARTHQUAKES IN THE NORTHWESTERN IBERIAN PENINSULA

José M. L. SALAZAR, Nemesio M. Pérez (both at the Environmental Research Division, ITER, 38594 Granadilla, Tenerife, Canary Islands, Spain; e-mail: jsalazar@iter.rcanaria.es); George Igarashi (Laboratory for Earthquake Chemistry, Univ. Tokyo, Bunkyo-ku, Tokyo 113, Japan); Hiroshi Wakita (Gakushuin Women's College, 3-20-1 Toyama, Shinjuku-ku, Tokyo 162, Japan); and Sun'ichi Nakai (Earthquake Research Institute, Univ. Tokyo, Yayoi, Tokyo, Japan)

Significant CO2-rich ground water and alkaline sulphide spring discharges occur in the NW part of the Iberian Massif, the largest outcrop of the Hercynian orogenic belt in Europe. Most of the CO2-rich ground waters are discharged along old NNE-trending faults, which had been reactivated during the Quaternary. Recent seismic activity in the region might be related to these NNE trending faults. In the search for precursory geochemical signatures related to recent major earthquakes in Galicia, secular variation analysis of dissolved Cl- in commercial, bottled, and mineralCO2-rich ground water exploited at Cabreiroa's well (SW of Galicia) have been performed. Temporal variations of Cl- concentrations showed a uniform pattern from February to August 1995, about 24 mg/L. By the end of August, Cl- contents increased and reached relatively high Cl- levels (>26 mg/L) almost two months before two magnitude 4.6 earthquakes occurred on November 29 and December 24, 1995. In April 1996, Cl- content went back to background levels. After the finding of this sensitive well, in April 1997 a continuous radon monitoring system was installed at Cabreiora. The initial results showed a significant increase of dissolved gas radon reaching levels up to 70,000 cph four weeks prior to the magnitude 5.1 earthquake of May 21, 1997. The radon peak lasted until early May when radon activity levels were about 30,000 cph. Data after July 1997 showed background radon values about 25,000 cph with daily variations much smaller than previous observed anomalous changes.

SEISMIC SHORT-TERM PRECURSORS OF VOLCANIC ERUPTIONS AND EARTHQUAKES

Victor V. MYACHKIN, Lidia B. Slavina (both at Institute of Physics of the Earth, Russian Academy of Sciences, Bolshaya Gruzinskaya 10, Moscow 123810, Russia, e-mail: myachkin@uipe-ras.scgis.ru)

A method of medium- and short-term prediction of strong earthquakes, volcanic eruptions and rock bursts is proposed. It is based on study of dispersion of P and S wave travel times from weak local earthquakes located in a concrete active seismic region. An algorithm and programs for calculation of the prediction curve are developed. The method was used in various cases: volcanic eruptions in Kamchatka: the Large Tolbachik Fissure Eruption in1975, several eruptions of Klychevskoi Volca - no, the eruption of Karymsky Volcano in January, 1996), before the Spitak earthquake of 7.12.1988, in the Kopet-Dag region for a long period of time, and during preparation of a rock burst. A precursor occurs 5-45 days before a strong event. Duration of the alarm interval depends on intensity of the earthquake under preparation and on remoteness of the observation station from the source. Duration of precursor manifestation decreases at a station near the forthcoming event. This method can be successfully used as for a network of regional stations, so for a telemetric network, in the last case online regime of data obtaining and calculations is possible.

CLOUDINESS REVEALS CRUST FAULTS AND FORECASTS EARTHQUAKES (RESULT OF A NUMEROUS-EVENT ANALYSIS)

Vladimir A. ALEKSEEV (Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation, Russian Academy of Sciences (IZMIRAN), Troitsk, Moscow region, 142092 Russia, email: ogm@fly.triniti.troitsk.ru), Tamara N.Bibikova and Tamara A. Proskuryakova (both at Department of Physics, Lomonosov Moscow State University, Vorob'evy Gory, Moscow, 119 899, Russia, email: ann@geos34.phys.msu.su)

During field works in the seismological region of Crimea peninsula, we studied sharply outlined clouds (sometimes these clouds were of a layered structure). The method of stereophotogrammetrical shooting (with 2% precision) was used. We find that the clouds nearly follow the fault line revealed by the seismic method. We suppose these "tectonic clouds" are due to the injection of submicronic aerosols during the process of degasation in tectonic active zones, the aerosols being the centres of condensation of atmospheric water vapours. The events of 296 earthquakes, which occurred during 50 years, are investigated. We demonstrate the overall enhancement of cloudiness before earthquake. There are two pronounced maximums of the cloudiness, the first being in the diapason 66 - 42 hours before the beginning of the earthquake and the second being in the diapason 30 – 24 hours. The majority of the clouds are of thunderstorm character. This shows enhancement of electric field intensity, thus supporting the idea about aerosols injections. Similar form of clouds occurs in Taiwan and New Zealand. Also we show some data on temperature variation preceding the earthquake. Observing the specific temperature variation and the cloudiness over crust faults is appropriate for monitoring the Earth' surface with a system of small satellites to evaluate seismic hazards.

TIME SERIES ANALYSIS OF THE RADON CONTENT IN GROUNDWATER AND OTHER GEOCHEMICAL PARAMETERS MONITORED IN THE LABORATORI NAZIONALI DEL GRAN SASSO (ITALY)

Francesco Bella (Physics Department, University "Roma Tre", via della Vasca Navale, 84, 00146 Roma, Italy, email: bella@fis.uniroma3.it); and Wolfango PLASTINO (Physics Department, University "Roma Tre", via della Vasca Navale, 84, 00146 Roma, Italy, email: plastino@fis.uniroma3.it)

Physics Department of the University "Roma Tre" performs, beginning from the May 1996, measurements of the radon content in groundwater and other geochemical parameters in the L.N.G.S. to study the following topics: a) correlations between the possible variations of the radon with the stress-strain processes of the rock; b) study of the diffusive processes of the radon related to the water geochemistry. This monitoring activity is a part of the geophysical and geochemical research of the Gran Sasso aquifer, the most important of the central Italy. Then, we have planned and realized a multiparametric equipment and we have set up in the underground laboratory of the Istituto Nazionale di Fisica Nucleare. The geochemical measurements carried out in the L.N.G.S. seem to point out a good reability and stability of the automatic equipment and a correlation with the local seismicity and with the seismic sequence of the Umbria earthquake.

VARIATIONS OF APPARENT RESISTANCE: EARTHQUAKES PRECURSORS OR SEASONAL EFFECTS?

A.V. Descherevsky, (Russia, Moscow, Bolshaya Gruzinskaya 10, Union Institute of Physics of the Earth, email: deshere@uipe-ras.wscgis.ru); A.Ya. SIDORIN (Russia, Moscow, Bolshaya Gruzinskaya 10, Union Institute of Physics of the Earth, email: sidorin@uipe-ras.wscgis.ru)

Statistic structure of variations of apparent electrical resistance of rocks observed in Garm by long-standing dipole soundings is surveyed. By method of mid-seasonal function the seasonal component of time series is recognized, and its functions are observed. Using the data of long-standing vertical sounding with the distance of 6 m to 3 km between the feeding AB dipoles, the dependence of phase and amplitude seasonal components from the dimensions of using adjustments (sounding depth) are studied. It was determined the seasonal variations of apparent resistance observed with the help of dipole adjustment (placing) with about 6 km distance are lagged behind the variations of surface layer resistance on approximately 4 months. Amplitudes of seasonal variations decrease smoothlessly with the increasing of the distance; if the distance becomes more then 3km the amplitude extremely increases. Residual series, received after the filtration of primary series of seasonal component, have the peculiarities of flicker-noise. The result of this residual series analysis by formalized method on the basis of quantum (photon) detector is the definition that during the "anomalous" periods of low values of apparent resistance the strong local events have occurred twice more frequently then during the background values of this parameter. Thus, the prognostic significance of the observed resistance variations has been confirmed.

Makropoulos (Seismological Laboratory, University of Athens; email: kmacrop@cc.uoa.gr); G. Veis (Dyonisos Satellite Observatory, National Technical University of Athens); G. Stavrakakis (National Observatory of Athens; email: g.stavr@egelados.gein.noa.gr); F. Scherbaum (University of Potsdam; email: fs@geo.uni-potsdam.de); B. Ducarme; M. VanRuymbecke (all at Observatoire Royal de Belgique; email: vruymbek@mailserv.oma.be)

The rift of Corinth is one of the most active continental structure of the Euro-Mediterranean region. Its opening rate is 1 to 1.5 cm/year, with an associated strain rate of 10-6/year, and 6 earthquakes with magnitude larger than 5.8 in the last 35 years. The European GAIA project (1996-1998) has allowed the installation of a multiparameter geophysical observatory continuously monitoring the activity of the rift, complementing the seismometer and accelerometer arrays: shallow borehole tiltmeters, strainmeters and tiltmeters in a cave, radon probes in soil near fault zones and in karstic springs, and magneto-telluric and radio stations. Its aim is to detect and analyze short-term crustal instabilities within the long-term deformation context of the whole seismic cycle: coseismic and postseismic perturbations from large earthquakes, aseismic instabilities and clusters of small earthquakes, and possible precursory instabilities. The paper presents the recent achievements of the GAIA project, and mentions the objectives of a future project proposing a "Multiborehole Observatory in the Gulf of Corinth" (Cornet et al., 1997).

LOW-RESISTIVITY STRUCTURES AS CONVERTERS OF SEISMIC WAVES' ENERGY INTO ELECTROMAGNETIC SIGNALS

OLEG NOVIK (Moscow State Geol. Prospect. Acad., 117246, POB 51, Russia.
email: onovik@glasnet.ru) Sergey Ershov (Keldysh Institute for Appl. Mathematics of Russian Academy of Sciences, Moscow) Irina Mikhaylovskaya (Moscow State University.
email: irina@nw.math.msu.ru)

Trying to clear out the physical nature of electromagnetic (em) and temperature (t) signals observed in seismically active regions (some of them occurred to be precursors to earthquakes), we use the theory of magnetothermoelasticity to construct the mathematical model and calculate the elastic-em -t field interaction caused by displacements (ampl., freq. and duration are of order of a few cm, Hz and sec resp.) in the upper mantle domain of a model lithosphere zone containing the low-resistivity structures (LRS) in this domain and in the crust. According to MT-soundings in seismic regions, the LRSs' conductivity is 0.1 to 0.5 S/m and cross-section sizes and depths are of order of 10 km or mo-re. It is clear from the computed pictures of the evolution of the interacting fields that em-signals arises near the contacts of the seismic waves' (s.w., from upper mantle in our runs) fronts with the boundaries of LRSs, as a result of their deformations in presence of geomagnetic field. The em- emission into atmosphere arises during the diffraction of s. w. by LRSs (60 pT at the Earth's surface and 10 pT at the height of 30 km). The t-signal (up to 0.02 K in the sedimentary layer) propagates together with the s.w. and is not influenced by ionosphere. The main frequencies of the computed em and t-signals (ULF field oscillations) are nearly the same as ones of displacements and are changing, together with the amplitudes, because of changing of displacements at the depth. The computed em and t-signals' amplitudes, frequencies, the delay of the seismic wave arrival at the surface in regard to em-signal and its delay in regard to beginning of displacements are of orders observed.

EARTHQUAKE NUCLEATION TO DYMANIC RUPTURE

INFLUENCE OF CHANGES IN THE GEOMETRIC SHAPE OF THE EARTH ON THE INITIATION OF COMMON AND LOCAL CENTERS OF STRAIN

Anatoly DYCHENKO, (Department of Mechanical Engineering, Ukrainian State University of Food technologies, Volodymyrska St., 68, Kyiv, 252610, Ukraine, tel.: 380 (44) 558 8313, fax.: 380 (44) 212 4267, E-mail: dychenko@uduft.niiit.kiev.ua)

Each geometric shape is characterized only by its inherent metric properties. The changes in the geometric shape lead to the changes in metric properties, which under the conditions of real physical rigid body results in inevitable initiation of centers of strain. For example, a maximum volume at a minimum area of surface characterizes a body of spherical shape. The deformation of a spherical body under the change of its shape for the ellipsoidal one leads to a modification of relationship volume / area of the surface and modification of lengths of characteristic lines on the body's surface.
Continuous deformation of the Earth under the influence of constant changes in an exterior force field also results in the initiation of common and local centers of strain in the body of the Earth. Depending on the peculiarities of deformation both contracting, and stretching strains of high intensity arise in the rigid basis of the Earth resulting in local manifestations, sometimes disastrous for mankind.
Detecting small (related to a determining size of the Earth) deformations, and correspondingly arising deformation strains is possible only in the case when the mathematical means used for processing and analysing of input data allow to obtain results of required exactitude. Such exactitude can be provided by the new analytical technique based on the natural unity of spatial and other physical parameters.

PHYSICAL GEOMETRY OF ACTUAL SPACE

Anatoly DYCHENKO, (Department of Mechanical Engineering, Ukrainian State University of Food technologies, Volodymyrska St., 68, Kyiv, 252610, Ukraine, tel.: 380 (44) 558 8313, fax.: 380 (44) 212 4267, E-mail: dychenko@uduft.niiit.kiev.ua)

When studying the influence of geometric shape of a body on physical processes, proceeding in it, there is a necessity for describing the relation between geometric and other physical parameters. Existing geometric mappings of real physical space cover only the relations and shapes of objects and phenomena similar to spatial ones but regardless their concrete physical content. It superimposes essential restrictions at a research.
To analyse the influence of geometric shapes of real bodies on physical processes proceeding in them and to determine the field of distribution of physical parameters in these bodies, the principles of physical geometry have been developed. The physical geometry reflects the organic natural constraint between spatial and other physical parameters. The initial geometric concepts of elementary geometric objects are defined proceeding from a physical state of real space elements, whose geometric mappings these objects are.
The use of physical geometry when investigating the influence of geometric properties on physical processes has allowed to improve the accuracy of some existing theoretical provisions, to reveal the reasons of erroneous results of determination of physical state of system as a whole when analysing the system in its separate elements, and to develop a new technique for analysing distribution of interior forces in bodies of complicated geometric shape.

A MODEL FOR FRACTURING PROCESS OF INTACT ROCKS UNDER AXIAL LOADING OF COMPRESSION: THE SIZE-EFFECT OF STRENGTH FOR FRACTURE OF SPECIMENS

Kiyohiko YAMAMOTO (Graduate School of Science, Tohoku University, Sendai, 980-8578 JAPAN, email: yama@aob.geophys.tohoku.ac.jp)

A simple model called strength distribution model has been proposed to elucidate the process to the macroscopic fracture, or the fracture of an intact rock specimen, under tri-axial loading of compression. This model is constructed on the assumptions as follows: 1) A specimen consists of small volume elements of the same size. 2) Fracture of an element, or a micro-fracture, occurs according to the Coulomb's criterion, where the internal friction coefficient is taken to be proportional in magnitude to the cohesion force. 3) The strength distribution for the elements is expressed by a power function. 4) The applied load to a specimen is equally shared among the elements that have remained un-fractured. The model provides the analytical expression for the relation between density of micro-cracks and applied stress and that for the relation between a decrease in the macroscopic strength and an increase in the average size of generated micro-cracks. It has already been confirmed that the former expression well explains the experimental data. The analytical expression for the size-effect of macroscopic strength is derived by assuming that the average size of micro-cracks is proportional to specimen volume. There exist the experimental data obtained for quartz diorite and coal under uni-axial loading. Although an abundance of tensile micro-cracks are generated in specimens under uni-axial loading, the expression is fitted to these data on the idea that tensile micro-cracks are generated due to the tensile stresses locally induced by shear micro-fractures even under uni-axial loading. It is found that the expression can be well fitted to the data in the wide range of specimen volume over more than 3 order of magnitude. This result together with the previous one shows the validity of the present model. This validity of the model implies that the internal friction coefficient is not an essential physical constant but a variable with regard to specimen size.

COMPREHENSIVE SOURCE ANALYSIS EMPLOYING A UNIVERSAL KINEMATIC MODEL

Yeugeny Chirkov, Nadezhda KONDORSKAYA, Ilya Zyrkis, Natalia Lagova, and Yelena Khrometskaya (all at the Russian Academy of Sciences Institute of Physics of the Earth, 123810, GSP, Moscow, Russia)

The elaboration of physical models is one possible way to get the understanding of the complicated processes that occur within the earthquake source. A kinematic model of earthquake source is presented which allows to obtain analytical approximation of P-waves in the teleseismic zone (with respect for attenuation and instrument characteristics) in the form of finite series. The model's time function is physically substantiated (finite, continuous and differentiable), and its parameters have been determined via simultaneous approximation of

S

source P-waves in the teleseismic zone and in a wide azimuth range. Seismic moment has been assessed employing a nonconventional ethod and with the help of kinematic model presented herein.
The model, by analogy with seismic moment, allows to describe frequency spectrum of the earthquake's source emission in term of conventional parameters, that is dimensions of the rupture, maximum speed of displacement, initial and final speed of fracturing. An algorithm is presented for automated selection of source P-waves.
Model's applicability is illustrated on the example of the Racha-Djava earthquake (Caucasus) of April 29, 1991 (Ms =6.9). The work has been carried out with support of the Russian Found for Fundamental Research.

RESPONSE OF SPRING SYSTEMS TO EARTHQUAKES IN ARMENIA

V. LEONARDI (Magmas et Volcans UMR 6524 & CNRS, Clermont-Ferrand, France, email: leonardi@opgc.univ-bpclermont.fr); A. Tovmassian (National Survey for Seismic Protection of the Republic of Armenia. 4 Yerevan 375054 Armenia)

This study present the relationship between local seismicity and springs discharge, in which the microseismicity modifies the state of stress of the aquifer matrix and these modifications of the local stress control the aquifer behaviour from an example of a basaltic reservoir crossed by a seismic fault. Along the right-lateral Garni seismic wrench fault, the distribution in space and time of more than 500 micro-earthquakes has been studied providing a pattern of stress distribution. Together with this tectonic survey, the hydrographs of springs issuing from an aquifer located in basaltic lava flows and crossed by the fault have been gauged for four years. According to its tectonic, geologic and hydrodynamic properties, the reservoir has been divided in several parts. The hydrological behaviour of the reservoir and of each of its parts has been modeled, based on the rainfall and hydrodynamic properties of the basaltic reservoir and of nearby reservoirs. The model allows us to define the "normal behaviour" of the springs, when their discharge is not affected by an earthquake. An anomalies to the normal hydrometric curves are defined, and correlated to small (M<3.5) earthquakes along the Garni fault. We propose that the circulation of underground water in the area around the fault depends largely on the fracture pattern of the basalts and the aquifer basement, as pointed out from field observations. Changes in springs discharge are explained by variations in the state of stress around the Garni fault, induced by the alternation of elastic strain and stick-slip movement on the fault and by creep far from the fault. A model of stress distribution correlated with microseismic activity is proposed which explains changes in fracture charateristics before and after earthquakes.

A DYNAMIC MODEL FOR INTERSEISMIC VARIATION IN GROUND DEFORMATION RATES

Nipun KAPUR, (Department of Earthquake Engineering University of Roorkee, Roorkee - 247 667 India)

Geodetic observations during earthquake cycle at a number of fault / subduction zones show variation in ground deformation rates. A rapid post seismic to low preseismic values is characteristic of deformation rates. A dynamic model is proposed in which nonlinear friction and material response during interseismic period along the Main Thrust Zone (MTZ) contributes to the characteristic strain rates. Such, nonlinear time dependent interseimic phenomenon may be active for both situations of a locked as well as unlocked MTZ as hypothesized in various subduction models. The model exclusively explains slow preseismic strain rates. Moreover it infers that an unlocked interseismic MTZ does not rule out the possibility of strain accumulation.

TUNNEL EFFECT OF FRACTAL FAULT AND TRANSIENT S-WAVE VELOCITY RUPTURE (TSVR) OF IN-PLANE FAULT

LI SHI-YU and Chen Yun-tai Chen (Institute of Geophysics, China Seismological Bureau, Beijing 100081, China, email: lisy@cdsndmc.css.gov)

Transient S-wave velocity rupture (TSVR) means the velocity v of fault propagation is between S-wave velocity _and P-wave velocity _Á. It¡¯s existence in the rupture of in-plane fault was proved, but there are two difficulties, i.e. initialisation difficulty and divergence difficulty in 2-D LEFM model. The initialisation difficulty means, when v¡ûvR (Rayleigh wave velocity), the dynamic stress strength factor K2 (t) ¡ú0, and change from positive into negative in the forbidden of (vR,_). The divergence difficulty means K2 (t) ¡ú+¡_ when v¡__. Here we introduce the concept of fractal and tunnel effect of fault. As we know, v is differentiate of the length of the fault respect to time, so v is also fractal. The tunnel effect means the dynamic rupture cross over the interval of the cracks, and the coalescence of the interval is slower than the propagation of disturbance. Suppose the area of earthquake nucleation is critical or sub-critical propagation everywhere. The arriving of disturbance triggers or accelerates the propagation of cracks tip, and the observation system can¡¯t distinguish the front of disturbance and the tip of fracture. Then the speed of disturbance may be identified as velocity of fracture velocity, and the phenomenon of TSVR appears, which is an apparent velocity. The dual character of rupture velocity means that the apparent velocity of fault and the real velocity of micro-crack extending, which are different in physics, but are unified in rupture criterion. Introducing the above concept into the calculation of K2(t), the difficulty of initialisation can be overcome, and the integral equation of triggering the initialization of TSVR is given quantitatively. By solving this equation, the lower limit of TSVR is 1.1053_, not _, then the divergence difficulty is also overcome. TSVR is unstable solution, and may degenerate to sub-Rayleigh wave velocity rupture immediately where the non-critical condition can be measured. The results of this paper show that the initialisation and continuum depends on the condition of earthquake nucleation area.

INFLUENCE OF LOADING RATE ON THE STABILITY OF A UNIFORM FAULT WITH VARYING NORMAL STRESS

Changrong HE, Shengli Ma (both at Institute of Geology, China Seismological Bureau, Beijing 100029, China, email: rmlab@public.bta.net.cn)

We analyzed the stability and dynamic motion of a single degree of freedom spring-slider system as a model of a uniform fault with a rate- and state-dependent friction law that the effect of normal stress. When the fault is inclined to the driving direction, critical stiffness that separates stable sliding and cyclic stick-slip is velocity-dependent. More over, the critical stiffness decreases with increasing velocity. Accordingly, higher velocity stabilizes a system for a predetermined stiffness lower than the critical value and may change the motion from cyclic stick-slip to stable sliding, and vice versa. Our numerical simulations in full dynamic motion confirmed such transition, and agree well with the analytical result.
Sensitivity of such transitions to change of loading rate is also discussed. The sensitivity depends on how close the stiffness is to the critical point and on the fault angle. A higher angle between the maximum principal stress and the fault surface favors the transition, i.e. a smaller change in loading rate can activate the transition with a higher angle. Nonlinear analysis is also discussed on the boundary in rate change that separates stable sliding mode and single triggered instability when the system stiffness is greater than the critical value.

SOURCE RETRIEVE BY EMPIRICAL GREEN'S FUNCTION DECONVOLUTION IN VRANCEA REGION (ROMANIA)

Mihaela Popa (National Institute for Earth Physics, P.O. Box MG-2, 76900 Bucharest, Romania, email: mihaela@infp.ifa.ro); Mircea RADULIAN (National Institute for Earth Physics, P.O. Box MG-2, 76900 Bucharest, Romania, email: mircea@infp.ifa.ro)

Vrancea seismic region is characterized by a highly confined subducted focal volume in the depth range between 60 to 200 km, where strong earthquakes (Mw,max of 7.7-7.9) occur. The seismicity rate is relatively high (around 10 events/month with ML > 3) for such a small volume. At present a network of 14 short-period Teledyne S13 stations (vertical component) and a network of 30 K2 accelerometer stations (three components) are monitoring the Vrancea seismic activity. They offer a sufficient number of digital waveforms within an magnitude range from 3.0 to 7.0 suitable for application of the EGF deconvolution.
The source parameters (seismic moment, source size and stress drop) are determined for a set of 30 intermediate-depth earthquakes, localized all along the subducting slab. Most of the sources are simple unipulse-like with relatively short rupture duration. It is assumed that the existence of a fluid-assisted faulting mechanism at intermediate depth can explain the particularities of the Vrancea source. In a few cases significant source directivity effects are detected for moderate size events (Mw ~ 5). Scaling of the seismic moment with magnitude, source dimension and stress drop is analyzed. Possible dependencies on depth of the source parameters and scaling properties are discussed in correlation with the distribution of the seismicity and energy along the subducting lithosphere.

SOURCE PARAMETERS OF CRUSTAL EARTHQUAKE SEQUENCES IN THE FOREDEEP AREA OF EASTERN CARPATHIANS BY EMPIRICAL GREEN'S FUNCTION DECONVOLUTION

Emilia POPESCU (National Institute for Earth Physics, P.O. Box MG-2, 76900 Bucharest, Romania, email: epopescu@infp.ifa.ro) Mircea Radulian (National Institute for Earth Physics, P.O. Box MG-2, 76900 Bucharest, Romania, email: mircea@infp.ifa.ro)

Source parameters of a few earthquake sequences of moderate-size (M < 5) crustal earthquakes occurred in the foredeep area of Eastern Carpathians (Romania) are retrieved using the empirical Green's function (EGF) technique. The digital waveforms recorded by Romanian local seismic telemetered network are considered. To apply the EGF deconvolution, we select for each studied sequence pairs of main and Green's events with similar location and focal mechanism. The apparent source time function and source spectrum of the main event are obtained using the seismograms of adjacent small events as empirical Green's functions. The deconvolved pulses and spectra are implicitly corrected for instrument and propagation effects. The analysis of the retrieved parameters outlines a heterogeneous faulting process in the seismic source. Scaling relationships between seismic moment, magnitude, source dimension, stress drop, peak velocity parameter are estimated. They agree also with a complex rupture process in the focal area. The SW-NE trend of the epicenter distributions for the earthquake sequences in the foredeep area is related to a dominant crustal fault orientation and a specific focal mechanism. Our results are finally discussed in connection with the seismicity and seismotectonics of the Eastern Carpathians foredeep area and the possible relation with the subducting process at the Eastern Carpathians arc bend (Vrancea).

CRUSTAL STRUCTURES AND DYNAMICS OF THE 1983(MS6.6) TUAN GIAO EARTHQUAKE EPICENTRAL REGION

Cao Dinh TRIEU and Nguyen Xuan Binh (Institute of Geophysics,VNCST, P.O.Box 411 Buu Dien Bo Ho, Hanoi. Vietnam)

In this paper, the authors present a solution of source process of the Tuan Giao earthquake and its tectonic implication. The crustal structures and Dynamics of the Epicentral Region are also described. Based on obtained analytical results, the following conclusion can be made:
1. Epicentral area of Tuan Giao earthquake located in northwest margin of M River zone and coincided with uplifted zone of lower boundary surface of the earth crust, where shifting amplitude into both sides of the Son La fault reached value of 2-3 km.
2. The Son La fault strongly activated during Mesozoic-Cenozoic period and Neotectonic and recent movement. Uplifting movement into northeast part of the fault reached value of about 1-2 mm/year.
3. The largest surface ruptures was characterized by system of 3 parallel fracture which have an azimuth 130o, a width 10-17 cm, and a length of about 200 m, that continuously of distributed at the total length of at least 20 km. The surface ruptures, at smaller level, has maximum length a fracture about 20 m of which direction is NW-SE, concentrated at the displacement on surface pure right lateral strike-slip was observed.
4. The fault plane solution from the inversion teleseismic body waves indicates pure right-lateral strike-slip, striking N290E, which the fault orientation in this area. The focal mechanism determined from the P-wave fist motion data has the different strike N120E. This fact suggests that the initial rupture occurred at the fault with the different from that of the main rupture.

EXPERIMENTAL STUDIES ON CONSTITUTIVE PROPERTIES FOR THE SHEAR FAILURE OF ROCK IN SEISMOGENIC ENVIRONMENTS

Aitaro KATO, Mitiyasu Ohnaka, and Hiromine Mochizuki (Earthquake Research Institute, University of Tokyo, Tokyo 113-0032, Japan, email: akato@eri.u-tokyo.ac.jp)

Elaborate laboratory experiments have been performed to evaluate in quantitative terms how the constitutive property for shear failure of intact granite is affected by seismogenic environments with increasing depths. In the present experiments, we simply assumed the crust to consist of granite, the lithostatic pressure gradient to be of 30 MPa/km, and the temperature gradient to be of 30C/km. We further assumed the interstitial pore water pressure to be hydrostatic (its gradient of 10 MPa/km) in one series of experiments, and suprahydrostatic (24 MPa/km) in another series of experiments. Tsukuba granite was selected for the present experiments, and the shape of test samples was a circular cylinder (40 mm long and 16 mm in diameter). All the tests were conducted at the strain rate of 10^(-5)/sec. It has been confirmed by these experiments that all the test results can well be represented in terms of the slip-dependent constitutive law. The experiments showed that the peak shear strength increases linearly with depth shallower than 10km, while it becomes virtually constant at deeper

depths. The critical slip displacement was virtually constant over the depth range up to 12km, beyond which it increased with depth. These results clearly show that mechanical instability is suppressed at depths greater than 12km, which corresponds to the brittle-plastic transition regime.
