Technical Report Profile DEKORP 1984-2S

(Manfred Stiller, GFZ German Research Centre for Geosciences, Potsdam, Germany)

1. Introduction

This is the technical description of the DEKORP 1984-2S seismic reflection data. The original PHX and SEGY format descriptions and the applied transcription rules (enclosed documents) are attached to this report in the Appendix. These documents might help the experienced user to follow the details of the transcription process from the original PHX tape format to the provided SEGY disk format:

- Barry et al., (1975) Recommended Standards for Digital Tape Formats' Official SEG-Y technical standard description, revision 0
- SCC/SSL Manual: implemented 'SEGY' Tape Format Description
- SSC/SSL Manual: 'PHXI' Phoenix 'I' Tape Format Description
- SSC/SSL Manual: 'PHX F' Phoenix FamilyTape Format Description
- SSC/SSL Manual, Internal Disk File (IDF) Format Description
- Applied transcription table PHX → SEGY (phx-ordered)
- Applied transcription table PHX → SEGY (segy-ordered)

When using the data please cite:

2. General

The folder **DEK84-2S_Data** contains all seismic data and corresponding meta data as well as additional information like, e.g. high-resolution graphic representations of final processing results. All data are based on the original processing carried out at the former DEKORP Processing Centre (DPC) at the Geophysical Institute of the Technical University Clausthal, Germany (Stiller & Thomas, 1989). The seismic data were originally stored on ½-inch 9-track magnetic tapes in PHXF or PHXI trace format as output from the SSC/SSL seismic processing package used at that time. In recent years these tapes have been step-by-step transcribed to SEGY disk files to allow for handling the data with any actual soft- and hardware. The attached format description files (see Appendix B) describe in detail the structure of (1) the SEGY format according to the SEG standard, of (2) the PHXF, PHXI and IDF formats according to the SSC/SSL software manual and (3) the applied conversion tables from PHX to SEGY.

All provided SEGY files are IEEE-32bitFP rev0 with proper binary header and with lots of remapped PHX header entries in addition to the regular ones. In the following, a complete and for all SGY-files identical remapping list is given, however not all of these headers are always filled with values for all files. The template is in Landmark ProMAX format, i.e. *header name, description, Integer/float format, , byte start.* This allows an easy remapping definition for the SEGY input routine of any other software:

In a PDF document in the **DEK84-2S_Data** parent folder all files contained in the subfolders are again listed together with additional information for a full overview.

3. Seismic Data

The seismic trace data are divided into **MainData** and **AdditionalData**. The main data are the ones most likely required for further evaluation, the additional data are old versions or special processing attempts and will be added step by step later on.

The seismic main data are divided into **PreStack** and **PostStack** data. The pre-stack data are well suited for an entire reprocessing, the final post-stack data to get a structural overview or for reinterpretation.

In the MainData/PreStack subfolder **FFsorted** there is a set of SGY files, each single one is a 1:1 transcription of a FF-sorted (FieldFile) magnetic tape from the respective original processing. The records may extend via two consecutive files. If the order of input during import is correct, the final dataset will contain sorted ensembles with increasing FF numbers, each with increasing channel numbers. The file names are consistently structured like xxx_yyyy.idf.segy where the xxx means a sequentially increasing tape index number within the respective processing stage (in this case ascending FF/Chan-sorted ensembles, unprocessed, but with all geometry

information in the trace headers) from tape 1-19. The yyyy is the unique original tape label number, idf is the source format (SSL-PHX Internal Disk Format). A PDF document in the parent folder lists all SGY files again together with additional Information.

In the MainData/PreStack subfolder **CDPsorted** there is a set of SGY files, each single one of which is a 1:1 transcription of a CDP-sorted (CommonDepthPoint) magnetic tape from the respective original processing (crooked-line geometry based on smoothed line through the midpoint scatter points). Again, the gathers may extend via two consecutive files. If the order of input during import is correct, the final dataset will contain sorted ensembles with increasing CDP numbers, each with increasing Offset (Source-Receiver distance). The file names are again structured like xxx_yyyy.idf.segy where the xxx means a sequentially increasing tape index number within the respective processing stage (in this case ascending CDP/Offset-sorted ensembles, unprocessed except bad trace elimination, but with all geometry information in the trace headers) from tape 1-18. The yyyy is the unique original tape label number, idf the source format (SSL-PHX Internal Disk Format). The PDF document in the parent folder lists again all SGY files again together with additional information.

All information that is necessary for recording geometry definition should be already present in the headers (source-/receiver-/CDP locations/coordinates/elevations/static corrections, shot/channel numbers, offsets etc.), so it should be easily possible to set up a matching database by extracting them accordingly.

In the MainData/**PostStack** folder there are SGY files with the results from the final processing carried out at the DPC, they are arranged in subfolders according to the respective poststack processing stage, i.e. **unmigrated** or **migrated**, **without** or **with** additional **coherency** enhancement, **without** or **with** additional trace **summation** of 2 adjacent traces to reduce the number of traces, and last not least automatic **LineDrawings**. Again, each single one is a 1:1 transcription of the corresponding magnetic tape from the respective original processing. They are always CDP-sorted and structured like xxx_yyyy.idf.segy where the xxx means a sequentially increasing tape index number, if several versions exist. The yyyy is the unique original tape label number, idf is the source format (SSL-PHX Internal Disk Format). The PDF document in the parent folder lists all SGY files again together with additional information.

Some SGY files come with an additional text file of the same name (but with the extension *.his instead of *.segy). Each of these so-called "history" files contains the entire processing history of the same-named SGY file by accumulation of protocols and processing parameters from all processes applied to the respective dataset. The syntax for these 80-column ASCII rows corresponds to the punch card coding of the SSC/SSL seismic software used for the original data processing. Even if no corresponding manual for a detailed explanation is at hand, most of the coding is self-explaining for an experienced operator.

4. Graphic data

The folder **GraphicData** contains graphic representations of the seismic data results. The originally in highresolution prepared raster files for Versatec VR222, Calcomp CC442 and Geospace GS64 camera plotter were transcribed to PNG which can be displayed with all common graphic viewers that are able to handle images with 25 000 pixels and more. In general, the images come with top label (showing profile-km, topography, geology etc) and with side label (showing field parameter, processing parameter etc.). In some cases, the images are horizontally split into 2 or 3 overlapping fractions which can be easily merged together.

The GraphicData folder structure is analogous to the SeismicData folder and subdivided into MainData and AdditionalData. The GraphicData/MainData folder contains in the subfolders FinalStacks, FinalMigrations and AtlasData the different DPC final results in different graphic scales including the sections depicted in the DEKORP Atlas (Meissner & Bortfeld, 1990). Into the GraphicData/AdditionalData subfolder, images of old versions or special processing attempts will be added step by step later on.

File name structure is similar to the seismic data files: xxx_yyyy.ras2pbm.png, where the xxx is a sequentially increasing tape index number, if several versions exist, yyyy is the unique original tape label number and ras2pbm indicates the conversion from the original raster source via the portable bitmap.pbm into the png.format. The PDF document in the parent folder lists all PNG files again together with additional information.

5. Metadata

In the folder **MetaData** there is accompanying information to the seismic data. The subfolder **SurveyData** contains scans of the original (PRAKLA) field report including appendices, as well as the original location maps and the original evaluation of field static corrections. The scans might be overlapping and have not been merged together as they are slightly distorted by the optical scanning procedure from blueprints. Unfortunately, everything is in German language, but they are hopefully of help nevertheless.

In the subfolder **Geometry** there are ASCII tables with all source-/receiver-/CDP-, spread and static information, just in case, that for one or the other file something, e.g. the CDP coordinates, might be missing in the trace headers and have to be externally imported. The tables for **Receivers**, **Sources**, **CDP**s, the **Relation** describing the actually active spread and **Misc** (like additional particulars like static corrections if not included in the other files) are self-explaining by the first comment line in each file. The coordinates are given in the rectangular Gauß-Krüger system (Bessel ellipsoid), the used abbreviations are LOCN (geophone location), SPON (shotpoint order number), SLOC (source location), NSPON (nearest SPON to CDP), NLOC (nearest LOCN to CDP) and VEL (either weathering layer velocity or main refractor velocity in m/s). For import into maps or GIS the CDP line is additionally given in geographic coordinates (Longitude, Latitude, WGS84) in ASCII and kml format. The PDF document in the parent folder lists all Metadata files again together with additional information.

The field parameters are compiled in *Table 1* and the processing sequence in *Table 2* in Appendix A.

8.1. Barry et al., (1975) Recommended Standards for Digital Tape Formats (Official SEG-Y technical standard description, rev0)

This document has been converted from the original publication: Barry, K. M., Cavers, D. A. and Kneale, C. W., 1975, Report on recommended standards for digital tape formats: Geophysics, 40, no. 02, 344-352.

RECOMMENDED STANDARDS FOR DIGITAL TAPE FORMATS¹

K. M. BARRY², D. A. CAVERS³, AND C. W. KNEALE⁴

INTRODUCTION

Recently, a new demand for demultiplexed formats has arisen in the seismic industry due to the utilization of minicomputers in digital field recording systems, and because of a growing need to standardize an acceptable data exchange format.

In 1973 a subcommittee of the SEG committee on Technical Standards was organized to gather information and develop a nine-track, ¹/₂-inch tape, demultiplexed format for industry acceptance. Guidelines set for this new format were based on prior work and on the SEG Exchange Tape Format (Northwood et. al, 1967). As a result of the subcommittee's effort based on suggestions from industry personnel, the following demultiplexed format recommendations are made.

The present SEG Exchange Tape Format is often referred to as the SEG "Ex" Format. Because of this, it is recommended that the new demultiplexed format be designated the "SEG Y Format." The Technical Standards committee has elected to withdraw support of the SEG "Ex" Format.

The SEG Y Format was developed for application to computer field equipment and in the present data processing center with flexibility for expansion as new ideas are introduced. Current information for standardization is placed in the "fixed" portion of the format, while new ideas can be added to the unassigned portions later as expansion becomes necessary. It is assumed that this format will accommodate the majority of field and office procedures and the techniques presently utilized.

FORMAT SPECIFICATION

The following general information describes the recommended demultiplexed format (Figure 1):

 Tape specifications, track dimensions and numbering, and all other applicable specifications shall be in accordance with IBM Form GA 22-6862 entitled "IBM 2400-Series Magnetic Tape Units Original Equipment Manufacturers' Information".

At the present time, IBM has proposed an American National Standard for the 6250 CPI group coded recording format. Should this format be used within the geophysical industry, the applicable IBM specifications would apply. The additional formatting required by this proposed method is a function of the hardware and thus becomes transparent to the user.

- 2) Either the NRZI encoded data at 800-bpi density, or the phase encoded (PE) data at 1600-bpi density may be used for recording.
- All data values are written in two's complement except the 320bit floating point format, Figure 3-A, which is sign, characteristic, and fractional part.
- 4) Data values are written in eight-bit bytes with vertical parity odd.

Nine Track, 800 bpi NRZI or 1600 bpi Phase Encoded (PE) Demultiplex (Trace Sequential) Format

Fig. 1. Recommended demultiplexed format.

Notes:

- 1. Preamble-Proceeds each of the 45 blocks within the reel identification header and. each trace data block when 1600 bpi PE is used. Consists of 40 all-zero bytes followed by one all-ones byte.
- 2. Postamble-Follows each of the 45 blocks within the reel identification header and each trace data block when 1600 bpi PE is used. Consists of one all-ones byte followed by 40 all-zero bytes.
- 3. Interblock Gap (IBG)-Consists of 0.6" nominal, 0,5" minimum.
- 4. End of file (EQF)-Consists of an IBG followed by:
 - a) PE tape mark having 80 flux reversals at 3200 fci in bit numbers F,0,2,5,6, and 7. Bits 1,3, and 4 are dc-erased, or
 - b) NRZI tape mark having two bytes with one bits in bit numbers 3,6, and 7 separated by seven all-zero bytes
- 5. PE Identification Burst-Consists of 1600 flux reversals per inch in bit number P; all other tracks are erased.
- 5) Definitions:
 - a) *Interblock gap (IBG)* Consists of erased tape for a distance of 0.6 inches nominal, 0.5 inches minimum.
 - b) *End of file (EOF)* Consists of the 800-bpi NRZI tape mark or the 1600-bpi tape mark character, as appropriate, preceded by a standard IBG.
 - c) Erased tape The tape is magnetized, full width, in a direction such that the rim end of the tape is a north-seeking pole. The readback signal from such an area shall be less than 4 percent of the average signal level at 3200 flux reversals per inch.
- d) PE identification burst Consists of 1600 flux reversals per inch in bit number P with all other traces DC erased. This burst is written beginning at least 1.7 inches before the trailing edge of the beginning of tape (BOT) reflective marker and continuing past the trailing edge of the marker, but ending at least 0.5 inches before the first block.
- e) Block Continuous recorded information, preceded and followed by a standard IBG. In PE (1600 bpi), a preamble precedes each block and a postamble follows each block.
- f) *Preamble* Consists of 41 bytes, 40 of which contain zero bits in all tracks; these

2-A EBCDIC CARD IMAGES Free form coding, left justified – 40 card images, 80 bytes per card, card image numbers 23-39 unassigned, for optional information.

are followed by a single byte containing one bits in all tracks.

- g) *Postamble* Consists of 41 bytes of which the first byte contains one bits in all tracks; it is followed by 40 bytes containing zero bits in all tracks.
- h) Two's complement Positive values are the true binary number. Negative values are obtained by inverting each bit of the positive binary number and adding one (1) to the least significant bit position.
- 6) The seismic reel is divided into the reel identification header and the trace data blocks. The reel identification header section contains identification information pertaining to the entire reel and is subdivided into two blocks, the first

containing 3200 bytes of EBCDIC card image information (equivalent of 40 cards) and the second consisting of 400 bytes of binary information. These two blocks of the reel identification header are separated from each other by an IBG. Each trace data block contains a trace identification header and the data values of the seismic channel or auxiliary channels. The reel identification header and the first trace data block are separated by an IBG.

7) Each seismic-trace data block is ungapped and is written in demultiplexed format with each trace data block being separated from the next by an IBG. The last trace data block on the reel is followed by one (or more) EOF>

- 8) When recorded 800 bpi (NRZI), the first block of the reel identification header begins at least 3.0 inches past the trailing edge of the BOT marker.
- 9) The following conventions pertain to the reel and trace identification headers:
 - a) All binary entries are right justified. All EBCDIC entries are left justified.
 - b) All times are in milliseconds with the exception of the sample interval which is designated in microseconds.
 - c) All frequencies are in hertz.
 - d) All frequency slopes are in dB/octave.

- e) All distances (lengths) are in feet or meters, and these systems are not mixed within a reel. The distance or measurement system used is specified in card image 7 and in bytes 3255-3256 of the reel identification header.
- f) A scaler may be applied to certain distance measurements where greater precision is required. See bytes 69-70 and 71-72 of the trace identification header.
- g) The energy source and geophone group coordinates designated in bytes 73-88 of the

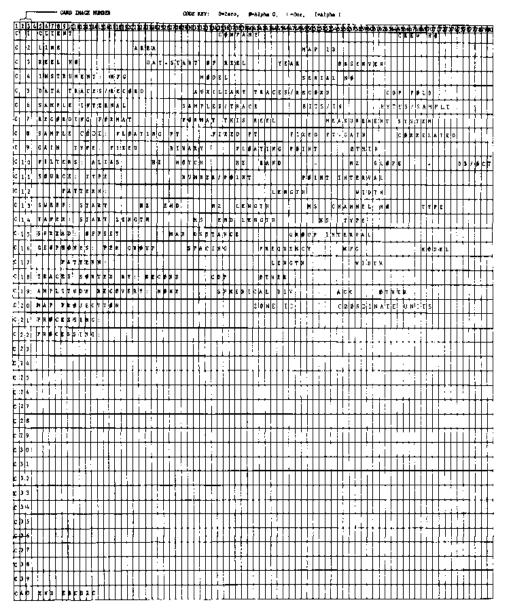

Fig. 2A. Reel identification header. Part 1, the EBCDIC card image block.

trace identification header can be measured in either length or latitude and longitude. The measurement unit used is specified in bytes 89-90 of the trace header. For the latitude/longitude system, the coordinate values are expressed in seconds of arc.

- h) All velocities are in feet per second or meters per second, and these units are not mixed within a reel.
- i) Elevation is represented by "+" above "—" below mean sea level.
- 10) The binary coded information convention is defined in Figure 1-C.

DESCRIPTION OF REEL IDENTIFICATION HEADER

The reel identification header (Figure 2) consists of 3600 bytes and is divided into two parts:

- 1) The card image EBCDIC block (3200) bytes— 40 cards equivalent) followed by an IBG.
- 2) The binary coded block (400 bytes) followed by an IBG.

The EBCDIC part of the reel header describes the data from a line of shotpoints in a fixed specified format consisting of 40 card images with each image containing 80 bytes. All unused card image characters are EBCDIC Blank. Card image numbers 23 through 39 are unassigned for optional use. Each card image should contain the character "C" in the first card column. Each 80 bytes would yield one line of format print to produce the form shown in Figure 2-A.

The binary coded section of the reel header consists of 400 bytes of information common to the seismic data on the related reel as shown in Figure 2-B. There are 60 bytes assigned; 340 are unassigned for optional use.

There are certain bytes of information that may not apply to a particular recording or processing procedure. It is strongly recommended that bytes designated with an asterisk (*) in Figures 2-B and 3-E always contain the required information

The data in the reel identification header could be printed and edited prior to the actual input of seismic data for processing. A complete header listing of both the EBCDIC and binary parts would accompany an exchange tape and serve as a table of contents and summary of specifications for that reel* of seismic data. No more than one line of seismic data is permitted on any one reel. Additional reels would be used for long lines, and each reel must start with a reel identification header.

DESCRIPTION OF THE TRACE DATA BLOCK

Each trace data block (Figure 3) consists of a fixed 240-byte trace identification header and the seismic trace data block is separated from the next by an IBG. The trace header is written in binary code (refer to Figure 1-C for the binary code information) and is detailed in Figure 3-E.

The trace data samples can be written in one of the four data sample formats described in Figures 3-A, 3-B, 3-C, and 3-D. The trace data format for each reel is identified in bytes 3225-3226 of the reel identification header. Only one data sample format is permitted within each reel.

Figure 3-A details a 32-bit, floating point format in which each data value of a seismic channel is recorded in four successive bytes, in IBM compatible floating point notation as defined in IBM Form GA 22-6821.

The four bytes form a 32-bit word consisting of the sign bit Q_S , a seven-bit characteristic Q_C , and a 24-bit fraction Q_F . Q_S indicates signal polarity and is a one for a negative value. Q_C signifies a power of 16 expressed in excess 64 binary notation allowing both negative and positive powers of 16 to be represented by a true number. Q_F is a six hexadecimal digit (24 amplitude recovery can be described in the binary bit) number with a radix point to the left of the significant digit. The data value represented by a floating point number is

Figure 3-B details a 32-bit, fixed point format and each data value of a seismic channel is recorded in four successive bytes. This format consists of a sign bit \mathbf{Q}_{s} (one represents negative) and 31 data bits \mathbf{Q}_{D} with a radix point at the right of the least significant digit.

Figure 3-C represents a 16-bit, fixed point format, and each data value of a seismic channel is recorded in two successive bytes. This format is similar to figure 3-B except there are 15 data bits Q_{D} .

Figure 3-D represents a 32-bit, fixed point format with gain values. The first byte of this format is all zeros. The second byte provides eight available gain bits 2^0 through 2^7 . The last two bytes are identical to Figure 3-C.

In all four data formats, the channel or trace data should represent the absolute input voltage at the recording instrument. The 32-bit, floating point field format defined as the SEG C (Meiners et al, 1972) comprehends the input voltage level. The fixed point formats 3-B and 3-C require a trace weighting factor (trace identification header, bytes 169-170), defined as 2^{-n} volts for the least significant bit, to comprehend the absolute input voltage level.

In cases where processing parameters such as amplitude recovery are present, the type of amplitude recovery can be described in the appropriate reel identification header sections, and the algorithm described in the unassigned portions.

CONCLUSION

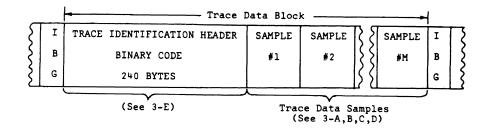

Individual oil companies and contractors may be convinced of their own format's merits, but the use of this recommended exchange demultiplexed format must be given serious consideration in order to achieve some level of industry standardization. Such thought and many suggestions from users have been utilized in establishing a flexible format that yields specifics and can be used by all companies in the industry. Adoption and use of this format will save substantial sums of money in computer time and programming effort in the future.

ACKNOWLEDGEMENTS

Grateful appreciation goes to many companies and individuals for their suggestions at the start of the subcommittees' work and for their final recommendations. We are also for the assistance of Fred Tischler, Texas Instruments, who was the original subcommittee chairman.

FIG. 3E. Trace identification header written in binary code.

Digital Tape Format

| Byte | |
|---------|--|
| Numbers | Description |
| 105-106 | Lag time A. Time in ms. between end of 240-byte trace identification header and time break. |
| | Positive if time break occurs after end of header, negative if time break occurs before end of |
| | header. Time break is defined as the initiation pulse which may be recorded on an auxiliary trace |
| | or as otherwise specified by the recording system. |
| 107-108 | Lag Time B. Time in ms. between time break and the initiation time of the energy source. May be |
| | positive or negative. |
| 109-110 | Delay according time. Time in ms. between initiation time of energy source and time when |
| | recording of data samples begins. (for deep water work if data recording does not start at zero |
| | time.) |
| 111-112 | brute timestart. |
| 113-114 | Mute timeend. |
| 115-116 | * Number of samples in this trace. |
| 117-118 | * Sample interval in µsec for this trace. |
| 119-120 | Gain type of field instruments: $1 = $ fixed. $2 = $ binary. $3 = $ floating point. |
| | 4 - N = optional use. |
| 121-122 | Instrument gain constant. |
| 123-124 | Instrument early or initial gain (dB). |
| 125-126 | Correlated: $1 = no. 2 = yes$. |
| 127-128 | Sweep frequency at start. |
| 129-130 | Sweep frequency at end. |
| 131-132 | Sweep length in ms. |
| 133-134 | Sweep type: $1 = \text{linear}$. $2 = \text{parabolic}$. $3 = \text{exponential}$. $4 = \text{other}$. |
| 135-136 | Sweep trace taper length at start in ms. |
| 137-138 | Sweep trace taper length at end in ms. |
| 139-140 | Taper type: $1 = \text{linear}$. $2 = \cos 2$. $3 = \text{other}$. |
| 141-142 | Alias filter frequency, if used. |
| 143-144 | Alias filter slope |
| 145-146 | Notch filter frequency, if used. |
| 147-148 | Notch filter slope. |
| 149-150 | Low cut frequency, if used . |
| 151-152 | High cut frequency, if used . |
| 153-154 | Low cut slope |
| 155-156 | High cut slope |
| 157-158 | Year data recorded . |
| 159-160 | Day of year. |
| 161-162 | Hour of day (24 hour clock) |
| 163-164 | Minute of hour. |
| 165-166 | Second of minute. |
| 167-168 | Time basis code: $I = local$. $2 = GMT$. $3 = other$. |
| 169-170 | Trace weighting factordefined as 2-N volts for the least significant bit. ($N = 0, 1,, 32, 767$.) |
| 171-172 | Geophone group number of roll switch position one. |
| 173-174 | Geophone group number of trace number one within original field record . |
| 175-176 | Geophone group number of last trace within original field record. |
| 177-178 | Gap size (total number of groups dropped). |
| 179-180 | Overtravel associated with taper at beginning or end of line: |
| | I = down (or behind). 2 = up (or ahead). |
| 181-240 | Unassigned—for optional information. |
| | |

Description of 'SEGY' Reel Identification Header

The SEGY reel identification header consists of 3600 bytes and is divided INTO two parts:

- The card image EBCDIC block (3200 bytes 40 images equivalent) followed by an IRG.
- 2. The binary coded block (400 bytes) followed by an IRG.

'SEGY' Binary Reel Header

The Binary header consists of 400 bytes of integer data as defined below.

| Byte | Word | Description |
|--------------|--------|---|
| Numbers | Number | Description |
| *3201-3204 | 01 | Job identification number. |
| *3205-3204 | 02 | Line number (only one line per reel). |
| *3209-3212 | 02 | Current reel number. |
| *3213,3214 | 1h-04 | Number of data traces per record (includes dummy and zero |
| ~ 5215, 5214 | 111-04 | traces inserted to fill out the record or common depth |
| | | point). |
| 3215,3216 | rh-04 | Number of auxiliary traces per record (includes sweep, |
| 5215,5210 | 111 04 | timing, gain, sync and all other non-data traces). |
| *3217,3218 | 1h-05 | Sample interval in microseconds (for this reel). |
| *3219,3220 | rh-05 | Sample interval in microseconds (original reel). |
| *3221,3222 | 1h-06 | Number of samples per data trace (this reel). |
| *3223,3224 | rh-06 | Number of samples per data trace (original recording). |
| *3225,3226 | 1n-07 | Data sample format code: (Auxiliary is the same). |
| , | | 1 = IBM floating point (32 bits or 4 bytes) |
| | | 2 = 32-bit fixed point (twos compliment) |
| | | 3 = 16-bit fixed point (twos compliment) |
| | | 4 = Fixed point with gain (4 bytes) |
| | | 5 = 36-bit Univac floating point |
| *3227,3228 | rh-07 | CDP fold (expected number of data traces per CDP ensemble), |
| | | or (maximum fold). |
| *3229,3230 | 1h-08 | Trace sorting code: |
| | | 1 = As recorded (no sorting) |
| | | 2 = CDP ensemble |
| | | 3 = Single fold continuous profile |
| | | 4 = Horizontally stacked |
| *3231,3232 | rh-08 | Vertical sum code: 1 = no sum, 2 = two sum, etc. |
| 3233,3234 | 1h-09 | Sweep frequency at start. |
| 3235,3236 | rh-09 | Sweep frequency at end. |
| 3237,3238 | 1h-10 | Sweep length (milliseconds). Sweep type code: 1 = linear 3 = exponential |
| 3239,3240 | rh-10 | Sweep type code: 1 = linear 3 = exponential 2 = parabolic 4 = other |
| 3241,3242 | lh-11 | Trace number of sweep channel. |
| 3241,3242 | rh-11 | Sweep trace taper length in milliseconds at start if |
| 5245,5244 | LU-TT | tapered (the taper starts at zero time and is effective |
| | | for this long). |
| 3245,3246 | 1h-12 | Sweep trace taper length in milliseconds at end (the ending |
| 5245,5240 | | taper starts at sweep length minus the taper length at end). |
| 3247,3248 | rh-12 | Taper type: $1 = linear$ $3 = AGC$ |
| 021730210 | | $2 = (\cos)^{**2}$ |
| 3249,3250 | 1h-13 | Correlated data traces: $1 = no$ $2 = yes$ |
| 3251,3252 | rh-13 | Binary gain recovered: 1 = yes 2 = no |
| | | |

*Note: These fields are set by the SSC TRACE DRIVER.

TRACE DRIVER 'SEGY'

Page S-12

| Trace He | ader Layout, 'SEGY' Format |
|----------|---|
| Byte | Occariation |
| Numbers | Description |
| 1-4 | * Trace sequence number within line; numbers continue to increase if additional reels are required on same line. |
| 5-8 | * Trace sequence number within reel; each reel starts with trace number one. |
| 9-12 | * Original field record number. |
| 13-16 | * Trace number within the original field record. |
| 17-20 | Energy source point number; used when more than one record occurs at at the same effective surface location. |
| 21-24 | CDP ensemble number. |
| 25-28 | Trace number within the CDP ensemble; each ensemble starts with trace number one. |
| 29,30 | * Trace identification code: |
| | 1 = seismic data $4 = time break$ $7 = timing$ |
| | 2 = dead $5 = uphole$ $8 = water break$ |
| 31,32 | 3 = dummy $6 = sweep$ 9 to N = optional use (N=32,767) Number of vertically summed traces yielding this trace. (1 is one |
| 22 24 | trace, 2 is two summed traces, etc.) Number of horizontally stacked traces yielding this trace. (1 is |
| 33,34 | one trace, 2 is two summed traces, etc.) |
| 35,36 | Data use: 1 = production, 2 = test. |
| 37-40 | Distance from source point to receiver group (negative if opposite to direction in which line is snot). |
| 41-44 | Receiver group elevation; all elevations above sea level are positive and below sea level are negative. |
| 45-48 | Surface elevation at source. |
| 49-52 | Source depth below surface (a positive number). |
| 53-56 | Datum elevation at receiver group. |
| 57-60 | Datum elevation at source. |
| 61-64 | Water depth at source. Water depth at group. |
| 65-68 | Scaler to be applied to all elevations and depths specified in |
| 69,70 | bytes 41-68 to give the real value. Scaler = 1, ± 10 , ± 100 , ± 1000 , or $\pm 10,000$. If positive, scaler is used as a multiplier; if negative, scaler is used as a divisor. |
| 71,72 | Scaler to be applied to all coordinates specified in bytes 73-38 to give the real value. Scalar = 1, ± 10 , ± 100 , ± 1000 or $\pm 10,000$. If positive, scaler is used as a multiplier; if negative, scaler is used as a multiplier; where the scaler is used as a divisor. |
| 73-76 | Source coordinate X. <u>Note</u> : If the coordinate units are in seconds of arc, the X values represent |
| 77-80 | Source coordinate Y. longitude and the Y values latitude. A positive value designates the number |
| 81-84 | Group coordinate X. of seconds east of Greenwich Meridian or north of the equator and a negative |
| 85-88 | Group coordinate Y. south or west. |
| *Note: | It is strongly recommended that this information always be recorded. |

| 89,90 91,92 | Coordinate units: 1 = length (meters or feet) 2 = seconds of arc. Weathering velocity. |
| 93,94 | Subweathering velocity. |
| 95,96 | Uphole time at source. |
| 97,98 | Uphole time at group. |
| 99,100 | Source static correction. |
| 101,102 | Group static correction. |
| 103,104 | Total static applied. (Zero if no static has been applied) |
| 105,106 | Lag Time A. Time in milliseconds between end of 240-byte trace |
| | identification header and time break. Positive if time break occurs after end of header, negative if time break occurs before |
| | end of header. Time break is defined as the initiation pulse |
| | which may be recorded on an auxiliary trace or as otherwise |
| | specified by the recording system. |
| 107,108 | Lag Time B. Time in milliseconds between time break and the |
| | initiation time of the energy source. May be positive or negative. |
| 109,110 | Delay recording time. Time in milliseconds between initiation time |
| | of energy source and time when recording of data samples begins. |
| | (For deep water work if data recording does not start at zero time.) |
| 111,112 | Mute time, start. |
| 113,114 | Mute time, end. |
| 115,116 | * Number of samples in this trace. |
| 117,118 | * Sample interval in microseconds for this trace. |
| 119,120 | Gain type of field instruments: 1 = fixed, 2 = binary, |
| | 3 = floating point, 4 to N = optional use. |
| 121,122 | Instrument gain constant. |
| 123,124 | Instrument early or initial gain (db). Correlated: 1 = no, 2 = yes. |
| 125,126 127,128 | Sweep frequency at start. |
| 129,120 | Sweep frequency at end. |
| 131,132 | Sweep length in milliseconds. |
| 133,134 | Sweep type: 1 = linear, 2 = parabolic, 3 = exponential, 4 = other. |
| 135,136 | Sweep trace taper length at start in milliseconds. |
| 137,138 | Sweep trace taper length at end in milliseconds. |
| 139,140 | Taper type: $1 = 1$ inear, $2 = \cos^2$, $3 = $ other. |
| 141,142 143,144 | Alias filter frequency, if used. Alias filter slope |
| 145,144 | Notch filter frequency, if used. |
| 147,148 | Notch filter slope. |
| 149,150 | Low cut frequency, if used. |
| 151,152 | High cut frequency, if used. |
| 153,154 | Low cut slope. |
| 155,156 | High cut slope. |
| 157,158 | Year data recorded. |
| | It is strengly recommended that this information always be recorded |

*<u>Note</u>: It is strongly recommended that this information always be recorded.

'.IDF' DISK FORMAT

Trace File Description

The first block of data in this disk file contains information about the data itself; number of samples, sampling increment in seconds, number of channels, maximum fold, the total number of traces put in the file, etc. Then there are three empty blocks left for future expansion if needed. After these four blocks about the data, each trace is put into the file with a 256 word header.

After all the data has been output to the file, a section is added at the end containing 24 pertinent words from each trace, used in INTRACT to read the data from the file. Finally, history blocks are added to the file if present.

Page I-4

Sort Buffer Format:

The sort buffer is made up of the following 24 I*2 words for each trace.

| 1-2 | CDPN | - | Common depth point |
|-------|------|---|---------------------------|
| 3 | ESPN | - | Source position number |
| 4 | CDPT | • | Trace number |
| 5 | FFNO | - | Field file number |
| 6 | FFTR | - | Field file trace number |
| 7 | LRNO | - | Record index number |
| 8 | LRTR | - | Record index trace number |
| 9,10 | ADIS | - | Distance |
| 11,12 | RCLC | - | Receiver location number |
| 13,14 | STNO | - | Source location number |
| 15,16 | | - | Block number of data |
| 17 | SLAC | - | Nearest surface location |
| 18-24 | | - | Spare |

There are 10,667 sort buffers per 512 byte block.

The sort buffers are written to disk in a 24000 I*2 array, taking up 94 blocks and containing 1000 traces. Even though the 94th block is not completely filled, the 1001st trace starts in block 95 and continues through trace 2000.
